Table of Contents

Applying Fuzzy PERT in Cycle Time Management for Supply Chain System.....	1
A User Preference Perception Model Using Data Mining on a Web-based environment.....	8
The Integrated Approach to E-Commerce Curriculum Success	18
On Improving an Integrated Inventory Model for a Single Vendor and Multiple Buyers with Ordering Cost Reduction	23
The Environment Factors Analysis of Electronic Commerce Credit System in China	33
Internet-enabled e-Banking Systems and Customer Responses	39
Electronic Business (EB) in the Context of Global Sourcing: A Proposed Framework	42
An Empirical Examination of the Use of Mobile Technology – A Social Pressure Perspective.	51
Investment Strategy Analysis using Support Vector Machines	56
Understanding Issues in Regulating Privatized State-owned enterprises.....	61
The Management of Debris Flow in Disaster Prevention using an Ontology-based Knowledge Management System	67
Legal Protection for the E-Commerce in Indonesia: A Study on the Development and the Future of Cyberlaw in Indonesian Legal System	72
The Subjective Value of Information: Trading expertise vs. content, copies vs. originals in E-Business.....	80
Success Factors for Implementation of Electronic Commerce by Small and Medium Enterprises	89
The Impact of Strategy on Corporate Success in Electronic Business	94
The Adoption of E-Procurement and Its Impact on Corporate Success in Electronic Business.....	103
Creating Start-up New Ventures: A Conceptual Approach.....	112
Consequences of e-Business Initiatives on Business Process Performance – A Model for Analysis	122
Understanding User Empowerment In Enterprise Systems Context: Is User Empowerment Predictive Of Enterprise Systems Success?	125
The Design of Agents Oriented Collaboration in SCM.....	134
Strategic Learning and e-Business Solutions in a Pharmaceutical Organization.....	141
Customized Web Interaction and Its Effect on Consumer Behavior and Evaluations	151
An Algorithm for Warehouse Capacity and Replenishment Scheduling Decisions....	156
Transcending the Digital Divide: Paving Itinerary for Conducive Digital Economy	161
B2B E-commerce and BPR for Establishing the Competitive Supply Chain	164
A Knowledge Management Performance Evaluation Model Based on Fuzzy Set Theory	173
An Integrated Lot-size Model of Deteriorating Item for one Vendor and Multiple Retailers Considering Market Pricing Using Genetic Algorithm.....	181
IT Diffusion Stages in the Network Era of Chinese Companies	189
A Case Study of VMI using TOC.....	196
Branding in Cyberspace: Implications for Marketing & Management.....	205
Key Problems to be solved in Supply Chain Collaboration Management	210
Beyond Tayloristic Hierarchies: More Flexibility and Autonomy or “electronic Babel of tongues”?	

Consequences and Perspectives of Organizational Changes	214
T2B Model – Experiencing the Successful Conversion of Traditional Enterprise to e-Business	218
Implementing a Three-Tier Data Warehouse	225
A Study of Traditional Versus e-Government Service Channels in The UK	234
Tracking a Web Site’s Historical Links with Temporal URLs	243
E-Governments: Utilizing Customer Relationship Management (CRM) Platforms to Serve Citizens	250
Towards an Electronic Commerce Growth Stage Model	253
Taxonomy of Web-Based Shopping Systems	261
An Integrative Framework for Examining Customer Loyalty in Online Environments	271
Contextual Criteria to Select a Framework for Enterprise Architecture	277
The Use of Real Options to Evaluate Business-To-Business Companies	285
Investigating the Influence of Learner Diversity on the E-learning Acceptance	294
A Fuzzy Selection Model of Microwave System Procurement	301
The Effects on Workers in the Privatization Process in Taiwan A case study: An empirical Analysis of privatizing SOEs	306

ABSTRACT

As the fast technology evolution and the globalization trend, the competition among businesses transform into supply chain network gradually. However, the operation performance of the supply chain network influenced by many uncertain factors. These uncertain influence factors include the demand of the customer, the response time of delivery, operation lead time, stock level and cost. Under foregoing conditions, enterprises cannot control the variations in actual environment precisely and satisfy customers' requirements. Therefore, the linguistic variables are used to express these uncertainties in this paper. First, this paper presents a procedure to transform the operation processes of the supply chain network into a diagram to indicate the activities among members of supply chain. Second, combining fuzzy set theory with the program evaluation and review technique (PERT) to estimate the cycle time of supply chain system. According to the fuzzy PERT model, we can calculate the cycle time and find out the critical path of a supply chain system. Furthermore, we can compute the possibility of the order fulfillment of a supply chain system. Finally, a numerical simulation is presented to illustrate the procedure of this proposed model.

Keywords: Supply chain system, Fuzzy numbers, Program evaluation and review technique (PERT), Fuzzy PERT.

1. Introduction

Today the enterprise faces many rigorous and challenges, including the globalization of competition and cooperation, a varieties of customer requirements and shortened product life cycles. The enterprise has to look for the effective methods to adjust strategic and manageable models and maintain operations and competitive advantages. For example, Material Requirement Planning (MRP), Manufacturing Resource Planning (MRPII) and Enterprise Resource Planning (ERP) [10, 21] are used to integrate the operation processes and resources for enterprises. The purpose of these tools is to reduce the response

time of the market demand and increase the customer satisfactions.

As the Internet and information technology grow rapidly, the industrial environment becomes more competitive for individual enterprise. Nowadays global marketplaces, no longer an individual enterprise competes as an independent entity but rather as an integral part of supply chain links [10]. In other words, each enterprise will depend on its management abilities to integrate and coordinate the complicated network of business relationships among supply chain members [5]. Therefore, supply chain management (SCM) has become one of the most important issues for enterprises.

A supply chain may be viewed as an integrated system that performs the procurement of raw material, its transformation to intermediate and end-products, distributor and promoting of the end-products to either retailers or customers [5, 21]. In recent years many researches are very interested in supply chain management problems and the concepts of SCM from different view points that were presented in [4, 5, 20, 27,28]. Unfortunately, there is no explicit description of supply chain management or its activities in the literature [30]. For example, New and Payne [23] described supply chain management as the chain linking each element of the manufacturing and supply processes from raw materials to the end user, encompassing several organizational boundaries. Jukka et al., [16] described supply chain management as a new way to provide goods and services to the end customer at the lowest cost and high service level, and the centric approach to manage the supply chain is no longer appropriate. SCM is an integrated approach to increase the effectiveness of the logistics chain by improving cooperation between members in the chain. Figure 1 shows the activities of a supply chain is comprised two fundamental procedures: (1) the Production layout and Inventory control process, and (2) the Distribution and Logistics process [1].

There is a growing interest in exploiting supply chain models in real applications and in developing decision support system to enhance supply chain management and control. Thus, a real supply chain operates in an uncertain environment. Different sources and types of uncertainty exist along the supply chain and make supply chain management

problems more complex [6, 7, 20, 24, 25, 26]. Facing the dynamic states of the supply chain market, a supply chain network system that its internal and each operation of links in fast supply chain express effectively, and responds and makes more accurate forecasting to the market demand in time, is the problem that we want the important concerns the topic.

Program Evaluation and Review Technique (PERT) [3, 11, 12] is the management technique of a kind of project scheme and makes use of the mode of the operation network, marking whole scheme in the correlation of each operation activity. Making use of mathematics function compute possible complete times that are the earliest start time, the latest start time, the earliest finish time, the latest finish time, float time and total float time. Therefore, PERT is suitable to compute the order completion time and forecast the order fulfillment ability in the supply chain network system.

However, in traditional program evaluation and review technique, various dynamic activity durations must be the crisp number or obedient to certain probability distribution. Under the real situation, the operation time of each activity is usually difficult to define and estimate. Therefore, in recent years there are many researchers combining the concepts of the fuzzy set theory with program evaluation and reviews technique in developing the fuzzy program evaluation and review technique (FPERT)[3, 9, 12, 14, 15, 19, 22, 29]. In FPERT, the duration time of each activity is expressed by a fuzzy numbers.

In this paper, FPERT is applied to deal with the cycle time management problem of supply chain system. First, we can calculate the fuzzy completion time of the supply chain system by Fuzzy PERT method. Second, we will indicate the critical path of the supply chain system. Finally, the possibility of promise delivery can be calculated.

2. Fuzzy sets and notations

Zadeh introduced a theory whose objects fuzzy sets are sets with boundaries that are not precise. The membership in a fuzzy set is not a matter of affirmation or denial, but rather a matter of a degree[31].

A fuzzy set can be defined mathematically by assigning to each possible individual in the universe of discourse a value representing its grade of membership in the fuzzy set. This grade corresponds to the degree to which that individual is similar or compatible with the concept represented by the fuzzy set. Thus, individuals may belong in the fuzzy set to a greater or lesser degree as indicated by a larger or smaller membership grade. As already mentioned, these membership grades are very often represented

by real number values ranging in the closed interval between 0 and 1[13].

2.1 Fuzzy Numbers

The fuzzy number \tilde{A} is a fuzzy set, its membership function $\mu_{\tilde{A}}(x)$, satisfies the following conditions [18]:

1. $\mu_{\tilde{A}}(x)$ is piecewise continuous.
2. $\mu_{\tilde{A}}(x)$ is convex fuzzy subset.
3. $\mu_{\tilde{A}}(x)$ is normality of a fuzzy subset, then the existence a real amount x_0 make $\mu_{\tilde{A}}(x_0) = 1$.

2.2 Triangular Fuzzy Number (TFN)

The triangle fuzzy number is a popular type of fuzzy number. A triangle fuzzy number can be expressed as $\tilde{T} = (l, m, u)$. When $l > 0$, then \tilde{T} is a positive triangle fuzzy number (PTFN)[8,32]. The membership function of positive triangle fuzzy number \tilde{T} is defined as (shown in Figure 2):

$$\mu_{\tilde{T}}(x) = \begin{cases} \frac{x-l}{m-l}, & l < x < m \\ \frac{u-x}{u-m}, & m < x < u \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

where $l > 0$.

2.3 The operation of the fuzzy numbers

Given two positive triangle fuzzy numbers $\tilde{T}_1 = (l_1, m_1, u_1)$ and $\tilde{T}_2 = (l_2, m_2, u_2)$, then the additive operation between them can be expressed as follows [17]:

$$\tilde{T}_1 \oplus \tilde{T}_2 = (l_1 + l_2, m_1 + m_2, u_1 + u_2) \quad (2)$$

$$\tilde{T}_1 \ominus \tilde{T}_2 = (l_1 - u_2, m_1 - m_2, u_1 - l_2) \quad (3)$$

2.4 Ranking method of the fuzzy numbers

There are many ranking methods to transform fuzzy number into crisp value [2], Let $\tilde{T} = (l, m, u)$ be a triangle fuzzy number, then the defuzzified value is computed as [2]:

$$G(\tilde{T}) = \frac{l+m+u}{3} \quad (4)$$

Suppose \tilde{T}_1 and \tilde{T}_2 are two triangle fuzzy numbers, if $G(\tilde{T}_1) > G(\tilde{T}_2)$ then $\tilde{T}_1 > \tilde{T}_2$. If $G(\tilde{T}_1) = G(\tilde{T}_2)$ and $D(\tilde{T}_1) < D(\tilde{T}_2)$ then $\tilde{T}_1 > \tilde{T}_2$. If $G(\tilde{T}_1) = G(\tilde{T}_2)$ and $D(\tilde{T}_1) = D(\tilde{T}_2)$ then $\tilde{T}_1 \approx \tilde{T}_2$. Where $D(\tilde{T}_1) = u_1 - l_1$ and $D(\tilde{T}_2) = u_2 - l_2$.

2.5 The critical path method in fuzzy PERT

In this paper, we adopt an activity-on-node graph to represent a supply chain network. This graph includes two virtual tasks of null duration, start node and end node. For each task i the following notations will be used:

1. Succ(i)(respectively Pred(i)) refers to the set of tasks that immediately follow task i , while SUCC(i)(resp. PRED(i)) refers to the set of all the tasks that come after task i ;
2. \tilde{d}_i is the fuzzy duration of task i ;
3. \tilde{t}_i is the fuzzy earliest starting dates of task i ;
4. \tilde{T}_i is the fuzzy latest starting dates of task i ;
5. \tilde{m}_i is the fuzzy float time of task i .

These variables are restricted in following relations:

$$\tilde{t}_i = \max_{j \in \text{Pred}(i)} \tilde{t}_j \oplus \tilde{d}_j \quad (5)$$

$$\tilde{T}_i = \min_{j \in \text{Succ}(i)} \tilde{T}_j \ominus \tilde{d}_i \quad (6)$$

$$\tilde{m}_i = \tilde{T}_i \ominus \tilde{t}_i \quad (7)$$

If $G(\tilde{m}_i) = 0$, then task i is a critical activity. The critical path is a path which connected these critical activities from start node and end node.

3. Order Fulfillment Analysis model

Suppose that there are 2 suppliers, 3 manufacturers, 3 distributors and a final retailer the supply chain system. The duration time from receiving the order to deliver materials to manufacturer of suppliers S_i ($i=1, 2, \dots, m$) is denoted by $\tilde{T}_{S_i} = (S_{i1}, S_{i2}, S_{i3})$. The duration of the production of manufacturer M_k is denoted by $\tilde{T}_{M_i} = (M_{i1}, M_{i2}, M_{i3})$. The duration of the assembly

and distributor is denoted by $\tilde{T}_{D_i} = (D_{i1}, D_{i2}, D_{i3})$.

The duration of the final retail is denoted by $\tilde{T}_{R_i} = (R_{i1}, R_{i2}, R_{i3})$.

Two possible cases in supply chain system are discussed as follows:

- (1) The one supplier delivers materials to one manufacturer, one manufacturer products to one distributor, and the business sends the products to the final retail. In this case, the completion time of the supply chain system can be computed as:

$$\tilde{t} = \tilde{T}_{S_i} \oplus \tilde{T}_{M_i} \oplus \tilde{T}_{D_i} \oplus \tilde{T}_{R_i} \quad (8)$$

- (2) Several suppliers deliver materials to several manufacturer, several manufacturer delivers products to several distributor, and the business sends the products to the final retail. In this case, the completion time of the supply chain system can be computed as:

$$\tilde{t} = \max\{\tilde{T}_{S_i}, \tilde{T}_{S_j}\} \oplus \max\{\tilde{T}_{M_i}, \tilde{T}_{M_j}\} \oplus \max\{\tilde{T}_{D_i}, \tilde{T}_{D_j}\} \oplus \max\{\tilde{T}_{R_i}, \tilde{T}_{R_j}\} \quad (9)$$

Suppose the requirement due date of the customer is $RDD = \tilde{R} = (r_1, r_2, r_3)$, the completion time of supply chain system is denoted by $EF = \tilde{T}_{end} = (e_1, e_2, e_3)$, the promise delivery possibility (PDP) can be defined as (shown in Figure 3):

$$PDP = \begin{cases} 1 & , \quad r_1 - e_3 \geq 0 \\ \frac{\delta_1}{\delta_1 + \delta_2} & , \quad r_1 - e_3 \leq 0 \leq r_3 - e_1 \\ 0 & , \quad r_3 - e_1 \leq 0 \end{cases} \quad (10)$$

where

$$\delta_1 = \int_{x \geq 0} \mu_{\tilde{R} \ominus \tilde{T}_{end}}(x) dx, \quad \delta_2 = \int_{x \leq 0} \mu_{\tilde{R} \ominus \tilde{T}_{end}}(x) dx$$

In other words, when the value δ_1 is larger, it represents the order fulfillment ability of supply chain system is higher. Thus, the responds ability of supply chain system is stronger.

Therefore, the order fulfillment ability analysis of supply chain system is described as follows:

- (1) If $r_1 - e_3 \geq 0$, then the order fulfillment ability is 100%.
- (2) If $r_1 - e_3 < 0 < r_3 - e_1$, then the order fulfillment ability is denoted by PDP.
- (3) If $r_3 - e_1 \leq 0$, then the order fulfillment ability is

zero. In other words, the supply chain system can't delivery on time.

4. The results of simulation

In this paper, assumptions of supply chain processes considered are as follows:

1. The production facilities have unlimited capacities.
2. Customer demand is confined to a single product.
3. The raw material inventory is supplied from an external source.
4. External demand is fulfilled from the end-product inventory.

In order to implement the simulation analysis, we suppose the structure of the supply chain system as Figure 4. In Figure 4, S_1 and S_2 indicate the suppliers, M_1 , M_2 and M_3 indicate the manufacturers, D_1 , D_2 and D_3 indicates distributor, and the R_1 indicates the final retailer. Furthermore, the duration time of suppliers, manufacturers, distributor and the retailer are triangle fuzzy numbers and can be shown as Table 1. In Table 1, according to the LF- EF or LS- ES, we can compute the m value. According to the simple center method [2], we can compute the $G(\tilde{m}_i)$. If $G(\tilde{m}_i) = 0$, then task i is a critical activity. If completion time can't satisfy the customer requirement due date, we can adjust the duration time of activity on the critical path.

4.1 Requirement due date is crisp values

Suppose $RDD=(20,20,20)$ and $\tilde{T}_{end}=(13,18,25)$ then $\tilde{R}\Theta\tilde{T}_{end}=(-5,2,7)$. The PDP of supply chain network system can be computed as

$$PDP = \frac{\delta_1}{\delta_1 + \delta_2} = \frac{\frac{(25-13)*1}{2} - \frac{(25-20)*0.71}{2}}{\frac{(25-13)*1}{2}} = 0.70$$

Suppose $RDD=(15,15,15)$ and $\tilde{T}_{end}=(13,18,25)$ then $\tilde{R}\Theta\tilde{T}_{end}=(-10,-3,2)$. The PDP of supply chain network system can be computed as

$$PDP = \frac{\delta_1}{\delta_1 + \delta_2} = \frac{\frac{(15-13)*0.4}{2}}{\frac{(25-13)*1}{2}} = 0.07$$

When $\tilde{T}_{end}=(13,18,25)$ and RDD are different crisp values, the PDP of a supply chain system can be computed as above definition in this paper. In this case, if \tilde{T}_{end} is unchanged and RDD is smaller then the PDP of supply chain system is lower.

4.2 Requirement due date is fuzzy numbers

(1) Suppose $RDD=(12,20,23)$ and $\tilde{T}_{end}=(13,18,25)$ then $\tilde{R}\Theta\tilde{T}_{end}=(-13,2,10)$. The PDP of supply chain network system can be computed as

$$PDP = \frac{\delta_1}{\delta_1 + \delta_2} = \frac{\frac{(13+10)*1}{2} - \frac{(0-(-13))*0.86}{2}}{\frac{(13+10)*1}{2}} = 0.51$$

(2) Suppose $RDD=(10,15,21)$ and $\tilde{T}_{end}=(13,18,25)$ then $\tilde{R}\Theta\tilde{T}_{end}=(-15,-3,8)$. The PDP of supply chain network system can be computed as

$$PDP = \frac{\delta_1}{\delta_1 + \delta_2} = \frac{\frac{(0-(-8))*0.73}{2}}{\frac{(8+15)*1}{2}} = 0.25$$

(3) Suppose $RDD=(15,18,21)$ and $\tilde{T}_{end}=(13,18,25)$ then $\tilde{R}\Theta\tilde{T}_{end}=(-10,0,8)$. The PDP of supply chain network system can be computed as

$$PDP = \frac{\delta_1}{\delta_1 + \delta_2} = \frac{\frac{(0+8)*1}{2}}{\frac{(8+10)*1}{2}} = 0.44$$

When $\tilde{T}_{end}=(13,18,25)$ and RDD is a fuzzy number, the PDP of a supply chain system can be computed easily in this paper. According to the critical path, this method can indicate the critical activities and shorten their operation time to improve the PDP value. Therefore, the supply chain system can response the market requirement quickly and increase customers' satisfaction.

5. Conclusions

Along with the information technology growing fast, the competitions among enterprises have transformed into the competition between two supply chain systems. Thus, the robust management and operation model of supply chain system will increase

the competitiveness for the enterprise. Besides, the order fulfillment ability of supply chain system is the key factor for increasing their competitive advantages.

In this paper, the triangle fuzzy numbers are used to stand for the various uncertainty of duration time. According to the FPERT, we can find out the fuzzy earliest / latest final time and critical path in the supply chain network system quickly. In this paper the fuzzy model has proposed to analyze the order fulfillment ability of supply chain system for considering the uncertain duration time. According to the proposed model, we can immediately understand the status of each critical path of the supply chain system. If the completion time of critical path is not satisfy customer requirement due date, we can adjust the critical activities to raise PDP value and customer satisfaction. From the simulation results, it shows that if enterprise can hold duration time more precise, the order fulfillment ability of the supply chain network system more high.

This research is continued in two directions to further examine supply chain behavior in an uncertain environment.

- (1) To include additional sources of uncertainty into the fuzzy model, such as rush time or rush cost.
- (2) To examine the sensitivity of supply chain performances to various types of customer demand and fuzzy external supplier reliability.
- (3) In the future, we can to creative new better critical path method application in fuzzy program evaluation and review technique in supply chain network system.

Abstract

In a competitive environment, how to provide the information and products to meet the requirements of customers and improve the customer satisfaction will be the key criteria to measure a company's competitiveness. Customer Relationship Management (CRM) becomes an important issue in any business market gradually. Using information technology, businesses can achieve their requirements for one to one marketing more efficiently with lower cost, labor and time.

In this paper, we proposed a user preference perception model by using data mining technology on a web-based environment. First, the users' web browse records are aggregated. Second, fuzzy set theory and most sequential pattern mining algorithm are used to infer the users' preference changes in a period. After the test had processed, we use the on-line questionnaire to investigate the customer satisfaction degree from all participators. The results show that the degree of satisfaction was up to 72% for receiving the new information of participants whose preferences had been changed. It indicates that the proposed system can effectively perceive the change of preference for users on a web environment.

Keywords: Preference Perception, Data Mining, Fuzzy Set Theory, Most Sequential Pattern Mining Algorithm (MSPMA)

1. Introduction

Due to the information technology development and the World Wide Web (WWW) prevalence, the traditional business model has a tremendous revolution. As Customer Relationship Management (CRM) concept arises, more and more businesses pay much attention to the interaction between business and customers gradually. Every interaction and modification improves your ability to fit your product to this particular customer [26]. In a real business environment, it is a huge expense in time and labor to implement a one to one marketing solution in the past. Today, information technology can accelerate businesses to improve their interaction with customers more easily and efficiently.

Using the Internet to provide customers' personal products or services, it is an applicable solution to establish a low cost and high performance channel to accelerate interaction between businesses and customers

[7]. As the Internet users and information explosively grow, providing users' personal information or services actively that has become an important issue for those Website owners to retain customers' loyalty and satisfaction [31]. In the other hand, analyzing the users' personal searching or reading behavior that is also useful to accelerate businesses to understand the customers' requirements indeed. According to analytic data, the marketing salesman can provide customers one to one promotion activities.

Over these years, data mining and data warehouse become to power tools for businesses to sense the complicated market trend. Data mining and data warehouse retrieve useful knowledge or information from an enormous database, then integrate, accumulate and translate them into a part of the business wisdom [1]. In other words, data mining provides business managers an effective solution to retrieve valuable information from a variety of data sources.

As data mining and data warehouse grow, businesses can analyze customer's consumptive behavior and divide into several different kinds of groups or communities efficiently[30]. In this paper, we propose a user preference perception model using data mining and fuzzy set theory to detect user's preference trends or changes. It is applicable to accelerate businesses to understand what customers' preferences and their changes. Businesses can provide customers more fit and valuable information or services according to their preferences, and improve customer's satisfactions and achieve the aim of CRM.

The organization of this paper is as follows. First, we introduce some literatures include Data Mining, Knowledge Discovery in Database, Web Mining, Fuzzy Set Theory, and Mining Path Traversal Patterns. Second, we proposed a user preference perception model to calculate the degree of user's preferences and obtain the user's browsing patterns. Third, we built a website to demonstrate the feasibility and effectiveness of the proposed model. Finally, we make some conclusions at the end of this paper.

2. Literature Review

2.1. Data Mining and Knowledge Discovery

As information technology grows, businesses can aggregate and store mass data more easily and efficiently. But businesses expend a lot of space, money and labor in

maintaining those data and cannot acquire any additional benefit from them in the past. As the number of data and dimensions swift increases, analytic experts are harder to analyze and interpret data than the past. Therefore, Data Mining (DM) and Knowledge Discovery in Database (KDD) arose to support analyst and retrieve valuable information from mass data [14].

Data Mining is one of the most general approaches to reducing data in order to explore, analyze and understand it [15]. In the other views, scholars identify it is one method that can discover and extract implicit previously unknown and potentially valuable information, relationship and knowledge from previous data [4,10,15]. Knowledge discovery in Database (KDD) is the knowledge intensive processes of discovering knowledge that is implicit in large and diverse database [13,22,28]. It is an inherently iterative process of selecting data, preprocessing it, transforming it into a workable form, data mining over it, and interpreting the results [27]. According to the foregoing definition of DM and KDD, we identify the common aim of them is providing an efficient method to retrieve valuable information or knowledge from mass data. By these ways, businesses can acquire valuable information to make important decisions or strategies and enhance their competitiveness.

2.2. Web mining

The Internet has become one of the most popular information communication media in the world recently. It provides abundant, varied, and interactive information through the Web [4,11,18]. Although users can acquire amounts of information from Internet resources, they also face the serious information overload problem. Thus far, browsers and search engines cannot provide the information to meet users' requirements exactly and solve the information overload problem on the Internet effectively [7,20,21]. Web mining is one of effective tools to analyze users' browsing behavior and provide users the information meet their need respectively [18]. Web mining can be broadly defined as the discovery and analysis of useful information from the WWW [11,24]. Etzioni [12] divided Web mining into three parts as follows:

- (1) Resource discovery. Locating unfamiliar documents and services on the Web.
- (2) Information extraction. Extracting specific information from newly discovered Web resources automatically.
- (3) Generalization. Uncovering general patterns at individual Websites and across multiple sites.

Furthermore, there are three major categories in Web mining area as follows [2,5,11,18,20]:

- (1) Web content mining. The discovery of useful information from the Web.
- (2) Web structure mining. Trying to discover the model underlying the link structure of the Web.
- (3) Web usage mining. Trying to make sense of the data generated by the Web surfer's sessions or behaviors.

Web usage mining obtains logs file, user profiles, registration data, user sessions or transactions, cookies and any data as the results of interactions from web servers or proxy servers [18]. It mines those data to discover valuable information about user's intention. In this paper, we use Web usage mining to discovery the user's browsing patterns and perceive preference changes from his/her cookies.

2.3. Fuzzy Set Theory

A fuzzy set \tilde{A} in a universe of discourse X is characterized by a membership function $\mu_{\tilde{A}}(X)$ which associates with each element x in X a real number in the interval $[0,1]$. The function value $\mu_{\tilde{A}}(X)$ is termed the grade of membership of x in \tilde{A} [8,32].

Definition 2.1. A fuzzy set \tilde{A} of the universe if discourse of X is convex if and only if for all x_1, x_2 in X ,

$$\mu_{\tilde{A}}(\lambda x_1 + (1-\lambda)x_2) \geq \min(\mu_{\tilde{A}}(x_1), \mu_{\tilde{A}}(x_2)), \quad (1)$$

where $\lambda \in [0,1]$.

Definition 2.2. A fuzzy set \tilde{A} of the universe if discourse of X is called a normal fuzzy set implying that $\exists x_i \in X, \mu_{\tilde{A}}(x_i) = 1$.

A fuzzy number \tilde{n} is a fuzzy subset in the universe of discourse X whose membership function is both convex and normal (shown in Fig. 1).

Fig. 1 A fuzzy number \tilde{n} .

Definition 2.3. The α -cut of a fuzzy number \tilde{n} is defined as

$$\tilde{n}^\alpha = \{x_i; \mu_{\tilde{n}}(x_i) \geq \alpha, x_i \in X\}, \quad (2)$$

where $\alpha \in [0,1]$.

\tilde{n}^α is a non-empty bounded closed interval contained in X and it can be denoted by $\tilde{n}^\alpha = [n_l^\alpha, n_u^\alpha]$, n_l^α and n_u^α are the lower and upper bounds of the closed interval, respectively. Fig. 2 shows a fuzzy number \tilde{n} with α -cut [17,33].

Up to now, the fuzzy set theory has applied in many areas such as fuzzy logic control [6], fuzzy decision-making [19], fuzzy expert system [16], and fuzzy information retrieve [23] etc. In this paper, we apply the membership function of fuzzy set theory to represent and calculate the degree of user's preferences. It can help us to deal with the relationship between user's browsing time and the length of web page content efficiently.

Fig. 2 A fuzzy number \tilde{n} with α -cut.

2.4. Mining Path Traversal Patterns

In a distributed information-providing environment where documents or objects are lined together, users are apt to traverse objects back and forth in accordance with the links and icons provided [10]. Therefore, extracting the patterns from user's log data in such environment is referred to as mining path traversal patterns. It facilitates web-site owners or managers to understand what access paths are users interested in and relationships between web pages. These information or relationships will be the important references for website owners or managers to improve the website structure or content. For the sake of extracting valuable user's access patterns from log data, there are several procedures as described as follows [9].

- (1) Determining maximal forward references from the original log data. Using algorithms to convert the original sequence of log data into a set of traversal subsequences. Each traversal subsequence represents a maximal forward reference from the starting point of a user access.
- (2) Determining the large reference sequences. Using algorithms to determine the frequent traversal patterns and the termed large reference sequences from the maximal forward references. A large reference will appear a sufficient number of times

in the database.

- (3) Determining the maximal reference sequences. After large reference sequences are determined, maximal reference sequences can then be obtained in straightforward manner. A maximal reference sequence is a large reference sequence that is not contained in any other maximal reference sequences.

3. User Preference Perception Model

In this paper, we analyze log data from web servers to obtain user's surfing tracks and browsing time. Then both of fuzzy set theory and maximal reference sequences are applied to perceive the changes of user's preference in our model.

3.1. Converting log data

Obtaining user's surfing paths from the log data of web servers and convert them into user's traversal subsequence sets by user's number respectively. The traversal subsequence is a set of web-page nodes and sorted by the time-stamp in a determinate period, e.g. $T_1 = \{Y, B, H, C, T, I, H, J\}$ and $T_2 = \{Y, H, P, T, I, K, H, J\}$.

3.2. Eliminating the uninterested nodes

Eliminating the node whose browsing time exceeds the maximum threshold value from the user traversal subsequence set. In this paper, the maximum threshold value is denoted by t_{\max} . When the number of users visit the web page, we can compute the average of browsing time (t_{avg}). If a visitor's browsing time exceeds the average of browsing time in this web page, the degree of the visitor's preference is regarded as 1. It means that this visitor shall interest in this web page completely. Contrary to the foregoing situation, a visitor's browsing time more short means the visitor has much less interests about this web page. Therefore, the degree of the visitor's preference that depends on the browsing time is represented by the membership function of fuzzy set theory (shown in Fig. 3). The degree of preference (P) is calculated as follows.

$$P_{ki} = \begin{cases} 0, & t_{\max} < t_{ki} \\ 1, & t_{\text{avg}} \leq t_{ki} \leq t_{\max} \\ \frac{t_{ki}}{t_{\text{avg}}}, & 0 \leq t_{ki} < t_{\text{avg}} \end{cases} \quad (3)$$

where, t_{ki} is the browsing time of the k th visitor in the i th web page, P_{ki} is the degree of the k th visitor's preference in the i th web page.

According to the membership function of the preference degree, α -cut is applied to divide the web pages into two categories as follows.

- (1) If $P_{ki} \geq \alpha$, we think that the k th visitor has

interests about the i th web page. We reserve this web page in database to analyze the preference of this visitor at the rest of procedures.

- (2) If $P_{ki} < \alpha$, we think that the k th visitor has no interests about the i th web page and eliminate this web page in our model.

Fig. 3 The membership function of the preference degree.

3.3. Extracting browsing patterns

After the foregoing procedures, the interesting web pages of all users will be stored in database D_T . In this paper, each web page belongs to a category. Then, Full Scan (FS) algorithm, essentially utilizes the concept of DHP (Direct Hashing and Pruning), is applied to solve the discrepancy between traversal patterns and association rules [25].

For example, a user's traversal subsequence set is shown in Table 1. Recall that L_k represents the set of all large k -references and C_k is a set of candidate k -references. The procedures of the FS are described as follows.

- Step 1. Candidate 1-reference sequences and their support value (appearance frequency) are listed in G_1 (shown in Table 2).
- Step 2. After scanning through D_T , those k -references in C_k with count exceeding the threshold become L_k . Thus, FS gets L_1 and makes a hash table to count the number of occurrences of each 2-reference.
- Step 3. Starting with $k = 2$, FS generates C_k based on the hash table count obtained in the previous pass and determines the set of large k -references L_k , and makes a hash table to determine the candidate $(k + 1)$ -references. If L_k is nonempty, the iteration continues for the next pass (shown in Table 3 and 4).

In mining association rules, a set of candidate references C_k can be generated from joining L_{k-1} with itself, denoted by $L_{k-1} * L_{k-1}$. If we set the threshold equal to 3, the results of extracting browsing patterns are listed in Table 5.

3.4. Perceiving user's preferences

According to user browsing patterns and the degree of preference in each category, changes of a user's preferences will be perceived in the proposed model. In this study, each browsing pattern is regard as a document and its web pages that belong to the same category are regarded as a same term. The vector and the weighted value are applied to represent the degree of preference in different categories. The degree of preference in each category is calculated as follows.

$$P_i = (w_{i1} w_{i2} \dots w_{ik}) \quad (4)$$

where, the P_i is the i th user's preference degree in each category, w_{ij} is the i th user's preference degree in the j th category. ($j=1, 2, \dots, k$)

If a category appears in the almost of browsing patterns, it's the degree of importance should be less than the other categories appears in little patterns. Categories that are less important for browsing patterns should be assigned lower weights, whereas categories that are more important in a browsing pattern should be assigned higher

weights. According to this concept, we use TFIDF (Term Frequency – Inverse Document Frequency) [29] to adjust the degree of preference in each category from a browsing pattern. The formula is described as follows.

$$w_j^* = \sqrt{\frac{f_j}{n} \times \log \frac{p_n}{p_j} + 1} \quad (5)$$

where, w_j^* is the degree of preference in the j th category, f_j is the appearance frequency of the j th category, n is the total number of appearance frequency from each category in all browsing patterns, p_n is the total number of browsing patterns, p_j is the number of browsing patterns that contain the j th category.

For example, if the i th user's initial preferences are both of H and T categories, his/her preferences are denoted by $P_i = (w_H, w_P, w_Y, w_I, w_J, w_T) = (1, 0, 0, 0, 0, 1)$. After a determinate period, if the system gets user's browsing patterns are as same as table 5. The degree of preference in the H category is calculated as follows.

$$w_H^* = \sqrt{\frac{9}{19} \times \log \frac{7}{7} + 1} = 0.377$$

According to the results of preference measurement, user's preferences are denoted by $P_i = (0.377, 0.262, 0.212, 0.262, 0.726, 0.262)$. When the threshold of the degree of preference is 0.3, we filter out those preferences whose degree of preference are lower than the threshold and retain those preferences whose degree of preference are equal or higher than threshold. Thus, user's new preferences are denoted by $P_i = (w_H, w_P, w_Y, w_I, w_J, w_T) = (1, 0, 0, 0, 1, 0)$. Comparing the discrepancy between initial and new preferences, the change of user's preferences are perceived easily and obviously.

4. System design and experiments

In this paper, a website for providing personal news is built to demonstrate the feasibility and effectiveness of the proposed model. The system architecture and experiments are elaborated as follows.

4.1. System architecture and functions

In this study, a website for providing personal information is built in a personal computer with a Pentium 4 processor and Linux operation system. The architecture of this proposed system is shown in Fig. 4. The major components of this system and their functions are described as follows.

- (1) Web server log database. When a registered member logged in the website, all of his/her surfing paths and browsing time are recorded and stored in the server log database.
- (2) Converting log data. The system will convert log data into user's traversal subsequence sets by user's

registered number respectively.

- (3) Eliminating user uninterested nodes. In this stage, the system depends on threshold limit value of browsing time and α -cut to eliminate those web pages whose browsing time are excess long or the degree of preference are excess low.
- (4) Extracting browsing patterns. FS will extract applicable browsing patterns from user's traversal subsequence sets.
- (5) Perceiving user's preferences. After a determinate period, user's new preferences are perceived in this component. The system will provide user news according to his/her new preferences.
- (6) Providing general or personal news. User can select any ways that meet his/her requirements for providing news. If the function of general news providing is selected, website will provide all categories of news in news database by date. Otherwise, website will provide user personal news by his/her preferences in user profile database.
- (7) News search engine. users can search news that they needs manually; even both of date and the type of category are avail conditions in the news search proceeding.
- (8) User profile database. When a user registered in the web site, all of information, including name, password, email, initial preferences and the others data are stored in user profile database.
- (9) News database. The news from several news providers are stored and sorted by their category attribution. In periodical, the system will update

news database every four hours.

4.2. Experiments and results

In order to verify the feasibility and effectiveness of the preference perception model we proposed, a website is built and experiments are implemented at Da-Yeh University in Taiwan. The results of the experiment sufficient indicate this proposed model is effective in perceiving the change of user preferences.

4.2.1. Experimental procedure

In this experiment, the participants are students at Da-Yeh University. The topical categories are divided into "Stock and Security", "Society and Culture", "International", "Home and Living", "Mainland China", "Business and Economy", "Regional", "Government", "Entertainment", "Science and Computer", "Recreation and Sports". The experimental procedure is described as follows (shown in Fig.5).

- Step 1. Member registration. All participants filled out their profiles like name, password, email address and preferences in the registration form. (shown in Fig.6).
- Step 2. Providing member personal news. When a member login the website, he/she will see the personal news by category according to his/her preferences from user profile database (shown in Fig.7).

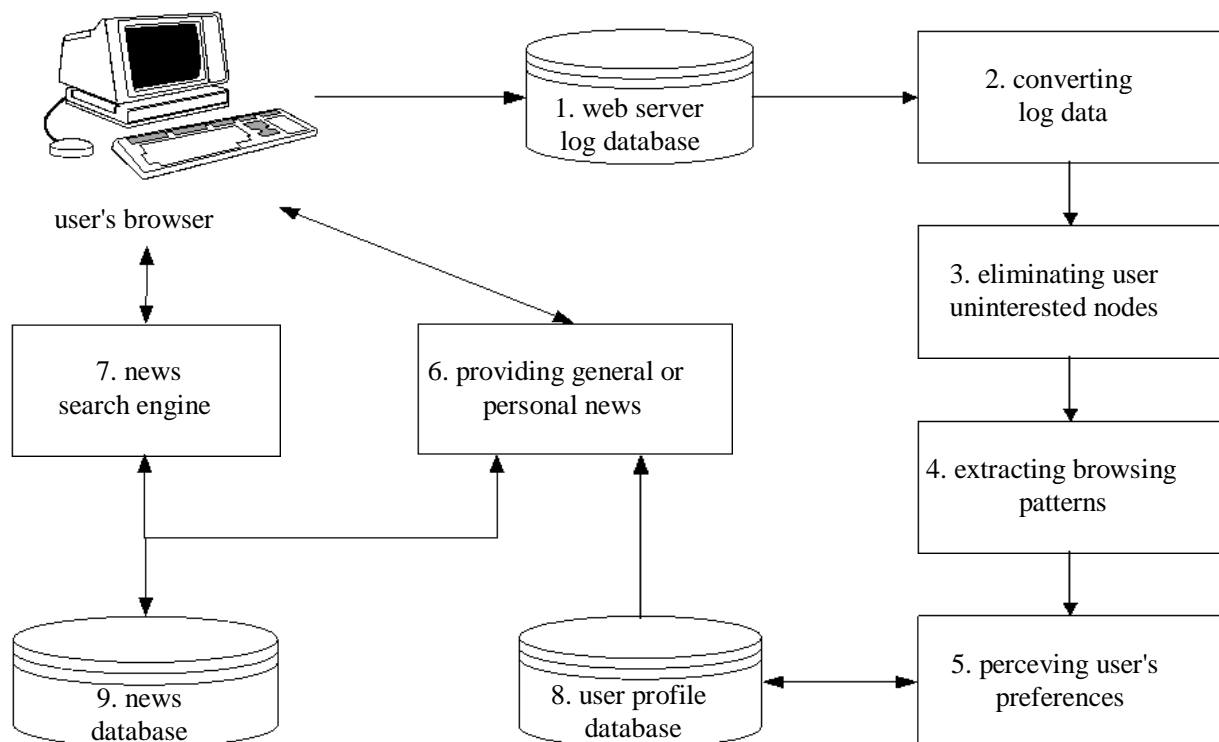

Fig. 4 The system architecture of the website.

- Step 3. Recording member's browsing behavior. The cookies in the member's browser are used to record all of surfing web pages, browsing time and timestamp. Till the member access the next web page, the cookies will be sent to the web server and stored in web server log database.
- Step 4. Perceiving member's preferences. According to the log data in three weeks, user's preferences are analyzed based on the user perception model we proposed. Due to the average of adult reading speed is 200 words per minute approximately [3], the average of reading time is applied to filter out those web pages that average of browsing time are excess long. In addition, the α is set 0.5 and threshold of traversal sequences is set 9. Thus, both of user browsing patterns and the degree of preference in each category are obtained from log data.
- Step 5. Providing member personal news. The website selects several news from those categories that meet user's preferences randomly. Members can see those selected news by category.
- Step 6. Satisfaction survey. In each bottom of news web page, members were asked to fill the questionnaire of satisfaction. The entire members and individual degree of satisfaction are calculated by the formula of satisfaction measurement.

4.2.2. Results analysis

During the experiment for the proposed preference perception model, there are 16176 pieces of news and 8087 log records are retrieved. Using the preference perception model, 576 avail maximal reference sequences and 314 browsing patterns are extracted and the changes of preference in 23 participants are perceived (shown in Table 6).

The results of the degree of satisfaction measurement for all participants are shown in Table 7. According to the results of satisfaction measurement, the average of the degree of satisfaction from member 3, 10 and 21 (their preferences had not changed) is 0.637. In the other side, the average of the degree of satisfaction from the other members (their preferences had changed) is 0.724. Thus, we can discover the degree of satisfaction for all members that preferences had been changed is higher than the others with no changes. In other words, the almost members can satisfy the results of the preference perception model we proposed.

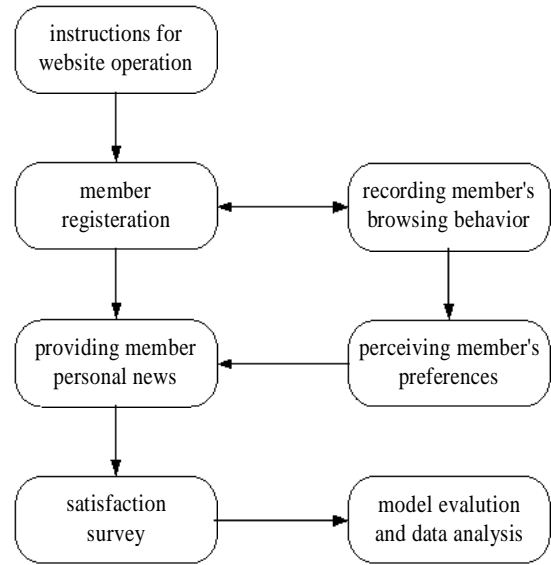

Fig. 5 A flowchart for experimental processes.

The screenshot shows a web interface for a 'Personal Intelligence' system. On the left is a sidebar with a tree view of categories. The main area is titled '新新聞目錄' (New News Directory) and contains a list of news items with checkboxes and radio buttons. Below this is a section for '個人資訊' (Personal Information) with fields for name, age, gender, etc. At the bottom, there are buttons for '新增新聞' (Add News), '刪除新聞' (Delete News), and '查詢新聞' (Search News).

Fig. 6 Fill out form of the member profile.

The screenshot shows a web interface for a 'Personal Intelligence' system. It displays a list of news items with their titles and categories. The interface includes a sidebar with a tree view of categories and a main area with a list of news items. Below the list, there are sections for '個人資訊' (Personal Information) and '新聞分類' (News Classification) with buttons for '新增新聞' (Add News), '刪除新聞' (Delete News), and '查詢新聞' (Search News).

Fig. 7 Personal news and category title.

5. Conclusions

In this paper, we proposed a user preference perception model using data mining on a web-based environment. After aggregating the user's web browse records, fuzzy set theory and most sequential pattern mining algorithm are applied to perceive the changes of user's preferences in a period. According to the user preference perception model, a web site for providing personal news is built to demonstrate the foregoing model we proposed. As the result of the degree of satisfaction survey from all participators, the degree of satisfaction are up to 72 % from the users whose preference had been changed in the test period.

Because of the convenience and prevalence the Internet provides, more and more businesses provide

information, service and product through it. If businesses can provide customer suitable service or products, they will improve not only competitiveness but also customer satisfaction and loyalty. The user preference perception model we proposed would accelerate businesses to provide more suitable information, services and products that meet the customer's requirements and make both of them enjoy the benefit through a web-based environment.

Abstract

The Internet has the potential to improve teaching and learning processes [1]. Learning and educational effectiveness of the integration of IT into the classroom has become a major issue. The purpose of this paper is to report on insights gained in integrating e-learning and classroom learning into my on-campus e-commerce courses over the last three years, and to explore planned and controlled approach to integrated model success for expected learning outcomes. A framework of the integrated model effectiveness is presented, which frames success dimensions, defines four dimensions of success, and addresses interrelated relationship. A survey study is used to demonstrate the analytic utility of the framework in the context of measurement of student learning experiences.

Keywords: Integrated Learning Model Success, Integrated Mode, Integrated Pedagogy, Student Satisfaction, Individual Impact and Evaluations.

1. Introduction

Recent years have witnessed the rapid expansion of online technology and its use in education and training. The Internet and web technologies are used for courses of study as small as self-paced tutorials and as large as entire degree programs [2]. Many educators intuitively feel that the integration of computing and communication technology into the classroom will enhance learning and the student ability to apply knowledge and skills to problem-solving situations. Despite this belief, pedagogic practice has not yet fully integrated information technology (IT) into the curriculum and classroom

activity, and computers remain greatly under-utilized in this context. [3]. The integration requires a fundamental change in the instructional mode, pedagogy design and learning process. The most critical challenge has been how to find effective approach to the integrated learning model success. The difficulty is to figure out how to perform the integrated strategies well.

Being an early adopter of the Internet in my traditional on-campus courses, I initiated a teaching research project for integrating Internet-based learning and classroom learning in E-Commerce course in 2000. I have reported an integrated learning model that has been used successfully in the course [4]. The objective of this study is to explore planned and controlled approach to integrated learning model success for expected learning outcomes. First, a framework of the integrated model effectiveness is presented, which frames success dimensions, defines four dimensions of success, and addresses interrelated relationship. Following that, a survey study is used to demonstrate the analytic utility of the framework in the context of measurement of student learning experiences. We expect the framework could be developed to serve as the conceptual basis for analysing and comparing education practice in integrating e-learning and classroom for enhancing education quality at university levels.

2. Background

A long practice in integrating e-learning and classroom learning in my traditional on-campus e-commerce courses has been developed since 2000. This year I published a paper to address the integrated mode of learning e-commerce. The integrated way is to create a supportive environment for learner centred learning process, which encompassing multimedia based

instruction teaching, Internet based learning, and teamwork. As Figure 1 illustrates, in each mode we design relevant methods for expected object of pedagogic practice. Grading consists of three portions that are commensurate with the activities existed in the learning process. A total of 930 students took the e-commerce course from 2000 to 2003, and 186 of them are graduate student. An analysis of students' feedback highlights strengths and features of such an approach. Statistical analysis revealed that successful use appears strongly related to the integration of the various course components based on IT, relevant methods fit for student satisfaction with a learning experience in the integrated environments, and the strategic instructional design for quality education.

Modes	Methods	Objects	Grading
Classroom	Multimedia instruction	Introducing foundation of e-commerce	Written examination: 40%
	Case teaching		
Internet-Based learning	Online virtual learning system	Providing a Individual learning in an asynchronou s mode	Experiment: 20%
	Online shopping	Providing an experience-oriented way to learn e-commerce from real world situation	
	Evaluation of Web sites		
	The virtual e-market operation		
Teamwork	Team project and presentation	Enhancing students' problem-solving skills and Collaborative ability	Project: 40%
	Building Web site		
	Business plans fore-commerce company		

Fig.1 The Integrated mode of learning E-Commerce

3. A Framework for Integrated Learning Model Success

The measurement of the integrated learning model success or effectiveness is critical to our understanding of the value and efficacy of new learning processes. We

attempt to synthesize our previous findings in the integrated mode of learning e-commerce into more coherent body of knowledge and to have an insight into the strategic design of such integration, which may be of benefit for universities with similar objectives. We proposal a taxonomy and an interactive model as framework for conceptualizing and operationalizing the integrated learning model success. The model consists of four interrelated dimensions of success: INTEGRATED MODE, INTEGRATED PEDAGOGY, STUDENT SATISFACTION AND INDIVIDUAL IMPACT.

The resultant integrated learning model success is produced in Figure 2.

Fig.2 The Integrated learning model success

Four interrelated dimensions of success can be interpreted as follows:

Integrated Mode

It is related to adopted modes in an e-commerce curriculum, such as Classroom, Internet-Based and Teamwork. There are important considerations on what should and shouldn't be placed in Internet-based learning environment and which tools work best to reach instructional goals. Integrating the online and face-to-face mode for different subjects and different courses need a careful analysis and design.

Integrated Pedagogy

Effective use and integration of e-learning and classroom learning in on-campus courses requires development of

the integrated pedagogy for student-centered so that faculty can make correct decisions regarding methods fit for student satisfaction with a learning experience in the integrated environments, course content development and strategic design for each activity in the learning process and so on.

Our research shows four elements exist in integrated learning processes, which are Experience-Oriented learning, Case Teaching, Individual learning through on-line virtual teaching system and Collaborative learning. It is considered to provide appropriate integration of four elements into pedagogic design; effort will have significant impact on education practice. Our finding indicates that relevant method used in integrated learning mode is of critical importance and understanding the way individuals learn is the key to improving the pedagogic practice [4].

Student Satisfaction

The innovative feature of integrated learning model is to transform the learning process from the instructor-centered into student-centered. This learner centered approach are that it is experience-oriented and activity-based, and in the approach students can create their own ideas, both individually and collaboratively. Evaluations of the learning model success will centre on student satisfaction. So strategy design for measurement should systematically combine individual measures from the model success categories to create a comprehensive measurement instrument.

Individual Impact

Student satisfaction and individual impact are closely interrelated. Positive experience with student will lead to greater impact on student's knowledge, ability and quality in a causal sense.

Effective learning is a process of building and transforming mental models. Transformations entail changes in organization and structure of knowledge, development of problem-solving ability and critical thinking ability, and enhancing student quality.

Four interrelated dimensions of success imply a planned and controlled approach in identifying,

integrating and evaluating the different modes, methods and activities in student-centered learning process for the intended education purposes.

4. Data Analysis and Result

In the study, the effects of the integrated learning model was measured in terms of students' evaluation of their learning experience. The subjects in the study were the one-hundred-and-seven student who took the courses in the fall of 2002. There were forty-three undergraduate (42.1%) students and sixty-four graduate (57.9%) students, and sixty male (56.1%) and forty-seven female (43.9%) students in these classes. Students participated all learning activities in the integrated learning model including On-line shopping, the Virtual e-market operation, Case teaching and Team-project. The students may also access, Online Virtual Teaching System at any time and any place. It provides an online learning platform as a supplement to classroom learning. The students learn by themselves in an asynchronous mode. They can view teaching material and use source of e-commerce course at their convenience. This system is mainly made up with six modules: course teaching, case discussion, exercise option, experiment teaching, team activities and BBS.

The 11 items used to measure students' evaluation of their learning experience were included in the post-course questionnaire. Five-point likert-type scales were used to measure all items. The questionnaire also contained two multiple-choice questions eliciting the subjects' comments on learning modes and teaching methods that they liked or disliked.

Participants' final exam scores were also available. The exams consisted of two parts. One was on material covered in the course, a written examination, and another was oral presentation of team project at class. It was impossible to connect questionnaire responses with these test scores because the questionnaires were administered anonymously.

Subjects reported higher levels of satisfaction with the modes and methods in integrated learning process, which are in correspondence with four elements in integrated pedagogy dimensions shown in Fig.2:

Experience-Oriented Learning, Individual learning, Collaborative learning and Case teaching. Mean and Variance for four elements are reported in Table 1. Univariate analysis of variance for the evaluation of four elements in integrated learning model is presented in Table 2.

SUMMARY					
Elements	Variables	Count	Sum	Mean	Variance
Experience-oriented	On-line shopping	107	448	4.186916	0.511903
	The virtual e-market operation	107	430	4.018692	0.754364
Individual learning	On-line virtual teaching system	107	431	4.028037	1.178452
Collaborative	Team-project	107	417	3.897196	0.942162
Case teaching		107	431	4.028037	0.65015

Table 1. Summary: Mean and Variance for four elements of the integrated learning model

Indeed, the medians for all four elements are well above a rating of 3.89, indicating that students rated the integrated model on the positive side. In fact, as demonstrated by the three elements with medians of 4.0, the students found the experience-oriented learning, case teaching and individual learning particularly important and valuable.

Source	SS	df	MS	F	P-value	F crit
Between Groups	4.534579	4	1.133645	1.404058	0.231316	2.388752
Inside Group	427.9252	530	0.807406			
Total	432.4598	534				

Table 2. Univariate Analysis of Variance for the evaluation of four elements in Integrated Learning Model

Students' response to the open-ended question related to learning mode and method are reported in Table 3. This feedback provided further insight into the characteristic of each mode. It was highlighted that especially the Virtual E-Market operation was regarded as an exciting element of this integrated mode. Students

seem to be aware of the increasing importance of this experience-oriented approach. Besides the learning outcome regarding further understanding of real-world e-business process, the developed skills in making exchange and collaboration in the process was very much appreciated by the students. For Online Virtual Teaching system and Teamwork, It had a higher proportion of positive opinions than Classroom teaching, while Case teaching was very much appreciated by the students. The feedback corroborated that Case teaching is a good teaching method in traditional face-to-face learning mode, and students would prefer to be in the classroom with the professor for hands-on enlightening and teaching.

Question	Multiple-choice	Percentage
My most favourite learning mode in this course	Classroom teaching	11.2 %
	The Virtual E-Market operation	49.5%
	Teamwork	41.1%
	Online Virtual Teaching system	44.8%
Which method should be used in the e-commerce learning model	Instruction in basic e-commerce	61.6%
	Case teaching	75.7%
	The chapter exercises	28%
	The Virtual E-Market operation	78.5%
	Class discussion	42.9%
	Teamwork	71%

Table 3. Result of students' response to the open-ended question related to learning mode and method

Data analysis supported the utility of the framework, indicating that overall, students' affective reactions to the integrated learning model and pedagogy were powerful positive. That is, students have experienced integrated learning process in support of their knowledge construction, active learning, cooperation and learning via problem solving, and individual self-efficacy through On-line virtual teaching system.

5. Further Research and Conclusions

Based on previous research we develop a framework of the determinants of the integrated learning model effectiveness and report the results of a survey study to empirically test it. The framework for integrated learning model success seems to be flexible means that are amenable to the implementation of different learning modes, and to be planned and controlled approach to evaluate how learning model, pedagogy, and subject matter interact to produce desired learning outcomes.

These preliminary results have revealed possible topics of research. Our next step will be to improve our survey instrument to better isolate the effect of pedagogy used in right mode for subject satisfaction. It is important to attention to the possible interactions among the success dimensions and the effect of various independent variables on one or more of these dependent success dimensions. Four success dimensions that we identified in our framework also await systematic measurement in the context of empirical investigation.

With our efforts and practice in the project the framework could be developed to serve as the conceptual basis for analysing and comparing education practice in integrating e-learning and classroom for enhancing education quality at university levels.

On Improving an Integrated Inventory Model for a Single Vendor and Multiple Buyers with Ordering Cost Reduction

Liang LIANG, Yugang YU, Yu DONG

(School of Business, University of Science and Technology of China, Hefei, Anhui, 230026, P R China, lliang@ustc.edu.cn, ygyums@hotmail.com)

Abstract

In this paper, we propose a new model for improving lot size as obtained on applying the model given in “An integrated inventory model for a single vendor and multiple buyers with ordering cost reduction” (Int. J. Production Economics 73 203-215) proposed by Woo, Hsu, and Wu (2001) and our model provides a lower or equal joint total relevant cost as compared to Woo, Hsu, and Wu’s model. And a numerical study based on the example used by Woo, Hsu, and Wu is presented.

1. Introduction

Reducing inventory levels of raw materials, work-in-process, and finished items simultaneously in different stages has become the major focus for supply chain management. In recent years, there has been a growing trend in both research work and practical applications of VMI (vendor managed inventory) policy for various industries. Goyal (1977) [3] proposes a joint economic lot size (JELS) model where the objective is to minimize the total relevant costs for a single vendor, single buyer system. Banerjee (1986) [1] generalizes Goyal's model by incorporating a finite production rate for the vendor and gives the optimal joint production or order quantity. Goyal (1988) [4] extends Banerjee's model again by relaxing the lot-for-lot production assumption and argues that the economic production quantity will be an integral multiple of the buyer's purchase quantity and shows that its model provides a lower or equal joint total relevant cost as compared to Banerjee's model. Kohli and Park [5] investigate joint ordering policies as a method to reduce transaction costs between a single vendor and a homogeneous group of buyers. They present expressions for optimal joint order quantities assuming all products are ordered in each joint order. Lu [6] considers a one-vendor multi-buyer integrated inventory model and gives a heuristic approach for joint replenishment policy. Banerjee and Banerjee (1992) [2] consider an EDI-based vendor-managed inventory (VMI) system in which the vendor makes all replenishment decisions for his/her buyers to improve the joint inventory cost. Woo, Hsu, and Wu (2001) [7] extend the previous work to three level supply chain in which raw materials and EDI are considered. In the work, they considered that the

replenishment cycle is an integral multiple of the common replenishment cycle of the vendor and all buyers. The work also relaxes the lot-for-lot production assumption and performs a good effect since many optimal integer multiple used in the numerical example of Woo, Hsu, and Wu's paper are greater than 1, that is, the replenishment cycle of raw materials is no less than that of finished items. This may be true when ordering cost per raw material order for vendor is quite high, the inventory cost for raw materials is relatively low and the ordering cost for finished items is quite low etc. Otherwise, the replenishment cycle for raw materials may be less than that of finished items. So In this paper, we propose a new model for improving lot size as obtained on applying the model given in “An integrated inventory model for a single vendor and multiple buyers with ordering cost reduction”(Int. J. Production Economics 73 203-215) proposed by Woo, Hsu, and Wu (2001). And a numerical study based on the example used by Woo, Hsu, and Wu is presented.

2. Assumptions and Notations

2.1 Assumptions

1. Shortages are not allowed for the vendor.
2. The information of each buyer's replenishment decision parameters is available to the vendor.
3. The planned ordering cost for each buyer depends on the expenditure incurred per unit time to operate the new ordering system. This expenditure could be the leasing cost of equipment and the operating cost to keep the system working effectively.
4. The vendor purchases raw materials outside to produce finished items. The procurement cycle of raw materials is assumed to be an integral multiple of the common replenishment cycle for finished items or the common replenishment cycle for finished items is assumed to be an integral multiple of the procurement cycle of raw materials.

Assumptions 1-3 follow the assumptions of Woo, Hsu, and Wu (2001), and assumption 4 is a relaxation to that

of Woo, Hsu, and Wu (2001).

2.2 Notations

M	Number of buyers considered
$i=1,2,\dots,m$	Index of buyers
D_i	Demand rate for buyer i , which is a known constant
n	Integral number or fraction which denominator is an integer and numerator is one, which indicates the production batches per raw material procurement cycle and n is a decision variable
K	Expenditure per unit time to operate the planned ordering system between vendor and all buyers, which is a decision variable
C	Common cycle time for buyers, which is a decision variable
f_i	Fraction of backlogging time in a cycle for buyer i , which is a decision variable
M	Usage rate of raw materials for producing each finished item
A	Ordering cost per raw material order for vendor
S	Setup cost for production run for vendor
x	$x=0$ if $n \geq 1$ and $x=1$ if $n < 1$ which is a binary variable
T_{0i}	Original ordering cost per buyer i 's order
$T_i(K)$	Planned ordering cost per buyer i 's order, which is a strictly decreasing function of K with $T_i(0) = T_{0i}$ and $T_i(K_0) = 0$
H_{vm}	Carrying cost per unit of raw materials held per time for vendor
H_{vp}	Carrying cost per finished item held per unit time for vendor
H_{bi}	Carrying cost per unit held per unit time for buyer i
L_i	Backlogging cost per unit backlogged per unit time for buyer i
TC_{bi}	the buyer i 's total inventory cost for finished items per unit time
TC_{vp}	Vendor's total cost per unit time for finished items

TC_p	the inventory cost of finished items for all buyers and the vendor
HC_{vm}	Vendor's carrying cost per procurement cycle for raw materials when $n \geq 1$
TC_{vm}	Vendor's total cost per unit time for raw materials when $n \geq 1$
JTC	Joint total cost per unit time for vendor and all buyers
HC_{vm}'	Vendor's carrying cost per procurement cycle for raw materials when $n < 1$
TC_{vm}'	Vendor's total cost per unit time for raw materials when $n < 1$

3. Model

The behavior of inventory levels for the vendor and all buyers for finished items is illustrated in Fig.1 which is the same as that of Woo, Hsu and Wu's. Therefore, the buyer i 's total inventory cost for finished items per unit time is

$$TC_{bi} = \frac{T_i(K)}{C} + \frac{C}{2} [H_{bi}(1-f_i)^2 D_i + L_i f_i^2 D_i] \quad (1)$$

The vendor's inventory for finished items is

$$TC_{vp} = \frac{1}{C} [S + H_{vp} \sum_{i=1}^m \frac{D_i^2 C^2}{2P}] = \frac{S}{C} + \frac{CH_{vp}}{2P} \sum_{i=1}^m D_i^2 \quad (2)$$

Then the inventory cost of finished items for all buyers and the vendor is

$$TC_p = \sum_{i=1}^m \frac{T_i(K)}{C} + \frac{C}{2} \sum_{i=1}^m [H_{bi}(1-f_i)^2 D_i + L_i f_i^2 D_i] + \frac{S}{C} + \frac{CH_{vp}}{2P} \sum_{i=1}^m D_i^2. \quad (3)$$

The inventory levels for raw materials in the paper of Woo, Hsu and Wu (2001) is illustrated in Fig.2. The arrival of each raw material procurement will coincide with the start of a new production run. The procurement lot size of raw materials is equal to n multiple of the usage of each production batch and hence each procurement cycle equals nC time units. The stock of raw materials will be consumed continuously during each production run period $\sum_{i=1}^m D_i C/P$, and then be held until the next production run starts.

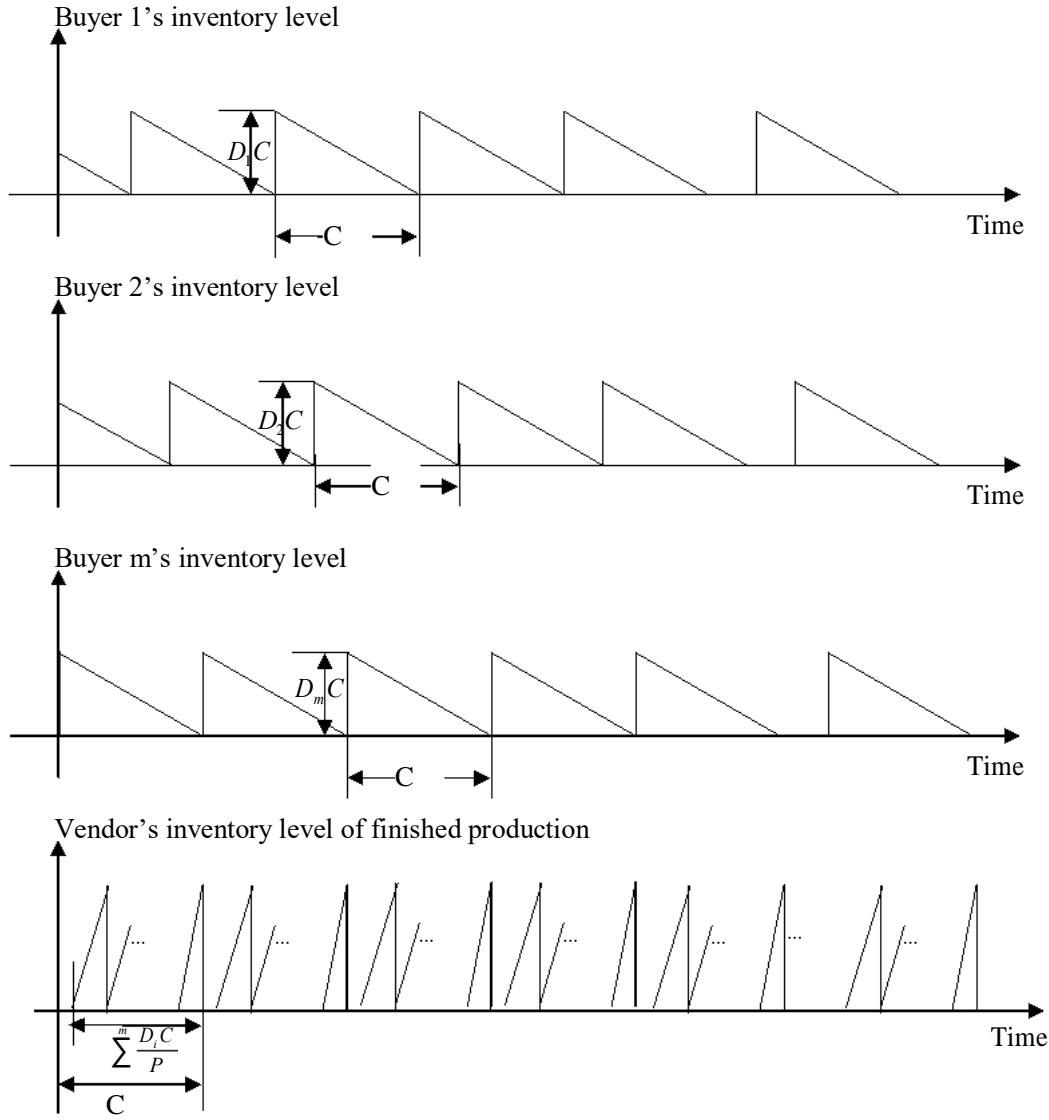

Fig. 1. The inventory level for finished items

Therefore, the vendor's raw materials stock per procurement cycle consists of n triangles and $(n-1)$ rectangles and the carrying cost for raw materials per cycle is

$$\begin{aligned}
 HC_{vm} &= H_{vm} \left[\frac{1}{2} (nM \sum_{i=1}^m D_i C) \left(\frac{\sum_{i=1}^m D_i C}{P} \right) \right. \\
 &+ \sum_{i=1}^{n-1} \left(\sum_{i=1}^m D_i C^2 \right) \left. \right] \\
 &= \frac{nMH_{vm}}{2P} \left(\sum_{i=1}^m D_i C \right)^2 + \frac{n(n-1)MH_{vm}}{2} \sum_{i=1}^m (D_i C^2). \quad (4)
 \end{aligned}$$

Thus, the vendor's total inventory cost for raw materials per unit time is

$$TC_{vm} = \frac{1}{nC} (A + HC_{vm}) = \frac{A}{nC} + \frac{CMH_{vm}}{2} \sum_{i=1}^m D_i (n-1)$$

$$+ \frac{\sum_{i=1}^m D_i}{P}. \quad (5)$$

From the inventory formulation of raw materials above, the least procurement cycle of raw materials is the common replenishment cycle, C . These may be true when the ordering cost per raw material order for the vendor is larger enough than setup cost per production run for the vendor. However, if the ordering cost per raw material order is small, for example, all raw materials being sent by all suppliers of the vendor or in JIT (just in time) setting), the procurement cycle of raw materials may be relatively short comparing with that of the common replenishment cycle for all buyers. In this setting we assume the usage of each production batch is an integral multiple of the procurement lot size of raw materials. That is, the procurement cycle of raw materials

is the fraction multiple of the production run of finished items. For the fraction (notified by n), the denominator is an integer and the numerator is one. By this policy, the

change of inventory levels of raw materials is shown in Fig. 3.

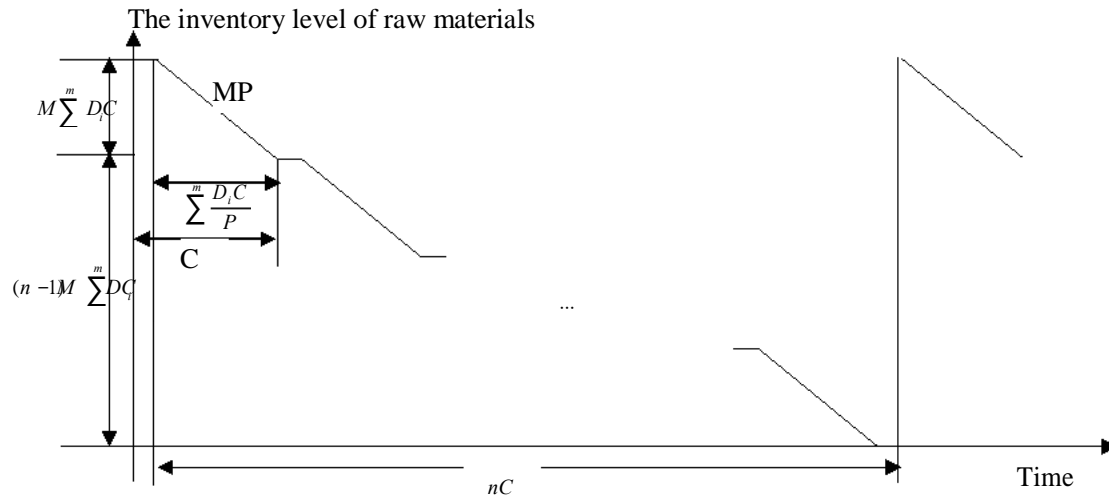

Fig. 2. One kind inventory level for raw materials

Fig. 3. Another kind inventory level for raw materials

The vendor's raw materials stock per procurement cycle consists of n triangles and the carrying cost of raw materials per cycle is

$$HC'_{vm} = \frac{nMH_{vm}}{2} \sum_{i=1}^m (D_i C) \left(\sum_{i=1}^m \frac{D_i C}{P} \right) \\ = \frac{nMC^2 H_{vm}}{2P} \left(\sum_{i=1}^m D_i \right)^2. \quad (6)$$

Thus, the vendor's total inventory cost for raw materials per unit time is

$$TC'_{vm} = \frac{1}{nC} (A + HC'_{vm}) = \frac{A}{nC} + \frac{nMCH_{vm}}{2P} \left(\sum_{i=1}^m D_i \right)^2. \quad (7)$$

Therefore, comparing with lot-for-lot policy and that of Woo, Hsu and Wu (2001) a more general model (notified by GM) is proposed here.

Model GM:

$$\min_{K, n, C, x, f_i} JTC = K + TC_p + (1-x)TC_{vm} + xTC'_{vm} \\ = K + \frac{1}{C} \left[\frac{A}{n} + S + \sum_{i=1}^m T_i(K) \right] + \frac{C}{2} \sum_{i=1}^m [H_{bi}(1-f_i)^2 D_i \\ + L_i f_i^2 D_i] + \frac{CH_{vp}}{2P} \sum_{i=1}^m D_i^2 + \frac{CMH_{vm}}{2} \left[(1 \right.$$

$$-x) \sum_{i=1}^m D_i (n-1 + \frac{\sum_{i=1}^m D_i}{P}) + x \frac{n(\sum_{i=1}^m D_i)^2}{P}, \quad (8)$$

subject to:

$$1 - n \leq x(\sum_{i=1}^m D_i C) \quad (9)$$

$$\sum_{i=1}^m D_i < P, \quad (10)$$

$$T_i(K) = T_{0i} e^{-rK}, \quad r > 0 \text{ and } i=1,2,\dots,m \quad (11)$$

where K , f and C are nonnegative variables; x is a binary

variable; and $n \in \{\frac{1}{\infty}, \dots, \frac{1}{2}, 1, 2, \dots, \infty\}$.

4. Analysis of the Model

Model GM gives an alternative for raw material procurement cycle; one is that the procurement cycle is integral times common cycle time and another is that the common cycle time of finished items is integral times the procurement cycle of raw materials. When $n > 1$ the model in this paper is the same as that of Woo, Hsu, and Wu (2001). From the paper of Woo, Hsu, and Wu (2001), the optimal result is derived as:

$$f_i^* = \frac{H_{bi}}{H_{bi} + L_i} \quad (12)$$

$$C^* = \sqrt{\frac{2[A/n + S + \sum_{i=1}^m T_i(K)]}{H \sum_{i=1}^m D_i}} \quad (13)$$

$$n^*(K) = \begin{cases} \frac{AG}{MH_{vm}(S + \sum_{i=1}^m T_i(K))} \leq n^*(n^*+1) & \text{if } G > 0, \\ 1 & \text{otherwise,} \end{cases} \quad (14)$$

$$K^* = \begin{cases} \frac{1}{r} \ln \frac{Hr^2 \sum_{i=1}^m D_i \sum_{i=1}^m T_{0i}}{1 + \sqrt{1 + 2Hr^2 \sum_{i=1}^m D_i ((A/n) + S)}} & \text{if } n > N, \\ 0 & \text{otherwise,} \end{cases} \quad (15)$$

where

$$H = MH_{vm} (n-1 + \frac{\sum_{i=1}^m D_i}{P}) + \frac{1}{\sum_{i=1}^m D_i} [\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i}], \quad (16)$$

$$G = \frac{1}{\sum_{i=1}^m D_i} [\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} - MH_{vm} (1 - \frac{\sum_{i=1}^m D_i}{P})] \quad (17)$$

$$N = \frac{2(S + \sum_{i=1}^m T_{0i}) - Gr^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2}{2MH_{vm} r^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2} + \frac{\{[2(S + \sum_{i=1}^m T_{0i}) - Gr^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2]^2\}}{2MH_{vm} r^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2} + \frac{8AMH_{vm} r^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2}{2MH_{vm} r^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2} \quad (18)$$

We have $x = 1$ from Model GM when $n < 1$. Model GM can be rearranged as model RGM.

Model RGM:

$$\min_{K, n, C, x, f_i} JTC' = K + \frac{1}{C} [\frac{A}{n} + S + \sum_{i=1}^m T_i(K)] + \frac{C}{2} \sum_{i=1}^m [H_{bi} (1 - f_i)^2 D_i + L_i f_i^2 D_i] + \frac{CH_{vp}}{2P} \sum_{i=1}^m D_i^2 + \frac{nCMH_{vm} (\sum_{i=1}^m D_i)^2}{2P}, \quad (19)$$

subject to Equations (10) and (11).

From Equation (19), for any given C , K , and n , the optimal value of f_i can easily be obtained as

$$f_i^* = \frac{H_{bi}}{H_{bi} + L_i} \quad (20)$$

By substituting (20) into (19) and rearranging the result, we can have

$$JTC' = K + \frac{1}{C} [\frac{A}{n} + S + \sum_{i=1}^m T_i(K)] + \frac{C}{2} [\sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} + \frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \frac{nMH_{vm} (\sum_{i=1}^m D_i)^2}{P}]. \quad (21)$$

From Equation (21), for any given K , and n , the optimal value of C can be obtained as

$$C^* = \sqrt{\frac{2[A/n + S + \sum_{i=1}^m T_i(K)]}{H \sum_{i=1}^m D_i}}, \quad (22)$$

where

$$H' = \frac{nMH_{vm} \sum_{i=1}^m D_i}{P} + \frac{1}{\sum_{i=1}^m D_i} \left[\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} \right] \quad (23)$$

Substituting (22) into (21), the joint total cost for any given K and n becomes

$$JTC'(n, K) = K + \sqrt{2H' \sum_{i=1}^m D_i \left[\frac{A}{n} + S + \sum_{i=1}^m T_i(K) \right]} \quad (24)$$

Theorem 1 For any fixed K, the optimal value of n for (24) can be determined as

$$\frac{1}{n^{*2}}(1 - n^*) < \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \leq \frac{1}{n^{*2}}(n^* + 1) \quad (25)$$

where

$$B = \frac{A}{\sum_{i=1}^m D_i} \left[\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} \right] \quad (\text{see Appendix A for proof}).$$

for proof).

Lemma 1 With the increasing of K, n^* is decreasing and the minimal n^* is bounded by the case when K=0 (see Appendix B for proof).

Lemma 1 implies that the greater the expenditure in ordering cost reduces the shorter raw materials procurement cycle is. When $n^*=1$, JIT setting occur. It is intuitively appealing and also the main reason why the integrated inventory system is willing to invest to reduce the ordering cost.

Theorem 2 The optimal K can be determined by

$$K^* = \begin{cases} \frac{1}{r} \ln \frac{H' r^2 \sum_{i=1}^m D_i \sum_{i=1}^m T_{0i}}{1 + \sqrt{1 + 2H' r^2 \sum_{i=1}^m D_i ((A/n) + S)}} & \text{if } n > N', \\ 0 & \text{otherwise,} \end{cases} \quad (26)$$

where $N' =$

$$\frac{P(2(S + \sum_{i=1}^m T_{0i}) - Br^2(\sum_{i=1}^m T_{0i})^2) + \{8PAMH_{vm} r^2(\sum_{i=1}^m T_{0i})^2\}}{2MH_{vm} r^2(\sum_{i=1}^m T_{0i})^2}$$

$$+ \frac{[P(2(S + \sum_{i=1}^m T_{0i}) - Br^2(\sum_{i=1}^m T_{0i})^2)]^{1/2}}{2MH_{vm} r^2(\sum_{i=1}^m T_{0i})^2} \quad (27)$$

(see Appendix C for proof)

5. Algorithm Steps

Through the above analysis, we present an algorithm for solving Model GM by the following steps:
Step 1: Give the all solutions by Equations (14)-(15) which are given by the paper of Woo, Hsu, and Wu (2001). If $n > 1$, these solutions are considered as the optimal solutions of Model GM, set $n=0$ and go to Step 3; else, go to Step 2.

Step 2: For each $n \in \{n | n(K=0) \leq n \leq 1\}$, calculate the

corresponding optimal K by Equation (26), and give the optimal K and n. Then gives the other optimal solutions f and C by Equations (20) and (22), set $n=1$ and go to Step 3.

Step 3: substitute the optimal n, K, f and C into Equation (8), and get minimal JTC.

6. Numerical Analysis

This section presents numerical example to Model GM. Some of related input parameters which no change come from the paper of Woo, Hsu, and Wu (2001) are given in Table 1. The other parameters changed are shown in Table 2. These parameters are changed five times and the corresponding results are shown in Table 2 too for comparing with the policy of Woo, Hsu, and Wu (2001). The unit time is one year and the monetary unit is U.S. dollar.

Table 1 Values of input parameters

Parameters	Value	Parameters	Value

*The results with the policy of Woo, Hsu, and Wu (2001). ** The results with Model GM

From Table 2, we have two interesting findings:

1. When $x^*=1$ the joint total cost with Model GM is less than that of Woo, Hsu, and Wu (2001), such as points 1 and 2. In these settings, $n^*=1$ with the policy of Woo, Hsu, and Wu (2001). However since in these points A is lower and S and T_{0i} are higher than those at point 3, the vendor prefers more ordering times in a common replenishment cycle C, and we have a lower joint total cost than the results with the policy of Woo, Hsu, and Wu (2001). For example, at point 3, $n^*=1$ and $JTC^*=\$21767$ in results 1, however $n^*=1/3$ and $JTC^*=\$21171$ in results 2. Model GM adopts the policy of ordering three times in one common replenishment cycle while lot-for-lot policy is implemented with the policy of Woo, Hsu, and Wu (2001) and the joint cost is reduced from $\$21767$ to $\$21171$ by $\$596$.
2. When $x^*=0, n>1$ the results with Model GM are the same as those with the policy of Woo, Hsu, and Wu (2001) where $n^*\geq 1$, such as at point 3, 4 and 5.

7. Conclusion

In this paper, a general model and the corresponding algorithm are proposed. From the last numerical example, it can be seen that Model GM provides a lower or equal joint total relevant cost as compared to that of Woo, Hsu, and Wu's model.

Appendix A:

For any fixed K, the minimization of $JTC'(n, K)$ in

Equation (24) is equivalent to

$$\begin{aligned}
 \min_n \{ & \frac{nMH_{vm} \sum_{i=1}^m D_i}{P} + \frac{1}{\sum_{i=1}^m D_i} [\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 \\
 & + \sum_{i=1}^m \frac{H_{bi}L_iD_i}{H_{bi}+L_i}] [\frac{A}{n} + S + \sum_{i=1}^m T_i(K)] \\
 = & \min_n \frac{AMH_{vm} \sum_{i=1}^m D_i}{P} + n \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{P} \\
 & + \frac{A}{n} \frac{1}{\sum_{i=1}^m D_i} [\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi}L_iD_i}{H_{bi}+L_i}] \\
 & + \frac{1}{\sum_{i=1}^m D_i} [\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi}L_iD_i}{H_{bi}+L_i}] [S + \sum_{i=1}^m T_i(K)]
 \end{aligned} \tag{A-1}$$

Thus $\min_n JTC'(n, K)$ is equivalent to

$$\min_n \{ n \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{P}$$

$$+ \frac{A}{n} \frac{1}{\sum_{i=1}^m D_i} \left[\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} \right] \quad (A-2)$$

And let

$$Y(n') = \left\{ \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{n' P} \right.$$

$$\left. + \frac{n' A}{\sum_{i=1}^m D_i} \left[\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} \right] \right\}$$

and $n' = \frac{1}{n}$, we have

$$Y(n' + 1) - Y(n') =$$

$$\begin{aligned} & - \frac{1}{n'(n' + 1)} \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{P} \\ & + \frac{A}{\sum_{i=1}^m D_i} \left[\frac{H_{vp}}{P} \sum_{i=1}^m D_i^2 + \sum_{i=1}^m \frac{H_{bi} L_i D_i}{H_{bi} + L_i} \right] \end{aligned} \quad (A-3)$$

and

$$[Y(n' + 1) - Y(n')] - [Y(n') - Y(n' - 1)] =$$

$$\frac{2}{n'(n'^2 - 1)} \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{P} > 0. \quad (A-4)$$

So $Y(n')$ is a strictly convex function and the

sufficient and necessary condition for $Y(n')$ to be minimal at n is therefore

$$Y(n' + 1) - Y(n') \geq 0 \quad \text{and} \quad Y(n' - 1) - Y(n') > 0.$$

That is,

$$n'(n' - 1) < \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \leq n'(n' + 1)$$

Therefore,

$$\frac{1}{n^2} (1 - n) < \frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \leq \frac{1}{n^2} (n + 1).$$

Appendix B:

When $n < 1$,

$$\frac{\partial}{\partial n} \left[\frac{1}{n^2} (1 - n) \right] = \frac{n - 2}{n^3} < 0 \quad \text{and}$$

$$\frac{\partial}{\partial n} \left[\frac{1}{n^2} (1 + n) \right] = \frac{-n - 2}{n^3} < 0.$$

So we have the minimal n when

$$\frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \text{ get its maximum.}$$

Since

$$\frac{\partial}{\partial K} \left[\frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \right]$$

$$= \frac{MH_{vm} \sum_{i=1}^m D_i}{PB} \sum_{i=1}^m \frac{\partial T_i(K)}{\partial K}$$

$$= \frac{MH_{vm} \sum_{i=1}^m D_i}{PB} \sum_{i=1}^m \frac{\partial T_i(K)}{\partial K}$$

$$= - \frac{MH_{vm} \sum_{i=1}^m D_i}{PB} \sum_{i=1}^m T_{0i} r e^{-rK} < 0.$$

$$\frac{MH_{vm} \sum_{i=1}^m D_i [S + \sum_{i=1}^m T_i(K)]}{PB} \text{ is a decreasing function}$$

with respect to K .

So when $K=0$, n^* get its minimum.

That is,

$$n(K=0) \leq n \leq 1.$$

Appendix C:

From Lemma 1, we know that $n \in \{1, \frac{1}{2}, \frac{1}{3}, \dots$

$\dots, n^*(K=0)\}$ for any n . that is, n is numerical. So we can

calculate optimal K to minimize $JTC'(n, K)$ for any

fixed n . So for any fixed n , from

$$\frac{\partial}{\partial K} JTC'(n, K) =$$

$$1 + \sqrt{\frac{H' \sum_{i=1}^m D_i}{2[A/n + S + \sum_{i=1}^m T_i(K)]}} \sum_{i=1}^m \frac{\partial T_i(K)}{\partial K}$$

$$= 1 - \sqrt{\frac{H' \sum_{i=1}^m D_i}{2[A/n + S + \sum_{i=1}^m T_{0i} e^{-rK}]}} \sum_{i=1}^m T_{0i} r e^{-rK} = 0, \quad (C-1)$$

the solution of Equation (C-1), notified by K_1 can be obtained as

$$K_1 = \frac{1}{r} \ln \frac{H' r^2 \sum_{i=1}^m \sum_{j=1}^m T_{0i}}{1 + \sqrt{1 + 2H' r^2 \sum_{i=1}^m D_i ((A/n) + S)}}, \quad (C-2)$$

and

$$\sum_{i=1}^m \frac{\partial T_i(K_1)}{\partial K_1} = - \sqrt{\frac{2[A/n + S + \sum_{i=1}^m T_i(K_1)]}{H \sum_{i=1}^m D_i}}. \quad (C-3)$$

Since

$$\begin{aligned} \frac{\partial^2 JTC'(n, K)}{\partial K^2} &= \sqrt{\frac{H' \sum_{i=1}^m D_i}{2[A/n + S + \sum_{i=1}^m T_i(K)]}} \left\{ \sum_{i=1}^m \frac{\partial^2 T_i(K)}{\partial K^2} \right. \\ &\quad \left. - \frac{\sum_{i=1}^m (\partial T_i(K) / \partial K)^2}{2[A/n + S + \sum_{i=1}^m T_i(K)]} \right\} \end{aligned} \quad (C-4)$$

, substituting (C-3) to Equation (C-4), we have

$$\begin{aligned} \frac{\partial^2 JTC'(n, K_1)}{\partial K_1^2} &= \sqrt{\frac{H' \sum_{i=1}^m D_i}{2[A/n + S + \sum_{i=1}^m T_i(K_1)]}} \left\{ \sum_{i=1}^m \frac{d^2 T_i(K_1)}{dK_1^2} \right. \\ &\quad \left. - \frac{1}{H' \sum_{i=1}^m D_i} \right\}. \end{aligned} \quad (C-5)$$

Since

$$\begin{aligned} \sum_{i=1}^m \frac{d^2 T_i(K_1)}{dK_1^2} &= - \frac{1 + \sqrt{1 + 2H' r^2 \sum_{i=1}^m D_i (A/n + S)}}{H' \sum_{i=1}^m D_i} \\ &> \frac{1}{H' \sum_{i=1}^m D_i}, \end{aligned} \quad (C-6)$$

we have

$$\begin{aligned} &\times \left(n - \frac{P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2) + \sqrt{8PAMH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2 + [P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2)]^2}}{2MH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2} \right) \\ &\times \left(n - \frac{P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2) - \sqrt{8PAMH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2 + [P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2)]^2}}{2MH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2} \right) > 0. \end{aligned} \quad (C-11)$$

Therefore, $K_1 > 0$ if and only if

$n >$

$$\frac{P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2) + \sqrt{8PAMH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2 + [P(2(S + \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2)]^2}}{2MH_{vm} r^2 (\sum_{i=1}^m T_{0i})^2}.$$

$$\frac{\partial^2 JTC'(n, K_1)}{\partial K_1^2} > 0. \quad (C-7)$$

That is, $JTC'(n, K_1)$ is a strictly convex function

and have only a unique solution in Equation (C-1).

So if $K_1 > 0$, the optimal K is K_1 .

Note that $K_1 > 0$ if and only if

$$\begin{aligned} &\frac{H' r^2 \sum_{i=1}^m \sum_{j=1}^m T_{0i}}{1 + \sqrt{1 + 2H' r^2 \sum_{i=1}^m D_i ((A/n) + S)}} > 1. \text{ That is,} \\ &H' r^2 \sum_{i=1}^m \sum_{j=1}^m T_{0i} \\ &> 1 + \sqrt{1 + 2H' r^2 \sum_{i=1}^m D_i ((A/n) + S)} \end{aligned} \quad (C-8)$$

By rearranging the inequality and taking square for both sides, we can have

$$\begin{aligned} &(H' r^2 \sum_{i=1}^m \sum_{j=1}^m T_{0i} - 1)^2 \\ &> 1 + 2H' r^2 \sum_{i=1}^m D_i ((A/n) + S) \end{aligned} \quad (C-9)$$

That is,

$$\begin{aligned} &((\frac{nMH_{vm} \sum_{i=1}^m D_i}{P} + B)r^2 \sum_{i=1}^m \sum_{j=1}^m T_{0i} - 1)^2 \\ &> 1 + 2(\frac{nMH_{vm} \sum_{i=1}^m D_i}{P} + B)r^2 \sum_{i=1}^m D_i ((A/n) + S) \\ &(n + \frac{BP}{H_{vm}M}) \{ MH_{vm} r^2 \sum_{i=1}^m D_i (\sum_{i=1}^m T_{0i})^2 n^2 - P(2(S \\ &+ \sum_{i=1}^m T_{0i}) - Br^2 (\sum_{i=1}^m T_{0i})^2) n - 2PA > 0 \} \end{aligned} \quad (C-10)$$

that is, $(n + \frac{BP}{H_{vm}M})$

Else, there is no solution in Equation (C-1). The optimal K is zero since $JTC'(n, +\infty) = +\infty$.

The Environment Factors Analysis of Electronic Commerce Credit System in China

Yang Wei

Wuhan university of technology

Wuhan Hubei China

yangw@sz.gov.cn

Abstract

This essay raises that the problem of credit lacking is the major reason which hinders the development of electronic commerce in China through investigating the existing environment in our electronic commerce. The credit problem of electronic commerce is showed in three aspects: the reliability of information flow, security of currency payment and the reliability of service and commodity delivery. From the practical environment of the Chinese cultural moral tradition, the planned economy transferring to the market economy and the analysis of the electronic commerce in social environmental system in which the China's government changes its duty, there are six key system factors will influence the credit environments: technological standardization, laws and regulations, cultural morality, property right institution, government, and information delivery and open scheme. This essay Sets up two models of structure model and dynamic model for electrical commercial credit system analysis. The focus is to discuss the effect of this system factors' relationship among laws and regulations, credit cultural morality's influence on electronic commerce, property rights institution and the functions government takes a role in setting up the credit system.

Keywords: electronic commerce environment factors credit system analysis

1. Introduction

Modern market economy is the production and exchanging system of society and the professional division supported by credit.

2. Analysis model of Electronic Commerce Credit System

2.1 The Structure Model and Electronic

Commerce Credit System

Electronic commerce is the continuation of traditional commerce relationship and commerce activities. The traditional commerce relation needs a long period to be acknowledged and agreed in order to set up a trust. In the practice of electronic commerce, there is a strong virtuality in the net exchange. The biggest difference between net shopping and traditional shopping is that the buyers and sellers don't meet face to face. The effect of credit problem on the electronic is not only technology but all aspects of the social economy that is supporting the electronic commerce.

Comparing with the practical commerce activities, the basic factors of forming electronic commerce haven't been greatly changed^[1]. The credit scheme between buyers and sellers, the choosing scheme of products, the payment scheme of currency, the transferring scheme of goods and service all make up the foundation of electronic commerce activities. Thus, three aspects are the most important in investigating the growing environment of electronic commerce.

First, providing the net station of product information and choice as the trading activity place on net to set up a link of the customers' net space with the indefinite physical place without planning so that the circulation of commerce information realizes.

Second, electronic payment can make customers to pay for their buying or flowing fund through banks or credit cards on net anywhere they are.

Third, product allotment on net can send the products to customers efficiently at a low cost in order to realize the flowing of service and goods in the geographical space.

From the basic procedure of the electronic commerce, its credit system is showed in three aspects: the trustworthiness of information flow, security of currency payment and the reliability of service and

commodity delivery. From the establishment of the credit system, these three parts can be divided into one foundation, one motivation, and three supporting layers :one is the technological standardization, the other two are the lawful and cultural moral standardizations. Property right institution is the base of credit system existence. Information spread and its open scheme are the motive power of credit system .The technological standardization includes the technology of information security, electronic currency system , and the technology and management of the service and commodity delivery. The lawful standardization includes two kinds: limits of the principal part involving the electronic commerce and the government administrative behavior mainly focusing on the security, privacy , protection of knowledge property and the lawful efficiency of electronic contracts

ect. which involving the benefits of the right protection of the country and consumers, and supervision of the commercial activities. Cultural moral standardization shows the moral sense and human sense attached to the market economy, respecting the private right and cooperation spirit including the rights of survival, property, free choice and so on . It reflects the foundation of linking and developing the whole market economical social association. The key problem of the credit in our country is the institution. So the main contents of building credit system are that to build credit information network, to improve the basic construction of property right institution, to improve the host of credit government, form, and citizen., to improve the three support systems of law, technological standardization , and cultural moral standardizations(figure .1).

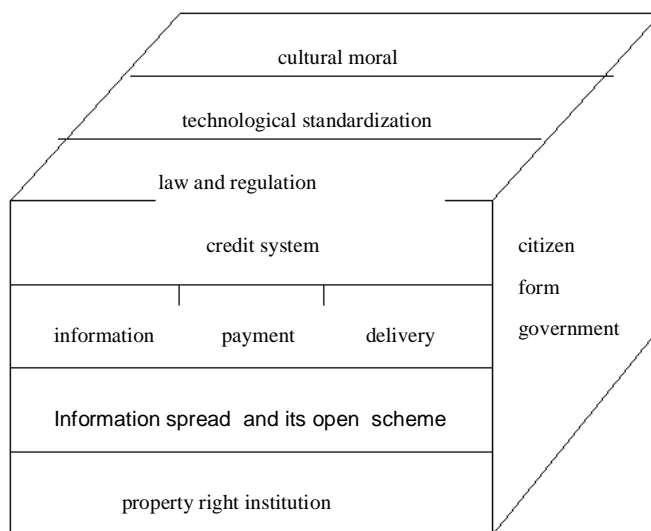

Figure.1 Structure model of the electronic commercial credit environment analysis

2.2 Dynamic Model of the Electronic Commercial Credit Environment Analysis

From the aspect of the credit environmental analysis of the electronic commerce, there are six key factors will influence the three aspects of environment: technological standardization, laws and regulations, cultural morality, government, property right institution, Information spread and its open scheme. The credit environments indicate the regulations in the activities of the market economy and a series of rules limiting the people's behaviors. Their formal form includes laws, regulations, property right institution, related procedures and technical requirements.

The informal forms include culture, customs and morality, etc. It's quite obvious and regular for the Technical regulation and laws and regulations to influence the electronic commercial credit problems (as illustrated in solid line) while the cultural morality, property right institution, and government's influence on the electronic commercial credit problems is indirect and indefinite (as illustrated in break line). Cultural morality, property right institution, and government will have an effect on the credit problems through technical choice and setting up the laws and regulations. The information spread and its open scheme gives the relation for all this factors,

delivery the effect for each other(show as solid line and break line in figure2). Their relations between them can

be illustrated as figure 2.

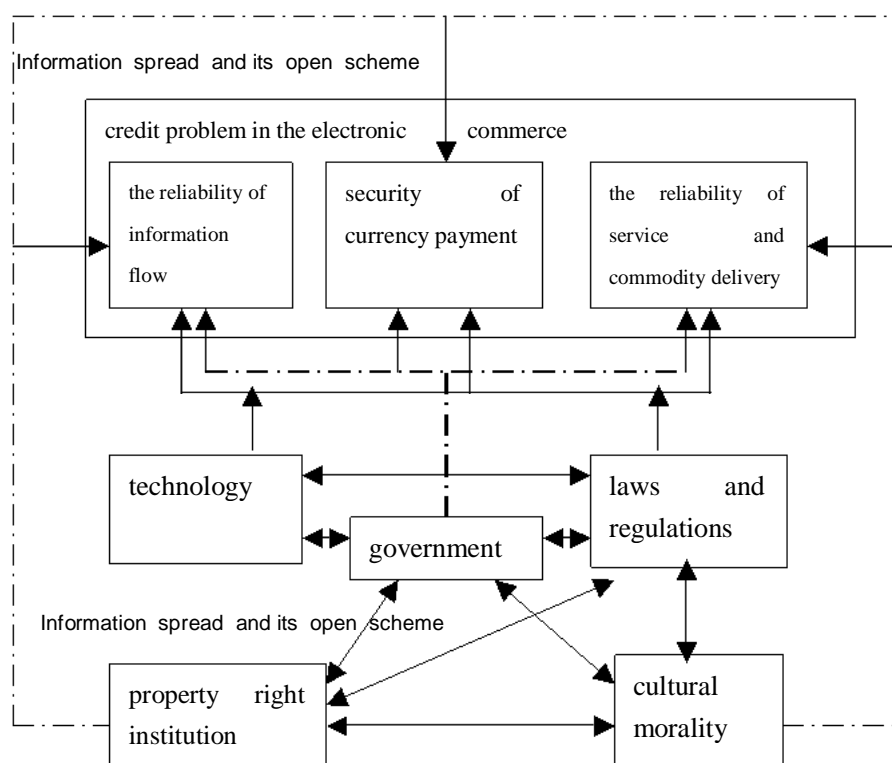

Figure.2 Dynamic model of the electronic commercial credit environment analysis

3. Analysis of the credit environment factors of electronic commerce

Credit problem is a question that every economic system should face. Individuals, society and government may all have the problems of credit losses. Serious credit problem widely exists in the economic lives and every field such as finance stock, contract, advertisement, medium, construction, statistics and so on. China has just its special situation of economic transfer. The credit problem of the electronic commerce should be paid more attention. Technology is always the major factor in its credit environment. Lots of economic issues and judicial cases involve the dependence on the technology for electronic commerce. Many theses have been deeply discussed in the aspect. Thus this essay will focus on the effect of the laws and regulations, cultural morality, property right institution, Information spread and its open scheme, and government on the electronic credit problem.

credit system evolution.

The law of the electronic commerce makes its credit perfect^[2]. Electronic commerce's happening must bring the innovation of the trade ways, business model and administrative management ways also with a series of law problems. The fixed ones of the electronic information media cause the characteristics of electronic commerce's legislation. The internet has got rid of the traditional physical limits of the countries, which communicates rapidly and easily while electronic contracts and documents can be revised, copied and deleted without any mark. As for the traditional commercial activities, the electronic commerce based on the new media brings a series of new policy problems, mainly focusing on the law efficiency of the security, privacy, knowledge property right protection, and electronic contracts. Meanwhile it requires new demands for the country's power, consumers' right and interest protection, surveillance to the commercial activities and statistics and

3.1 Law system is the necessary assurance of

etc.

Electronic commerce's legislation aims at setting up credit system, protecting property right institution, Information spread and its open scheme, credit morality, which can force all the social members follow. The premise and key rules of the designing the credit system are based on seeking for the own interest for all people legally. First of all, everyone is equal to have the right to ask for his or her legal interests. The idea of most important for the right and regulation from the market economy is the logical origin of electronic commerce's legislation.

3.2 Government credit is the core of the credit system evolution.

Government credit is the major factor of setting up the social credit environment that electronic commerce needs^[3]. The role of the government is great importance in the process of developing the credit environment construction of the electronic commerce. The largest challenge to the electronic commerce in China is not the problem of technology, but the arrangement of policy's consistence and institution frame. Electronic commerce is challenge with the traditional trading ways' laws and institutions in trade. The remains of the division of the administrative right lead to the policy frame which is hard to form an inter-department and consistence. The sense of lacking credit from institutions is the major factor damaging the existing environment of the electronic commerce.

It is not long for China to carry out the market economic institution while law system is not perfect. The enterprise as the "homo economicus" seeks for the largest revenue. It can hardly avoid hurting the social and public interests in order to obtain the revenue. Under such real social environment, the social credit should depend on the support of the administrative surveillance provided by the government. Without the government forcing management, the social credit will not set up. Without the government's support, the whole social credit system will degenerate and be destroyed.

Heightening the government's transparency is the effective method of ensuring government credit. The urgent thing to establish the credit system is setting up the

efficient surveillance and controlling system to the government behavior and building the policy credit of the government surveillance.

3.3 Moral environment is the support of credit system evolution

Credit culture and credit morality are the basic support of electronic commerce^[2]. For two thousand years, the moral theory in the society of China has been the theory of Confusion and Meng(孔孟学说), that is the basic of the Chinese moral instruction. The new moral instructions have been brought since the New China was founded. The communist morality is to think of others first, devote all to the society, and be unselfish; all these provide the moral rules for the effective social operation. As the transfer from the planned economy to the market economy gradually, the economical activities have surpassed people's relation of the traditional natural economy and planned economy, at the same time, the adaptable credit moral regulation falls behind clearly. The market economy requires the related support of the credit moral regulation, but the market economy itself cannot produce the adaptable credit moral regulation. According to the principle of economics, we can predict the establishment of the credit moral regulation is based on the Cost- Revenue Principle, which ensures the credit cost of breaking contracts higher than the revenue of breaking contracts during using the credit. Any reasonable people may compare the cost and revenue to make a sensitive choice between the short-term revenue of breaking contracts and long-term credit loses and limits their own behavior to keep promise for a very long time. If the credit devalue in social opinion occurs, and related laws and regulations are not established, the risk of the credit and cost is less than the revenue. Credit morality will develop as an evolution process of "bad money drives out good". Once the credit social value gets into process of devalue, it will encourage more and more people to destroy credit. It goes on and on, at last becomes the great increase of the trading cost and the social economy may be destroyed. The electronic commerce will also lose the base of existence.

The credit morality is the base to promote market resource allocation efficiency. The support of the law

relies on punishment while morality on criticism. It is the high cost to keep the social credit by laws, such as lawsuit, judicature and enforcing the law. It may cost a lot to ensure the fair judgment. But the judgment of morality is quite different. Its social cost is very low, to get the same result as the law punishment. Therefore, it is the most effective method to get the social total utility by the moral limit.

3.4 Property right institution is the base of credit system existence

The base of credit system evolution originates from the long-term expectation for the social members to the social economic developing environment. In the market economic activities^[4], the distinct property right is the motive force seeking for long-term benefits that makes people have a stable expectation for the future. Meanwhile it will make the once game behavior change into a repeated long-term game behavior. In Hayek's viewpoint, the market economy itself is an increasing expanding of the cooperation rules between people. The base of this rule regards property right as the core labor cooperation relationship. Credit will be followed only by seeking for long-term benefit. Distinct property right will ensure to form a scheme of keeping credit and protecting its own right to punish other's cheat for long-term benefit. Property right institution keeps a long-term expectation for every market agent to exist and grow in a transparent and expectable environment that protects the social credit system. The problems about credit in China are brought out because of imperfect property right institution, which causes short-term behavior and breaking credit to occur again and again.

3.5 Information spread and information open scheme are the motive power of credit system evolution.

The wide revelation of credit information is the necessary motivation of the credit system evolution. One important character of electronic commerce is the expanding of credit trading area to every way of the social lives. Under the closed natural economy, the people involving the trades come from relatively closed natural

areas. They can support and protect their credits by the relationship of religion, neighborhood and social public opinions. Therefore, they can't find who will make a trade with if lacking of the credit. In the open electronic commerce market, it is becoming more and more complicated about the trading objects, trading varieties, trading amounts, trading places and trading ways. The initial information communicating ways and moral binding of the two trading objects cannot meet the needs of the electronic commerce. Especially for China in the period of transferring market economy, the wide revelation of credit information is an effective binding force. The wholly open information helps to reduce the credit shortage caused by information non-symmetry. By the government credit and law authority, the supplies of low-cost increasing information through modern information spreading way will help to prompt social credit system evolution. The inter-department management under the government, including the credit information of banks, business management, public security, taxation, helps improve the condition of information non-symmetry so as to set up the confidence of electronic commerce. This will make a decisive affect on our present credit system construction.

4. Conclusion

In the world, the development of the electronic commerce is growing faster than the social culture, and establishment, revising and perfecting the government policies, standards, and laws. In China, although the electronic commerce lies in the very initial period of introduction, the credit problem is seriously obvious because of our traditional natural economy and planned economy and its related moral principles, imperfect laws and regulations and the vague location of the government's role in the process of the economic transfer. The provisions of the electronic commerce rely on the building and perfecting the whole social information infrastructure, the form of the credit culture and moral regulations, and the support and cooperation of the country's laws and regulations and etc. Government can take a great important role in the building process of the credit environment that the electronic commerce needs. The choice and innovation of the institution are the most

important factors involving the credit problems in China's electronic commerce.

Abstract

This paper presents an empirical study of Internet-enabled e-banking systems and customer responses on the basis of structural equation modeling. The results suggest that perceived usefulness, ease of use, system security, quality services and convenience represent the major avenues affecting customer interactions with e-banking services. The findings provide commercial banks with meaningful information for developing commercially sustainable Internet-enabled e-banking systems.

1. Introduction

Many commercial banks implement Internet-enabled e-banking systems with an aim to provide an effective channel for the delivery of innovative banking services [17]. However, it seems very challenging to extend market penetration and achieve the expected value of Internet banking in competitive marketplace. As far as this is concerned, this paper explores various factors associated with Internet-enabled banking systems from the customer point of view. In particular, it empirically elucidates customer response in light of their experience from using the existing Internet banking services. The influences of individual variables are tested using confirmatory factor analysis and structural equation modeling. The empirical results are discussed in an analytical manner to examine the impacts of different variables on the issue concerned.

2. Research Model

Technology Acceptance Model (TAM) enables the explanation of user behavior across a broad range of end-user computing technologies and the acceptance of computer-based information systems [10]. It asserts that the influence of external variables upon user behavior is mediated through user beliefs and attitudes. Actually, TAM adapts the Theory of Reasoned Action (TRA), which is specifically tailored for modeling user acceptance of information systems [9]. Attitudes are related to individual affective feelings about performing a behavior. Both perceived usefulness and perceived ease of use are belief constructs. Perceived usefulness refers to the prospective user's subjective probability that using a specific system might enhance job performance within an organizational context [10]. It captures the extent to which a potential adopter views the innovation as offering value over alternative ways of performing a similar task [2]. On the

other hand, perceived ease of use refers to the degree to which the prospective user expects the use of a system to be free of effort [10]. A number of previous empirical studies have proved that both perceived usefulness and perceived ease of use affect the acceptance of information systems implemented within an organization [1] [3] [14].

In terms of technology-based self services, customers usually apply a compensatory process to evaluate multiple attributes and gradually form their expectations based on experience [11] [15]. The quality of services can be assessed using consumption-based perceptions [8]. The evaluation that individuals can rationally provide in such situations would be derived from their expectations. For instance, the expectations assigned to speed of delivery, ease of use, and reliability determine expected service quality, which might in turn affect the individual's intention to consume [12]. Internet-enabled e-banking is an innovative alternative of banking services. However, it is not an unfamiliar phenomenon at this stage because it has been implemented for several years. Therefore, it is meaningful to examine customer responses in terms of the actual use of the services beyond individual attitudes and intention to use. The evaluation of online banking systems should involve multiple considerations in addition to perceived usefulness and perceived ease of use. In this paper, a research model is developed to examine such constructs as perceived usefulness, perceived ease of use, systems security, service quality and convenience.

3. Research Methods

This project involves a survey of individual assessments of e-banking services provided by commercial banks. In terms of the design of a questionnaire for our survey, a complex construct should be rich in meaning and multi-dimensional. Multiple measures were employed to evaluate the constructs mentioned in the previous section. Respondents are requested to give their opinions regarding the perceived importance of each variable, on the basis of a seven-point Likert-scale, with which 1 represents "Not important at all" or "Strongly disagree," while 7 represents "Extremely important" or "Strongly agree." Our questionnaire was circulated to individuals in a random manner. Respondents were requested to access various attributes with respect to Internet banking currently provided by banks. They were also requested to tell to what extent they have actually used Internet banking services within a particular period of time. As a result, we

received the feedback from three hundred individuals who possess experience on Internet banking services. On the basis of the assumed causal relationships of different variables and their potential impacts on customer responses to e-banking services, we validate each set of measures in an egalitarian way through reliability test, exploratory factor analysis (EFA) and confirmatory factor analysis (CFA).

4. Results

The results show that factor loadings are greater than the cutoff value of 0.4 [13]. Hence, all items seem relevant to those major factors being examined. Firstly, the factor loadings of those items associated with “Usefulness” are 0.9302, 0.8788, and 0.6047, respectively, which are positively significant. These three items together explain 65.45% of the variance. Secondly, the factor loadings of five items in relation to “Ease of Use” are 0.8346, 0.8464, 0.8321, 0.8759 and 0.8424, respectively, explaining 70.52% of the variance. Thirdly, the factor loadings of four items in relation to “System Security” are 0.8803, 0.8807, 0.5057, and 0.7888, respectively, explaining 60.55% of the total variance. Moreover, the factor loadings of the two items associated with “Quality Services” are 0.8989 and 0.8989, explaining 80.42% of the total variance. These factor loadings considerably support the convergent validity and discriminant validity of factors. The values of Cronbach alpha resulted from reliability analysis prove the internal consistency of the sample data. The values of Cronbach alpha are 0.7606 (Usefulness), 0.8987 (Ease of Use), 0.8327 (System Security), and 0.7238 (Quality Services), respectively, further indicating that the items associated with each factor mentioned above are relatively consistent [13] [19].

The t values (estimated factor loadings divided by their standard errors) for the factor loadings of manifest variables are all above two (for example, 17.7048, 24.7869 and 21.3946 for the three items associated with “Usefulness”), supporting the statistical significance of the parameter estimations and indicate the unidimensionality of each exogenous latent variable and the convergent validity of our model. In addition, the relatively large squared multiple correlations (R^2) for each exogenous latent variable (minimum value of R^2 is 0.5250 in the present case) not only supports the assertion that items are reasonable measures of the constructs [6] [13], but also indicates that the items are well represented the exogenous variables.

The estimates of the path coefficients from β_1 to β_5 are calculated using Latent Variable Equation [6]. The results indicate that the path coefficients in the CFA model for perceived usefulness, perceived ease of use, system security, service quality and perceived convenience are 0.2939 ($p < 0.01$), 0.2747 ($p < 0.01$), 0.1219 ($p < 0.05$), 0.1372 ($p < 0.05$), and 0.0757 ($p < 0.1$), respectively.

Our analysis shows that the Goodness of Fit Index (GFI) [5] is 0.9125 and the GFI Adjusted for Degrees of Freedom (AGFI) is 0.8469. AGFI values higher than 0.80 suggest a good fit of the hypothesize model [4]. The Root Mean Square Residual (RMR) is 0.0521. The RMR value less than 0.1 is considered a good fit and a value less than 0.05 is considered a very good fit of the data to the research model. It also suggests that the model fits well. GFI is a measure of the relative amount of variances and covariances jointly accounted for the model [18], while RMR is a measure of the average of the residual variances and covariances [16]. Bentler and Bonett’s Non-normed Index is 0.9149, Bollen Non-normed Index is 0.9438 and Bentler’s Comparative Fit Index is 0.9433. The Chi-square statistic is 211.47 with d.f. = 52 which is a statistically significant validity of constructs within the model [7]. Finally, the test Statistics (e.g. GFI, AGFI, and RMR) suggest a good fit of the hypothesized model, which shows that 36.81% of the variation of the endogenous variable can be explained by the exogenous variables.

5. Discussion

This empirical investigation elucidates critical factors of Internet-enabled e-banking services from the customer point of view. In particular, the reliability analysis and exploratory factor analysis show that the individual items are relevant. The convergent validity of these items is strongly supported by the resulted factor loadings. Our hypothesized model is supported by the results presented in the previous section. The constructs within the model have also been validated, because the estimates of path coefficients indicate that perceived usefulness, ease of use, system security, service quality and convenience considerably influence individual customer responses to Internet-enabled e-banking.

In general, the use of e-banking services varies from looking for information to conducting transactions. Banks should pay attention to customer concerns because the e-banking platform ultimately is built for individuals. The improvement of Internet banking systems should focus on functionalities, user friendliness, system security and service quality. An Internet-enabled banking website should improve the usefulness of Internet banking services by allowing customers to interactively search the latest banking information, conduct real-time transactions, and make investment plans. Therefore, the design of Internet banking systems should focus on navigation, content and interactivity. Most online customers seek a sophisticated service. A desirable platform for e-banking should be aesthetically appealing and user-friendly. It should also possess practical functionalities to meet the need of individual customers. In addition, customers are usually concerned about such uncertainties as authorized access, confidentiality, transaction restrictions, and serious security procedure implemented. It is necessary to continuously enhance the security level of online banking systems by implementing the latest security systems and

instruments. Additional resources must be allocated in this direction even though the investment might be significant.

Convenience would be a great advantage of Internet banking, because it enables individuals to easily access accounts and execute transactions through e-banking systems anywhere. Customers are no longer constrained by physical access and opening hours of branches. Many appreciate the convenience of e-banking, because they do not have to queue up for routine banking services in brick-and-mortar branches. Today, quality service is a must in the competitive environments. Similar to face-to-face services at a bank branch, customers are also expected quality services with e-banking systems. It is practically difficult to effectively provide assistance to customers and ensure consistent service performance in the virtual environment. However, it would be desirable if banks could respond to service request and process transactions in a reliable manner. Therefore, it is necessary for commercial banks to continuously reengineer their business processes and implement the best practices in the industry.

6. Conclusion

This paper has contributed to the development of knowledge because the theoretical approach of TAM for evaluating the acceptance of information systems has been extended to assess Internet-enabled banking systems. In addition to perceived usefulness and ease of use, systems security and quality services should be emphasized, because these aspects also considerably explain individual interactions with the present Internet-enabled banking services. Finally, our findings based on customer feedback have practical implications, because commercial banks are provided with useful information to enhance e-banking systems and services. By continuously improving critical features and sophisticated functions, Internet-enabled e-banking is likely to achieve greater customer acceptance and market penetration.

Abstract

Global sourcing operates under the challenges and pressures of intensive global-wide competition. Global sourcing can benefit from the functionality of electronic business (EB) by exhibiting more flexible structures and added opportunities in communications and transactions with partners among worldwide supply chains/networks. This study aims to answer two research questions, “what are the relationships between global sourcing and EB?” and “how do EB applications and strategies help global sourcing lead to better performance?”

Our literature review addresses the relationships between global sourcing and EB from three perspectives: the applied theories, the covered business scope, and the changing roles of flows. In analyzing the potential benefits of EB to global sourcing, the enhancement on SC components and alignment effects are discussed. Finally, a framework is proposed to highlight how EB and global sourcing interact with each other, resulting in five major issues: the enhancement of SC components, the changing micro-environment, the effect of accelerating evolution of global sourcing, the integration of activities, and the significant improvement on outcomes.

1. Introduction

Global supply chain management (GSCM) is regarded as one of today's key business trends. Global sourcing can benefit from the functionality of electronic business (EB) by exhibiting more flexible structures and added opportunities in communications and transactions with partners among worldwide supply chains/networks. This study aims to answer two research questions, “what are the relationships between global sourcing and EB?” and “how do EB applications and strategies help global sourcing lead to better performance?”

The paper is organized along an extensive literature review section, the primary focus of which emphasizes foundations of global sourcing, key issues of EB, and the concept of alignment. Subsequently, a framework is developed in which the relationships between EB and global sourcing are analyzed, followed by conclusions.

2. Literature Review

2.1 Global Sourcing

2.1.1. Definitions of global sourcing

Because of the types, as well as the scope of global sourcing, the literature offers various definitions of global sourcing. Some definitions are mainly based upon specific features of a particular industry [39]; some are based upon corporate goals [12]; while still others are based on the specific format of sourcing activities [37]. In addition, there exists a clarification battle between international sourcing and global sourcing [26] [5] [1] [35]. However, in order to cover broader evolution stages and all possible types of global sourcing, this study adopts a broader definition of global sourcing, taken from Murray, Kotabe & Wildt [30]: “(global sourcing) involves setting up production operations in different countries to serve various markets, or buying and assembling components, parts or finished products worldwide.”

2.1.2. Key determinants of global sourcing

Five key issues in global sourcing are identified in the literature: financial issues, strategic issues, structural issues, culture issues, and evolution and classification issues. Each of these is discussed in turn.

^{3/4} Financial issues

In the context of global sourcing, financial issues are the ones most often mentioned in the literature. Issues such as production cost, transfer pricing, exchange rate, and switching cost abound. For instance, Kouvelis [17] provides an in-depth analysis of how to make global sourcing an operational hedging mechanism to respond to fluctuating exchange rates. The main theme of Kouvelis' evaluation model is to compare the tradeoff between switching cost and exchange rate fluctuation for a certain period, so as to help a corporation make orders to suppliers based on total cost minimization. Lowe, Wendell & Hu [21] take a similar perspective. By utilizing the value of historical data and scenario-based mechanisms, a two-phased approach is proposed to look into the tradeoff between switching cost and exchange rate fluctuation.

Transfer pricing is another important tax issue multinationals face [34]. Based on the setting of four

“vectors” (i.e., material flows, transfer prices, profit and loss, and proportions of transportation cost allocation), Vidal & Goetschalckx [41] establish a mathematical model for maximizing net income after tax of a global SC.

The studies mentioned above lack the support of empirical evidence or real cases. More and more studies hold the opinion that “financial factors are important to global sourcing while the financial-deterministic perspective is doubtful.” Examples can be found in [19] [32].

From a theoretical perspective, financial issues still hold. Theories being cited include transaction cost theory, opportunity theory, resource based theory, macroeconomic theory, and contingent claim theory [28] [17] [29] [11].

³/₄ Strategic issues

Strategic issues, in comparison with financial issues, cover a relatively wider scope. It at least includes issues of design, product maturity, the level of global sourcing, and relationship management, which are all cited as critical success factors of global sourcing.

Based on optimal control theory, Mallick & Mukhopadhyay [22] propose that different goals of corporations lead to different requirements on supply chain design patterns, and the determinants of “global versus local” design include: product variety, product life cycle, and sales response to design decisions.

When focusing on relationship management, Samli, Browning & Busbia [37] provide a good reference for examining the relationship between global sourcing and corporate strategies. In this study, the authors not only validate the correlation between the intensity of international sourcing and a “strategic versus opportunistic” dichotomy, but also suggest that global sourcing should be regarded as a strategic tool rather than a goal of a strategy. Sheth & Sharma [38] hold similar opinions, which suggests that global sourcing is expected to be a strategic advantage and a key driver. Moreover, Bozarth et.al. [5] explore the relationships between sourcing decisions, sourcing strategies, and prior supplier performance. They conclude that global sourcing in early stages will tend to adopt the strategies of multiple sourcing and formal contractual relationships, while those in more mature stages of global sourcing will tend to focus on partnership or supplier relationship.

Overall, in contrast to the prediction by transaction cost analysis, studies that highlight the importance of strategic issues on global sourcing postulate that the adoption of intensive strategic alliance-based global sourcing for components will be the key for success, which is in line with Murray’s [29] propositions.

³/₄ Structural issues

In order to find the optimal structure for the global sourcing organization, two dimensions are highlighted [1]: the level of internationalization, and the level of centralization. Arnold suggests that the global sourcing organization model should take three types of fit into

consideration: intra-strategy fit, intra-structure fit, and structure-strategy fit. Further, when determining the degree or level of internationalization and centralization, both should be measured by company-layer and procurement-layer. By analyzing nine cases, three ideal types for the global sourcing organization were identified: central purchasing model, coordination model, and outsourcing model.

When flexibility is taken into consideration, Kouvelis [17] concludes that either having a flexible contract or adding more suppliers to the global sourcing structure will help solve the fluctuating exchange rate problems, at least in the short run.

In addition to the traditional structural change of global sourcing, a new business unit named international procurement office (IPO) is introduced [12], providing more autonomy and flexibility for companies, and regarded as another way of structural change or adjustment for the fit of global sourcing.

Kotabe, Murray and their colleagues did a series of research on the theme of global sourcing. From these studies, global sourcing activities can be categorized into eight types, based on three dichotomy dimensions: inter-firm (outsourcing) versus intra-firm, domestic versus foreign (abroad), and component versus assembly. This classification framework indeed helps to highlight the possible alternative structures of global sourced oriented companies, and then further identifies the interactions between structure and global sourcing behaviors [30] [31] [28].

Finally, Petersen, Frayer & Scamell [35] suggest, based on empirical study, that sourcing structure and processes, and sourcing capacity, are regarded as the keys for achieving effective global sourcing.

³/₄ Cultural issues

Culture plays an important role in explaining why organizations react and operate differently. The most well-known examples in the field of global sourcing are those comparing US firms and Japanese firms, such as [16] [11]. Furthermore, more and more studies argue the generalizability of the findings made by the US-based survey, because of the consideration of culture difference [12] [36].

When extending the global activities of a SC upstream and downstream, Ettlie & Sethuraman [11] found that culture will result in different patterns of global sourcing. For instance, Japanese corporations tend to more adopt a local supply source.

Hult [14] focuses on the sustainable competitive advantages of global sourcing. Hult finds that culture factors indeed affect the long term success of global sourcing for US companies. However, surprisingly, these cultural factors do not necessary impact performance independently.

Kotabe [16] compares the patterns of US companies and Japanese companies. Kotabe concludes that US companies, relatively speaking, stress cost efficiency (while compromised in the long run), while Japanese companies emphasize non-cost factors or effectiveness

(which will be improved in the long term). This study also implies how different cultures affect the outcome of global sourcing.

Rexha & Miyamoto [36] examine global sourcing issues on Australian subsidiaries of multinational corporations (MNCs), and conclude that intra-firm trade will play a different level of importance among different countries and areas. Besides, the drivers of global sourcing also differ from place to place.

$\frac{3}{4}$ Evolution and classification issues

Undoubtedly, the purposes and strategies of global sourcing evolve with time. Thus, not surprisingly, many frameworks for either vertical (evolution) or horizontal (classification) classifications of global sourcing are proposed in literature.

On the one hand, with regard to the evolution progress, Monczka & Trent [25] [26] [27] may have provided the most complete typology of global sourcing to date. According to Monczka & Trent, there are four phases in the evolution of global sourcing: domestic purchasing only (phase 1), foreign buying based on need (phase 2), foreign buying as part of a procurement strategy (phase 3), and integration of a global procurement strategy (phase 4) [5] [36] [35].

On the other hand, from the perspective on classification, Li, Murray & Scott [20] provide an interesting framework. Generally speaking, they divide the country-of-origin (COO) into three sub-categories: COO of design (e.g., designed in Japan), COO of assembly (e.g., assembled in Mexico), and COO of corporation (e.g., IBM known as a US firm). Besides, from the perspective on sourcing targets, Murray [28] proposes that firms make sourcing decisions on two phases: production-component sourcing and assembly sourcing, combining the concerns of “domestic versus foreign sourcing (i.e., location aspect)” and “internal versus external sourcing (ownership aspect).”

2.2 Electronic Business

2.2.1 Definitions and formats of electronic business

The Internet has become increasingly important to organizations for certain aspects of electronic business (EB) [4]. It helps to redefine how back-end operations are conducted, and in the process alters the roles and relationships of various parties. Hence, it is believed to have an even more profound impact on B2B interactions. Various terms, such as e-catalog, e-procurement, and B2B EC, that are relevant to EB, are all cited as enablers to efficient business operations. Even though different definitions abound in the literature, this study takes on Lee & Whang's [18] definition of EB, “the planning and execution of the front-end and back-end operations in the supply chain using the Internet.”

2.2.2 Perspectives on examining the effects of electronic business on SCM

The transition or evolution of buyer-seller relationships, in general, is from open market negotiation, through

cooperation and coordination, to collaboration [40]. This trend can be approached from three perspectives (i.e., from transaction-oriented, through information flow-based, to relationship-focused), when mapping global sourcing evolution. In the following, literature relevant to EB on SCM is reviewed and categorized into one of these three perspectives.

$\frac{3}{4}$ Transaction-cost-based perspective

In general, with regard to citing the benefits of applying IT into business, cost and efficiency are always regarded as key benefits and drivers. It is no exception for EB-based applications. For instance, Baron et.al. [3] propose that the major benefits of e-catalogs for both suppliers and retailers include drastically reduced production costs, expanded markets, and reduced processing costs.

In addition to the concern of the key components of eMarket hypotheses (i.e., search cost and coordination cost) [23]; Barua, Ravindran & Whinston [4] suggest the framework to be extended by an evaluation cost when deploying supplier-selection strategies and global sourcing activities. They develop an analytical model that allows a buyer to maximize the payoff from the selection process. In this model, three related but identical dimensions are stressed: medium of transaction (manual versus electronic), product type (standard versus unique), and types of costs (search, communication and evaluation), where costs are taken as a function of the nature of the product and the type of medium.

Essig & Arnold [10] enrich the economic impact of the eMarketplace from a theoretical perspective. Based on information economics theory, an analytical model with 6 steps is proposed. Step 1 analyzes the consequences of improved information and communication technology on a macro level. Step 2 takes a closer look at the transaction frame as a combination of macro- and micro-analysis. Step 3 and 4 take a closer look at the consequence for various purchasing situations and transactions based on information economics and transaction analysis. Step 5 provides general recommendations for their applications based on its e-procurement matrix, which is a combination analysis of information qualities and transaction analysis. Finally, Step 6 shows the consequences for e-marketplaces in bringing together suppliers and customers.

Markus [24] argues whether the phenomenon of EB activities can be fully explained by economic-centered theories. By taking a phenomenon-based approach, Markus investigates four famous and successful e-marketplaces (i.e., Global Sources, PartMiner, Converge, and Ecnnet), which represent those with different natures, founder background and major objectives. Markus finds various behavior patterns and operating philosophies, and concludes: (1) successful e-marketplaces do very different things; (2) they are highly dynamic in form and function; (3) they do not all increase price transparency; (4) there is no simple relationship between ownership/seller power; and (5) e-marketplaces have different IT implementations of the same functionality. In

other words, it is obvious that economic-based theories cannot fully explain the phenomenon of eMarketplaces in the real world, which is in line with [8].

$\frac{3}{4}$ Information-flow-based perspective

With regard to the impacts of EB on SC integration from an information-flow-based perspective, there are at least three issues or benefits being mentioned in the literature: negotiation mechanism, coordinated workflow, and information integration.

Negotiation and collaboration often work together to find appropriate supplying companies or solutions for supplier replacement processes. Besides, a backup mechanism can also be implemented by these activities. Ito & Salleh [15], hence, employ the idea of the open tender concept with intelligent agents and a blackboard-based negotiation mechanism to develop a collaborative SC system. It is then applied in a parts/material supply system in Japan in an effort to find alternative suppliers when origin suppliers have problems in time delivery.

Lee & Whang [18] regard coordinated workflow as one of the critical dimensions of SC integration. They suggest that workflow coordination helps to deal with three tasks: efficient procurement and automated services, facilitating order processing and financial flows, and procurement coordination (by supplier selection, order quote generation, and the integration of purchasing decisions).

Moreover, information integration, considered the foundation of SC integration, is also important in this regard. One common approach is the use of Internet information hubs. It is a node in the data network where multiple organizations interact in pursuit of SC integration. Besides, it has the capabilities of data storage, information processing, and push/pull publishing, which can be analogized to what “cross-docking” accomplishes in the physical logistics world [18].

$\frac{3}{4}$ Relationship-based perspective

Recently, relationship management and strategic issues are cited as key for those companies that want to implement EB applications successfully. This is because the implementation of EB in the SC is not only the realization of a technology change, but also a process of organizational change. More specifically, different implementation phases reflect different levels of complexity in terms of technical implementation, process changes and trading partner relationships [33].

Nguyen & Harrison [33] explore the roles of EB in maintaining different types of supplier-buyer relationships. They propose a two-dimensional framework that can be used in assessing the relationship of SC to EB: the means of communication (different types of electronic business applications) and the type of information being exchanged (operational or strategic approach). Besides, this framework also suggests three possible alternatives for developing and maintaining supplier/buyer relationships when integrating EB into business processes: step-by-step formulation, quick build up, and adaptation.

Dai & Kauffman [8] argue that, in addition to cost reduction, other benefits such as maintaining established long-term relationships with preferred suppliers should be highlighted as well. These mechanisms are taken as the reasons for the existence of private hub and public market mechanisms. In other words, private aggregating and negotiating mechanisms are being adopted for large quantity business supply purchases, while public market mechanisms are more often adopted when firms face uncertain and high variance demand.

Besides, previous research reports that buyers prefer to transact with just a handful of suppliers (rather than having a larger supplier base) so that suppliers have incentives to make specific investments in systems that enable and support buyer-supplier coordination [2]. Dai & Kauffman [8] conclude that private aggregating and matching networks are not predicted by the theory of electronic markets, which again highlights the importance of relationship management. Besides, online B2B markets are also found to be a driver in promoting expertise sharing and collaboration among multiple players.

Lee & Whang [18] propose that, due to the establishment of new buyer-seller relationships, new business models will emerge in the context of SC integration. The first model comprises “virtual resources,” which can be pooled to create a secondary market of virtual resources. Secondly, SC will restructure for gaining efficiencies, especially in the substitution and separation of information flows, financial flows, and physical flows.

2.2.3 Future trends of electronic business with regard to SCM

With the spread of digitalization, one could argue that EB has taken on many of the characteristics of financial trading: from simple to complex transactions, from middlemen to speculators, from transactions to solutions, and from buyer-seller exchange transactions to seller side asset swaps.

Deloitte Consulting, and Deloitte & Touche [9] propose six possible trends of B2B: (1) the formation of X2X networks, which will help to seek new business models to leverage core competencies; (2) the proliferation of niche exchanges; (3) the development of industry-wide standards; (4) the rise of private vertical hub and co-investment with existing partners; (5) companies take a portfolio approach to effectively leverage value chain capabilities by utilizing the means mentioned above; and (6) re-optimization of Internet processes to leverage the new environment and its dynamics.

2.3 Strategic Alignment

A well-known framework for analyzing the impacts of IT on organizations and business networks is the strategic alignment model [13]. In this model, the authors distinguish between the business domain (business strategy and business architecture) and the technology domain (information strategy and IT architecture) in an

organization. The two domains can influence each other in two ways. They distinguish two main perspectives on how the alignment between the domains can take place. In the first perspective (alignment) the business strategy is the driving force for business architecture or information strategy, ultimately affecting the IT architecture. In the second perspective (impact) the IT strategy is the driving force for IT architecture or business strategy, ultimately affecting business architecture. Furthermore, when analyzing the enabler or the inhibitors to alignment, Henderson & Venkatraman [13] proposed four strategic perspectives, namely strategic execution, technology potential, competitive potential, and service level.

3. Framework for E-Business and Global Sourcing

The study aims at summarizing the relationships between EB and global sourcing, as well as the (potential) benefits that EB might contribute to global sourcing. The relationships between EB and global sourcing are analyzed from two angles, namely from a theoretical basis (i.e., what theories are applied), and covered business scope; based on an extensive literature review. Benefits that EB can contribute to global sourcing will be discussed at two levels: SC components and alignment. Finally, a framework providing insights in global sourcing and EB is developed.

3.1 Analysis on the Relationship between EB and global sourcing

3.1.1 Theoretical aspect

From the perspective of the theoretical foundations of EB and global sourcing, both fields take economic oriented theories as their foundation. Amongst these theories, cost driven issues are cited most often, particularly when emphasizing the development stage. As a result of significant differences between the nature and implied assumptions of EB and global sourcing, not all economic theories are equally applied in both fields. In other words, studies of EB rely less on economic disciplines in comparison to global sourcing. For instance, the core theory in EB is the e-market hypothesis [23], which is derived from transaction cost theory. On the contrary, global sourcing applies more economic theories. Generally speaking, the major differences lie in the assumption of the world-view. EB assumes that the whole business is positioned within a theoretical (or virtual and perfect) world, which implies that there is no significant difference between global reach and local reach. Consequently, some practical issues such as transfer price, tax and exchange rate fluctuation are not considered in most EB applications. On the contrary, global sourcing, which is an extension of regional operations aiming for efficient operations across the world, stresses the practical concerns that are relevant to sourcing structure, locations, and stability; hence, it

regards such financial topics as practical means for improvement.

3.1.2 Applied aspect

The breadth of covered business scope, generally speaking, can be measured on two dimensions: vertical (i.e., the number of functions), and horizontal (i.e., the variety of the support of sourcing business with various focuses and locations).

On one hand, with respect to the vertical dimension, global sourcing creates close linkage with overall operations via adopting new strategies or changing the physical settings; whereas EB deploys a new infrastructure for integrating all relevant tasks without changing the existing structure. In other words, due to the mechanisms offered, EB enables the possibility of integrating or bundling the forward and downward activities of global sourcing more tightly (such as supplier selection, performance evaluation, and contracting), which in turn, streamline the overall global sourcing operations without requiring much extra effort.

On the other hand, for the horizontal dimension, according to the evolution stages of buyer-seller relationships of global sourcing [37], and that of EB [40], both take similar transformation patterns. Because various EB applications weigh players, founders and concerns (such as public versus private) differently, they can satisfy different requirements of global sourcing in different stages. For instance, the public hub offers the mechanism for cost efficient operations such as lowering switching cost, coordination cost, and ordering cost; while the private hub helps to strengthen the relationship by information sharing and coordination.

3.1.3 Flow perspectives

When talking about the roles of flows (i.e., information flow, physical flow, and financial flow), global sourcing and EB have different focuses. Global sourcing focuses more on financial flows and physical flows, and bundles all the flows tightly with the existing structure. On the contrary, EB stresses mainly information flows, and assumes that there is no further need to change organization structures or to be concerned about physical flows. Hence, different investment strategies and integration paradigms arise. More specifically, EB tends to synchronize flows and structure by investing in information infrastructures, while global sourcing prefers to invest in physical / business infrastructures so as to streamline all flows and structures.

3.1.4 In Summary

The evolution stages and reference theories of global sourcing are similar to that of EB. Global sourcing is a kind of strategy for improving the performance, while EB is a type of application or mechanism for satisfying new requirements. As a consequence, EB can be regarded as a means for solving the requirements of global

sourcing.

Moreover, the literature suggests a contingency perspective due to the variety of contexts in global sourcing [29]. This argument is consistent with what is observed from the linkage between EB and global sourcing, which might imply that lots of opportunities exist for utilizing the EB mechanisms for supporting various types of global sourcing in different contexts.

3.2 How does EB benefit global sourcing?

In this section, benefits of EB to global sourcing are discussed at two levels: Supply Chain components and alignment issues.

3.2.1 Supply Chain components

Structure, control, and optimization are regarded as three main components of a SC [6] [7], all within the context of globalization. These four components are elaborated on below.

$\frac{3}{4}$ Structural aspect

When analyzing the effects of global sourcing structure, EB helps to deal with at least six issues: (a) extend the possible set of global supplier base (i.e., extending to those suppliers are in foreign countries with external format); (b) substitute physical IPOs by virtual EB applications; (c) create complete competition markets and eliminate the effects of (supplier) switching costs; (d) separate but ensure the synchronization of the flows and the structure (which will result in better management policies and higher flexibility of structure adjustment); (e) offer the possibility of global reach by using public hubs; and (f) transform partnerships by using the private hubs and replace the means of conventional vertical and horizontal integration.

$\frac{3}{4}$ Control aspect

By integrating the functions of information hubs, agent-based coordination mechanisms, and blackboard-based negotiation systems, real time monitoring and collaboration will help to speed up response to those situations in emergency (e.g., an order cannot be delivered on time or on schedule). In short, a backup mechanism of global sourcing (especially for standardized materials) is thus established.

Meanwhile, in regard to non-standardized parts, EB applications are also helpful in transforming some non-standardized parts (i.e., e-hierarchical oriented products) into standardized types (i.e., e-market based products). It implies that not only intensive knowledge sharing and information exchange will be established, but EB also assists in examining the quality of suppliers and keeping those with good quality as long-term partners.

From a market perspective, a public hub is also beneficial for competitors to source collectively and globally (i.e., achieving the goal of “co-competition” for non-core parts). Besides, reverse auction can be efficiently executed for those parts with excess sourcing

[24]. Hence, under existing control mechanisms and bargaining power structure, buyers might have more choices and means to face the sourcing issues, with the help of EB applications.

Finally, with regard to financial control, EB is able to help real time decisions such as negotiation for the appropriate transfer price and identification of the formulation and formalization of a sourcing contract. However, unfortunately, EB cannot contribute much in this area up till now; but it is expected to provide better solutions or mechanisms (such as real time clearance and flexible contracting) in the near future by creating new EB business models and functions.

To sum up, because of information sharing and coordination mechanisms, global sourcing becomes more easy to control, and in turn, raises the possibility of stronger partner relationships.

$\frac{3}{4}$ Optimization aspect

The optimization aspect reflects how global sourcing is optimally designed for, hence EB cannot directly enhance the outcome or operations.

$\frac{3}{4}$ Micro-environment aspect

It is believed that if EB is taken in the context of global sourcing, it will evoke the changes of the existing corporate culture, (the speed of) product maturity and popularity, SC maturity, and the stages of global sourcing. It might even result in the transformation of existing corporate paradigms, and the next wave of revolutions in global sourcing and SC operations.

3.2.2 Alignment aspect

Conceptually, if global sourcing is regarded as a managerial / strategic issue, with proper business architecture and strategy, whereas EB is regarded as an IT issue, with proper IT architecture and strategy as well, different alignment strategies can be taken. In general, when integrating EB and global sourcing, two alignment strategies can be found: “strategic execution” and “technology potential”. The most significant examples include the stories of eMarketplaces such as PartMiner, Converge, and Cnet [24].

To sum up, due to the features of EB and its variety of functionalities, it may propel global sourcing towards improved performance. However, as mentioned earlier, EB cannot ensure the stability of physical flows and financial flows for global sourcing, unless potential partners are involved in this system.

3.3 An insight in EB and global sourcing: A proposed framework

In this section, two research questions will be addressed:

$\frac{3}{4}$ “what are the relationships between global sourcing and EB?”

$\frac{3}{4}$ “how do EB applications and strategies help global sourcing lead to better performance?”

“What are the relationships between global sourcing and EB?”

can be answered from three aspects. In the first place, from the theoretical perspective, both EB and global sourcing are mainly based on economic-oriented theories, and include the concerns of strategic relationship management. In terms of business scope, EB helps to speed up the evolution of global sourcing stages. Beyond that, integrating and extending relevant activities into global sourcing (such as supplier selection and evaluation, and afterwards reverse sourcing) can be achieved without huge investment. Moreover, with regard to the flows, because EB and global sourcing have different focuses (i.e., information flows versus physical flows plus organizational structures), integrating both fields might lead to better control and coordination for all flows (but still having limited benefits on financial flows).

“How do EB applications and strategies help global sourcing lead to better performance?” can be explained as follows. Firstly, EB helps to enrich SC components in structure elements (such as more players and more alternatives for location expansion) and control mechanisms (such as sense response more quickly, and more tightly monitoring and communications). Meanwhile, the micro-environment will also be influenced either directly or indirectly by the adoption of EB. Secondly, from the alignment perspective, with the help of EB, global sourcing has the potential for evoking alignment strategies such as “strategic execution” and “technology potential,” and thus creating better outcomes (such as better performance, improved partnership, and new business models).

As such, a framework is proposed to illustrate how EB and global sourcing interact, and is illustrated in Figure 1.

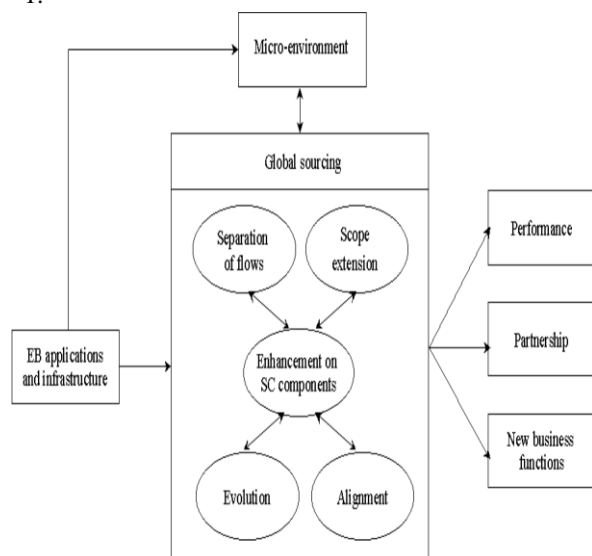

Figure 1 : A proposed framework of how EB and global sourcing interact

4. Conclusions

Global sourcing can benefit from the functionality of electronic business (EB) by exhibiting more flexible structures and added opportunities in communications and transactions with partners among worldwide supply chains/networks. This study aims to answer two research questions, “what are the relationships between global sourcing and EB?” and “how do EB applications and strategies help global sourcing lead to better performance?”

Our literature review addresses the relationships between global sourcing and EB from three perspectives: the applied theories, the covered business scope, and the changing roles of flows. In analyzing the potential benefits of EB to global sourcing, the enhancement on SC components (i.e., structure, control, and optimization), and alignment effects are discussed. Finally, a framework is proposed to highlight how EB and global sourcing interact with each other, resulting in five major issues: the enhancement of SC components, the changing micro-environment, the effect of accelerating evolution of global sourcing, the integration of activities, and the significant improvement on outcomes (i.e., better performance, improved partnership, and new business models). This framework sets the stage for future empirical validation in creating an operational framework and roadmap for improved global sourcing.

An Empirical Examination of the Use of Mobile Technology – A Social Pressure Perspective

Abstract

Mobile technology has been predicted to create new challenges and competitions to organizations. To business decision makers, the understanding of mobile technology would then become critical in helping organizations to better manage relevant technological issues. The theoretical analysis and empirical examination of mobile phenomenon, however, remain scarce. In addition, conventional wisdom tends to emphasize the economic aspect of information technology. Such emphasis, nonetheless, lacks the explanatory power to understand social factors of the use of technologies. Social aspects of technologies could significantly influence the success of adoption. Derived from institutional theory, which emphasizes the influence of social pressures on collective members' isomorphic behavior, the paper proposes how three different social pressures—coercive, mimetic, and normative pressures would positively influence a group member's use of mobile technology. Our findings suggest that the influence of social pressures on the use of mobile technology might be contingent upon the types of technologies. While normative pressure is positively related to the use of cellular phones, coercive and mimetic pressures are significant to the use of laptops. Business decision makers might thus employ various strategies to create certain social pressure and in turn promote the use of corresponding mobile technologies.

1. Introduction

The need of studying mobile technology appears to be increasingly critical as its exponential development would be likely to present tremendous challenges and opportunities to individuals and organizations. As amazon.com CEO Jeff Bezos once asserted, "If you look five to ten years out, almost all of e-commerce will be on mobile devices" [19, p.74]. In line with his view, practitioners have predicted that the transaction of mobile hardware is expected to exceed 3.9 billion by 2006 [2]. In addition, the US market would have 171.1 million mobile Internet users by 2005 with 111 million consumers accessing mobile Web on a monthly basis [5]. Cell phones, for example, would become a 'retail outlet' in a customer's packet [9] [18] and would be the second highest potential advertising medium next to television [26]. More importantly, mobile technology would significantly change firms' business model [19] and

information technology (IT) strategy [7] [13] [15] [25].

However, the current understanding of mobile technology remains mostly at the conceptual level [e.g., 8, 20, 21, 23, 24]. Empirical studies that help to understand and manage mobile phenomenon appear inadequate. With rapid changes and competitions in the business world, such insufficient understanding of the mobile phenomenon might cause organizational and managerial inability to respond to, let alone to manage its technological impacts. It is thus critical to be more actively examining the mobile phenomena. In addition, traditional IT literature tends to investigate emerging technologies through the economic perspective [17]. While this perspective such as transaction cost economics helps explain the cost efficiency of technological adoption, it lacks the power to disclose social factors that drive IT usage behavior. Guided by institutional theory, the paper thus seeks to shed light on how social factors promote the use of mobile technologies. Specifically, we investigate the relationship between social pressures and the usage behavior of two mobile technologies—cell phone and laptop. The findings could help us better understand the rationale of IT usage behavior and further provide insights to business decision makers on the importance of considering social factors when marketing and managing mobile technologies.

2. Social Pressures and Mobile Technology

Institutional theorists argue that the rationale behind an actor's action is, not to increase cost benefits or efficiency, but to gain legitimacy [11]. To survive in a collective field, actors have to first obtain social recognition. Such social recognition could be gained through acting to accommodate collective expectations, regardless of efficiency or cost benefits [16]. In modern society, organizations often adopt similar structures because of the isomorphic pressures they face [12]. Hiring a Nobel Prize winner in a university, for example, does not justify the immediate cost effectiveness; investing in an expensive yet inefficient technology, similarly, might cause financial loss. Organizations, however, could tend to undertake such actions because they perceive the need to gain social recognition or legitimacy. Such a need is normally resulting from the fear to be different or to be left behind [1].

Abrahamson [1] argues that in the context of adoption of innovation, actors often imitate a fashion setter or an

“opinion leader” [14] because fashion setters possess certain power to inspire others to “trust their choices of technologies and to imitate them.” [p.596]. Consequently, actors would imitate other actors’ choice of an innovation “when it obtains from these adopters’ knowledge that reduces ambiguity about the innovation” [1, p.597]. In so doing, the actor would appear more legitimate as it confirms to “emergent norms that sanction these innovations” [1, p.597]. Such an action sometimes is derived from “bandwagon pressures”—“pressures to adopt an innovation that increase according to the number of other organizations that have already adopted it” [1, p. 597].

The pressures that drive an actor to imitate or follow other actors have been well articulated by DiMaggio and Powell [4]. They explain that actors would often move toward the same direction as others because of coercive, mimetic and normative pressures. Coercive pressure is a strong force implying an action that actors must undertake. Failing to undertake such an action could result in fatal failures. At the organizational level, such urgency is often created by governmental regulation, industrial standard [10] or the dominance of powerful organization [22]. At the individual or group level, coercive pressure emerges when individual actors fear to be left behind [1] or being excluded from a social group. In the context of individual use of mobile technology, it is likely that individual actors would sense the need to use mobile technology to ensure that they could compete with their peers and/or be embraced by a social group. As such, we hypothesize:

H1: Coercive pressures will positively correlate with the use of mobile technology

Mimetic pressure, on the other hand, is mainly derived from environmental and technological uncertainty. While facing such uncertainty, actors tend to model themselves after those who have been well established and recognized as a legitimate player in the group [4]. In line with this view, Rogers [14] indicates that opinion leaders often influence later adopters who possess less knowledge or information about an innovation. Abrahamson [1] further suggests that while facing uncertainty, actors often fear to be different. Therefore, they would simply follow the fashion setters or group leaders when adopting an innovation. Considering the emerging nature of mobile technology, individual actors would inevitably face the technological uncertainty. As such, mimetic pressure would emerge and drive individuals to model themselves after those who have regularly used mobile technology. In the context of college education where students often engage in social groups, it is very likely that their use of mobile technology would be influenced by opinion leaders in the group. As such, we hypothesize:

H2: Mimetic pressures will positively correlate with the use of mobile technology

Finally, normative pressure is associated with

professionalization—the process through which actors respond to the pressures that are caused by the exchange of information in a group [4]. The professionalization reveals the information regarding each individual’s action and in turn creates an inevitable comparison among group members. Such a comparison would create certain normative pressure to encourage individual actors to remain competitive by demonstrating similar capabilities as others’. In the context of mobile technology, an actor would then tend to adopt a mobile technology due to normative pressures generated through professionalization among group members. As such, we hypothesize:

H3: Normative pressures will positively correlate with the use of mobile technology

3. Methodology

A survey questionnaire was used for data collection and exploratory factor analysis and multiple regression analysis were used for data analysis. Multiple regression analysis suited our research purpose because it was appropriate for prediction and explanation with a single dependent variable and multiple independent variables [6]. The data was collected from six technology-related classes in the College of Technology at an urban university. Among 250 questionnaires distributed, a total number of 129 useful questionnaire responses were used for the analysis. The dependent variable, ‘the use of mobile technology’, was measured by ‘the frequency of usage’, which was the most widely used measure in the IT literature [3]. Specifically, students were asked to rate their frequency of usage from “do not use at all” to ‘use it several times a day’.

3.1 Factor analysis

To ensure construct validity, the initial 18 items of social pressures were selected through a two-step process suggested by Davis [3]. First, the items were derived from conceptual definitions of DiMaggio and Powell [4], and second, the items developed were then consulted with seven colleagues. Factor analysis with varimax rotation extracted four principle components whose eigenvalues were above 1.00. The scree test further confirmed the appropriateness of this extraction. A factor loading value of .50 was chosen as the criterion for selecting significant items [6]. The scale reliability with the item-total statistics helps finalize three remaining factors, which correspond to coercive, normative and mimetic pressures, respectively (see Table 1).

4. Results

While Table 2 and Table 3 demonstrate the descriptive statistics, Table 4 and Table 5 illustrate the three-step hierarchical regression analysis for the frequency of use of cell phones and laptops, respectively. The results indicate that only normative pressure is

significant at the level of 0.10 for the use of cell phones (Table 4) and that only coercive and mimetic pressures demonstrate significant relationships with the frequency of laptop usage (Table 5). As such, for the use of cell phones, only hypothesis 3 is supported while for the use of laptops, only hypothesis 1 and hypothesis 2 are supported.

Table 1: Results of factor analysis of social pressures

Variables	Factor Loadings After Varimax Rotation		
	Coercive Pressures	Normative Pressures	Mimetic Pressures
CP1	0.84	0.00	0.16
CP2	0.76	0.33	0.00

5. Discussion and conclusion

Hypotheses argue that social pressures in general and coercive, normative and mimetic pressures in particular would influence the use of mobile technology. The findings indicate that the influences of these pressures on the use of mobile technology might be contingent upon the types of mobile technologies. While normative pressures are significant to the use of cell phone, coercive and mimetic pressures provide better explanation for the use of laptop. One reasonable explanation for the difference is the fact that cell phone is widely adopted among college students. The device itself is relatively less expensive compared to a laptop. Furthermore, since its features and functions are constantly evolving¹, users are more likely to perceive cell phones as fashionable devices. Normative pressures that mainly concerned the social fashion resulting from information exchanged among social groups, thus, would be more likely to influence students' use of cell phones.

¹ For example, many manufactures recently launched new types of cell phone that allow not just the Internet connection but also the function of a digital camera.

Laptops, in contrast, are not as popular as cell phones among college students². Unlike cell phones, which could be shown in front of group members almost all the time, the laptop is not as portable and its functions and features do not change as frequently. As such, the influence of fashion and social norms (normative pressures) could then be less significant. Furthermore, the laptop is substantially more costly than the cell phone. Users might then perceive it to be more work oriented with higher risk involved. They might adopt the laptop only when necessary. Those who possess a laptop might thus be perceived as being in an elite group. Owning a laptop thus could denote certain symbolic group memberships; in other words, lacking a laptop means the possibility of being excluded by such a group. Coercive pressures, thus, could emerge to promote the use of a laptop for obtaining social recognition in such an elite group. Finally, since the laptop's features are more static, its usage might be based more on individual needs than on social fashion. If someone perceives a high degree of mimetic pressures in the use of laptops, they might be less knowledgeable about the technology in general. Less knowledgeable people would then tend to consider there to be less need for using a laptop because it is more costly with higher risk. The lower the needs for using a laptop, the less likely they will be to adopt it. This might help explain the negative relationship between mimetic pressures and the use of laptops.

The findings suggest the practical relevance of stimulating different types of social pressures when designing and marketing various mobile technologies. For low cost, highly portable devices (e.g., cell phones), a marketing strategy that aims for the influence of social fashion might be more effective. In contrast, for task oriented, high cost equipments (e.g., laptops), a strategy that focuses on easing technological uncertainty and creating an elite image might be more practical.

Abstract

Investment strategy is the key point of investors who can make profits or otherwise. Investors always focus on their viewpoints subjectively, which may make them fall into the logic puzzle. The purpose of this paper is to integrate the technical analysis of financial markets with an emerging neural network model, Support Vector Machine (SVM), to solve the problem of investment strategy in Taiwan Futures Market (TAIFEX). The evaluation of investment strategy is the most essential task of investment analysis. However, the evaluation is usually time-consuming and laborious for investment experts. An effective and efficient decision support tool could significantly alleviate his/her burden and improve decision quality. The experimental results from a real-case study demonstrate its salient features of generalization and usability compared with original technical analysis.

Keywords: Investment strategy, technical analysis, three-level prices analysis, support vector machines, neural networks

1. Introduction

While investors distribute their assets among various investments, factors such as individual goals, risk tolerance and horizon will be considered. That is the so-called investment strategy. A successful investment strategy improves investors' chances of profit. However, due to the lack of objectivity, investors usually need indicators to help them adjust investment strategy and determine a sensible planning. Technical analysis (TAs) [12] is one of them, which analyzes price and volume data with charts and graphs to predict future market trends. Most TAs, e.g. MACD, KD, are too complicated and sometimes uncertain, which leads to confusion of investment analyzers, so three-level prices analysis is introduced in this paper. Three-level prices analysis is the extension of candlestick charts, and inspired by Elliott's Wave Theory [6] and Fibonacci Numbers [12]. Meanwhile, neural network techniques are introduced to enhance the performance of three-level prices analysis.

Recently, support vector machines (SVM) have been shown another novel approach to improve the generalization property of neural networks [3], [4]. Since its emergence, SVM has been widely applied to many kinds of field in the past few years, such as text

categorization, handwritten digit recognition and face detection. Most of them are with the engineering and science fields. The major advantages of SVM over other neural network models are better generalization performance, smaller number of parameters setting and capability of handling higher dimension data set.

The remaining sections of this paper are organized as follows. Section 2 describes the problem nature of technical analysis. Section 3 introduces the concept of SVM in solving classification problems. Section 4 exhibits the experiments with SVMs, parameters setting. Section 5 concludes this paper.

2. Technical Analysis

It is well understood that the ultimate purpose of investment is to make profits, so the technical analysis focuses on its profitability. Depending on different approaches used in analyzing the financial trading data, different sets of factors are considered. Technical analysts keep devoting to finding out the knowledge of stock price's movement and many famous theories were appeared, like Elliott Wave Theory, Dow Theory or technical indicators.

Many past research have devoted in data mining for the stock trading strategy, but many of them lack a usefulness knowledge presentation or took they effort to increase the accuracy [15].

Therefore, the investors not only need to understand the forecast solution but also need to realize the knowledge of the decision solution. The greatest contribution of the research which devoted to increase accuracy is focus on how to keep the expert's knowledge into the system. If the case appear again in the future, the system can response the solution very quickly.

2.1. Three-Level Prices Analysis

Three-Level Prices Analysis is one of the technical analyses, which is inspired by Elliott's Wave Theory [6] and Fibonacci Numbers [12]. It consists of three basic indicators, i.e. upper price (UP), middle price (MP), and lower price (LP). Table 1 details these three indicators and other notation conventions of 3-Level Price Analysis.

Table 1. Notation conventions of 3-level prices

UP	upper price $UP(t+1) = L(t) + (H(t) - L(t)) \times 1.382$
MP	middle price $MP(t+1) = (H(t) + L(t)) / 2$
LP	lower price $LP(t+1) = H(t) - (H(t) - L(t)) \times 1.382$
O	opening price of candlestick chart
H	highest price of candlestick chart
L	lowest price of candlestick chart
C	closing price of candlestick chart

The basic definition of three-level prices analysis is shown in table 2.

Table 2. Basic definition of three-level prices analysis

Rule 1	If today's close price is higher than UP then tomorrow's price movement range will be between UP and MP. The highest price do not to predict, and the LP will not be appeared.
Rule 2	If the today's close price is between UP and MP, then tomorrow's price movement range will be between UP and MP, and the LP has low probability appear.
Rule 3	If the today's close price is between LP and MP, then tomorrow's price movement range will be between MP and LP, and the UP has low probability appear.
Rule 4	If the today's close price is lower than UP then tomorrow's price movement range will be between LP and MP. The lowest price does not be predict, and the LP will not be appeared.

Rule1 and Rule2 are generalized to be RuleA; Rule3 and Rule4 are generalized to be RuleB.

Table 3. Generalized definition of three-level prices analysis

RuleA	If today's close price is higher MP then tomorrow's close price will be higher than MP.
Rule B	If today's close price is lower MP then tomorrow's close price will be higher than MP.

3. Theory of SVM

Support Vector Machine, pioneered by Vapnik in 1995, is the state-of-the-art neural network technology based on statistical learning [17], [16]. In recent years, it has drawn over-whelming attentions from diverse research communities thanks to its outstanding performance in solving classification problems. SVMs were originally designed for binary classification, whose objective is to construct an optimal hyperplane that the margin of separation between the negative and positive data set will be maximized. However, in practice, the data set of

interest is usually linear nonseparable. In order to enhance the feasibility of linear separation, one can usually perform a non-linear transformation to the data set into a higher dimensional space, the so-called feature space. Unfortunately, the curse of dimensionality makes the non-linear mapping too difficult to solve. One of feasible approaches is the mechanism of inner-product kernel. The ideas of optimal hyperplane and the kernel-product feature space establish the fundamentals of SVM and will be discussed in the following two sub-sections.

3.1. The Optimal Hyperplane

In order to describe the SVM mechanism clearly, we simplify a general classification problem to be binary and separable. Figure 1 exhibits the basic concept of SVM. There exist uncountable decision functions, i.e. hyperplanes, which can separate the negative and positive data set well, but of which only one has the maximal margin. This indicates that the distance from the closest positive samples to a hyperplane and the distance from the closest negative samples to it will be maximized. The hyperplane with maximal margin is the optimal hyperplane, as shown in Figure 1. The data points located on the dash-lines are support vectors, which satisfy the condition with the equality sign, defined in Eq. (3).

Figure 1. The basis of the support vector machines

Assuming the training data set \mathfrak{I} is in this form

$$\mathbf{x}_i \in \mathfrak{R}^n, y_i \in \{-1, 1\} \quad (1)$$

$$\mathfrak{I} = \{(\mathbf{x}_i, y_i)\}_{i=1}^n$$

There are n training examples, where \mathbf{x}_i is n -dimensional input space over \mathfrak{R} and y_i is the corresponding output. The decision boundary is defined by the following equation

$$\sum_{i=1}^n x_i w_i + b = 0, \text{ or} \quad (2)$$

$$\mathbf{x} \cdot \mathbf{w} + b = 0$$

Let \mathbf{w} and b be the weight vector and bias of the SVM, respectively. A specific pair (\mathbf{w}, b) represents the one hyperplane. The goal of training a SVM is to find a pair of (\mathbf{w}, b) with the largest margin, subject to the following constraint:

$$y_i(\mathbf{x}_i \cdot \mathbf{w} + b) \geq 1 \text{ for } i=1,2,\dots,K, \quad (3)$$

The margin of separation between two classes is $2/\|\mathbf{w}\|$ [7], therefore, the optimization problem is equivalent to minimizing the Euclidean norm of the weight vector \mathbf{w} . The constrained optimization problem, also called the primal problem [3], can be stated as follows:

$$\begin{aligned} \text{minimize } \Phi(\mathbf{w}) &= \frac{1}{2} \mathbf{w} \cdot \mathbf{w} \\ \text{subject to } y_i(\mathbf{x}_i \cdot \mathbf{w} + b) &\geq 1 \text{ } i=1,2,\dots,K, \end{aligned} \quad (4)$$

The cost function $\Phi(\mathbf{w})$ is a convex function of \mathbf{w} and the constraints are linear in \mathbf{w} . Based on the context, we exploit the characteristics of Lagrange multipliers [1] to solve the constrained optimization problem, which could be stated as:

$$\begin{aligned} \text{maximize } Q(\alpha) &= \sum_{i=1}^K \alpha_i - \frac{1}{2} \sum_{i=1}^K \sum_{j=1}^K \alpha_i \alpha_j y_i y_j \mathbf{x}_i \cdot \mathbf{x}_j \\ \text{subject to } \sum_{i=1}^K \alpha_i y_i &= 0 \text{ and } \alpha_i \geq 0, \text{ } i=1,2,\dots,K, \end{aligned} \quad (5)$$

where the aiding nonnegative variables α_i are the Lagrange multipliers, then the weight vector could be stated as

$$\mathbf{w} = \sum_{i=1}^K \alpha_i y_i \mathbf{x}_i \quad (6)$$

which only consists of the training data, as well as the objective function $Q(\alpha)$.

Nevertheless, most of classification problems are linear nonseparable, i.e. it is impossible to construct a linear hyperplane without misclassification. The so-called slack variables ξ_i are thus introduced to Eq. (3) in order to be tolerant of classification error. In this way, Eq. (3) is redefined as

$$y_i(\mathbf{x}_i \cdot \mathbf{w} + b) \geq 1 - \xi_i \text{ for } i=1,2,\dots,K, \quad (7)$$

That is, the goal of optimization becomes to find out the hyperplane with maximal margin and minimize the probability of classification error.

$$\Phi(\mathbf{w}) = \frac{1}{2} \mathbf{w} \cdot \mathbf{w} + C \sum_{i=1}^K \xi_i \quad (8)$$

where C is a user-specified parameter which controls the trade-off between complexity of the model and the number of misclassification points.

3.2. Kernel-Induced Feature Space

The introduction of the feature space is to allow the mapping of the input space onto a higher-dimensional space via a nonlinear transformation, which is capable of separating the data set easier.

$$\begin{aligned} j: \mathcal{S} &\rightarrow \mathcal{S}' \\ \mathbf{x}_i &\rightarrow j(\mathbf{x}_i) \end{aligned}$$

where \mathcal{S} is the input space, ϕ is a non-linear transformation and $\phi(\mathbf{x}_i)$ is the value of \mathbf{x}_i projected to the feature space \mathcal{S}' . Therefore, the cost function of Eq. (5) can be transferred to:

$$\sum_{i=1}^K \alpha_i - \frac{1}{2} \sum_{i=1}^K \sum_{j=1}^K \alpha_i \alpha_j y_i y_j j(\mathbf{x}_i) \cdot j(\mathbf{x}_j) \quad (9)$$

In order to separate the training data set linearly, one usually projects the input space into an higher-dimensional feature space, which results in the complexity of mapping and the curse of dimensionality. Based on this, the concept of inner-product kernel is introduced as follows.

$$K(\mathbf{x}_i, \mathbf{x}_j) = j(\mathbf{x}_i) \cdot j(\mathbf{x}_j) \quad (10)$$

Instead of calculating the exact value of $\phi(\mathbf{x}_i)$, only the inner-product of $\phi(\mathbf{x}_i)\phi(\mathbf{x}_j)$ is concerned, which is easier to implement. Referred to Eq.(2), Eq.(6) and Eq.(10), the decision boundary is redefined now in the following,

$$\begin{aligned} \sum_{i=1}^K \alpha_i y_i j(\mathbf{x}_i) \cdot j(\mathbf{x}) &= 0 \\ \Rightarrow \sum_{i=1}^K \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}) &= 0 \end{aligned} \quad (11)$$

The kernel function, ϕ , can be any function which satisfies Mercer's theorem [10], where the radial-basis function is one of the most popular one:

$$K(\mathbf{x}_i, \mathbf{x}_j) = \exp\left(-\frac{\|\mathbf{x}_i - \mathbf{x}_j\|^2}{2s^2}\right) \quad (12)$$

Besides, the kernel function can be also polynomial learning networks or two-layer perceptron networks. The determination of appropriate kernel functions is usually case-dependent.

4. Experiments and Evaluation

In this section, we discuss a real case study of applying SVM to evaluating Futures trading strategy in Taiwan.

4.1. Collection of empirical data set

Our experiment data was collected from Taiwan stock exchange, the collected period was between 1991 to 2002, 12 years daily data. Each record includes the Open Price, Highest Price, Lower Price and the Close Price.

The original data is composed of daily candlestick charts; each candlestick chart consists of the opening price, closing price, highest price, and lowest price. Given the candlestick chart one day, the information of the trend next day, especially the closing price will help investors determine your investment strategy. However, the information provided by candlestick chart is limited, so three-level prices analysis is introduced here in order to enhance the consequence. The original data plus three-level prices analysis indicators are like this:

Table 4. Experimental data

Output	O	H	L	C	UP	MP	LP
1	9853	9988	9789	9862	0162	9819	9475
1	9862	9939	9752	9927	0064	9888	9713
0	9927	10053	9879	9964	0011	9846	9581
M				M			

Because of the nature of SVMs, we try to turn the prediction issue into a simple binary classification problem. The output y of each row is determined by the following equation:

$$y(t) = \text{sgn}(C(t+1) - MP(t+1))$$

$$\text{sgn}(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases} \quad (13)$$

Output value of 1 means the closing price next day will be higher than the MP generated by current data, and value of 0 means the closing price will be lower. The main purpose of the classification problem is that given a pattern composed of O, H, L, C, UP, MP, and LP, the classifier would determine its corresponding output.

4.2. SVM Simulations

The experiments are conducted by implementing a SVM simulator using OSU SVM Classifier Matlab Toolbox [5] built upon LIBSVM [8], which is capable of selecting parameters of model automatically based on the cross validation accuracy, implements the fast training SMO algorithm [14], and provides a cache memory management mechanism to enhance the operation of the algorithm. The simulation environment is Solaris 7 on SUN Ultra80 with 1GB memory. The Radial-basis function, referred to Eq. (12), is used as the kernel function in order to solve the non-linear classification effectively and the one-against-one algorithm is used to deal with the multi-classification problem, which has been proved to achieve better performance [8], [18].

In order to reduce the bias of simulation, the 5-fold cross validation is conducted. That is the raw data set is randomly permute into five folds; of which fold is used as the validation set and the rest is as the training set. The overall generalization is the averaged generalization on the evaluation set over five runs. The parameter C is determined empirically, which obtains the best performance in generalization. Besides, in order to prove the outstanding performance of SVMs, the experiment is also implemented by radial basis function networks [9]. Radial basis function networks (RBFNs), introduced by Broomhead and Lowe [2], also known as networks with locally-tuned overlapping receptive fields [11], have attracted interest for engineering applications due to their advantages over traditional multiplayer perceptrons in the past decades. Table 4 illustrates the comparison of SVMs with RBFNs and original three-level prices analysis. It is shown that SVM outperforms RBFN.

Table 5. The comparison of SVM and RBFN

	Generalization accuracy	Setting
SVM	67.1836 %	$C = 100, \sigma = 0.001$
RBFN	63.96 %	
3level prices	62.5%	

Table 5 details the accuracy by confusion matrix. The accuracy of targeting class 0, RBFN performs as well as SVM. As to class 1, SVM has a bit higher accuracy.

Table 6. Confusion matrix of SVM and RBFN

Desired \ Computed	0	1
0	66.27%	33.73%
1	35.48%	64.52%

SVM

Desired \ Computed	0	1
0	66.27%	33.73%
1	36.77%	63.23%

RBFN

Our outcome 67.1836% was calculated by real trading result, we want to know if the accuracy is the limited by the original three-level prices trading strategy or limited by SVM. So we compare the outcomes, we find the SVM is good algorithm, it learned the original very well, the consistency is about 90%. This compare result prove the 67.1836% accuracy is not limited by SVM.

In order to visualize the decision boundary generated by SVM and RBFN, the input space is reduced from 7 indicators to only 2 indicators, C and MP . The visualization is demonstrated in Figure 2.

5. Conclusions

The SVMs has been proved to outperform most other artificial intelligent algorithms in solving classification problem, that's why it becomes so attractive in recent years. This paper is devoted to applying SVMs to investment strategy in which three-level prices analysis introduced. The outstanding performance of SVMs, exhibited in the experimental results, reveals that the SVMs is capable of generalizing well, i.e. avoid overfitting. On the other hand, we also find out that while the training data is chaotic, i.e., the structure in the training data are declared improperly, it will usually lead to lower prediction accuracy. There are rooms for future work. Not only three-level prices analysis, but also various kinds of financial analysis technique could take advantage of the characteristics of SVMs to enhance their performance.

Understanding Issues in Regulating Privatized State-owned enterprises

Steve CHEN

International Graduate School of Management
University of South Australia
Steve.chen@xshowbiz.com

Abstract

In the recent decades, the privatizations of state-owned enterprises have becoming a global trend. There are many nations privatized their infrastructure and services, such as gas, electricity, water, railway, sewerage... etc. However, the privatized monopoly enterprises have achieved the fruit of super-profit; the general public began to question the effectiveness of the privatization towards to the newly created monopoly enterprises. So the regulations of the public utilities required immediate attentions from government.

The main objective of this research is to review on literature on the privatization of the monopoly enterprises through its procedures and investigate whether the government required to apply necessary regulations onto it. As a result, the governments of the developed nations are relying on the effective control to create more economic benefits.

At last, this research would combine all the regulating models used in the developed nations and may use as a reference to any government or who else required such relevant findings towards to privatization in their nations.

1.1 Motivation

In the recent decades, the privatizations of state-owned enterprises have becoming a global trend. There are more and more nations privatized their infrastructure and services after UK made a lead, such as gas, electricity, water, railway, sewerage... etc. However, the privatized enterprises are not simply transferring the ownership from public owned to private enterprises but required governmental regulation onto it. Each nation was expecting better economic performance from the private ownership and effective governmental regulation.

However the public started to question the super profit from the privatized enterprises (so called "privatized monopoly enterprises") achieved, and doubts the effectiveness on the regulation of the privatized enterprises. In the recent years, UK government has raised over £ 5,000 million of 'windfall tax' from the privatized enterprises and its shareholders. Due to the public discontent, the labor government has set up an inter-departmental committee to launch investigations to study this phenomenon. The key point of this research is to study whether regulatory office may stop the

privatized monopoly enterprises from huge profits and make sure the service quality are maintained.

State-owned-enterprises (shorten as S.O.E. hereafter) are commonly monopolized characteristics due to its network economics of scale and scope. If competitors would like to enter the industry, they must rebuild the whole distribution network repeatedly. The result from that would be a great waste and increase the costs and lowering the general public's interests and the economic efficiency. (Chanter, 1993) Based on this factor, most nations controlled the monopolized industries directly or nationalized to solve the monopoly issues. However, the operation performances of S.O.E. have shown some severe flaws on: governmental direct control and the ownerships of the S.O.E. There are also some flaws on S.O.E. over the years: 1) lack of sufficient profit motivation; 2) lack of own decision-making power; 3) politics intervention operational decisions to cause the increase of costs and capital wastage. (Aharoni, 1986)

Thus, privatization is an important scheme to solve the flaw of the public asset ownerships. However, it may affect the consumers' rights inevitably in the post-privatization era. Thus, the general public believed the intervention of the governmental regulations onto the private monopoly enterprises is highly necessary. In theory, the effective governmental regulation shall establish a virtual near competition environment. Thus the effective regulation can lower the costs of public services, increase the efficiency, and maintain the near market competition standards. (Shapiro & Willig, 1990) In another word, the goal of the effective government regulation is to replace the market competition, and the general public will be benefits from total market competition efficiency. (Burton, 1997) The privatization and appropriate governmental regulation are the two key actions to expect to solve the monopoly and the issues derives from the public ownerships. This paper will review on the nature of the privatization regulation in the post-1984 era and explore the experiences from the other developed nations. It is highly beneficial to some nations, which have not initiated the privatization, or as a reference towards to their privatization legalization.

2. Paper Review

The remarkable case of privatization in UK is the British Telecom (hereafter named: BT) in 1984. Prior 1984, the privatization in UK remained small and unnoticeable. Post-1984 is a great move towards the privatization era. During the privatization of BT in UK, government also established the Office of Telecommunication, which shortens as Oftel, as a regulatory office for the new privatized monopolized industry. It regulated the licenses for new telecommunication industry, call charges, wholesale rates. The Oftel model was also adopted in the privatization of the other large-scale state-owned-enterprises in UK. Thus, the industry, which regulated by the office, would be termed as “regulated enterprises”.

During 1984-1991, the ruling party, conservative party, overturned the trend of the nationalized the state-owned-enterprises since WWII. The government began to privatize the infrastructure of a nation, such as telecommunication, gas, water, waste-sewerage, electricity. After that, the follow on governments also privatized the British railway while it was in government. The UK Government appointed one industry regulatory office to regulate the operation of the privatized monopoly industry after privatized one infrastructure. The UK regulatory office is operating different from the US governmental regulation commission. On the contrary, the regulation office was lead by a single administrator in the office. The office was empowered with high independence and jurisdiction even though it is a governmental office. The administrator is not entitling as public servant and the budget of the office is collecting from its regulated enterprises.

Because of that, the regulatory office is being defined as “independent” office. However the operation of the office is never independent and not empowered with necessary power. The totally “independence” literally means its zero liability to the public, because the office only report to parliament via the minister while the members of parliament have to liable to the general public. Thus, the administrators have to publish its annual operation report to define its progress on regulation in the assigned industry. The office also needs to make public hearing requested by its not parliament commission and/or auditing department. However, the UK government was not entitled to overturn or amend the established rules and the behaviors of the administrator/regulation office. The undoubtedly fact is the parliament does have certain influence towards to regulation office and the ministers do have the actual power to intervene by exercising his/her entitlement. Until now, there was no obvious evidence to prove that any ministers ever intervene the regulation offices’ decision and its behaviors.

Apart from the independence in the politics, the regulation office shall be a highly specialized

organization in its field. Each regulation offices are consists of many specialized experts, such as economists, accountants, and lawyers. The UK government was trying its best efforts to maintain the independence of the regulation office, but the office shall consult the public to maximize the coverage in its policy. For instance: the consumer councils of each monopolized enterprises shall raise some reference opinions on behalf of the consumers’ benefits. Thus, the regulation system in UK does not represent any parties, but playing a totally independent, fair role to legislate the regulation rules to the general public. It may not be an easy task to maintain with these two key factors, but it has been achieved in UK. It is due to both the regulators and ministers to obeying the rules strictly to maintain such equilibrium. This may not be an easy task in some nations where politics are severely involved with all legislations and operations throughout the government system.

In the UK, the authority of the regulation office was empowered from the legislation of the privatization and the Competition and Services (Utilities) Act, 1992. In this Act, it forces the public utilities to follow the regulation on its service quality and the supplying. The UK laws request the regulation office to complete two basic targets:

1. To ensure that public services/utilities can meet all the reasonable demands from public.
2. To ensure that all regulated enterprises to maintain the sufficient financial operation to supply high quality public utilities/services.

Generally speaking, the regulation criteria are varying from industry to industry. For instance in the gas industry (Gas Act, 1995), the first priority is to intensify the competition, while this is second priority in other industries.

In UK, the legislation of the regulation rules does not just empower the regulation office to enforce the regulation rules, but to leave more space for regulation office to operate with norm. (Colmon, 1997; Parker, 1997) In most privatization legislation, it is commonly seen the similar clause such as: *“the minister and regulator were empowered to exercise their duty... and take the relevant necessary action...”*. According this clause, we can foresee that all the regulation bodies would take different approaches and subject to the terms of regulation administrator. For instance, the current Gas Supply industry regulator has different measure in their term in office with their former regulators, although the regulations were all based on the Section 42(b) of 1986 Gas Acts. Thus it can be seen that the regulators are empowered with huge power to exercise. However, in many countries, it is difficult to accept that an authorized single regulator with huge authority to exercise. While the US model would be a more acceptable model, and the regulation offices were consisted of many committee

members to operate according to their prior legislations.

Apart from the relevant regulations, each regulated enterprises must obtain the licenses from the ministers or its regulation office. It must state the terms and conditions of operation in full details on the license, such as pricing, the wholesale rate, the rate of distribution network to other competitors. In another words, the licenses are generally over hundred pages and have all details within. However, the regulator remained power to define or amend the terms and conditions if necessary.

Key difference between UK & US models

When UK government began to privatization, they have studied the long established regulation system in US. But the UK regulation system is varying in four basic structures than US system:

1. UK system centralized its authority to a single administrator rather authority-shared committee system.
2. The UK government established one regulation office for each individual industry; while one US regulation commission is generally controls over number of industries.
3. The level of juridical authority. The UK system offers less likelihood of legal appeal for its regulated industry than US model.
4. The profit regulation of pricing capping.

The reason why the UK parliament adopted the single administrator model rather than US model? There are three main reasons:

1. At the time UK government establishing regulation commission, there were not many regulation experts available at the time. Thus, the UK government has to assign the regulation experts more precisely due to the human resource scarcity.
2. The single administrator model can adopt into the regulated industry faster and enable an effective regulation.
3. The ease of the accountability: it is relatively easy to measure the performance of the administrator. The UK model is the appropriate model for those nations without prior-privatization-experiences. In contrast, the advantages of the US model enable the inter-industries regulations commission to transfer its effective regulations experiences to other industries. While US model can also build a systematic regulations across the industry.

Why the UK parliament adopted the model, which assigned a single regulator per industry, rather than US model? There are three major factors:

1. At the time, UK established the regulation office for the privatization; there were not too many regulation experts available. Thus, the UK government has to assign precisely and thrifty due to the experts scarcity.
2. Single regulator can adopted into the characteristics of the industry much faster and perform the regulation more effectively.
3. Ease of measures the performance: it is relatively easy to measure the performance of the regulator. The UK model is appropriate to those countries, which never have privatization experiences. In adversely, the advantage of the US model is the possibility to transfer their effective experience to other industries via the inter-industries regulation commission. The US model can also build a more systematic regulation for other industries.

Until now, the UK government has no signs of showing to abandon the single administrator model, but there were some initiations to make amendments. For instance, the business of the Ofel has expanded to across all telecommunication categories and likely to combined all as one. The gas regulation office and electricity regulation offices may combine as one energy regulation office in the nearest future. In the fact, the reality has forced the UK government to make some amendments to combine its regulation system. For instance, the traditional telecommunication enterprises were challenged by the new emerging telecommunication enterprises. The multi-faceted UK gas corporation has initiated its business in its power generation business while some electricity companies on the market began to offer gas supply service. From these two cases, it has illustrated the UK regulations model would shift towards to US model in the future.

According to the US government regulation, all parties include the regulated enterprises, consumer groups, and other interest groups shall report in the regulation public hearing. According to the Federal Administration Act 1984, the US regulation model had developed in a model with more juridical contents.(Sappington, 1986) In adversely in UK, the juridical department played a minor role in the regulation system. It is almost impossible to challenge the regulation office's decisions. The Law can only offer the legal advises towards to the regulation decision procedure, such as obvious illegal and/or unreasonable policy making procedure rather than the comments on its decisions. Until now, it is rarely seen any juridical investigation towards to the regulation procedure.

Since the legal procedure can not offer any appeal opportunities to their regulated enterprises, thus the MMC. (Monopoly and Merging Commission, shorted as MMC) has become the important organization to

investigate any comments from the regulated enterprises. However, the MMC would involve to arbitrate only when the regulated enterprises conflicts with their regulated office in the license amendments. Since 1992, the MMC has involved in 6 pricing amendments and dissolutions between the regulator and the regulated enterprises. The MMC would only focus on any disciplines, which may obviously against public interests. If any of regulators' operations may against the public interests, then MMC would request regulator to amend the existing policy and/or take necessary actions to recover the loss to the public interests. However the MMC would not accept any appeals other than license operation conditions. The less effective appealing has turned down the regulated enterprises to take any actions to against its regulation office, regardless from legally nor administratively. Furthermore, the regulated enterprises are reluctant to solve any issues via MMC, because it normally makes the share prices fluctuate once the news disclosed to public. The regulated enterprises also concerned that the excess internal information may disclose to the public during the investigation. Thus, it is rarely seen any enterprises willing to appeal for a solution with its regulator via the MMC. Therefore the UK has limited results to appeal via the administration and legal methods. Since UK does not have appropriate formal law to regulate the regulator, thus there were many experts concerned that the UK regulators have been over-powered.

Veljoneski (1991, p.16) criticized the regulation office is a monster in the Constitution because the incompliance to its principles of control, audit, balance rule in the tradition democratic government system. This criticism is based on the viewpoints from the democratic regulation and the public liability. Thus, some researchers of the same viewpoints emphasized that all regulation office shall account for the public liability and accept the certain democratic procedures such as the formal governmental norms, assignment procedure, and public hearings. This statement may seem reasonable but may mislead to the general public.

Common regulation models

At the moment, the common democratic supervising procedures may not be appropriate to apply to the regulation office. In the contrast, the substantive model could be more appropriate than democratic supervising procedures. The legitimate of the substantive model shall acknowledge to the consistency of the government's policy, the specialization in problem solving, public interests, exact regulation goals, and clearly defined power. However, all these goals would be hard to achieve under the direct political controls. (Majone, 1996,1997) The UK regulation model is classified as this substantive model. The first goal the regulation is the effective regulation, which enhances the specialization in its practice, and maintains the independence in regulation. In adversely, the US public utility regulation model is a hybrid model of the

democratic model and substantive model. Thus, the specialization and independence of regulation have to subject to the outcomes from the public hearings and legal investigations.

We must admit that: the substantive model would be more appropriate than democratic model to reach the goal of "Economic efficiency" and "Pareto Optimum". However, it is more appropriate to adopt the democratic model if some social goals wish to be achieved, such as equilibrium between the wealth and incomes. Certainly, the regulation may result some resources re-distribution inevitably during the regulation, such as employment opportunities and the wealth. Thus, it may not be easy to distinguish the social goals of the "economic efficiency" and "re-distribution" strictly. Even though, the UK model can still view as a standard and substantive regulation model. Until now, we can understand that why UK regulators did not involved with any "social engineering" and the UK researchers' rejections to expand the regulation coverage to any social issues. (Foster, 1992, Ch.9) If there were too many social issues involved in the regulations, it means more political, society democratic issues would take into account of the regulation model. However, it may not be an easy task to seek an equilibrium state between the specialization independence and public liability. From the routine operation of the regulation office, it may highly likely that any political interventions may involve while political frequently over power of its operation in some nations.

In some nations, the society is difficult to accept any over-power economic forces, it would be necessary to induce some appropriate models to regulate. Therefore the appropriate model would suggest per: replaced the single administrator with panel of committee members, addition of the public hearings, judicial procedure, more intensify parliamentary supervision.

In UK, the most of the public enterprises had turned nationalize since 1945. The main motivation for such move was: the S.O.E. would perform better and fairer services because S.O.E. may not pursuit maximized profit as a goal. To fulfill this goal, the UK government established the board of directors to all S.O.E.. The purpose of establishing board of directors is to minimize the excess interventions from government. However, in reality, there were large numbers of political interventions remained existed and did not change even with the existence board of directors. Till late 1970s, the S.O.E. had a very low morale internally regardless of the level of positions. Furthermore, there were huge numbers of evidence and data has proved that the S.O.E. did not even meet the expected goals in its costs, capital investment ratio, and productivity. (Victors and Yarrow, 1988, p.151)

The Conservative party ruling government was blamed for the failure of the public ownerships in 1979.

General public are now viewing the privatization as a wonder solution towards the poorly performed S.O.E. but may not necessarily lead to an improvement of the economic performance. (Martin & Parker, 1997) For instance, the Jaguar automotives had privatized in July 1984 but remained in poor economic status till the transferring of ownership to Ford in 1989. In reality, the S.O.E. would generally improving in its operation performance due to the newly entered competitors.

4. Discussions and Suggestions

Discussion

Generally, government is less likely to introduce too much competition from its S.O.E., because excess competition may influence the profits to yield to the government and may cause bankruptcy or requirement of restructure to the S.O.E.. If any of these situations happened, the government must accountable for extreme liabilities and pressure. All these facts are understandable while the UK's experience in privatization also proved that it is rarely seen totally fair and effective competition for any S.O.E. in their industries. It is because the government may offer S.O.E. with some subsidies and other aids from government while the private competitors hardly receive any. For instance, UK began to liberate the market competition in the gas industry since 1982/3; however the real competition did not come into the game until the whole industry privatized. The privatization of the telecommunication, gas and electricity had speed up the pace of the competition in those industries for the two major factors: 1. Privatization; 2. the effective regulation. Under the efforts from the UK regulatory office, they have intensified the competition in one industry. UK gas has lowered its market share to 45% and the competition from its competitors remained growing. The whole gas market was liberated in 1998. In the electricity industry, the electricity generation has entered the era of competition as beginning; while the electricity distributions industry was fully liberalized after 1999. The competition in the telecommunication is never calm if compared to other infrastructure industries in UK. By the year of 1996, the telecommunication regulation office has issued 1,260 licenses, which included 3 public service licenses, 44 international call licenses and 18 international call resell licenses. (Oftel, 1997, p.96)

4.1 Suggestions

At the end, the performance measure of a regulated enterprises can be conducted from its productivity, profitability, price, service quality and numbers of staff employed. To summarize the available regulation models of the developed countries, it is found that all government expecting to create better economic benefits via its effective governmental regulation. As a result of that, the research is highly valuable for those developing countries or any government who are willing to conduct privatization in its nation as a reference.

Abstract

In recently years, the government, academia and business have applied different information technologies to disaster prevention and diverse web sites have been developed. Although these web sites provide a large number of data about disaster-prevention, they are knowledge poor in nature. Furthermore, disaster-prevention is a knowledge-intensive task and a potential knowledge management system can overcome the shortcoming of knowledge poor. On the other hand, ontology design plays the key role toward designing a successful knowledge management system. In this paper, we introduce a three-stage life cycle for ontology design for supporting the service of disaster prevention of debris flow and propose a framework of an ontology-based knowledge management system with the KAON API environment. In addition, by appealing to the technology of component reuse, the system is developed at lower cost thus knowledge workers can focus on the design of ontology and knowledge objects. The objectives of the proposed system is to facilitate knowledge accumulation, knowledge reuse and dissemination for the management of disaster prevention. This work is expected to enable the promotion of the traditional disaster management of debris flow towards the so-called knowledge-driven decision support services.

Keywords: knowledge management system, ontology, disaster prevention of debris flow, ontology, component reuse

1. Introduction

In the information overloading age, one has to not only concern the way of how to collect information, but also needs to focus how to utilize the existing information. In recently years, many experts and researchers have devoted to the disaster prevention. They collected large numbers of data such as weather and geology which are related to disaster factors. In order to reduce the occurrence of debris flow and to protect people's life and property, the government, academia and business have applied diverse information technologies for disaster prevention. A number of information systems including decision support

systems and expert systems have been developed in addition to different kinds of web sites. Although these web sites provide large data about disaster prevention but they are usually knowledge poor. Moreover, they lack of the ability of transforming disaster-prevention data into resource of decision support strategically.

Knowledge is an important factor in the application of disaster prevention, which is a knowledge intensive task. Decision makers usually need to analyze changes of the environment, to ignite the alarm and to plan rescue work and procedure. It is obvious that one who can contribute to disaster prevention should own the essential knowledge for disaster prevention. It will be greatly helpful if the essential knowledge of disaster prevention can be retained and enhanced by successors or the community. This is the time which knowledge management can contribute to. Therefore, in the data rich disaster-prevention environment, it is important for moving the focus from data to knowledge management for disaster prevention.

In the knowledge management the most important issues is knowledge integration [2, 4], which focuses on the issue of the integration of different databases and different forms of knowledge representation [5]. In disaster prevention, there are two reasons that we should apply knowledge management. First, data format is adherent to uniformity. For example, many researchers collected data and then tried to explore the reason causing the occurrence of disaster. However, the data sets under investigation did not follow the standard format, therefore, the reusability of data is hindered. Secondly, documents of disaster prevention are usually semi-structured or non-structured so that reusing the knowledge and data existing in the documents is difficult as well. There are different approaches to define knowledge representation [7, 8], however, if one wants to achieve an objective of semantic search in a knowledge base and to suit in the open communication environment, ontology should come in to play. Ontology defines shared vocabulary of knowledge management systems to facilitate knowledge communication, search and knowledge representation [6]. It can help data integration and avoid data inconsistency. In terms of knowledge sharing and reusing, it also can reduce developing cost of knowledge management systems. Ontology has played a key role toward a

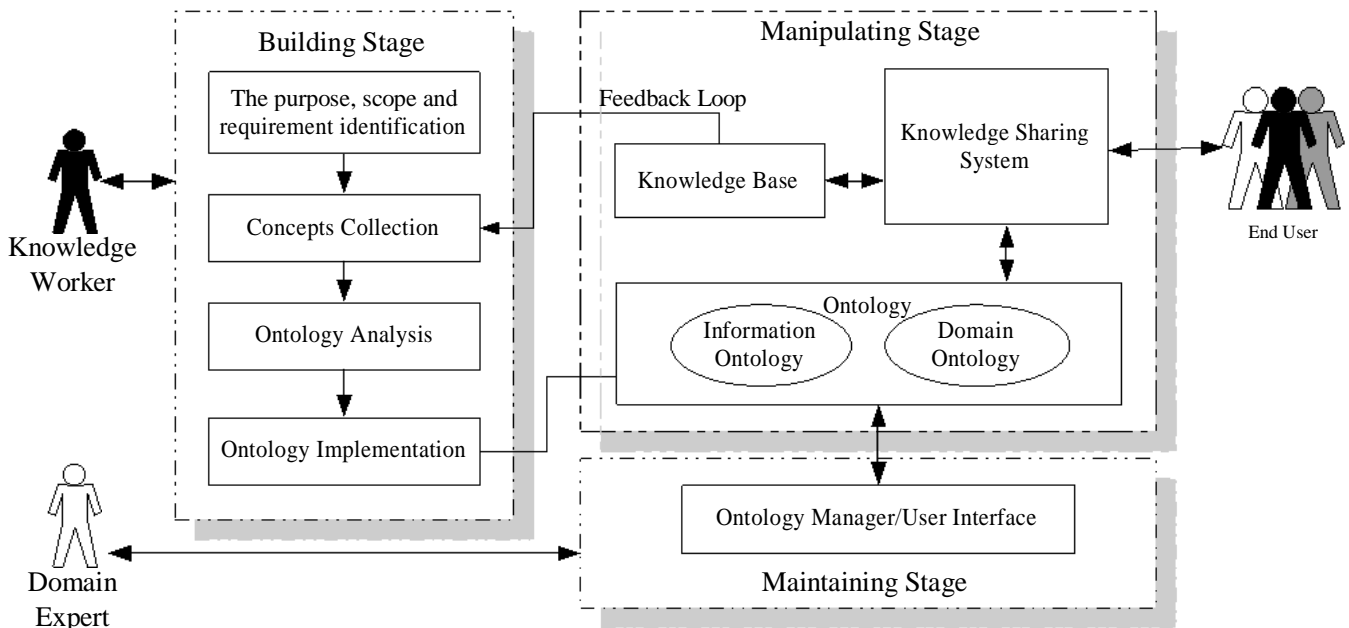

Figure 1. The framework of ontology-based knowledge management system

successful knowledge reuse in many projects [3].

In [1], we proposed a framework of a knowledge management system for the disaster prevention and designed a web-based knowledge management system for supporting disaster management of debris flow. In this paper, we focus on the discussion of system design and aim at knowledge sharing and knowledge dissemination. We propose a framework of the an ontology-based knowledge management system. The system can provide a semantic searching and facilitate knowledge sharing in the disaster prevention of debris flow.

This paper is organized as follows. Section 2 gives brief background knowledge for knowledge management and ontology. The ontology-based knowledge management system is presented in Section 3. Experiments conducted in disaster prevention of debris flow are demonstrated in Section 4. Section 5 concludes the paper.

2. Knowledge Management and Ontology

The basic activities of knowledge management are knowledge acquisition, creation, sharing/diffusion, and utilization. There also exist different knowledge management systems (KMS) that facilitate the activities of knowledge management [2, 9, 10]. In 1990s, the knowledge reuse and sharing already became the major issue in knowledge engineering [11]. In order to achieve the goal of knowledge reuse, the concept of object orientation has been introduced to knowledge management systems. In the sense a knowledge entity can be treated as a knowledge object (KO). KOs can be numerical data, text streams, validated models, meta-models, movie clips, or animation sequences [7], how to integrate and share KOs among different KMS is of great necessity and is a crucial challenge. In the literature, metadata has been widely used in the

integration of existed knowledge bases [12] whereas the ontology has been considered as a meta-level description of knowledge presentation [13]. Thus using ontology could made knowledge generalization and promoted knowledge sharing quickly.

Ontology is to play the important role of knowledge representation and represent knowledge domain hierarchy. Ontology could promote sharing and commonness and push knowledge sharing more quickly. The ontology can be divided into information ontology and domain ontology [14]. The information ontology is a meta model that describes knowledge objects and contains generic concepts and attributes of all information about knowledge objects, such as the title, authors, date, keywords, and other related information. The domain ontology consists of the concepts, attributes, and instances of domain.

In [14], a three-level architecture for intelligent decision support has been proposed. It contains application level, description level, and object level. The object level comprises various information and knowledge sources, the so-called KOs. Ontologies are in the description level, which enable users in the application level to intelligently access object-level sources. Ontologies are metadata that provide the search engine with the functionality of a semantic match. It is different from traditional search engines that directly search for the contents of data. From the viewpoint of ontology, XML is not suited to describe the interrelationships of resources in the Internet [15].

KAON, Ontoprise, and Ontopia [16] provide a complete set of ontology tool suites for building, maintaining and utilizing ontologies. In particular, KAON and Ontopia these tool suites can be deployed onto Java J2EE [17] architecture, a distributed component-based architecture, which makes the ontology-based system

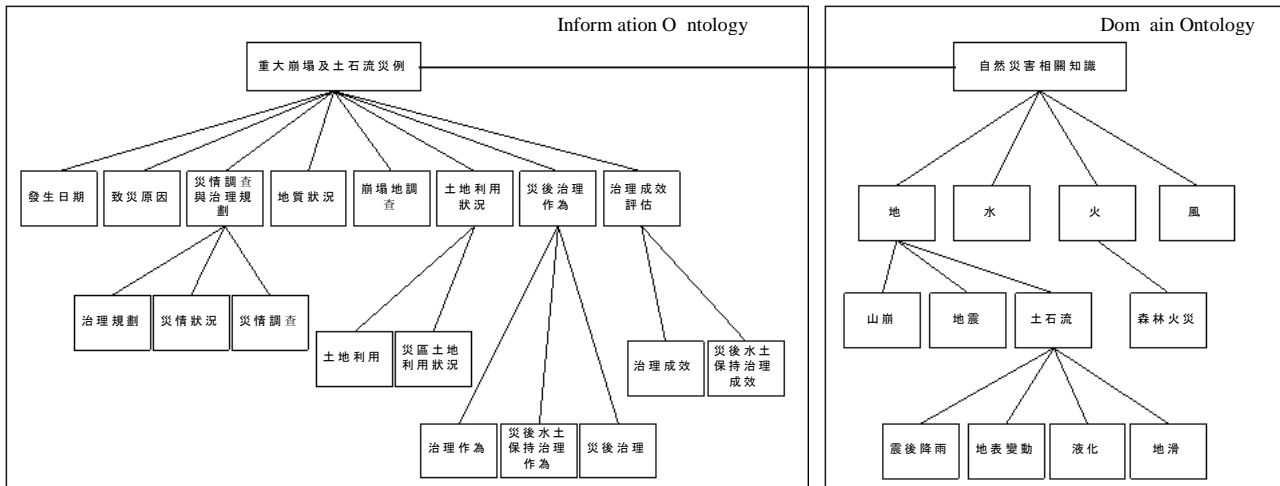

Figure 2. Disaster prevention of debris flow ontology

more flexible and robust. For this reason and the consideration of open source, KAON is chosen as the ontology development platform in this study.

In the past years, many information systems have been developed for different purposes. However today we should emphasize that the important of component reuse. The advantages of reusing components are faster developing time, better quality, and cheaper costs [21]. In this paper, we hold on the view of component reuse and reuse the system components that we developed an ontology-based knowledge management system for the metal industry to help develop this system [20].

3. Ontology-Based Knowledge Management System

This section describes how ontology can be built and interacted with a knowledge management system. We propose a framework of ontology-based knowledge system for disaster prevention of debris flow that exhibit in Figure 1. According to the literature [18], the life cycle of ontology design can be divide into three stages: building, manipulating and maintaining. In the building stage, we identify the purpose, scope and requirement of ontology. When we identified all requirements clearly, then we could begin to collect data and information about concepts of disaster prevention of debris. Next, we analyze the collected data and information. In the ontology implementation step, the ontology can be classified information ontology and domain ontology [19]. The information ontology is a meta model that describes knowledge objects and contains generic concepts and attributes of all information about knowledge objects, such as the title, authors, date, keywords, and other related information. The domain ontology consists of the concepts, attributes, and instances of disaster prevention of debris flow. In our research, we discussed with domain expert and defined the ontology display in Figure 2. The purpose of domain ontology is to achieve the objective of semantic match when searching for knowledge objects. In

the manipulating stage, the ontology is deployed to knowledge management system and supports the knowledge management tasks and searching when an end-user accesses the knowledge base. There is a feedback loop between knowledge base and ontology through both ontology analysis and implementation. With more and more various types of knowledge objects in knowledge base, the feedback loop provides the capability of expanding information ontology. In the maintaining stage, domain experts can add, update, and remove ontology via a user interface.

The architecture of the proposed system is composed of three layers: knowledge description layer, application layer and integration and presentation layer. We briefly describe the functionality of each layer as follows and more details can be found in [20].

(1) Data layer

All knowledge objects are stored in knowledge description layer. It contains several databases: system database, user database, personal knowledge base, common knowledge base, information ontology base, and domain ontology base.

(2) Business Logic layer

The proposed knowledge management system is built upon the Java J2EE environment, a distributed component-based platform. The J2EE server is deployed in application layer. It contains three major components: basic components, knowledge management components, and ontology management components.

(3) Presentation layer

The integration and presentation layer contains several JSP pages and Java servlets (lightweight Java applications in the server side). The major components are News, Forum, System Manager, Personal Knowledge Manager, and Knowledge Search Engine. All information in the forum can be treated as a part of information ontology.

4. Experiment

In our research, we apply knowledge management and information technology to disaster prevention of debris flow and propose a framework of the knowledge management system. The technologies of web and software component are used in designing the system. For knowledge management, it can reduce cost of development and maintenance, and one is supported by the functionality of searching related information quickly but also making right decision at the right time. The snapshots of system demonstration are shown in Figures 3, 4, 5 and 6.

Figure 3. The entry of knowledge management system

Figure 3 is the entry point of the system. The user has to login the system first and then start to engage in the activities of knowledge management, including creating, editing, browsing, and searching knowledge objects.

Figure 4. Information ontology Editor

The creation of knowledge object with information ontology is shown in Figure 4. The domain ontology editor is shown in Figure 5. Information and domain ontology have to be established by the system administrator that follow Dublin Core. The left side in the Figure 5 is the hierarchical classification of metal

ontology, and the right side is the viewer of concept.

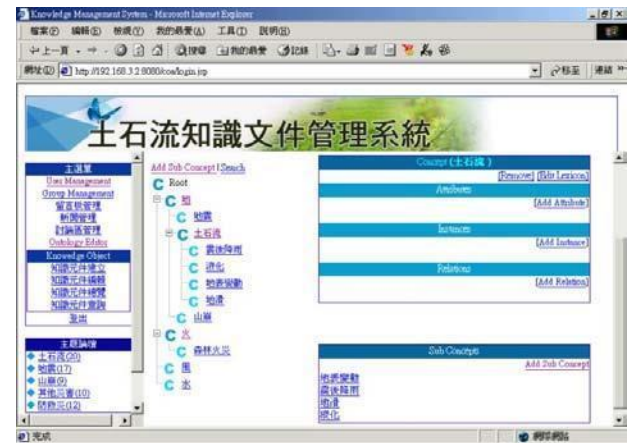

Figure 5. Domain Ontology Editor

When users want to search knowledge objects, they only need to fill out parts of Dublin Core then the knowledge search engine retrieves the matched objects from Information Ontology database as shown in Figure 6. In our system, we used semantic search, for example when we want to search something about typhoon, our system can retrieve information in disaster prevention of debris flow domain. And if we defined ontology include Chinese and English when we use Chinese to search information then we will find Chinese and English information both.

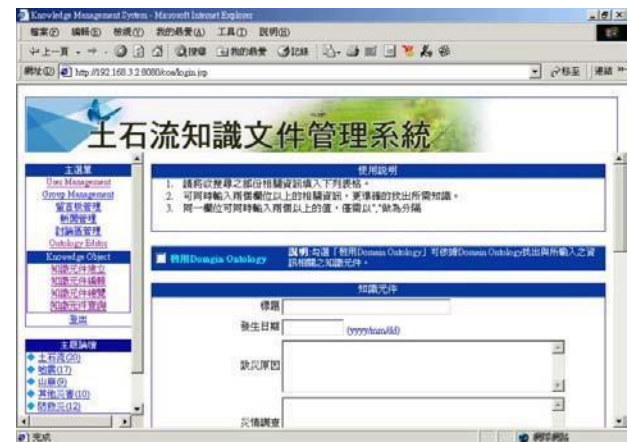

Figure 6. Search Knowledge object

5. Conclusions

For knowledge management, knowledge reuse and sharing already became the most important issue. In this paper, we proposed a framework of ontology-based knowledge management system and reused a prototype that we developed for supporting knowledge management in the metal industry in Taiwan previously. The system was built upon Java J2EE architecture for the sake of flexibility and robustness, and it utilized KAON API to communicate with KAON service for maintaining information ontology and domain ontology. This major advantage of the proposed system results from the salient features of component reuse so that researchers can focus on the design of knowledge objects and ontology without

the overhead of developing a new system.

In this study, we introduced knowledge management into the disaster prevention of debris flow and developed a pioneering prototype of ontology-based knowledge management system. Users can search relevant information and knowledge with the ability of semantic match. The system focuses on the issue of knowledge sharing and provides a simple way for knowledge searching. It is the objective of this study to accumulate knowledge about disaster prevention and to make people can get knowledge more easily. In such way, the traditional disaster management of debris flow can be prompted towards the so-called knowledge-driven decision support services.

Legal Protection for the E-Commerce in Indonesia: A Study on the Development and the Future of Cyberlaw in Indonesian Legal System

Sonny Zulhuda

Center for Regulatory Research
Jakarta – Indonesia
zulhuda@yahoo.com

Abstract

In this new economy, electronic commerce has paved its way for every business stakeholders, be it merchants, investors, distributors and consumers. Putting their contribution this way, they are understandably eager to see the road they are taking is safely guaranteed to deliver the aimed result. Due to this, efforts and strategies are being assessed, planned, undertaken and evaluated to mitigate and manage the risks associated with e-commerce, most notably from legal and regulatory approaches.

The thrust of this paper is to analyze current situation of e-commerce in Indonesia from the legal point of view. It will examine the problems that have accrued so far in the lacuna of a comprehensive cyberlaw in the country based on local incidents and cases. Special analysis will be given on main provisions of the Electronic Information and Transaction Bill to see how much protection it would give to the e-commerce activities in Indonesia and which parts should be better improved. At the end, the paper tries to summarize overall development and future of cyberlaw and its prospect of facilitating the growth of e-commerce in Indonesia.

This study serves to compliment as comparison for other assessments of the growth of e-commerce globally and regionally. Looking at the fact that Indonesia is just another crucial market power in this region, the study of its legal system in the e-commerce is both imminent and unavoidable.

1. Introduction

In this new economy, electronic commerce has paved its way to become another 'new kid on the block' where more investors are putting their shares and more players are taking their parts. Not only this phenomenon is imminent in the developed economies, but also it is witnessed in the developing countries. It is the consequence of this intensified situation that more stakeholders want to see the road they are taking is safely guaranteed to deliver the aimed result. Due to this, more efforts are now undertaken to mitigate and manage the

risks associated with e-commerce, most notably from legal and regulatory approaches.

Nevertheless, before moving further to defining the nature that the e-commerce has, and the risks it comes along, one would need to take a look back on how this new dimension of economy manages to get its place in most of the countries on this globe. In as much as the e-commerce begins to reshape the developed country's economy, it also takes its way in the developing countries.

E-commerce has certainly allured developing countries mainly due to several characteristics it has to offer. First, as Minges [11] indicates, it certainly increases the sales and thus generates hard currency. In other word, subject to different level of success indifferent places and situations, the e-commerce proves to be workable. This fact will in turn boost employment and welfare, and apparently has some effect on reducing brain drain and urbanization alike.

What attracts business players most is the unprecedented level of transparency and efficiency that is offered by e-commerce, especially in the infant democracies such as found in the developing countries. These factors of transparency and efficiency have apparently rejuvenated business players in conducting their course of business. Taken together, all these factors provide explanation on the emerging role given to the e-commerce sector in reshaping the new economy in many developing countries.

2. E-commerce in Indonesia

2.1 Facts and Figures

Indonesia is the largest archipelago country in the world with more than 16,700 islands, spreading across 5,000 km of equatorial line. With a population of more than 210 million (Source: Indonesia Bureau of Statistics at www.bps.go.id), Indonesia is the 4th most populous country in the world. Although the country covers a large area, the population is concentrated in the islands of Java, Bali and Sumatra.

Like many other countries in Asian region, Indonesia also felt the effects of the economic crisis, which prevailed globally since 1997. That crisis hit Indonesian economy very badly. Data show that since 1997, GDP (gross domestic product) and income per capita have been decreasing [17]. But those numbers were improved in 1999 onwards because of the Indonesian economy recovery program under the new government.

Indonesia's demographic and geographic situation would appear to make it an ideal location for e-commerce. There is a large market spread over many islands. However, the current reality does not really reflect the expected impact. Indonesian 'e-readiness' – shorthand for the extent to which a country's business environment is conducive to Internet-based commercial opportunities— trails behind other developing countries in the region. The e-readiness ranking in 2002 placed Indonesia 52nd; trailing behind Singapore (11th), Malaysia (32nd), Thailand (46th) and the Philippines (49th), and only ahead of Vietnam (56th) [16].

The Indonesian Association of Internet Service Providers (APJII) [1] stipulates that the number of Internet users in Indonesia is 4.5 million in year 2002 (2.14% of the population), and at the end of 2003 is estimated at 7.550 million (about 3.5%). Refreshingly, until March 2003, the number of ISP that has been issued license reached 186 (See Table 1).

Table 1: Internet and e-commerce indicators in Indonesia. Source: Association of Internet Service Providers Indonesia (www.apjii.or.id)

	1999	2003 (till 1st quarter)
Internet Users	1,000,000	7,550,000
Internet Subscribers	256,000	800,000
Internet Service Providers	50	186
Country top level domain (.id)	3627	16,257

A survey performed by US-based Boston Consulting Group (BCG) of 14 Asian countries found that Indonesia's per-capita online spending was \$0.01 in 1999 (or a total of \$2m), leaving it behind India (\$0.03), Thailand (\$0.02) and Malaysia (\$0.05). BCG said 80% of the online transactions in Indonesia came via travel-related websites [3].

By volume, the accumulated value of e-commerce in Indonesia has been estimated at under US\$ 100 million in 2000, or less than 0.1 per cent of GDP [8] and only represents 0.026% of the total world transaction value that reached USD 390 billion in the same period [17].

Despite those discouraging figures, the future of e-business is still shining in Indonesia, provided that the existing barrier can be handled well. The hope can well emerge from the fact that Indonesia appears to be the freest Internet market in Indonesia. This is a direct impact of an unprecedented liberalization and freedom to speech unleashed by the current open political environment [8]. There are at present no limits on the number of Internet providers nor is content restricted in anyway.

According to recent statistics of Indonesian Association of Internet Service Providers (ISP), there is significant growth in all Internet-related figures: number of Internet users, Internet subscribers, Country Top Level Domain (CTLD), and number of ISP's in the last five years [1].

International Data Corp, a US research firm, estimated that the number of Indonesians who buy goods via the Internet would swell to 600,000 by 2003 (from 70,000 in 2000). It counted 3,544 websites managed by Indonesian companies, with upwards of 50 being Internet service providers [3].

2.2 E-commerce Barrier

Given the ideal expectation for the e-commerce in Indonesia, question may now be posed as to why e-commerce does not make a real big jump in Indonesia. This is purportedly due to existence of several barriers to e-commerce development, including lack of infrastructure (of both technological and regulatory), awareness, security, etc.

This paper foresees that legal, regulatory and policy frameworks count as among the major force to facilitate e-commerce development. For this reason also, this aspect has been made integral to the concept of e-readiness.

It is this importance that has been emphasized by the government of Indonesia when developing and formulating the national information system or called SISFONAS [15]. By virtue of this platform, the government of Indonesia shares the vision that there shall be an '*i before e*', or, infrastructure before going electronic. And this infrastructure includes regulation.

Looking at this fact, the fate of e-business certainly hinges on the adequacy of legal and regulatory frameworks that should serve as rule of the game. Inadequacy and lack of enforcement thus serve as detrimental barrier for the development of e-commerce.

The issues such as consumer protection, formation and delivery of contract, payment method, transaction security and data confidentiality have become a main menu when consumers consider e-business transaction.

The questions remains are to what extent all the stakeholders, mainly the authorities, have anticipated the legal and regulatory aspect of e-commerce.

3. Legal Protection for E-commerce in Indonesia

3.1 Current State of E-Business Law in Indonesia

In Indonesia, demand to upgrade the protection of laws for e-commerce environment is arising [5]. Steps have been initiated but considered very slow. While other countries in the region have had some pieces of legislation in place, there is no single act comprehensively addresses the issues of cyberlaw.

The main law currently deals with telecommunications sector is the Telecommunication Law No. 36/1999 [8]. However, this law mainly deals with the broad telecommunication sector, licenses, operation, network provision, and other procedural matters. It does not touch issues of content and other aspects of cyberlaws.

Despite the absence of a comprehensive cyberlaw, some redresses have been attempted from the existing traditional laws such as in online credit card fraud cases. But in many occasions it is proved that these laws are just not sufficient enough to accommodate special nature and challenges of e-commerce age. The penalties stipulated for cyber crime offenders often do not sufficiently bring about the deterrent effect, and existing punishment does not necessarily remedy the loss that may accrue.

Currently, Indonesia's Central Bank (Bank Indonesia or BI) is taking initiative to prepare draft law on fund transfer act. The law among other things will touch the issue of electronic transfer of fund between financial and banking institutions [2]. However, it submitted that the process that this draft will take to become law will still be long.

At administrative level, there is however a good signal from the Government when recently Presidential Decree No. 3/2003 was issued namely 'National Policy and Strategy on E-Government' in June 2003 [1]. The decree basically urges all sectors of government agencies in central and provincial levels to prepare and accommodate infrastructures, methods, procedures and human resources for the implementation of e-government. With this decree, the government is apparently ready to embark further with online environment of governance including official e-procurements.

To this extent, it can be summed up that the current state of e-business law in Indonesia is in its initial stage. Some scattered and conventional laws are still in use for cyberspace medium with limitations, while the government has taken some administrative measures to

embark themselves into online environment through the implementation of e-government.

On the top of this, it is worthy to note that this lacuna would be answered quite soon by the initiative to legislate a comprehensive cyberlaw legislation to be elaborated later in this paper. But first we would need to see some legal challenges that have been faced by e-business in Indonesia.

3.2 Challenges to Indonesia's E-business Law

The initial process of e-commerce in Indonesia that is discussed earlier may account partly for the present rudimentary state of Indonesian laws on electronic commerce. This condition, however, can also be seen as a reflection of the current state of the development of Indonesian business laws in general [6].

It is true in the sense that Indonesia still relies heavily on laws and regulations that are issued during the Dutch colonial rule to regulate such fundamental matters as contracts and evidence. This situation requires reform, which cannot accomplish overnight.

The urgency for legal reform in e-business area is furthermore warranted by rampant cases of infringement and violation of laws that relate to the e-commerce activities. Among those incidences are described in the following passages.

3.2.1 Online Copyright Infringement

The Ministry of Justice is responsible for Intellectual Property Rights. As far as copyright law is concerned, Indonesia has a copyright law and is a signatory to the Berne Convention. In general, foreign copyrights receive automatic protection in Indonesia but there is lack of resources for enforcement.

Indonesia has been cited as having the third highest software piracy in the world, 89 per cent in 2000 that results in a loss of US\$ 70 million [8].

Certainly, poor level of protection for the intellectual property rights is not a good signal for potential investors and consumers to come into Indonesian market. The government had just recently enforced the new copyright law (Copyright Law 19/2002) that comes with effect of more severe penalty for the copyright infringement.

The law has also accommodated what it needs to meet the e-commerce challenges. It expressly includes the Internet as one of the publication medium in which a copyrighted material may also be infringed. The law has made equal protection for the copyright in the online media, and thus clearing the way for e-business to operate safely.

For effective enforcement, the law gives more power to the law enforcers in order to conduct search and seizure of suspected infringement. This law has given a blow to online piracy movement in Indonesia; nevertheless, the effective enforcement of it still remains for us to see.

3.2.2 Internet Credit Card Fraud

Internet fraud is fast becoming a common factor in online retailing as e-commerce transactions rise and fraudsters develop more sophisticated methods. According to Gartner G2 research, the risk of Internet payment fraud is at least 12 times higher than it is for face-to-face transactions.

Unfortunately, this online credit card fraud (widely labeled 'carding') has been so much associated with Indonesia. In year 2002 an international online fraud survey by *ClearCommerce* listed the country in the two top twelve countries from where the most online credit card fraud originates, only second to Ukraine (see www.ocalasmostwanted.com). It was suggested that about 20% of credit card transaction from Indonesia was suspected to be illegal.

In year 2002 alone, there were 218 cases of credit card fraud reported to the Police [9]. Meanwhile, there have been 23 cases reported in 2003 (until August). Out of these incidences, only a handful cases have been successfully handled by the Police.

The victim of this scam is worldwide. In 2002, most of the victims were American (84 cases), and following the US are mainly victims from developed countries in the Canada, Europe, Australia, and East Asia.

This rampant incidence costs Indonesian e-commerce at inconvenience. According to *Gatra Magazine* [8], online transaction requests that originate from Indonesia's IP addresses have been rejected and blocked.

In dealing with these cases, law enforcers have encountered certain legal obstacles. This is mainly the result of absence of a comprehensive cyberlaw that would otherwise anticipate cases like these. It was reported that the Police in this instance seek remedy from the conventional Penal Code with so many limitations, especially in defining the constitution of commission of crime and defining evidentiary issues.

As said earlier, these rampant abuses of the e-commerce activities in Indonesia have warranted the urgency of enacting a comprehensive cyberlaw in order to ensure reliability of e-business, as well as the confidence of consumers, merchants and investors to embark in the new venture.

4. Assessment of Indonesia's Cyberlaw Bill: Electronic Information and Transaction Bill

The current Electronic Information and Transaction Bill ('the Bill') [12] is considered the first initiative of the country to enact a comprehensive legislation on cyberlaw. There were initially two government's agencies that came out with two different bill drafts at the same time. This fact reserves some comment in the later part of this paper.

The Ministry of Industry and Trade initiated the draft of Electronic Information and Electronic Transaction Bill. On the other hand, the Department of Tourism, Post and Telecommunication under the Ministry of Transport also came out with the draft of Information Technology Bill. This double initiative was uncoordinated creating prolonged, unfocused and unnecessary debates among academics and IT professionals.

Nevertheless, the debates were deemed to have brought constructive ideas as well. It is noteworthy that the two drafts took different approach in formulating cyberlaw into legislation. While the Electronic Information and Electronic Transaction Bill was concentrated on e-commerce law and related aspects taking into account the requirements under UNCITRAL model law on e-commerce, the IT Bill was a general law (some called 'umbrella law') dealing with so many issues on general terms.

After some years of debates, the government acted wisely to coordinate and merge the efforts together. The coordinating agency is now Ministry of Communications and Information, and the consolidated draft is now called Electronic Information and Transaction Bill.

The approach is somehow a hybrid of the two original drafts; it does cover quite extensive subject matters from e-contract to e-signature, from privacy and personal data to cyber squatting and intellectual property rights, and from cyber crimes to consumer protection. However, the Bill does not go lengthy enough in subject matters other than cyber crime, e-contract and related aspects. For other subject matters, the Bill provides that they will be governed by subsidiary regulations.

At present, the draft Bill had been finalized by relevant agencies after it was consulted to public for comment. It was reported in June this year that the Ministry has processed the Bill to be signed by the President and ready to be tabled to Parliament [14]. It is presumed that the Bill will be enacted not later than the first quarter of year 2004.

Since this draft bill is the first to accommodate cyberlaw requirements, once enacted the law will certainly provide basis for the reform or revision of other areas of laws including electronic fund transfer, e-

government, capital market, online taxation, and online banking.

4.1 Legal Position of Electronic Message & Admissibility of Electronic Evidence

The Bill acknowledges in section 4 that electronic information shall have legal effect as evidence. This proposition includes the print-out form generated from the electronic message. However, for its legal effect, the electronic message is required to have generated from electronic system that is reliable. Furthermore it also stipulates that the electronic information system must fulfill requirements of integrity, reliability, and accessibility. It also has to be able to retrieve the message it is required. Having said this, however, the Bill stipulates that there are some exceptions in certain matters where written document is still necessary & essential including the marriage contract and land matter.

4.2. Consumer Protection

It is stipulated in the Bill that everyone has the right to obtain accurate and complete information with respect to contract requirements, manufacturer, and product that is offered electronically section 10(1). For this purpose there can be reliability certification body to be jointly worked out by government and members of public.

In respect with dispute resolution methods, consumers are given variety of legal redresses by the Bill. In case there is found *any use of IT* by certain party that creates harm for society, a class action can be taken by virtue of section 37. Arguably, this '*use of IT*' is wide enough to cover many areas and issues to the favor of consumers.

Besides, civil action can also be brought to commercial court in the event there is a use of IT that causes commercial loss to the consumers. In certain circumstances where there is a threat to certain important aspect of public life, the government may instead take action to protect public interest.

Other than litigation, consumers are also given option to settle their e-commerce disputes by employing alternative dispute resolution (ADR) including arbitration as provided in section 42, and the decision resulting from such process shall be final and binding upon the disputing parties.

4.3 Electronic Contract

The principle of freedom of contract is strongly upheld by the Bill when it stipulates the freedom of contracting parties as to which law to govern, and in which forum to hear the disputes. In this respect, alternative dispute resolution is also available for the contracting parties to opt.

More than expected, the Bill does not only recognize the legal effect of an electronic contract and parties to it, but also places the e-contract inline with the requirements of international civil law. This international civil law would be the reference in the event where contracting parties do not specifically stipulate which law would govern their agreement. This stipulation in section 20 (3) is especially important in the event dispute arises and the parties did not specify which law is to be the governing law.

The constitution of e-contract still depends on the offer and acceptance of the offer; nevertheless the principles are being adjusted to the online environment. Furthermore, by virtue of section 23(3) the use of electronic agent for a contract can also be held binding as far as the electronic agent is functioning properly in the ordinary course of business. This provision accommodates among other things the widely used Automatic Teller Machines (ATM) by banking industries. Other kinds of payment methods that involve automatic arrangement e.g. through computers are also covered under this provision.

Given the relatively new and ever-developing circumstances of the information technology, the Bill does anticipate its limitation in governing the e-contract activities. As a result, the Bill also provides in section 25 that any business customs and commercial practice those are alive today and not in contravention with the provisions of the Bill shall remain applicable.

4.4 Writing & Signature Requirements

Electronic message can be held original and shall fulfill the requirement of 'writing' provided that its integrity, reliability, accessibility, and retrievability are guaranteed.

Electronic signature has a valid legal effect under section 11, and the requirements are set in section 13. The word used is 'electronic' and not 'digital'. Meaning, it is technology neutral. And interestingly, it does not ever touch the technology of public key infrastructure. Meanwhile, the certification authority is not made compulsory; instead it was made optional ('*dapat*') in section 15(1).

4.5 Cyber Squatting

Some aspects of domain name registration and related issues are touched in section 26 of the Bill. It recognizes any registration of domain names on first come first serve basis. However, this domain name shall not be registered under bad faith, should not trespass fair competition law, and should not infringe rights of others on the name.

If the latter occurs, the infringed party may take civil action for damages. While international system of registration is recognized, further procedure of names

registration would be regulated by subsidiary regulation. Arguably, this stipulation gives legal effect to the international arbitration procedures, e.g. those under WIPO, UDRP, etc.

4.6 Intellectual Property Rights

The Bill in section 27 recognizes and protects every intellectual property rights as the result of electronic information work, and same protection is given for Internet website design and any IP-righted materials it contains. This provision is very short and simple, purposely because there is already a comprehensive law deals with IP issues. Apparently the Bill tries to avoid overlapping with those IP legislations.

For instance, Indonesia's new copyright law No. 19/2002 does anticipate the information technology and what it may affect the copyrighted works. It already sufficiently provides that the same principles of copyright are applicable in the cyberspace medium.

4.7 Personal Data Protection

Personal data protection (PDP) has been among the most contentious issue in the cyberlaw discourse. This is due to many reasons, mainly its significance to two seemingly-contradictive things: human rights that demands maximum protection of privacy in one hand, and international trade that requires extensive personal data transfer on the other. This background leads to various international attempts to come with regulatory measures on PDP.

However, possibly to the surprise of many, the Bill only provides one section (section 28) to deal with PDP, and no subsidiary regulation is mandated by the draft.

It only stipulates that data subjects must give 'consent' before the 'use' of any information containing personal data and privacy rights of that party, except in relation to public information that are no longer confidential.

Questions arise as to whether there is similar protection in the event of collection, storage, or deletion of the same personal data? Also, what kind of 'consent' required? Is it an opt-in or opt-out model? Given the width of the issue, why very limited provisions in the Bill? And why no mandate is provided for any secondary legislation such as in other parts of the Bill?

4.8 Offences of Cyber Crime

The offences under proposed bill are among the most contentious issues. The first sight on Bill's provision suggests wide and extensive coverage of computer misuse types and categories.

First of all, it is Interesting to note that 'hacking' or a mere unauthorized access to a computer or electronic

system is not made an offence, in an opposite stand to the law in other major countries such as UK, Malaysia and Singapore. This is believed to be crucial since Indonesia has been known for its rampant cases on cyber crime involving hacking, web-defacing and credit card fraud.

Hacking is an offence only when, first, it is committed with the purpose of obtaining or altering information contained in that system. Secondly, it is committed with the intention to secure information classified as confidential, or that are detrimental for national security and international relations. It is argued that this provision on international relations and nation's critical information infrastructure would provide redress for the issues of cyber-terrorism.

Hacking is also an offence when it is committed against the electronic system of financial and banking industries, with the purpose of misusing it or gaining undue advantage out of it.

The Bill also criminalizes any action that posed harms to the proper functioning of nation's protected electronic system (e.g. those system under national critical infrastructures). 'Protected computer' is elaborated by the Bill's elucidation of section 34; to fall into two categories: first, special and exclusive computers that belong to the government's financial institutions, and secondly, the computers that are used by the state to communicate and trade with parties from other countries.

In other provision, the Bill makes it an offence for the wrongful communication of password, access code, or other means of access (section 35).

Credit card fraud is addressed in section 33, where it provides that, any way of unauthorized use or access of other people's credit card to gain benefit from e-commerce is an offence under the Bill. It is hoped that this provision may curb the existing problem and thus eliminate the notorious credit card fraud in Indonesia.

4.9 Summary

In this summary on our assessment on the Bill, there are some other aspects worth noting, including both advantages and weaknesses.

First appreciation worth to note is that draft has aptly acknowledged the nature of technology of the Internet and ICT that is ever changing, ever developing and very dynamic. Ready to face this nature, the draft expressly stipulates (in section 2) that the law to be enacted must be based on neutral technology basis.

This provision will enable the law to accommodate various and dynamic developments of the information and communication technology. All kinds of technology will be acknowledged and given legal effect as long as

the requirements of system integrity, reliability, and accessibility can be assured.

Since the cyberlaw is a '*lex specialis*' or special legislation, the drafts provides in section 3 another important provision, that any other existing laws that have some extent of ICT use and employment, will be deemed applicable. Thus, rather than repealing effect, the cyberlaws have instead acted as complimentary to other existing laws and regulation. This provision is very important to affect solid and comprehensive national legal system.

The Bill, however, reserves some considerations for improvement. The biggest limitation it posed may be associated to its wide but not-deep coverage, especially in the area of privacy and personal data protection.

Simple and short approach taken by the draft in dealing with other issues may also cause another inefficiencies of the law. The current draft Bill requires about eight regulations. Normally these regulations will take another time and process to achieve.

It appears that the civil procedures in the commercial court as provided by the Bill open room for delay of litigation. And this may create another factor of ineffectiveness of the law. By virtue of section 39, the court is given a maximum of 90 days from the date an action is registered to deliver judgment. An extension of 30 days is provided with the permission of Supreme Court. It submitted that a total of 120 days for the delivery of judgment is too a long period and may necessarily prejudice the action due to the nature of evidence that may be gone vary fast.

5. Final Remarks

The cyberlaw bill certainly is among the most long awaited legislation by anybody engaged in businesses in Indonesia. With e-commerce in Indonesia grows from time to time, legal and regulatory issues get more imminent and prevalent. It is very important that the current on-going process of the Bill's enactment be widely informed to all these business stakeholders.

While enacting the law is one remarkable achievement, attempts will need to be initiated to anticipate effective enforcement of the law itself. With the cyber crime cases getting more serious and rampant in Indonesia, the law once passed should be enforced as soon as possible.

To achieve maximum enforcement, at least three sectors need to be addressed. First, international and worldwide cooperation needs to be secured. This is due to the nature of cyber crime which is trans-border and extra-territorial. Certain kinds of collaboration needs to be initiated at region level first, and then to the global level.

Secondly, the Indonesian Government needs to ensure there are effective administrative measures, policies and strategies in executing the requirements of cyberlaw and e-government. The question such as which ministry or agency to take a lead will need to be answered to avoid overlapping tasks like what happened with the double draft bill on cyberlaw.

Last but not least, educational factor is urgent. Not only to create more Internet-literate society, but also to achieve most effective and efficient utilization of the ICT. It is foreseen that the problem of digital divide in the country is still an uphill task to solve. This is in anyway also to create more balanced and fairer digital society in the region.

With all these policies and strategies, the enactment of cyberlaw will serve its purpose especially in giving maximum protection for the future of e-commerce activities in Indonesia and the region.

Abstract

What is the subjective value assigned to information? Is the subjective value of information similar to the realistic or normative value, or are there deviations introduced by human processing, the framing of the information source, or the external qualities of packaging and ownership of the information? Do people assess information as having the same value when offered the chance to sell it (Willingness to Accept, WTA) as when facing the need to buy it (Willingness to Purchase, WTP)? This is an empirical, experimental investigation of the effects of expertise vs. content, and copy vs. exclusive original packaging of information on the WTA/WTP ratio. In an animated computer simulation of a business game players maximize their profits by making choices regarding inventory and prices. Participants were also offered the chance to bid in trade (buy or sell) information regarding the weather that may affect demand. We find, as hypothesized, that the subjective value of information does indeed follow the predictions of Endowment Effect theory. Participants revealed a ratio of Willingness to Accept to Willingness to Purchase (WTA/WTP) that resembles the ratio common in the case of private goods. In the decisions, choices and performance recorded for the 294 subjects, we also found support for the hypothesis that the WTA/WTP diverges from unity more often and in a more pronounced manner for information traded in the "original" form rather than as a copy of the original, although even for copies the WTA/WTP ratio is still double. Results yield a value of about three for the WTA/WTP ratio for original information regardless of whether the source is content or expertise. Valuations of content and expertise did not diverge. However, the source of information can be manipulated by system design to become more salient. Copy information received a subjective value which was significantly different (lower) than original information. Implications for both online trading and online sharing of information are discussed.

1. Introduction

One of the central subjects of trading in e-business is information itself. E-business thrives on both the availability and the exchange of information in various forms. Every commercial transaction involves transfer of information. Commercial transactions usually involve not just the item being traded (books, CDs, antiques etc.) but accompanying information as well. Information is a unique good since use and access rights are often transferred by copying without the transfer of exclusive ownership rights. Similarly, expertise is transferred by copying since it does not leave the expert's mind. An exception may be when an expert provides exclusive advice and will not share or sell it again. Information and expertise can be transferred both by sharing (advice giving) and by trading. Since information exchange has become an integral part of e-business, the value of information must be part of the total transaction value estimate. Lack of sufficient information creates uncertainty which in turn leads to under trading of the goods traded. Hence, information is a catalyst to economic activity.

So far information was discussed in the general sense of the word. Some definitions are in order before proceeding. Three closely-related concepts are defined: Data, information, knowledge. Different definitions can be found in the literature for these terms from an information systems perspective [1, 2] or from an economic perspective [3-5]. The definitions used here were adopted from the knowledge management literature [6]. While more complex and detailed definitions are available (for example, [7]), the following definitions have been selected because they are fairly simple and parsimonious and enable operationalization. Data are discrete, objective facts about events. Information is analyzed and/or contextualized data. Information carries a message and makes a difference as perceived by the receiver. Knowledge or expertise is a human quality that builds on data and information together with experience, values, and insight. In this study we focus on two

instantiations of information: information as content and information as expertise. Content is the more tangible of the two.

The value of information is enigmatic. Information is neither a private nor a public good. It is an experience good. The main focus of this paper is to offer a way to assess the value of information as content and expertise.

The present research proposes to investigate the subjective value of information and expertise by combining economic and psychological theory with information systems research. We use an experimental/simulation approach to suggest possible approaches to evaluating the intangible, subjective value of information.

2. The Value of Information

Several unique characteristics render information difficult to value. Information is an unusual good in many aspects - production, distribution, cost, and consumption. Information is both an end-product and an input into the production of other goods, decisions, or information. It often accompanies market goods as an integral part. For example, an increasing portion of all consumer goods are accompanied by user manuals. Our purchasing decision may also be based on the availability of expert advice and recommendation.

Information is expensive to produce and cheap to reproduce [3, 4]. In fact, distribution is accomplished mainly by reproduction or copying. The same content can be distributed by different media, and the price is often derived from the medium rather than from the value delivered by the content itself. In point of fact, people consume information both by sharing and by purchasing, while most other goods are consumed mostly by purchasing. The cost of information can be either direct or indirect. The quest for the value of information is further complicated by the fact that information is an experience good, meaning that its value is revealed only after consumption [4, 8].

The value of information can influence the value of objects of commerce, therefore, we set out to investigate the value of information and expertise as a first step of a broader question relating to the influence of the availability of information on trading market goods.

Theoretically, there are three ways to assess the value of information [1, 9]: Normative, realistic, and subjective. While user utility should be the base for calculating the price of information, utility varies by person and circumstance. Realistic methods are *ex post* and consequently inappropriate for evaluating information content (also referred to as the “inspection paradox”) [8]. We therefore focus on the subjective value of information.

The tradition of studying decision-making under uncertainty has addressed patterns of information use and the value assigned to information. This literature sets the

backdrop for understanding information business trends. The heuristics experiments [10] as well as later studies [11] demonstrated that people tend to ignore available information such as prior probabilities, sample size and the like. Instead, decisions are based on other subjective methods such as representativeness, availability, and adjustment and anchoring (also known collectively as heuristics). Earlier experiments have also shown that people tend to be conservative and undervalue information available for the revision of a prior opinion [12]. A recent study [13] tested the pursuit of information for daily decisions. Participants preferred to seek information and to base their choices on (objectively) noninstrumental information. In other words, people assigned positive subjective value to objectively worthless information. Theory also suggests that people seek information because it seems the right thing to do [14], implying over-demand for information and a high subjective value. People tend to accumulate information “just in case” they may need it in the future, again leading to excessive demand [8]. The theoretical tension is, therefore, between studies indicating that information is under-valued and research showing that information to be over-valued.

2.1 The Endowment Effect

Subjective value has been studied experimentally for many types of market goods (also called private goods) and nonmarket goods (also called public goods). One very interesting finding of experimental research on subjective value is the discovery of a disparity between the highest amount one is willing to pay (WTP) for a good and the lowest amount one is willing to accept (WTA) as compensation for giving up the same good. This disparity was coined as the Endowment Effect (EE) [15, 16]. Traditional economic assumptions imply that, when income effects are eliminated, the difference between WTP and WTA should be negligible (the difference should amount to the decreasing marginal utility). However, experiments with various types of goods have shown that WTA is significantly greater than WTP. By definition, WTA and WTP values are neither normative nor realistic. Instead, they are subjective values, since they represent an individual’s personal perception of an object’s worth for him or herself. The EE methodology itself is designed with the purpose of eliciting submissions of private values and is described in section 3.2 below. We apply the WTA/WTP methodology as used for various types of goods in order to investigate the subjective value of information with a view to determining what characterizes information as a good.

2.2 The WTA/WTP Disparity

The consistent, unexpectedly large and uni-directional difference between WTA and WTP observed in relation to traditional goods and services has generated much research interest. Attempts were made to explore whether the discrepancy can be explained by economic theory or

whether the difference belongs to the realm of less than- or bounded- rational choice and is rooted in psychological origins. We will summarize some of the pertinent literature on the WTA/WTP disparity and the explanations offered by economists and psychologists highlighting the common denominators of these two approaches.

Commonly, bidding is employed as the general experimental approach for researching the values of WTA and WTP. Participants in experiments are offered the opportunity to bid for the purchase of an item, or to state a reserve price for the sale of an item. There are many bidding mechanisms and there is no specific experimental design common to all the experiments described below. A comprehensive methodological review detailing the types of bids used in different papers can be found in [17]. Using the various bidding mechanisms, researchers have demonstrated a significant disparity to exist between the values of WTA and WTP for common market goods such as chocolates, pens, and mugs [18, 19], and a much larger disparity with regard to nonmarket goods such as health [15, 20]. Trading induced-value tickets, or tokens of known value, have not shown a WTA/WTP disparity [18, 21, 22]. Induced value tickets or tokens are characterized by having only pure monetary value. In this case, of “induced value” items, the expected number of trades took place, the expected number of trades being half of all possible trades. Herein lies one of the important implications of the disparity, namely that the existence of a significant difference between WTA and WTP leads to a reluctance to trade and results in undertrading. This was further confirmed by trading induced-value tickets of unknown value [21, 22] as well as lottery tickets [23, 24], which resulted in a WTA/WTP disparity and undertrading. Interestingly, uncertainty was not the cause for the disparity observed in the mugs experiment [18], since the bids were made on mugs marked with clearly visible price labels.

The studies mentioned here as well as dozens of others [17] reveal a continuum ranging from induced (known) value tickets, where WTA is found to equal WTP, through market goods, where the disparity exists, and on to nonmarket goods where the disparity is largest. The WTA/WTP ratio approaches unity for induced value items, being usually about 3 for market goods, while for nonmarket goods that ratio is very large, usually about 10.

2.2.1 Theoretical Foundation of the WTA/WTP Disparity

The main psychological explanations of the WTA/WTP disparity are loss aversion [18, 19, 25] which is based on Prospect Theory [26], and the degrees of similarity and uncertainty in the cases of induced value tokens and lottery tickets [23, 24]. The main economic explanations are the substitution effect [20, 27], the tradeoff between the price of information and the expected payoff [28] and intrinsic value [29].

The Prospect Theory approach received experimental economic substantiation [30]. Similarity observed in psychological experiments [31] is equivalent to economists’ explanations of the substitution effect. Psychologists also acknowledged that lack of commensurability is necessary for the EE to manifest itself [18], again a hint for the substitution effect. The immunity of induced value tickets to the Endowment Effect also supports the substitution effect explanation as such tickets have perfect substitutes when their values are known. The degree of uncertainty or the amount of information provided have also been researched both by psychologists and by economists. The results in all cases show similar trends. Psychological theory proposed in order to explain the WTA/WTP disparity is based on observations of human behavior. This is in line with economic models, which in this area of research are inductive and based on experimental markets rather than on traditional economic assumptions. Overall it can be said that economic and psychological research are moving in the same direction, thus lending support to each other. The main underlying causes of the EE seem to be loss aversion and the substitution effect with their respective outgrowths. Variables that influence the EE are the type of good traded (induced-value, market, nonmarket) and the existence and availability of substitutes, which imply the availability of information on the market.

2.3 Implications for the Subjective Value of Information

A choice to pursue information for decision making is a result of the desire to reduce the uncertainty that characterizes certain decisions. Information in this sense is not a regular consumer good; it is more like a raw material consumed in the production of other goods down the value chain. The decisions as to what kind of information will aid in reducing the uncertainty, where to look for information, and what is the information worth are in themselves made under uncertainty. One rarely knows in advance what kind of information one will find, what will be the quality of that information, and to what extent will it actually reduce uncertainty. All this stems from the fact that information is an experience good, the value of which is revealed only after consumption and from a lack of access to meta-information. Research that would shed light on the value of information prior to consumption or what influences value formation will be of importance to information consumers, content providers, decision makers, and information system designers.

The result of the WTA/WTP disparity, or of the EE, is that it creates undertrading. Fewer trades take place than should have occurred under standard economic assumptions. As cited earlier, lack of information contributes to an increase in the WTA/WTP divergence and hence leads to undertrading. Conversely, abundance of information suggests an accelerated pace of trade. Information is an economic catalyst. Increasing its

perceived value and the demand for it should be the objective of any market-oriented organization in wishing to increase the number of trades. Since information is often a crucial component of market goods, enhancing the value of that information would enhance the overall value of the goods and diminish undertrading.

Substitution effect theory should predict a large WTA/WTP disparity for information. This is due to its inherent nature as an experience good, each item of content being unique. On the other hand, the abundance of free information on the Internet and searchers' inclination to seek free content suggest a low subjective value for information producing parity between WTA and WTP. In light of this contradiction we have chosen to begin our investigation with a fundamental question about the WTA and the WTP for information in order to form a basis for further research on factors influencing these values and other issues of importance.

Our research questions are: Where is information found on the WTA/WTP disparity continuum? Where is expertise found on this continuum? What is the effect of originality? In other words, are people sensitive to originals versus copy in their valuation of information. Our hypotheses are: H1: The WTA/WTP ratio for information (content or expertise) is greater than unity and is similar to that of private goods. H2: The WTA/WTP ratio for content is larger than the WTA/WTP ratio for expertise. H3: The WTA/WTP ratio for original information (content or expertise) is larger than for copy information. H4: There will be an interaction between the source of information (content or expertise) and its originality (original or copy).

3. Methodology

3.1 Research Instrument

A Java-based animated computer simulation of an easy-to-understand business game called "The Lemonade Stand" was used as the experimental instrument. In this simulation the player owns a lemonade stand and must operate it so as to maximize his/her profits by selling to passers-by. Information about expected weather and assumptions about its effect on demand may affect choices regarding inventory and prices. Participants are offered the chance to trade (buy or sell) this information, in addition to making decisions about inventory and prices. A detailed description of the simulation game can be found in previous manuscripts [32-34].

3.2 Procedure

The experiment was launched by a detailed in-class presentation of the simulation along with handouts that consisted of the instructions and sample screenshots. A prize was offered to the player who would achieve highest profits. Participants were told that profits could be made in two ways: 1. By trying to optimize the inventory, lemonade quality, and price per cup depending on the

weather data (if available). 2. By trading information (selling generates direct income, while buying information can generate indirect payoffs if played wisely).

A full description of the experimental session can be found elsewhere [32, 34, 35]. Market prices of the information trades were built into the simulation but were not known or revealed to the players. They were only told that market prices were to be determined randomly and that trades would be executed at market prices if the bids they offered were acceptable. This was done to ensure incentive compatibility according to the Becker-DeGroot-Marschak principle [36], known in the literature as the BDM method. In BDM, trade takes place only if bids are compatible with current market prices. BDM is therefore a useful method in eliciting private values and is a popular tool in studies of the Endowment Effect.

Participants: Two hundred and ninety four students in two groups of, respectively, one hundred and fifty and one hundred and forty four participated in the experiment as part of a class requirement. One group was presented with information as content, the other group was presented with information introduced as expertise. Participants were told, variably, about the origin of the information as being either a document or a human expert. Within each group the order of presentation of bids changed according to a Latin Square so that some participants received the buying scenario first while others received the selling scenario first. Each participant had four opportunities to bid: Buy original, sell original, buy copy, sell copy. The experimental design was, therefore 2X2X2: Buy vs. Sell; Original vs. Copy and Content vs. Expertise.

The players were seated in a computer lab with an individual computer for each player. They were not allowed to interact with each other but were allowed to ask the experimenter for clarifications. The experiment yielded one value for each type of bid for the weather information for each participant. The entire experiment lasted an hour and a half, which included the presentation, the warm-up games, and the four games with bidding.

A brief introduction to the game, a Powerpoint presentation, and a link to the game itself are available at: <http://gsb.haifa.ac.il/~draban/lemonade/>

4. Results

This section details the results received in the EE experiments. These results reflect data collected from two hundred and ninety four (294) students who provided their private value bids for buying and selling information as described in section 3.2. The data from the four groups of each of the two levels of the independent variable 'source' (content and expertise) have been combined for the analysis that follows. This analysis has been performed in order to test hypotheses H1-H4 listed in Section 2.3.

Explanation of acronyms used in the tables that follow:
WTP – Willingness to pay for original weather

information

WTA– Willingness to accept payment for original weather information

WTPC – Willingness to pay for a copy of weather information

WTAC – Willingness to pay for a copy of weather information

WTA/WTP – EE ratio for original information

WTAC/WTPC –EE ratio for copy information

H1: The WTA/WTP ratio for information (content or expertise) is greater than unity and is similar to that of private goods.

To test this hypothesis one sample t-tests were performed to compare the mean ratios of content and expertise with the values of one and three. Table 1 summarizes the findings of these tests for original and copy content and expertise.

Table 1: Results for one-sample t-tests comparing the means of the ratios for original and copy content and expertise to values of 1 and of 3.

	Mean Ratio	Std. Dev.	Test Value=1		Test Value=3	
			t	Sig.	t	Sig.
Orig. Cont.	2.79	3.45	6.37	0.00	-0.73	0.46
Orig. Expt.	2.74	3.01	6.95	0.00	-1.03	0.31
Copy Cont.	2.04	2.76	4.60	0.00	-4.27	0.00
Copy Expt.	1.85	2.27	4.53	0.00	-6.07	0.00

Table 1 clearly shows that the mean ratios for original content and expertise are significantly different than unity. The mean ratios for original content and expertise are not significantly different from three while the same ratios for copy of content or expertise are significantly different (lower) than 3. Additional analysis revealed that the ratios for copy content and expertise are not significantly different from a value of two.

H2: The WTA/WTP ratio for content is larger than the WTA/WTP ratio for expertise.

To test this hypothesis independent samples t-tests were performed to compare the mean ratios of content and expertise. Table 2 summarizes the findings of these tests for original and copy content and expertise.

Table 2: Results for independent samples t-tests comparing the means of the ratios for original and copy content and expertise.

	Mean Ratio	Std. Dev.	t	Significance
Original Content	2.79	3.45	-1.33	0.89
Original Expertise	2.74	3.01		
Copy Content	2.04	2.76	-0.62	0.54
Copy Expertise	1.85	2.27		

Table 2 shows that the mean ratios for original and copy content and expertise do not significantly differ, meaning that participants did not assign different values to different sources of information.

H3: The WTA/WTP ratio for original information (content or expertise) is larger than for copy information.

To test this hypothesis a paired samples t-test was performed to compare the mean ratios of original content and expertise and copy content and expertise. Table 3 summarizes the findings of the test of the independent variable 'originality'

Table 3: Results for a paired samples t-test comparing the means of the ratios for original and copy content and expertise.

	Mean Ratio	Std. Dev.	t	Sig.
Original Content and Expertise	2.77	3.24	3.64	0.00
Copy Content and Expertise	1.95	2.53		

Table 3 reveals that original information is valued significantly higher than copy information.

H4: There will be an interaction between the source of information (content or expertise) and its originality (original or copy).

To test this hypothesis a univariate ANOVA was performed to compare the variances of original content and expertise ratios and copy content and expertise ratios and to test for interaction effects between the independent variables, source and originality. Table 4 summarizes the findings of the test of the independent variable 'originality'

Table 4: Results for a univariate ANOVA comparing the variances of the ratios for original and copy content and expertise and the interactions between them.

Independent Variable	F	Sig.
Originality	11.74	.00
Source	.24	.63
Originality*Source	.08	.78

Table 4 shows that while different levels of originality bear a significant influence on private values, there is no significant difference attributed to the source of information. This is in agreement with findings shown in Table 2. In addition, Table 4 shows there is no interaction effect between the two independent variables, originality and source. Originality is significant regardless of the source. The value attributed to a specific source does not change with different levels of originality.

3. Discussion

Based on performance in a simulated business management task we have found, as hypothesized, that the subjective value of information does indeed follow the predictions of Endowment Effect theory. Participants revealed a ratio of Willingness to Accept to Willingness to Purchase (WTA/WTP) that resembles the ratio common in the case of private goods. It should be emphasized that this ratio should (analytically) approach unity. However, the empirically revealed preference here places this ratio elsewhere. Of the 294 subjects, we also found support for the hypothesis that the WTA/WTP diverges from unity more often and in a more pronounced manner for information traded in the “original” form rather than as a copy of the original, although even for copies the WTA/WTP ratio is still double. In other words, the realization that information is owned exclusively attenuates the Endowment Effect.

Another way to examine the same result is to state that exclusive access to information, that is enforceable by information systems (such as information security, encoding, etc.) might strengthen the endowment effect on subjective valuation of information.

The high variance of the ratios for copy information occurred in part as a result of a large number of people submitting bids which resulted in ratios smaller than one. This is an interesting observation because it means that participants realized that they could make a quick profit from selling information which they could later still use for themselves. This indicates a very good understanding of the game rules. Further statistical analysis of the initial data confirmed our findings. When comparing the ratio components, WTA for expertise with WTA for content, as well as WTP for expertise and for content no significant differences are observed although values for expertise were always higher than for content. WTAC for expertise

and content have been found to have a statistically significant difference ($t=2.68$; $p<.01$) and so have WTPC for expertise and content ($t=2.38$; $p<.02$). This confirms the previous finding relating to the higher value assigned to original than to copy information.

The trend toward higher value for expertise without statistical significance raises some thoughts. It shows the flattening effect of the computer where the typical e-business decision maker has to imagine an expert or a document based on text displayed on a screen. In addition, the large bidding scale in this experimental setup induced variance. Participants could place bids between 0 and 100 dollars for either buying or selling. The scale is even larger considering that decimals were allowed. Research in social science usually involves using a smaller scale such as seven-point Likert scales. The scale was not defined by any anchors which provide meaning to specific choices. Again, scales used in social sciences often have anchors such as “agree” and “disagree”. In our scale there was no ‘right’ or ‘correct’ answer. Our scale in effect is a one item measure, in contrast to psychological measures where several items are used to quantify specific traits or constructs.

The high variance is in accord with the high uncertainty associated with buying and selling experience goods. The value of experience goods is not known a priori and there is no indication for it. Perhaps smaller variance will be achieved if a ‘preview’ is made available for the weather forecast in our game. Examples of ‘previews’ for other information experience goods include abstracts of articles and film previews.

If we look at the same issue from a different angle, in electronic commerce bidding is always a one item measure. This characteristic can be manipulated. For example, a wide scale without anchors may induce higher bids which are in the interest of auction sites.

The value assigned to specific information by a certain person can vary according to external circumstances. This implies that subjective value is inherently unstable. Social science usually aims to identify stable or generalizable phenomena. Here instability is inherent. External circumstances include parameters such as timeliness, form, and content[9]. These parameters change per person and between people and are perceived differently especially when there is uncertainty about information.

While the first and third hypotheses were held up by our data, we found no support for the hypothesis regarding differences in valuation due to the source of information. Attributing the information to expertise or to a document had no significant impact on the WTA/WTP ratio. In other words, the subjective value of information is not variously affected in these results by the nature of the information. This result is surprising as we intuitively assumed a difference and because previous research has identified a difference [37]. The difference originally reported in the literature was attributed to ownership. Expertise was perceived to be privately owned rather than owned by the

organization. Information as product, a computer program, was perceived to be more organizationally owned. Sharing an organizationally owned information product was found to be mediated by prosocial transformation, people weighed the social good more than their personal benefits. In other words, according to this research when it comes to tacit knowledge, personal ownership supported sharing more than organizational ownership. This finding runs contrary to the general consensus in the knowledge management literature, which stresses the main difficulty as sharing tacit knowledge [6]. Thus, the findings of the present study align better with the knowledge management literature than with our specific hypothesis H2. In a later study [38] a product, a computer program, was perceived to be organizationally-owned and led to less sharing than privately-owned expertise. Both studies cited here were concerned with sharing information while the present focus is on trading information. It seems that people may behave differently when sharing information than when they are faced with the choices of buying and selling information.

To summarize, when trading information, as opposed to sharing it, people are sensitive to originality but not to the source. When access to some information is limited to a privileged few sets of eyeballs, that information is accorded or assigned a high value. When the information, content or expertise, becomes commonplace, its value decreases. Is it possible that the well-known economic concept of 'scarcity' governs our trading behavior as it does for other market goods? Is scarce information valued higher than widely-available information? This would mean that either behaviorally or cognitively people have not yet absorbed the concept of 'network economy', that information is distributed mostly by copying and its value does not necessarily decrease because of that. On the contrary, in a network economy value sometimes increases with wider distribution. The value of software is one such example – end-user software is often more valuable as more people use it and become dependent on it for communicating with other users.

Although our findings do not support the distinction between content and expertise and the ownership status implied by these forms of information cited in previous studies, we did find an ownership effect that resonates with the studies on information sharing and studies on EE in other market goods. First, an EE was observed and was statistically significant. EE is attributed to ownership status in the literature [18, 39]. Secondly, the fact that originality played a significant effect in the results shows that ownership matters. If everyone has access then value does drop, but if only one person has exclusive access/ownership value increases. Of course, ownership itself and perceptions of it can be affected and manipulated via system design.

A possible explanation for the surprising lack of significance of the source variable may perhaps be explained by the experimental manipulation. Both sources were explained to the participants textually on screen.

This uniformity of presentation provided experimental control. However, it may be argued that a computer can be used to present different forms of information differently. Perhaps our 'bare bones' controlled design created a flattening effect where any kind of information looks and feels the same. Graphics, sounds, and more elaborate texts could have contributed to stronger differentiation between both forms of information. This would be difficult to operationalize while keeping experimental control. Another way to examine perceptions of types of information is to experiment with stronger contrasts. Information in our experiment was important for estimating market demand for lemonade but perhaps it was not perceived as critical information. Experimenting with more critical information may elicit a difference between sources. For example, if a life-or-death situation is described as expertise, say a doctor's advice, it would be valued more than content, say an article taken from an encyclopedia. Another topic which is not a life-death question but could carry strong implications is investment information. Is analyst advice valued more than an information flier distributed by a bank? Another example may be related to professional decisions. Would we value an article we read in a work situation more than seeking an expert's advice? It would be interesting to see if a larger gap between EE ratios is revealed with further research, running the simulation game varying the criticality of the information. Of course the most obvious path for further research is to expand work on sharing information. What are the equivalent dimensions to WTA/WTP when sharing rather than trading is at stake?

Our research shows a value of about three for the WTA/WTP ratio for original information regardless of whether the source is content or expertise. The similarity between content and expertise may be attributed to some extent to the trading scenario and to some extent to the flattening effect of our simulation. However, some of our results indicate that source may become significant depending on the degree of criticality, or, in other words, source can be manipulated by system design to become more salient. Copy information received a subjective value which was significantly different (lower) than original information. This observation invites further research into information system users' perceptions of the information economy. Information systems can be used to enhance understanding of network economy and they can be used to manipulate prevailing perceptions. Finally, since the 'source' variable did not display statistical significance, it came as no surprise that no interaction with the 'originality' variable was observed. In summary, studying the subjective value of information by using a computerized simulation of a simple business game as an experimental setting where EE methodology was applied proved to be a very productive research line which should be further elaborated by future work. The nature of information which is transferred by sharing, not just by trading, also invites research which would use a similar platform to assess the interplay or interdependence between trading and sharing content and expertise.

ABSTRACT

Electronic commerce becomes an essential part of business processes for many business firms. Electronic commerce has a particularly important implication for small-to-medium-sized enterprises (SME's) because the form of competition and business process has dramatically changed in the recent years due to the internet and on-line business activities.

This paper investigates various issues about implementation of electronic commerce by surveying a group of Korean SME's as a sample. This study focuses on finding out the critical factors for successful implementation of electronic commerce by SME's. Our research model is more comprehensive than the ones used in the previous research by including moderating variables in the context.

1. INTRODUCTION

Electronic commerce (EC) is rapidly becoming an essential part of business processes for many business firms. It has a particularly important implications for small to medium-sized enterprises (SME's) because the form of competition and business process has dramatically changed in the recent years due to the internet and on-line business opportunities.

Previous research on e-commerce has mostly focused on finding out the determinants of adoption and diffusion of e-commerce. [1] [4] [5] [7] Now that the engaging in e-commerce (EC) becomes a norm for most business firms, it is necessary to decide what type of EC would be most effective for a certain situation.

This paper investigates various issues about implementation of electronic commerce by SME's. Our study has two distinctive aspects compared to the previous research. Firstly, we focus on small to medium-sized business firms because they are different from large enterprises [2] [3], and comprise a large portion of national economy in the developing countries. Secondly, we use a more comprehensive research model than the previous research by including moderating factors in the model (Figure 1.).

2. RESEARCH METHODOLOGY

2.1 Research Model and Hypotheses

While previous studies focused on the adoption issues [1] [4], this paper is to investigate a more comprehensive relationship among the factors that affect the adoption, implementation, and performance of the EC by small and medium enterprises as shown in the research model (Figure 1). For each part of the relationship indicated as H1, H2 and H3, twelve hypotheses are constructed and tested. Table 1 contains the explanations of the factors, and 36 hypotheses in total are tested as shown in Tables 2 to 4.

Figure 1. Research model for E-Commerce.

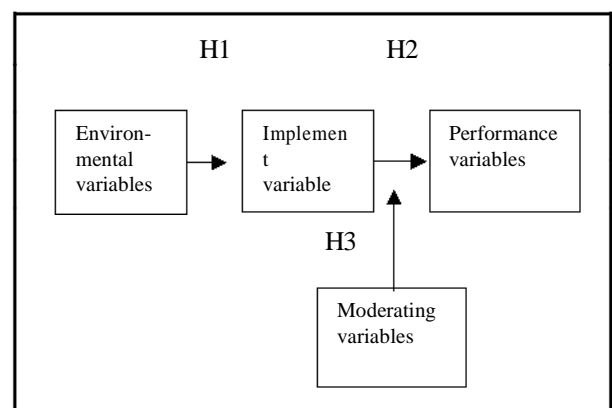

Table 1. Explanation of the variables.

Variables	Contents
Environmental variables	- Type of industry - Age of the firm - Environmental uncertainty
Implementation variables	- Type of EC (B2B, B2C, B2G) - Scope of EC - EC strategy - Characteristic of EC
Moderating variables	These are the general condition of a firm's information system (IS) measured by IS maturity.
Performance variables	These are the firm's performance measured by - Utilization of EC - Satisfaction from EC implementation - Usefulness of EC

H1: Hypotheses on firm environment and EC implementation:

The firm's decision on what type of EC to implement is

affected by the environment in which the firm operates. The external environment affects a firm's decision on EC implementation in such areas as the types, scope, strategy, and characteristics of EC. Twelve hypotheses are tested and the details are listed in Table 2.

H2: Hypotheses on EC implementation and firm performance:

The performance of a firm is affected by the type of EC which the firm implements. A firm's performance is generally improved by implementation of electronic commerce. The magnitude of improvement, however, would be different by the type of EC system implemented by a firm. The details of the hypotheses are listed in Table 3.

H3: Hypotheses on moderating effect:

The impact of the EC implementation on the firm's performance would be affected by the moderating variables that show the general condition of the firm's information system such as IS maturity. The details of the hypotheses are listed in Table 4.

Table 2. Hypotheses on firm environment and EC implementation.

Number	Hypothesis content
Hypothesis 1	Type of industry determines the type of EC that a firm implements.
Hypothesis 2	Type of industry determines the scope of EC that a firm implements.
Hypothesis 3	Type of industry determines the strategy of EC that a firm implements.
Hypothesis 4	Type of industry determines the characteristics of EC that a firm implements.
Hypothesis 5	Age of the firm affects the type of EC that a firm implements.
Hypothesis 6	Age of the firm affects the scope of EC that a firm implements.
Hypothesis 7	Age of the firm affects the strategy of EC that a firm implements.
Hypothesis 8	Age of the firm affects the characteristics of EC that a firm implements.
Hypothesis 9	Environmental uncertainty affects the type of EC that a firm implements.
Hypothesis 10	Environmental uncertainty affects the scope of EC that a firm implements.

Hypothesis 11	Environmental uncertainty affects the strategy of EC that a firm implements.
Hypothesis 12	Environmental uncertainty affects the characteristics of EC that a firm implements.

Table 3. Hypotheses on EC implementation and firm performance.

Number	Hypothesis content
Hypothesis 13	EC utilization is affected by the type of EC implemented.
Hypothesis 14	EC satisfaction is affected by the type of EC implemented.
Hypothesis 15	EC usefulness is affected by the type of EC implemented.
Hypothesis 16	EC utilization is affected by the scope of EC implemented.
Hypothesis 17	EC satisfaction is affected by the scope of EC implemented.
Hypothesis 18	EC usefulness is affected by the scope of EC implemented.
Hypothesis 19	EC utilization is affected by the strategy of EC implemented.
Hypothesis 20	EC satisfaction is affected by the strategy of EC implemented.
Hypothesis 21	EC usefulness is affected by the strategy of EC implemented.
Hypothesis 22	EC utilization is affected by the characteristics of EC implemented.
Hypothesis 23	EC satisfaction is affected by the characteristics of EC implemented.
Hypothesis 24	EC usefulness is affected by the characteristics of EC implemented.

Table 4. Hypotheses on moderating effect.

Number	Hypothesis content
Hypothesis 25	The impact of EC type on EC utilizat

	ion is affected by IS maturity.
Hypothesis 26	The impact of EC type on EC satisfaction is affected by IS maturity.
Hypothesis 27	The impact of EC type on EC usefulness is affected by IS maturity.
Hypothesis 28	The impact of EC scope on EC utilization is affected by IS maturity.
Hypothesis 29	The impact of EC scope on EC satisfaction is affected by IS maturity.
Hypothesis 30	The impact of EC scope on EC usefulness is affected by IS maturity.
Hypothesis 31	The impact of EC strategy on EC utilization is affected by IS maturity.
Hypothesis 32	The impact of EC strategy on EC satisfaction is affected by IS maturity.
Hypothesis 33	The impact of EC strategy on EC usefulness is affected by IS maturity.
Hypothesis 34	The impact of EC characteristics on EC utilization is affected by IS maturity.
Hypothesis 35	The impact of EC characteristics on EC satisfaction is affected by IS maturity.
Hypothesis 36	The impact of EC characteristics on EC usefulness is affected by IS maturity.

2.2 Data Collection and Analysis

We have circulated survey questionnaires to collect data from the SME's in Korea. A total of 74 firms returned the questionnaires, and 51 of these were used for analysis after excluding those with missing data and non-SME's. The profile of the respondents are as follows (Table 5). Statistical tests are used to analyze the data and to find out the answers for the hypotheses presented in the above.

Table 5. Profile of respondent firms.

Type of industry	Number of firms	Proportion
Manufacturing	25	49%
Sales/Distribution	6	11.8%
Service/IT/Technology	14	27.5%
Others	6	11.8%
Total	51	100%

3. ANALYSES AND RESULTS

Tables 6 through 8 show the results of the tests to find out

the relationship among the variables and to determine the acceptance of the hypotheses presented in the above.

3.1 Business Environment and EC Implementation

The hypotheses about the effect of the business environment on the firm's decision on EC implementation are tested. Three variables are selected to define the firm's business environment: type of industry, age of the firm, and environmental uncertainty. Four dimensions of the firm's decisions are analyzed: the types of EC, the scope of EC implementation, EC strategy, and EC characteristics. The types of EC for firm's selection include Business-to-Business (B2B), Business-to-Customer (B2C), and Business-to-Government (B2G).

The results in Table 6 show that among the three environmental variables only the industry type affected two aspects, EC type and EC scope, of a firm's implementation decision. The other two environmental variables are found to have no effect on the firm's decision on the various EC implementation issues such as type, scope, strategy, and characteristics of electronic commerce.

Table 6. Impact of business environment on EC implementation.

Environmental variable	Implementation variable	Test	Result (p-value)
Type of industry	EC type	X ² test (Cross tabulation)	accept (0.025)
	EC scope	ANOVA	accept (0.028)
	EC strategy	X ² test (Cross tabulation)	reject (0.119)
	EC characteristics	X ² test (Cross tabulation)	reject (0.554)
Age of the firm	EC type	X ² test (Cross tabulation)	reject (0.310)
	EC scope	ANOVA	reject (0.438)
	EC strategy	X ² test (Cross tabulation)	reject (0.410)
	EC characteristics	X ² test (Cross tabulation)	reject (0.406)
Environmental uncertainty	EC type	X ² test (Cross tabulation)	reject (0.731)
	EC scope	ANOVA	reject (0.826)
	EC strategy	X ² test (Cross tabulation)	reject (0.256)
	EC characteristics	X ² test (Cross tabulation)	reject (0.164)

* Results indicate whether the hypothesis is accepted at the significance level of $\alpha = 0.05$.

3.2 EC Implementation and EC Performance

We tested the relationship between the four EC implementation variables discussed above, EC type, EC scope, EC strategy and EC characteristics, and the EC performance experienced by the firm measured in utilization, satisfaction and usefulness. The average

performance is compared between the groups of firms implementing the same type of EC and with the same degree of scope, etc..

Among the hypotheses tested, three turned out to have significant results as shown in Table 7. EC scope is found to have significant effect on EC utilization and on EC usefulness. That is, those firms that use EC on a wide range of business activities show a higher level of EC utilization and usefulness. Also, EC strategy has significant effect on EC utilization. Firms that adopt differentiation strategy, i.e., using EC for differentiating themselves from the competitors, show a higher EC utilization than the other two groups adopting either cost-leadership or niche-market strategies.

Table 7. Impact of EC implementation on EC performance.

Implement- ation variable	Performance variable	Test	Result (p-value)
EC type	EC utilization	ANOVA	reject (0.207)
	EC satisfaction	ANOVA	reject (0.743)

3.3 Moderating Effect of IS Maturity

From the preliminary tests, we found that only information system (IS) maturity has a sizable impact among the three moderating variables, IS maturity, IS intensity and organizational capability. The IS maturity of a firm is measured by the firm's knowledge and attention for the EC system. The moderating effect of IS maturity on the relationship between EC implementation and EC performance is examined.

As shown in Table 8, IS maturity is found to have a significant impact on the some aspects of the relationship between EC implementation and EC performance. Firstly, IS maturity has affected the relationship between EC scope

and EC utilization in that the effect of EC scope on EC utilization increases as the IS maturity gets higher. Secondly, firms tend to show significant difference in satisfaction from the EC implementation depending on what EC strategy they adopt when their IS maturity level is low. However, when the IS maturity level is high, EC strategy does not cause difference in satisfaction among the firms. They tend to experience same level of satisfaction from the EC implementation regardless of the EC strategy adopted.

4. CONCLUSION

We have found several factors important for successful implementation of electronic commerce (EC). They are the type of industry for environmental factor, the scope of EC and the EC strategy that firms adopt for implementation factors. Lastly, IS maturity is found to be important as moderating factor for certain combinations of implementation and performance variables.

From the results, we could find that EC becomes more effective when firms use it for a longer period of time and for a wider range of business activities. In other words, the longer and larger the investment in EC, the better result a firm can expect. Electronic commerce are said to help small-and-medium enterprises (SME's) compete against large firms on a more level ground by moving the competition from the physical market place to cyber market space and thus reducing the marketing and distribution cost. It seems, however, that firms need a substantial and sustained investment in EC to enjoy the benefits from its use. SME's need to understand that EC is not a cheap solution to increase its competitive power as it seems.

Abstract

While the necessity for taking a strategic approach at the Internet and electronic commerce has often been stressed, there is a lack of broad empirical evidence for the resulting benefits. Existing work is either conceptual or, if empirical, rather specific, e.g. based on case studies.

We contribute to closing this research gap, providing empirical evidence from a numerical base of 443 general cases. Based on existing theory, we investigate the business value of having a dedicated Internet strategy and of pursuing each of the three competitive strategies according to Porter's typization, namely cost leadership, differentiation, and customer focus. With a simple path model, we test the impact of these four factors on corporate success in electronic business for different subsets of the numerical base.

We find that in general and for B2C companies, a dedicated Internet strategy as well as the pursuit of the cost leadership or customer focus strategy are success factors, whereas for B2B companies, only a dedicated Internet strategy and the pursuit of the cost leadership strategy prove to be effective. The general findings are independent of company size and of companies' experience on the Web. If the companies are divided into three groups according to the fraction of revenues they generate from online sales, only one distinct success factor remains for every group.

1. Introduction

Particularly since the burst of the dot-com bubble and the failure of many Internet ventures, which had been launched by start-ups as well as by traditional companies, the importance of taking a sound strategic approach on the Internet and in electronic commerce has often been stressed, yet the realization in practice seems to be far behind. As Porter complains in his 2001 article [17], "many of the pioneers of the Internet business [...] have competed in ways that violate nearly every precept of good strategy", leading to the consequence that "price has been defined as the primary if not the sole competitive variable". This may in part be due to a lack of insight from existing research in the area, which covers issues including:

- how the Internet impacts and transforms industries and markets, i.e. the environment in which companies operate and position themselves with their strategies, e.g. [6] [17],
- the process of designing and implementing a strategy for the Internet, e.g. [11] [19] [18], or [20], and
- how the Internet as an extra communications, sales, and distribution channel can be used and integrated with existing channels, [5] [10] [14] or [4], especially with respect to the pricing of goods and services offered online, [9] [2], or [8].

Yet, most of the existing contributions focus on a particular industry (e.g. the financial industry), business model (such as retailing, [6]), or customer segment (such as B2C, [18]). Plus, many of them are conceptual analyses. However, there has been only little work showing empirical evidence how, and if at all, the strategic use of the Internet and the pursuit of competitive strategies in electronic commerce contribute to the overall success which companies achieve with their Internet activities, e.g. [3] [13], whereas a rich body of literature studies the effect of corporate strategy on business performance in conventional companies, e.g. [12]. Due to this lack of general empirical evidence, the business benefit or business value from implementing a dedicated Internet strategy remains unclear, especially to corporate decision makers. For the same reason, executives are still unsure about what they can expect from the different options of competitive strategy in electronic commerce. We therefore posit the following research questions:

1. Is a dedicated Internet strategy a driver for success in electronic business?
2. Which competitive strategy is a success factor in electronic business? Is there any competitive strategy that works best or that doesn't work and why?
3. How (and why) does the role of the above factors vary depending on:
 - a. control variables, such as company size and online experience,
 - b. the main customer segment (i.e. if it is a B2B or a B2C-company), or

- c. the fraction of revenues generated online (i.e. degree of “digitization”)?

In order to investigate these research questions, we develop a research model which is then tested against empirical data collected in a large-scale survey with 443 cases in the German-speaking market, which is one of the key international E-Business markets.

The remainder of this article is structured as follows: The research model is developed in the next section, where we first give a concise definition of a dedicated Internet strategy and formalize different strategic options in electronic commerce. Then, we develop the model structure and explain our research approach. In the third section, the survey, the statistical analysis, and its results are presented. In the fourth section, we interpret and discuss the major findings, contributions and shortcomings of our research. Finally, we discuss the implications of our work for further research and for practice.

2. Research Model

2.1 Theoretical Background

In a general, we define the term “strategy” as “the manner in which a firm decides to compete, which encompasses the pursuit, achievement, and maintenance of competitive advantage” [12], “the creation of a unique and valuable position, involving a different set of activities”, “making trade-offs in competing”, and “creating fit among a company’s activities” [16]. A strategy should be a fundamental, long-term, and sustainable guideline for a company. Accordingly, we term a strategy that specifically targets Internet issues, i.e. the use of the Internet to support, transform, conduct, or extend a firm’s business activities, a dedicated Internet strategy. Further, we employ Porter’s 1980 typization [15] to review different options of competitive strategy, which we apply to electronic commerce:

1. Cost leadership, being the competitor with the lowest costs and cheapest prices.
2. Differentiation, realizing price premiums by distinguishing one’s product and service offering from competitors’ offerings with unique features.
3. Customer focus, concentrating on specific market segments and pursuing either the “cost leadership” or “differentiation” strategy within these segments.

There has been much dispute about which of these strategic options prove viable in electronic commerce. E.g., Sinha argues that the Internet greatly threatens the “differentiation” strategy, because it lowers buyers’ search costs and eventually leads to cost transparency [21], leading to competition mainly driven by costs. Clemons et al., on the other hand, propose that due to the abundance of available information, as “transparency goes both ways” companies have a larger knowledge about their customers than ever before. Therefore, through highly differentiated product and service offerings, they can charge prices nearly independent of actual costs, but largely depending on customers’ valuation [7]. Finally, Baker et al. contend that based on this level of customer knowledge, companies can segment their markets with high-resolution and precision (ideally target customers individually) and, through segment-specific pricing, particularly profit from skimming the high customer valuations [2].

2.2 Derivation of Hypotheses and Model Development

Based on the above discussion, we translate our research questions in order to formulate our model hypotheses. As the dependent construct for our analysis, we employ the construct of corporate success in electronic business, thus simplifying the consequential chain of causes and effects (implementation of a strategy determines the way a company acts on the market, which translates into reactions from the market, and, ultimately, contributes to the success or failure of a company) to the top-level outcome. We thereby assume an integrated perspective and choose the corporate level as the level of analysis as well as the whole company as the object under study. We obtain:

- H1: Having a dedicated Internet strategy increases companies’ success in electronic business.
- H2: Pursuing the ‘cost leadership’ strategy in electronic commerce increases companies’ success in electronic business.
- H3: Pursuing the ‘differentiation’ strategy in electronic commerce increases companies’ success in electronic business.
- H4: Pursuing the ‘customer focus’ strategy in electronic commerce increases companies’ success in electronic business.

Further, we neglect the impact which other factors not linked to strategy have on corporate success in electronic business. Our research model is displayed in Figure 1:

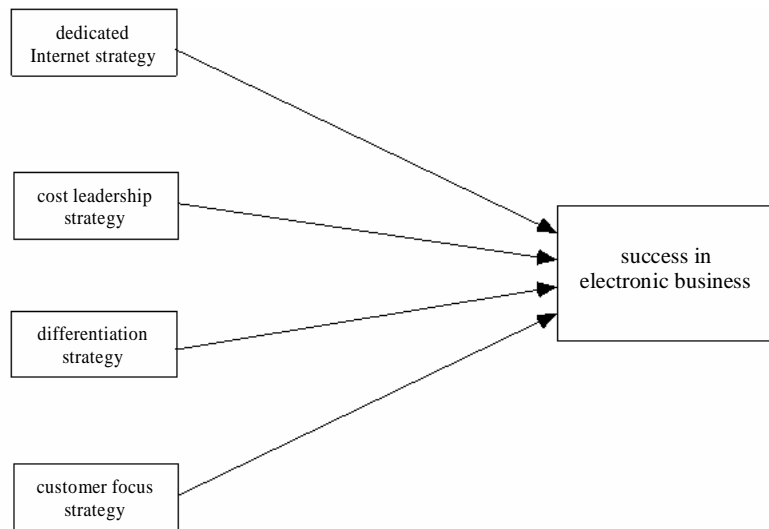

Figure 1: Research model

3. Method

3.1 The Survey

The numerical data used in the statistical analysis of this model has been collected in a large survey that was conducted from May to June 2000. The questionnaire and a comprehensive descriptive analysis of the results have been published as the “e-reality 2000” study in September 2000 [22]. Among other issues, such as readiness for electronic business or adoption of the Internet and electronic business concepts, the purpose of this survey was to measure companies’ strategic approach towards the Internet and electronic business on a corporate-level, and, especially, the success or failure so far achieved in electronic business.

To gather data, market research professionals conducted personal interviews with upper- to top-level executives in 1308 companies in the German-speaking area (Germany, Austria, and Switzerland), who were in charge of their companies’ electronic business activities. The sample of companies for conducting the interviews was drawn from a data base of companies, such as to render the survey representative with respect to geographic region, company size in terms of employees, and industry. In case that an interview could not be conducted as planned, a replacement was determined from the same superset in order to maintain the representativity of the sample.

3.2 Aggregation and Preprocessing of the Survey Data

Prior to the statistical analysis, the gathered raw data is reduced and condensed to an essential subset as follows: At first, we concentrate on companies who had a Web page online at the time of the survey, reducing the original data set of 1308 cases to 730 cases (or 55.8%). (Another 171 companies, or 13.0%, were still planning to

launch their site within the next 12 months.) In a second step, we focus on companies who specified that they had yet gained sufficient online experience such as to provide information on the success of their company’s electronic business activities, diminishing the number of cases to 469. Then, in a third step, we eliminated those cases exhibiting excessive missing values in the 13 question items (i.e. more than 6 items, corresponding to more than 50% of the items left unanswered) covering the success of their company’s electronic business activities, leaving a total of 443 valid cases for the numerical analysis.

3.3 Descriptive Analysis

Same as in the original survey, the remaining 443 cases constitute a heterogeneous selection of companies from all industry backgrounds, company sizes, and business models, even if the original claim to be a representative selection for the German-speaking market must be relaxed. The size of 136 companies (corresponding to a fraction of 30.8%) ranges between 1 and 19 employees, that of another 190 companies (42.8%) between 20 and 49 employees, and 95 companies (21.5%) have 50 or more employees.¹ Concerning companies’ experience on the Web, 211 (47.7%) have had a Web presence for up to 2 years, while 229 (51.8%) have owned one for 2 years or more.

A group of 210 companies (or 47.3%) specify consumers as their main customer segment, 205 companies (or 46.3%) state that they mainly serve businesses. Another 15 (or 3.4%) mainly serve administrations, thus consider themselves as B2A-companies. A number of 61 of the businesses (or 13.9%) generate none of their revenue from electronic commerce and can thus be considered traditional “bricks-and-mortar” businesses. Another 106 businesses (23.9%)

¹ In this section, the numbers (fractions) of cases short of the total of 443 (100%) are due to missing values in the question items covering company structure.

generate between 1 and 9% of their revenues from electronic commerce. This group of businesses can be viewed as being in the process of digitizing its processes and, therefore as “clicks-and-mortar” businesses. Further, 73 businesses (16.5%) generate 10 or more percent of their revenues from electronic commerce, suggesting that their electronic commerce activities have reached a stage of maturity, which is why they can be regarded as “true E-Businesses” [1]. Only 8 companies (or 1.7%) generate 50 or more percent of their revenues from electronic commerce.

3.4 Operationalization and Encoding of Variables

In the survey, single indicator variables are used for recording to what extent companies employ a dedicated Internet strategy or each of the three options for the competitive strategy in electronic commerce. The indicator variables constitute metric variables implemented on an equidistant interval (or Likert-like-) scale, ranging from “1” (worded “does not apply at all”, representing strong dissent) to “5” (worded “fully applies”, representing strong agreement). The wording of the indicator variables is as follows:

1. “Does the statement ‘we have defined a strategy which specifically targets Internet issues’ apply to your company?”
2. “Please specify to what extent you pursue each of the competitive strategies listed in electronic commerce, again employing the scale [between 1 and 5].”
 - a. “Cost leadership (cheapest prices within an industry or a segment).”
 - b. “Differentiation (separation from competition through uniqueness with respect to quality, innovative offerings, processing time, etc.).”
 - c. “Customer Focus (competitive advantage through individualization of customer relationships, concentration on smallest customer segments, mass customizing).”

3.5 Measuring Corporate Success in Electronic Business

We limit our view on the concept of corporate success in electronic business to the shareholders’ perspective. The concept is conceptualized such as to accommodate for the major theories on competitive advantage, value creation and firm performance [1]. It is operationalized as a score value obtained from an unweighted addition of the values of 13 indicator variables. Same as for the four items above, each of the 13 indicator variables is implemented as a metric variable on an equidistant

interval (or Likert-like-) scale, ranging from “1” to “5”. They are preceded by the question: “To what extent have the goals from this list actually been accomplished due to your Internet activities?”, and their wording is as follows:

1. “improved corporate image”
2. “increased market share”
3. “increased customer retention”
4. “reduced marketing costs”
5. “reduced sales costs”
6. “purchased more cheaply”
7. “developed new markets”
8. “increased revenues”
9. “offered new services”
10. “increased customer satisfaction”
11. “increased customer loyalty”
12. “increased overall corporate earnings”
13. “increased corporate value”

3.6 Statistical Analysis and Hypothesis Testing with Path Modeling

For testing the hypotheses in our research model, we employ the path analysis method. This method allows us to model correlations between independent constructs (in contrast to the multivariate regression method, e.g.), while we can employ constructs that are measured “directly”, i.e. via a single indicator variable (as opposed to covariance structure models, e.g., for which complex constructs should be employed).

The structure of the research model immediately translates into the path model for the numerical analyses. The correlations between the independent model variables are included in the path model, rendering it a saturated model (i.e. with zero degrees of freedom). Thus, model coefficients need not be estimated and can be calculated directly and without error from the correlation matrix, which is calculated from the numerical base employing the method of pair wise deletion of missing values. As perfect fit is achieved, fit measures such as GFI, AGFI, NFI, or the RMR assume extreme values.

In a first step, we perform an overall analysis employing the data from all 443 companies. In a second step, we perform a series of estimations each in order to control for company size and experience on the Web, employing the grouping of cases as introduced above. In a subsequent step, we perform two more series of estimations, separating companies according to their main customer segment (B2B or B2C) and according to the fraction of revenues they generate from electronic commerce. Based on the sample correlations, variances, and number of cases for each variable from the data set, the model coefficients are estimated using the unweighted least squares (ULS-) method. Significance values have been obtained from repeated bootstrap analyses (200 samples).

Table 1: Model parameters for the general case and depending upon different company sizes as well as experience on the web

	description of path or variable	general case	company size			experience on the web

Note: Path coefficients between constructs and selected fractions of explained variance (bold figures in the middle of each cell) and 95% confidence intervals (figure on top and bottom of each cell). Significance levels for the path coefficients are indicated as follows: ***= significant at the 1% level, **= significant at the 5% level, and *= significant at the 10% level.

3.7 Numerical Results and Findings

The resulting model parameters for the three steps of our numerical analysis are displayed in Tables 1 and 2. The findings from the numerical results can be summarized as follows:

In general, having a dedicated Internet strategy is a driver for success in electronic business. Similarly, the competitive strategies “cost leadership” and “customer focus” are also success factors. However, no empirical evidence can be found that pursuing the competitive strategy “differentiation” in electronic commerce has a positive impact on corporate success. Instead, the results for the specific group of “true e-businesses” suggests the opposite, i.e. that pursuing this strategic option may rather have a detrimental effect.

With just very few exceptions, these findings for the general case do not vary with company size or experience on the Web. The findings for different main customer segments and with varying fraction of revenues generated from online sales, however, vary considerably:

On the one hand, the path coefficients between each a dedicated Internet strategy and the competitive strategy “cost leadership” and corporate success in electronic business are almost the same for B2B and B2C companies. On the other hand, the “customer focus” strategy seems to be totally ineffective for B2B companies, while it appears to be a strong additional success factor for B2C companies.

Further, depending on the developmental stage of the company (i.e. “digitization” of the business in terms of the fraction of revenues generated online), the effectiveness of a dedicated Internet strategy and the three options of competitive strategy as success factors varies greatly:

- a. A dedicated Internet strategy is the only one success factor for pure “bricks-and-mortar” enterprises.
- b. Conversely, for “clicks-and-mortar” enterprises, pursuing the competitive strategy “cost leadership” is the key success factor.
- c. Finally, “true e-businesses” succeed only through applying the competitive strategy “customer focus”. For them, the strategic option “differentiation” clearly is a success inhibitor.

Finally, the influential factors in our path model account for 24.7% of the variance of the dependent construct of corporate success in electronic business in the general case (although this fraction varies for specific groups of companies).

4. Discussion

4.1 Interpretation of Selected Findings

The difference in the findings for B2B and B2C companies with respect to the effectiveness of the “customer focus” strategy can be attributed to the different nature of these customer segments. A typical

customer in the B2B segment (a B2B customer) is a professional buyer, often within an organization, for which (s)he purchases according to a set of rules, in which finding a good or service with a favorable cost-performance ratio usually has a high priority. His or her emotional involvement with the purchased good or service as well as with the process of purchasing is generally low. Thus, the buying process is conducted very rationally. Plus, for purchasing a certain group of good or services, there are usually several buyers in the same organization who, depending upon their location and position within that organization’s hierarchy, may constitute a rather heterogeneous group. Yet, B2B suppliers are normally expected to make the same product and service offerings (especially with respect to the pricing) to everybody inside the customer businesses or organizations. For all of these reasons, focusing on an individual buyer or small customer segment in B2B, personalizing product, services, and prices, and generating economic benefit from that may be very difficult, if not impossible.

On the other hand, a B2C customer usually is a private individual shopping in his or her personal interest. Overall, the typical shopping process and purchase decisions in B2C are conducted less rationally than in B2B and subject to a diverse and complex set of determinants: Generally, B2C customers’ emotional involvement with the purchased good or service and with the process of purchasing is much higher. E.g., they may shop for enjoyment and entertainment, make spontaneous purchases while surfing the Web or buy something because of its brand. Thus, B2C customers are a lot more susceptible for individualized product and service offerings.

Very interestingly, companies’ choice of the “customer focus” strategy in electronic commerce is just about the same for B2B and B2C companies: It is pursued by 84 (40.8%) of the B2B companies and 83 (39.5%) of the B2C companies. Also, the fact that this strategy is a success factor with medium effectiveness for all companies reflects that its strong effectiveness for the group of B2C companies has been “diluted” (or mitigated) by its lacking effectiveness for the group of B2B companies.

Another issue deserving further discussion is the lack of evidence for the effectiveness of the “differentiation” strategy in electronic commerce. This effect cannot be attributed to the reason that a comparatively large fraction of companies employ the “differentiation” strategy, since firstly, the surveyed companies come from diverse industry backgrounds and, thus, do not compete in the same market or market segment, and secondly, even if all surveyed companies were competitors, every single company could attain a unique competitive position through its specific “differentiation” approach. (The latter would not be possible if some or all companies pursued the “cost leadership” strategy in the same market, because, strictly speaking, there can only be one “cost leader” in every market or market segment.)

Table 3: Fractions of companies employing a dedicated Internet strategy or a certain competitive strategy as well as fractions of B2B and B2C companies (all in %). These fractions comprise those cases where the interviewee responded with a “4” or a “5” to the respective question item.

fraction of revenues generated through online sales	dedicated Internet strategy	cost leadership	differentiation	customer focus	B2B	B2C
0%	14.7	1.6	41.0	4.9	61.0	31.1
1-9%	22.6	12.0	47.5	37.5	47.9	48.6
≥10%	39.6	14.6	76.9	49.3	41.1	53.6
0-100%	32.0	12.2	58.9	39.8	46.3	47.3

Maybe the missing effectiveness of the “differentiation” strategy can be attributed to people’s buying behavior on the Internet at the time of the survey. Maybe most customers really focus on low prices, as Porter complains, and are therefore not willing to pay price premiums on the Internet. This speculation is backed by the fact that the “differentiation” strategy proves to be a factor ensuring failure especially for the group of “true e-businesses” (i.e. the group which most depends on online sales). Interestingly, an astounding figure of 76.9% of them pursues this strategic option, as shown in Table 3:

The change in relevance of a dedicated Internet strategy and the three options of competitive strategy depending on the degree of “digitization” of the business can also be explained with the information provided in Table 3. It shows that the use of a dedicated Internet strategy and of the other competitive strategies becomes more widespread with increasing level of “digitization”. Further, with the exception of the “differentiation” strategy, “bricks-and-mortar” businesses hardly employ any dedicated Internet strategy or competitive strategies in electronic commerce. This is not surprising, since, by definition, they do not generate any (noteworthy) revenues from online sales. Among the large majority of companies who do not employ a dedicated Internet strategy, those few companies who do are at a distinct competitive advantage.

Moreover, the figures for the group of “true e-businesses” suggest that a considerable fraction of them is pursuing more than one strategic option from Porter’s typology at the same time, e.g. a hybrid strategy. As companies become mature players on the Internet (and as their market environment also matures), they may increasingly need to implement hybrid strategies in order to maintain or improve their competitive standing.

Also, as the last two columns of Table 3 show, the effectiveness of the “customer focus” strategy for the group of “true e-businesses” cannot be attributed to the fact that they are mostly B2C companies. (Neither can the effectiveness of the “customer focus” strategy for B2C

companies be justified with the fact that a high fraction of them are “true e-businesses”, since only 18.7% of the B2C companies are “true e-businesses”, which is very close to the 16.5% in the general case). We conclude that – as far as we have been able to control in our analysis – the effectiveness of the “customer focus” strategy for the “true e-businesses” should be seen as a separate characteristic for this stage of “digitization”. Analogously, we propose that the effectiveness of the “cost leadership” strategy is a characteristic for the group of “clicks-and-mortar” businesses.

4.2 Limitations and Weaknesses of the Research

The core shortcoming of our research is that we chose single indicator variables (items), and not complex constructs, as the empirical instruments for recording the presence of a dedicated Internet strategy or the pursuit of any of the three competitive strategies in electronic commerce. Although the advantages of our approach are that the respective part of the survey is easy and quick to administer and that statistical modeling is straightforward and requires only a small number of cases, we might have made some measurements with higher resolution, reliability, and validity by operationalizing the concepts as complex constructs with several indicator variables.

The relatively high fractions of explained variance in the dependent variable for “corporate success in electronic business” in our model must also be reviewed critically. It is important to note that it is not *exclusively* accounted for by the exogenous variables in our model, but that (parts of) the same variance can also be explained by other influential factors, for which we did not control (cf. above).

5. Conclusion

5.1 Suggestions for further Research

Weighing the contributions of our study against its limitations and shortcomings, it is clear that our contribution must be viewed as a first-level analysis, as a

“snapshot”. It leaves a number of issues open for future empirical research. Some suggestions are:

The survey should be repeated in a similar manner in order to assess how the identified interrelations change with time – especially as electronic commerce slowly matures – and vary in different markets. Further, as a next step, the effectiveness of the strategies could be investigated with higher resolution to show differences between industries or industry segments.

Also, future research should also investigate how companies’ choice of strategic options might be interrelated, i.e. if companies pursue several strategic options of Porter’s typology at the same time and, if yes, which combinations these are. This leads immediately to the effectiveness of hybrid strategies (e.g. mass customization), an issue which should be investigated in future.

Moreover, in future surveys, the strategic concepts should possibly all be implemented as multi-item measures. Then, more advanced numerical techniques, such as covariance structure modeling, could be employed. Finally, the strategic options examined in this paper should be researched in combination with other instruments designed to support the strategic orientation of a company (e.g. integrated E-Business concepts such as ECCRM or one-to-one-marketing).

5.2 Managerial Implications

In general, a dedicated Internet strategy should be designed and implemented. Although the resulting competitive advantage may dwindle in the future as more and more companies adopt a dedicated Internet strategy, it seems feasible that it becomes a “must have”, meaning that not having a dedicated Internet strategy will put a company at a competitive disadvantage.

Further, managers must keep in mind that the following recommendations reflect the characteristics of the German-speaking area in spring 2000 and that they are based on findings for an average company. Therefore, decision makers should also strongly consider the market environment and the specific case of their own company in order to assess the applicability of the following recommendations.

In general, it seems advisable to pursue either of the competitive strategies of “cost leadership” or “customer focus” in electronic commerce. Companies concentrating on the B2C segment should also consider the “customer focus” strategy. With respect to the “cost leadership” strategy, decision makers should remember that there can be only one “cost leader” in every market or market segment. If this certain strategic option becomes too popular, competition in the respective market (segment) increases, and the strategic option may no longer be a success factor, but – in extreme cases – rather a performance inhibitor.

Managers should be very skeptical towards the “differentiation” strategy in electronic commerce. Our results indicate that the buyers in most markets or market segments may not be willing to pay price premiums on

the Internet to a sufficient extent such as to make the “differentiation” strategy a viable option. Instead, managers should fear that price still is “the primary if not the sole competitive variable”, as Porter formulated.

During the transition from being a traditional “bricks-and-mortar” company, via becoming a “clicks-and-mortar” company and, finally, a “true e-business”, decision makers should shift their strategic focus. They should begin with the implementation of a dedicated Internet strategy, then consider the “cost leadership” strategy, and finally the “customer focus” strategy. Finally, especially if their company has already matured to the stage of being a “true e-business”, managers might also want to consider hybrid strategies in electronic commerce, i.e. the combination of some of the three options of competitive strategy discussed above.

Abstract

E-procurement encompasses a spectrum of buying applications, from simple Web-shopping on suppliers' online interfaces or storefronts, participating in or organizing auctions to participating in or even actively operating buyside marketplaces, which can all be summarized as the "use of the Internet for purchasing and procurement". The benefits from e-procurement, especially the potential savings, are often emphasized, and companies spend large sums on implementations.

However, there is a lack of research providing broad empirical evidence on the effectiveness or business value of e-procurement at the corporate level. Based on a comprehensive theory background, we develop a research model for the adoption of e-procurement and its effect on corporate success in electronic business. Employing covariance structure analysis, we test our model against empirical data comprising 425 cases collected in a large-scale survey in the German-speaking market.

We find that the perceived benefits are a driver for adoption, whereas the perceived effort is an inhibitor. Contrary to expectations, the perceived effort has a positive impact on the perceived benefits. While our results suggest that adoption rises with companies' experience on the Web, no support can be found that adoption increases with company size. We also find that the adoption of e-procurement has a positive, but small impact on corporate success in electronic business.

1. Introduction

E-procurement encompasses a spectrum of buying applications, from simple Web-shopping on suppliers' online interfaces or storefronts, participating in or organizing auctions to participating in or even actively operating buyside marketplaces [24], [5]. For this paper we will employ a generic and comprehensive definition viewing e-procurement as the "use of the Internet for purchasing and procurement".

Due to the breadth of different applications it encompasses, e-procurement is – at least in parts – affordable for many more companies than its precursor EDI used to be. Yet, although a substantial amount of

research has been dedicated to EDI, only few works investigate the adoption of e-procurement and its organizational impact. The main shortcomings of existing research can be summarized as follows:

- Many studies on the business value of e-procurement are either conceptual analyses or based on case studies, e.g. [26]. There is still a lack of broad empirical evidence.
- Often, savings or process-oriented measures are used to analyze the organizational impact of e-procurement, such as in [11]. Top-level constructs, such as corporate success in electronic business, are seldomly employed.
- Also, due to the different characteristics of EDI and as research on EDI adoption often includes suppliers (e.g. [16]), the results are not readily transferable to e-procurement.

In order to address this research gap, we develop a research model which is then tested against empirical data collected in a large-scale survey comprising 425 cases from the German-speaking market, which is one of the key international E-Business markets.

The remainder of this article is structured as follows: The research model is developed in the next section, where we present an overview of prior research relevant for our work. Then, we derive the research hypotheses, develop the model structure, and explain our research approach. In the third section, the survey, the statistical analysis, and its results are presented. In the fourth section, we interpret and discuss the major findings, contributions and shortcomings of our research. Finally, we discuss the implications of our work for further research and for practice.

2. Research Model

2.1 Theoretical Background and Literature Review

The adoption or implementation of e-procurement can be considered as a specific case of information system/ information technology (IS/ IT) adoption or implementation. Analogously, its impact on corporate success in electronic business is linked to the issue of IS/ IT success and business value. As there is a rich body of literature available on these subjects, we will, in the following overview, discuss a selection of previous works from traits of research in the IS/ IT discipline relevant for building our research model and deriving our research hypotheses:

IS/ IT adoption

In their recent meta-analysis [18], Mahmood et al. aggregate the factors affecting the adoption or use of IT investigated in previous studies to a single model. They propose that the use of IT is determined by the following four dimensions of factors: the perceived benefits which an end user expects from using a particular IS, the individual characteristics of an end user, the IT maturity of the organization in which a particular IS is employed, and the characteristics of that organization (such as size and the degree of support for IS usage). They find that the perceived benefits which an end user expects is the key determinant for the usage of a particular IS. This dimension of factor has been introduced by Davis (cf. [9], [10]) as a part of the Technology Acceptance Model (TAM), proposing that the perceived ease of use of an IS influences the perceived usefulness and, in turn, that both of these factors determine an end user's usage decision. Davis' study has since been the subject of a multitude of replication studies for many different IS. Particularly companies' adoption behavior in dependence upon their size has been the subject of many studies suggesting that due to a different endowment with resources and a more long-term strategic orientation, large companies exhibit different adoption behavior from SMEs (e.g. [22], also see below).

The link between adoption of IS/ IT and corporate success

DeLone and McLean (cf. [12]) develop a taxonomy of different stages of IS success, covering system quality, information quality, use, user satisfaction, individual impact, and organizational impact. They derive this broad spectrum ranging from system- to top-level constructs from a "series of influence events" occurring "at the receiving end of an information system", thus establishing the conceptual link between these stages of IS success. For every stage, they review a number of previous studies employing IS success measures from the respective stage. They conclude that "not enough MIS field study research attempts to measure the influence of the MIS effort on organizational performance". Recently (cf. [13]), DeLone and McLean have reviewed past works based on their model and made some extensions to it, e.g.

service quality or the application to electronic commerce. They introduce net benefits as the new top-level construct to substitute individual and organizational impact, again strengthening the importance of this stage of measures.

The business value of IT

The issue of the business value of IT addresses the last stage of IS success in the DeLone and McLean model. Many studies have been undertaken to find empirical evidence for the business value of IT, yet their results have been inconsistent. The results of several works even suggest that IT might have a negative impact on business performance, leading to the so-called productivity paradox [3]. In an attempt to resolve this paradox, Hitt and Brynjolfsson separate the organizational impact of IT into three dimensions: productivity, consumer value, and business productivity [4]. While they find evidence that IT spendings increase productivity and consumer value, their results do not support the hypothesis that IT spendings drive business productivity. For a more recent and comprehensive discussion of related literature see the discussion e.g. in [7].

EDI – the precursor of e-procurement

Before the advent of the Internet as a universal open standard, companies could conduct electronic business transactions with other companies only if they participated in Electronic Data Interchange (EDI) mostly operated on specialized or proprietary systems and networks [15]. EDI can thus be regarded as an early stage of e-procurement and has already been widely investigated.

Based on a review of prior studies, Chwelos et al. develop and test a three-factor model to explain companies' intent to adopt EDI [8]. They find that all three factors, namely external pressure, readiness, and the perceived benefits (in that order), have a significant impact. However, their research is subject to some limitations severely impacting the generalizability of their results, including the facts that they do not measure actual adoption itself and that the subjects of their study are Canadian SMEs who have not yet implemented EDI.

Due to the high costs, EDI has first been implemented by large companies and been unaffordable for many SMEs. It is mainly due the diffusion of the Internet that EDI/ e-procurement has become available also for SMEs. Likewise, research has first concentrated on EDI/ e-procurement adoption in large companies and only recently shifted its attention to SMEs. Findings confirm that SMEs exhibit an adoption behavior different from large companies and are generally more reluctant [16], [6]. Similarly, research on the business value of EDI has also been conducted separately for large companies [20], [17] and SMEs [23], suggesting that the drivers for EDI success differ for large companies and SMEs.

Unique characteristics of E-Procurement

The main difference between e-procurement and EDI is that the former comprises a broader spectrum of buying applications with varying degree of complexity and

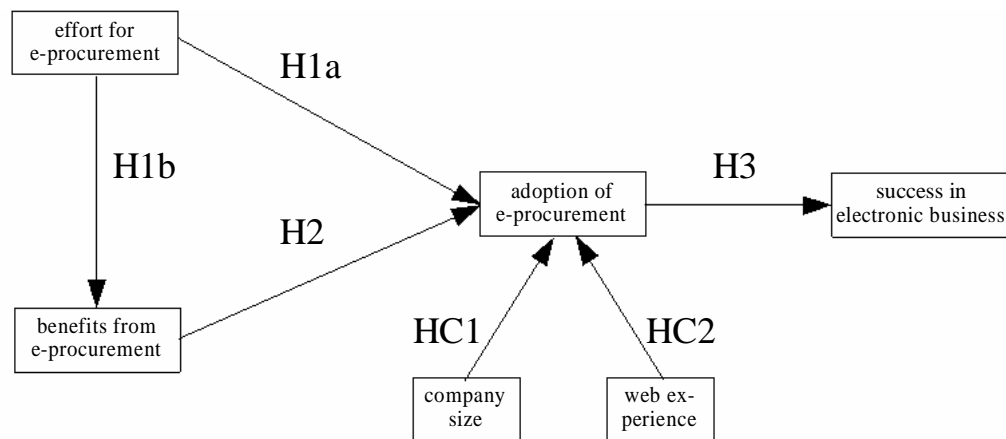

Figure 1. Research Model.

integration and (mostly) based on Internet technology [11]. Therefore, as adoption costs can be substantially lower, Web-based e-procurement can be implemented by SMEs who can rarely afford to participate in traditional EDI. Thereby, Web-based e-procurement can supplement traditional EDI. By operating traditional EDI with their bigger suppliers and Web-based e-procurement with their SME suppliers in parallel, large buying organizations, e.g., can conduct their purchasing 100% electronically [19].

2.2 Model Development and Derivation of Hypotheses

In order to pursue the research questions, we assume companies' perspective towards the adoption and success of e-procurement, choosing the corporate level as the level of analysis and the whole company as the object under study. We combine the insights gained from previous research on IS/ IT adoption and success to construct our two-stage research model:

In the first stage, we investigate the factors leading to the adoption of e-procurement. As we assume the *corporate* perspective, we drop the factors characterizing the *individual* user from the model proposed by Mahmood et al. For the same reason, we also omit intermediate stages from the TAM such as the attitude towards adoption or the intention to adopt. Further, in a simplified approach, we leave external factors related to competition, market pressure, or supply-chain relationships out of the model. We transfer the dimension of perceived benefits to the corporate level, yielding the two central factors perceived benefits of e-procurement and the perceived effort (which is a mere inversion of the ease of use construct). Thus, these factors measure the perceptions of decision makers or high-level representatives who judge e-procurement from the perspective of their company. According to Davis, we then postulate:

H1a: The higher the perceived effort, the less likely are companies to adopt e-procurement.

H1b: The higher the perceived effort, the less are the perceived benefits from e-procurement.

H2: The higher the perceived benefits, the more likely are companies to adopt e-procurement.

In order to account for companies' organizational characteristics and their IT maturity, as suggested by Mahmood et al., we further introduce two control variables to our model:

HC1: With increasing company size, companies are more likely to adopt e-procurement.

HC2: With increasing experience on the Web, companies are more likely to adopt e-procurement.

In the second stage of our research model, we simplify the causal chain between system characteristics and organizational impact in the DeLone and McLean taxonomy and directly test the impact of e-procurement on corporate success in electronic business:

H3: The adoption of e-procurement increases companies' success in electronic business.

The resulting research model is displayed in Figure 1.

3. Method

3.1 The Survey

The numerical data used in the statistical analysis of this model has been collected in a large survey that was conducted from May to June 2000. The questionnaire and a comprehensive descriptive analysis of the results have been published as the "e-reality 2000" study in September 2000 [25]. Among other issues, such as companies' readiness for electronic business or organizational and strategic measures, the purpose of this

survey was to measure companies' adoption of the Internet and electronic business concepts on a corporate-level, especially their adoption of electronic procurement. In particular, the survey recorded the success or failure companies had achieved in electronic business so far.

To gather data, market research professionals conducted personal interviews with upper- to top-level executives in 1308 companies in the German-speaking area (Germany, Austria, and Switzerland), who were in charge of their companies' electronic business activities. The sample of companies for conducting the interviews was drawn from a data base of companies, such as to render the survey representative with respect to geographic region, company size in terms of employees, and industry. In case that an interview could not be conducted as planned, a replacement was determined from the same superset in order to maintain the representativity of the sample.

3.2 Aggregation and Preprocessing of the Survey Data

Prior to the statistical analysis, the gathered raw data is reduced and condensed to an essential subset as follows: At first, we concentrate on companies who had a Web page online at the time of the survey, reducing the original data set of 1308 cases to 730 cases (or 55.8%). (Another 171 companies, or 13.0%, were still planning to launch their site within the next 12 months.) In a second step, we focus on companies who specified that they had yet gained sufficient online experience such as to provide information on the success of their company's electronic business activities, diminishing the number of cases to 469. Then, in a third step, we eliminated those cases exhibiting excessive missing values (i.e. more than 50% of the items left unanswered) in the 13 question items covering the success of their company's electronic business activities or in the items recording the perceived characteristics of e-procurement, leaving a total of 425 valid cases for the numerical analysis. Missing values in all of these items are each substituted by a value generated by linear interpolation and subsequent rounding to the nearest integer value on the measurement scale.

3.3 Descriptive Analysis

Same as in the original survey, the remaining 425 cases constitute a heterogeneous selection of companies from all industry backgrounds, company sizes, and business models, even if the original claim to be a representative selection for the German-speaking market must be relaxed. Among the surveyed companies 97 (or 22.9%) belong to the manufacturing sector, 42 (or 9.8%) to the construction industries, and 27 (or 6.2%) to the group of transportation, communications, and utilities. A fraction of 74 companies (or 17.3 %) are in the retail trade industry, whereas 41 (or 9.6 %) are wholesale trade businesses. Finally, 50 companies (or 11.7%) belong to the finance, insurance, and real estate sector, 81 (or

19.1%) to the service industries, and 3 companies (or 0.7%) to the public administration.

The size of 135 companies (corresponding to a fraction of 31.8%) ranges between 1 and 19 employees, that of another 182 companies (43.0%) between 20 and 49 employees, and 86 companies (20.3%) have 50 or more employees.¹ A group of 198 companies (or 46.5%) specify consumers as their main customer segment, 199 companies (or 46.9%) state that they mainly serve businesses. Another 15 (or 3.5%) mainly serve administrations, thus consider themselves as B2A-companies.

Concerning companies' experience on the Web, 204 (48.1%) have had a Web presence for up to 2 years, while 218 (51.3%) have owned one for 2 years or more. Finally, 256 (or 60.3%) already use e-procurement and another 61 (or 14.3%) plan to do so in the next 12 months.

3.4 Operationalization and Encoding of Variables

In the survey, indicator variables have mostly been operationalized as metric variables implemented on an equidistant interval (or Likert-like-) scale ranging from "1" (worded "does not apply at all", representing strong dissent) to "5" (worded "fully applies", representing strong agreement). The wordings for these indicator variables can be found in Table 1.

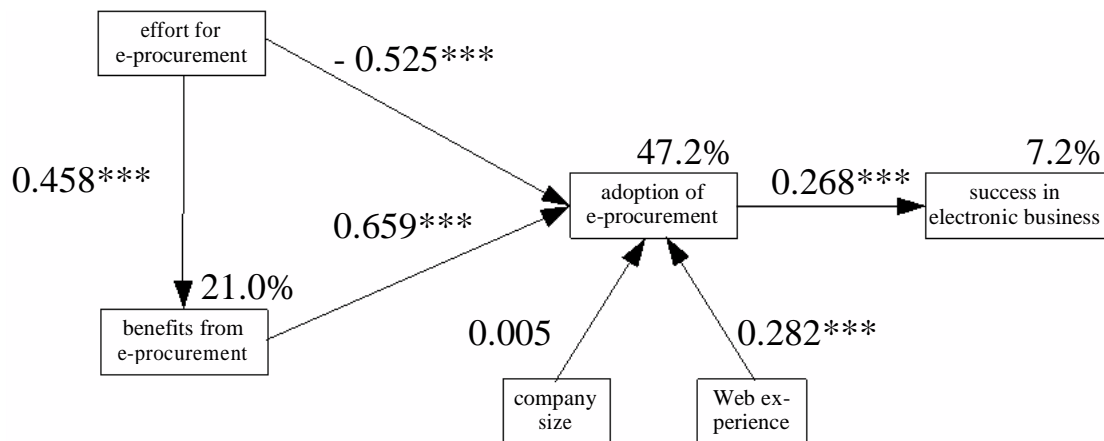

As an exception, the indicator variable for measuring companies' e-procurement adoption has been measured on a nominal scale with a choice of 3 items ("no usage and not planned, either", "no usage yet, but planned for the next 12 months", and "currently in use"). For the numerical analysis it has then been aggregated to a binary variable ("0" representing "not in use" and "5" representing "in use").² Similarly, company size and experience on the Web have also been recorded on a nominal scale with 9 or 7 items, respectively, which have then been projected on an equidistant interval scale.

3.5 Conceptualization and Operationalization of Corporate Success in Electronic Business

We limit our view on the concept of corporate success in electronic business to the shareholders' perspective. The concept is implemented as a construct comprising several subdimensions such as to accommodate for the major theories on competitive advantage, value creation and firm performance [1]. With the exception of the last, every subdimension consists of a score obtained from the unweighted addition of the values of two or three

¹ In this section, the numbers (fractions) of cases short of the total of 443 (100%) are due to missing values in the question items covering company structure.

² The scale items "0" and "5" have been chosen in order to match the scale of the remaining items, since the ULS estimation method employed for the numerical analysis (cf. below) is not scale free, i.e. the resulting path coefficients and even the identification of the model varies with the measurement scale of the underlying manifest variables.

Fit Measures:

GFI: 0.926, AGFI: 0.910, NFI: 0.841, RFI: 0.826, parsimony ratio: 0.912, PGFI: 0.764, PNFI: 0.768

Significance levels for the path coefficients are indicated as follows: *= significant at the 1% level, **= significant at the 5% level, and *= significant at the 10% level.**

Figure 2: Results of the numerical analysis: path coefficients between constructs and selected fractions of explained variance (percentage values) in the (partially) endogenous constructs.

underlying indicator variables for a total of 13 indicator variables:

- “Hard factors”, reflecting economic performance „increased market share”, “increased revenues”, and “increased overall corporate earnings”.
- “Soft factors”, accounting for a company’s achievements in the relation to- or perception by its customers „improved corporate image”, “increased customer retention”, “increased customer satisfaction”, and “increased customer loyalty”.
- “Cost reduction”, indicating a company’s improvements in process efficiency as well as procurement conditions, therefore covering firm performance from a transaction-cost economical perspective „reduced marketing costs”, “reduced sales costs”, and “purchased more cheaply”.
- “Innovation”, recording to what extent a company has strengthened its competitive position from the perspective of Schumpeterian theory, i.e. by being innovative „developed new markets” and “offered new services”.
- “Corporate value”, reflecting companies’ valuation and perception by third parties such as investors, therefore being the broadest subdimension and most susceptible to external influential factors „increased corporate value”.

Same as for the four items above, each of the 13 indicator variables is implemented as a metric variable on an equidistant interval (or Likert-like-) scale, ranging from “1” to “5”. They are preceded by the question „To

what extent have the goals from this list actually been accomplished through your Internet activities?”

3.6 Statistical Analysis and Hypothesis Testing with Structural Equation Modeling and Covariance Structure Analysis

For testing our model hypotheses, the research model is implemented as a structural equation model, which is displayed in Figure 2. Covariance structure analysis is employed as the numerical method. It allows us to make use of complex constructs for operationalizing our model constructs. Also, we can analyze the impact which several independent, yet interrelated constructs have on the dependent construct at the same time.

Based on the sample variances, covariances, and mean values from the data set, the model coefficients have been estimated using the unweighted least squares (ULS) method. Significance values have been obtained from repeated bootstrap analyses (1000 samples).

Further, in order to avoid “capitalizing on chance”, i.e. obtaining a model structure which happens to fit our data set very well, yet has little or no general validity, the coefficients for the model structure are not only estimated based on the data set as a whole. Instead, a variation of the cross-validation technique is employed: The model coefficients are estimated simultaneously for the full data set as well as two subsets with the constraint that the path coefficients within the complex constructs are fixed to the same value. The subsets (213 and 212 cases, respectively) have been generated by randomly dividing the data set in half.

Table 1. Constructs, indicator variables, and reliability measures.

construct	wording of the indicator variable or name of the subconstruct	standard. regr. weights	indicator reliabilities (≥ 0.4 ?)	factor reliability (≥ 0.6 ?)	avg. fraction of rec. variance (≥ 0.5 ?)	Cronbach's Alpha (≥ 0.7 ?)
effort for e-procurement	"e-procurement requires reengineering the whole purchasing process"	0.710 [†]	0.504	0.592	0.335	0.599
	"e-procurement necessitates expenses for training affected employees"	0.563	0.317			
	"e-procurement holds considerable problems in the integration with the company's existing IT/ IS"	0.429	0.184			
benefits from e-procurement (2 nd order construct)	"impact on processes" (1 st order construct)	0.867	0.752	0.910	0.772	(not computed)
	"impact on the supply chain" (1 st order construct)	0.871	0.759			
	"savings from e-procurement" (1 st order construct)	0.897 [†]	0.805			
impact on processes	"e-procurement reduces need for IT/ IS compared to prior systems, e.g. EDI"	0.517	0.267	0.540	0.374	0.526
	"e-procurement allows for delegating purchase decisions to the business units in charge while maintaining stronger centralized control"	0.694 [†]	0.482			
impact on the supply chain	"e-procurement leads to a re-evaluation of existing suppliers"	0.455	0.207	0.489	0.332	0.470
	"e-procurement leads to better purchasing conditions for us"	0.676 [†]	0.457			
savings from e-procurement	"e-procurement leads to shorter procurement cycles"	0.688 [†]	0.473	0.873	0.580	0.871
	"e-procurement leads to lower administrative costs"	0.812	0.659			
	"e-procurement allows for better data acquisition and automatic reporting"	0.720	0.518			
	"e-procurement leads to reduced stock-keeping"	0.792	0.627			
	"e-procurement causes purchasing managers to focus more on strategic tasks"	0.789	0.623			
corporate success in electronic business	"hard factors"	0.797	0.635	0.861	0.556	0.845
	"soft factors"	0.805	0.648			
	"cost reduction"	0.753	0.567			
	"innovation"	0.729	0.531			
	"company value"	0.631 [†]	0.398			

[†] indicates that the respective unstandardized path coefficient has been set to 1 for the numerical estimation.

3.7 Global Model Fit

Overall, the fit measures included in Figure 2 indicate a decent fit of our structural model with the sample covariances in the data set [2]. While the GFI and AGF values exceed the recommended value of 0.9, the NFI and RFI remain somewhat below. Similarly, the parsimony-adjusted PGFI and PNFI are close to the recommended value of 0.8. Part of this seemingly weak fit between the estimated model structure and the sample covariances should be attributed to the fact that the model structure was simultaneously fitted against the full data set as well as two subsets and that the global fit parameters reflect the discrepancy between the model structure and all three of these data sets.

3.8 Construct Quality

An overview of the constructs, wording of the indicator variables, resulting indicator loadings, and quality measures for the constructs is displayed in Table 1. The model construct “benefits from e-procurement” has been implemented as a second-order construct consisting of 3 first-order constructs. The quality measures indicate that the constructs largely meet the usually required minimum values [14], [21]. Yet, there are overall three indicator variables (the items “e-procurement holds considerable problems in the integration with the company’s existing IT/ IS”, “e-integration with the company’s existing IT/ IS”, “e-procurement reduces need for IT/ IS compared to prior systems, e.g. EDI”, and “e-procurement leads to a re-evaluation of existing suppliers”) with low loadings, implying poor indicator reliabilities, thus degrading the quality measures of the respective constructs. Typically, these three indicator variables would be deleted in a next step of model development, but, mainly for theoretical breadth, we have decided not to exclude this factor from the model at this stage.

3.9 Numerical Results and Findings

The resulting model parameters for our numerical analysis are displayed in Figure 2. With one exception, all path coefficients are found to be strongly significant. The findings from the numerical results can be summarized as follows:

The adoption of e-procurement can be explained by two main factors which account for almost half (47.2%) of the variance: the perceived effort for and benefits from e-procurement. While the perceived effort strongly deters companies from using e-procurement (i.e. acts as an adoption inhibitor, supporting **H1a**), the prospective benefits lead companies to employ it (i.e. act as an adoption facilitator, supporting **H2**). Interestingly, the perceived effort also has a strong positive impact on the prospective benefits constructs (explaining 21.0% of its variance, contradicting **H1b**). Further, no evidence can be found that the adoption of e-procurement depends on company size (**H3**) – on the contrary, the latter seems to have no impact at all. However, there is evidence that

adoption seems to increase with the time which companies have been on the Web (supporting **H2**).

The adoption of e-procurement, in turn, has a clear positive impact on companies’ success in electronic business (supporting **H3**). Yet, it only explains a small fraction (7.2%) of the variance in the latter construct.

4. Discussion

4.1 Interpretation of Selected Findings

While we have found empirical support for most of our research hypotheses, a few issues arising from the numerical results demand further clarification:

First, why does the perceived effort for e-procurement have a strong positive impact on the perceived benefits? From Davis’ results (cf. [9] [10]), one would expect that the perceived effort for e-procurement, being the opposite of the perceived ease of use, has a negative impact on the expected benefits. Maybe our findings are due to the fact that corporate decision makers assume a different perspective towards the adoption and usage of IT/ (M)IS in general and, specifically, electronic business concepts than end users do. While end users’ adoption decision is usually determined by short-term objectives (i.e. quickly and effortlessly fulfilling a certain operational task), decision makers’ point-of-view is more strategic and long-term. One could argue that in part, decision makers expect to reap benefits from the effort for implementing e-procurement (especially organizational and process changes, as we have operationalized it), which they also anticipate.

Second, how come that company size seems to have no effect on the adoption of e-procurement? A key reason for this finding may be that with the diffusion of the Internet and Worldwide Web, Web-based purchasing, depending upon the degree of its implementation, is easier, quicker, and cheaper to adopt than many other information systems or electronic business concepts. E.g., even very small companies can order office supplies over the Web, although certainly not every company is likely to build and operate a buy-side marketplace. Among the decision makers questioned in our survey, 43.1% agree to the statement “e-procurement reduces need for IT/ IS compared to prior systems, e.g. EDI”.

Third, as a fraction of 47.2% of the variance in the construct for e-procurement adoption is explained in our model, we conclude that companies’ decision to use e-procurement or not is also strongly determined by other factors not included in our model. There may be many such factors, e.g. corporate strategy, perceived competitive pressure, budget constraints etc. Similarly, the low fraction of 7.2% of explained variance in the dependent construct of corporate success in electronic business suggests that the adoption of e-procurement is only a minor success driver among many others (e.g. sell-side concepts, Web site management etc.).

4.2 Limitations and Weaknesses of the Research

The central shortcoming of our research is that we chose a single indicator variable (item), and not one or more complex constructs, as the empirical instrument for recording the adoption of e-procurement. Although the advantages of this approach are that the respective part of the survey is easy and quick to administer and that the statistical model is kept simple, the disadvantages are limited resolution, reliability, and validity. Ideally, it would have been desirable to further specify, qualify and quantify the implementation of e-procurement and of flanking (e.g. strategic-, organizational-, etc.) measures as well as the specific readiness of every company under these aspects.

Another weakness of the empirical design of our survey is that it was targeted at only one representative from every company who, as far as this study is concerned, had to assess the characteristics of e-procurement from the perspective of his or her company. Pursuing this approach implies that the resulting survey data may be influenced by a variable informant bias, depending upon the interviewee.

The fractions of explained variance in the three (partially) dependent variables in our model must also be reviewed critically. It is important to note that these fractions are not *exclusively* accounted for by the exogenous variables in our model, but that (at least parts of) the same variance can also be explained by other influential factors, for which we do not control.

Lag problems might be another shortcoming of our research. As the implementation of integrated electronic business concepts such as e-procurement may require a considerable investment and the accompanying structural changes take time, it also takes time for the effect on corporate success to become visible or measurable. The fact that e-procurement was still in the emerging phase at the time of the survey implies that a considerable fraction of companies in our survey may have been affected by lag problems. On the contrary, from case studies it is known that the ROI for e-procurement may be reached as quickly as within a year.

5. Conclusion

5.1 Suggestions for further Research

Weighing the contributions of our study against its limitations and shortcomings, it is clear that our contribution must be viewed as a first-level analysis, as a “snapshot”. It leaves a number of issues open for future empirical research. Some suggestions are:

- The survey should be repeated in a similar manner in order to assess how the identified interrelations change with time (as e-procurement further matures).
- Future surveys should be more refined and focus more on e-procurement. Different measures of e-procurement, its usage and implementation, and corporate readiness should be developed.

- Future research should examine if and how the business benefit from e-procurement varies between different industries or markets (market segments).
- Future research should investigate the integrated effect of e-procurement together with other potential success factors in electronic business (e.g. strategy, organization etc.).

5.2 Managerial Implications

Corresponding to the contributions of our research, we can formulate some implications and recommendations for managerial practice:

- E-procurement is one of the factors determining companies’ success in electronic business. It has a rather small, but significant impact.
- While the perceived effort and benefits are important factors governing companies’ adoption of e-procurement, there are also other influential factors which, in sum, are equally important.
- Assessing the necessary effort will in part help executives judge and appreciate the possible benefits their companies can gain from implementing e-procurement.
- Company size is not a relevant factor influencing companies’ adoption of e-procurement. Yet, companies with more experience on the Web are more likely to adopt e-procurement.

Creating Start-up New Ventures: A Conceptual Approach

July 2003

Abstract

There has been limited research into the creation process of new venture start up firms embedded in radical innovations such as the Internet. This study attempts to develop a theoretical perspective on this process that is primarily grounded in diffusion theory but also borrows from other disciplines. The objective is to develop theory rather than test theory. The study develops a number of working propositions and then demonstrates how these working propositions can be operationalized using case data. The result suggests that the process activities over time are dependent on macro and micro activities in line with a flexible master plan rather than a sequence of unrelated linear activities and static objectives.

1. Introduction:

Process innovation represents a new or improved way of developing or providing a product or services either to an end customer or a business [1]. Process innovation can be as simple as the improvement in the way in which a particular function is performed, or as radical as developing a entire new system e.g. just-in-time or creating a new venture based on radical technology such as the Internet. Scholars have split innovation research into two broad areas of inquiry [2]. The first is an economics-oriented tradition while the second is an organisational theory-oriented tradition. Nevertheless, product development is critical because new products are becoming the nexus of competition in industries ranging from software to cars. Furthermore, it is a critical means by which employees diversify, adapt and even reinvent their firms to match evolving markets [3]. More importantly, however, the theoretical question as to how and why suppliers and buyers adopt such innovations and the processes they go through are unclear. Understanding such questions will assist managers as theoretical guidance in this area is limited [6]. It can be argued that product and process innovations are not dichotomous in that process improvements are often driven by new product demands while new products frequently arise out of developments in process engineering.

This paper attempts to describe how start-up new ventures like the B2B e-market firms based on radical technology such as the Internet technology can develop new or improved ways to provide services to businesses using electronic centralised exchanges or B2B e-markets. B2B e-markets are defined as *independent new venture where business buyers and sellers perform marketing and logistics activities using the embedded technological*

innovation (the Internet) on which it is based [4]. Given this definition B2B e-markets are both a 'firm' as well as a 'technological innovation'. For the purpose of this paper, the focus is on the creation of such independent firms and the role of the participants there in.

Evolving high-technology markets such as those based on the Internet receives a great deal of attention as they promise to introduce technological innovations that often create a market discontinuity and lead to new markets [5]. Our understandings of management within the B2B e-market firm and of third parties who provide and develop the technology to the B2B e-market firm is incomplete [3]. There is also little understanding of the links between the creative processes by which managers within B2B e-market firms and other firms use to create an effective product concept [3].

The objective of this research is to develop theory but not test theory. As such the research develops a number of working propositions and is multidisciplinary in nature. Due to the multidisciplinary nature of the research objective, this research is grounded in *diffusion theory*. It also borrows from network literatures and hopes to contribute to new venture literature. The reason for grounding this research in a multidisciplinary context is that no one literature adequately addresses the two facets of the research, that is, the creation process and involvement of participants [6].

Diffusion theory is important to this research because (a) the aim is to understand the process of creating such new ventures by observing the nuances of planning and implementation decisions and (b) it intends to understand the roles played by the different participants in the creation process. Network literature draws on the concept of lead users. Von Hippel [7] claims that in the "high technology area, the world moves so rapidly that the related real-world experience of ordinary users is often rendered obsolete by the time a product is developed or during the time of its projected commercial lifetime". In contrast to Von Hippel [7], Biemans [8] claims that third party participants are the drivers of innovation. Building on the concept of lead users and third party participants, this study adds the concept of the involvement of network champions [9]. Network champions are likely to serve, in part, as brokers and deal makers to bring about new relationships amongst firms at multiple levels. In particular, the concept is one of a catalyst who builds new linkages among multiple firms that have not previously communicated with one another [10]. Thus this concept will be helpful in explaining the relationship of the participants in the business network. Here, a business network is defined as the participants in the B2B e-market firm and the third party participants.

2. Conceptual framework

2.1 Process

2.1.1 Formation of new ventures

Formation of new ventures based on innovation is composed of a set of stages or phases ordered along the

The distinction between macro and micro activity theory has been blurred in most development work [19]. In most macro long-run theories, immediate activity is only implicit and remains vague at best [19]. As a result this theory remains overly simplistic particularly in real-time situations. Micro theories, however, do not consider how immediate actions interact and aggregate into a larger context and as a result micro theories tend to have an overly simplistic view of the long run. However, both macro and micro perspectives are necessary in developing an adequate theory of innovation, because innovations are extended over long periods, yet driven through time by immediate action [18]. In order to develop theory in new

Traditional sequential models have been criticised by scholars because of their inability to illustrate the interactions between the various stages of the development process and the assumption that each stage is completed before the following activity occurs [20]. Moor [20] overcame these shortcomings by identifying parallel activities while at the same time linking the activities to the firm's objectives. More importantly, this linking of activities with the firm's objectives indicates that the business objectives were evaluated at every stage of the development process. This loop-back feature is captured in part by [21]. In contrast to the previous models, Cooper [21] suggests a roadmap for driving a new product/project from the idea stage to product launch by providing a comparison between the second generation stage-gate process and third-generation process that overlaps fluid or conditional 'go', 'no go' stages at the gates. Although an activity based model clearly shows the tasks carried out during each stage and the intermediate forms of development, the model of Cooper [21] suggests that an ordered sequence of activities is involved, by which innovation moves through a process.

Building on these models, this study extends the activity models by arguing that objectives are flexible in a dynamic new venture B2B e-market firm. Figure 1 depicts process activities as dynamic in nature and demonstrates that the external environment and technology may affect on the objective setting process of a B2B e-market firm.

```

The flowchart illustrates the dynamic process of new venture creation. It begins with a box labeled "New Venture coming to existence stage", which leads to a sequence of five boxes: "Idea Generation", "Screening", "Concept Testing", "Test Marketing", and "Commercialisation". Above the "Screening", "Concept Testing", and "Test Marketing" boxes is a box labeled "Business Evaluation". Arrows point from each of these three boxes to "Business Evaluation". Above "Business Evaluation" is a box labeled "Dynamic Objective Setting Process", with a double-headed arrow connecting them. Above "Dynamic Objective Setting Process" is a box labeled "External Market Demands by e.g. suppliers and buyers and the technology providers", also with a double-headed arrow. At the bottom of the diagram is a wide box labeled "Dynamic process activities", with arrows pointing upwards to each of the five main stages of the process.

115

In a process approach, the stages are interrelated, as mentioned before. However, process models suggest that each stage is planned and executed in sequence. This is not realistic to the extent that dynamic planning activities can and do take place over time and may not be executed in sequence. Planning activities in some instances may depend on market demands, where the capabilities of the firm and its resources can be configured or reconfigured to match market change [22].

Dynamic capabilities are the antecedent organisational and strategic planning routines by which managers alter their resource base, acquire and shed resources, integrate them together and recombine them to generate new value creating strategies [22-24]. Scholars [25, 26] have described dynamic capabilities in vague terms, such as 'routines to learn routines', that have been criticised as being tautological [22]. Yet, a dynamic capability actually consists of identifiable and specific routines, such as product development, that often have been subject to extensive empirical studies [22]. One can argue that in a B2B e-market environment, however, the creation process must 'fit' the requirements of the market. Dynamic changes could be triggered either by the product (e.g. new software in the market or limitations of the software) or the requirements of the sellers and buyers. More importantly, high-velocity markets (e.g. real-time marketplaces) involve the creation of new, situation-specific knowledge in order to focus on market situations that are fluid (not static) and use simple routines to address strategic planning [22].

Arguably, the B2B e-market environment is not a moderately dynamic market structure; rather it is a high-velocity market structure. As such, planning routines that focus on organisational changes in structure or processes are simple and flexible. Furthermore, the literature reviewed seems to suggest that the objective needs to match the market demands over time. In order to match market demands and the capabilities of the innovation (e.g. computer programming limits of the software) the macro and micro activities need to be flexible. In other words, *the formation of new venture B2B e-market firms depends on dynamic planning of macro and micro activities and a constant review of objectives rather than a sequence of unrelated events based on fixed objectives* in order to match market demands. Therefore, planning routines focus on events to match the market changes (over time) by using simple routines that are not completely unstructured, so that managers can act in highly uncertain situations where it is easy to become paralysed [22]. The preceding arguments based on literature suggest the following working proposition.

WP₁: The formation of new venture B2B e-market firms is dependent on a dynamic interrelated planning of macro and micro activities and a review of objectives, rather than a sequence of unrelated events based on a static objective.

2.1.3 Decision to adopt or reject an innovation

Decision processes play an important role in innovation because decision-makers in the organisation are faced with choices such as to innovate or not, to select from different innovations or to use different methods of implementation [11]. Taylor [27] argues that decision making usually involves four steps, (a) the generation of some subset of alternative courses of action available, (b) a set of consequences attached to each alternative (c) preference ordering in an attempt to rank the consequences of various alternatives and (d) the decision-maker's selection of the first alternative that meets some minimum standard of satisfaction. However, scholars have suggested that decision making is dependent on the condition of technical uncertainty [28, 29]. Schon [29] however, states that uncertainty attributes can be further classified into technical, novelty and marketing uncertainty. Technical uncertainty focuses on the question of whether the innovation is technically feasible, novelty uncertainty focuses on the question of other firms' approach to the innovation and marketing uncertainty focuses on the question of marketability of the innovation.

These attributes of the decision process are relevant to this study. The B2B e-market firms are based on innovation and therefore dependent on technology uncertainty and, being a new phenomenon, will be dependent on novelty and marketing uncertainties. As such, the decision to adopt an innovation such as in the case of B2B e-market firms is shared amongst the functional areas to address uncertainty as each functional area makes a decision on a particular aspect of the creation process and then argues the merits of the decision with other functional areas.

2.1.4 Linear and fixed innovation-decision process.

The decision models rest on the premise that the product development process can be split into a number of decision actions and, as such, the process is divided into several stages, separated by evaluation points [8]. At every point, a decision on 'go' or 'no go' must be made in order to go on to the next stage of the decision making process. However, in a B2B e-market environment, once the initial decision to commit resources to the development process is made, a number of decisions are dependent on subsequent process activities such as, by third parties. For example, selections of appropriate software or decision on selecting the systems design to meet the needs of suppliers and buyers. Furthermore, Rogers' [30] model suggests that the decision process is a sequential activity, yet in a B2B e-market environment the decision process could be a parallel set of activities with inputs by different actors and consequently the model is not flexible.

Generally decision models are easily constructed by taking the stages of the activity-stage model and linking them by evaluation points [8]. Based on Cooper's [31] decision stage model a more elaborate model that distinguishes between technical/production activities and

marketing activities was developed. Calantone and di Benedetto [32] provide empirical validation of Cooper's [31] decision process model that identifies the strength of the relationship between technical and marketing activities. This model suggests that the "needs" of the market (held by sellers and buyers in a B2B e-market environment) and the technical resources provided by third party technology suppliers have a strong or positive effect in contributing to the success or failure of the commercial product.

Arguably in a B2B e-market each stage of the decision process may have an evaluation point at which the decision to adopt or reject an innovation can take place. Furthermore, in a focal business network, suppliers and buyers may affect the design decision of the procurement documents or the process in completing these documents. In such situations, the technical and managerial personnel require input from the users of the system. Because of that, *the decision to adopt or reject an innovation can occur at any point in the decision process of adopting an innovation rather than at a particular point in the process.* This leads to the following working proposition.

WP₂: *The decision to adopt or reject an innovation can occur at any point within the linear innovation-decision process rather than at a fixed stage of this process.*

2.1.5 Implementation of innovation

The interest in diffusion theory for this study is in its consequences for the implementation process. This study seeks to understand implementation not as an outcome of a process but the process itself. In broad terms, the implementation or commercialisation stage of an innovation can be defined as the execution or commercialisation of the innovation where it is put to use [30]. Klein and Sorra [33] observe that innovation scholars have ignored research on innovation implementation. However, cross-organisational studies of determinants of innovation adoption are abundant (see [34]). More common are qualitative case studies that focus on single-site implementation of innovation [33]. Although these studies describe parts of the implementation process, an integrative model that captures and clarifies multilevel phenomenon of innovation implementation is largely missing [33]. Klein and Sorra [33] claim that researchers have neglected the implementation. Furthermore, researchers have neglected the phenomenon that an innovation can be changed or modified by the user [35]. Observations made during the initial interview of the B2B e-market firm suggested that in a B2B e-market environment, suppliers and buyers may request changes, for example, to the "procurement screen" so that it is more user friendly and contains standardised information.

Management scholars have developed an integrative model describing the determinants of the effectiveness of organisational implementation [33]. However, that model

does not focus on the process of implementation. Rather, it identifies a number of dimensions of effectiveness and urges researchers to understand implementation across organisations, using longitudinal data. Its authors believe that a number of single-site studies (e.g. [36]) have rich descriptions of the variety of innovation, implementation, organisational and managerial practices, and characteristics that may influence innovation. However, the use of information from across organisations in a network (e.g. B2B e-market environment) will provide a valuable understanding of the implementation process using longitudinal data [33].

This study focuses on understanding the implementation process of an innovation that can be changed by the user over time in order to meet the requirements of the user of the innovation. In so doing, this study will map the process of how a technological innovation is implemented in a B2B e-market firm over time.

2.1.6 Feedback and redesign

Feedback and redesign refers to the process by which information is collected about a new technology and redesign activities are initiated to enhance the operations of the innovation [37]. The basic assumption is that any new technology will evolve in structure, process and outcome [37]. The authors posit that the evolution is driven by (a) the perceived benefits of the technology (b) the benefits drawn from economies of scope and (c) the technology is subject to change as new opportunities are envisaged over time. Goodman and Griffith [37] argue that empirical evidence supports Goodman's [38] use of feedback and redesign in sustaining change. Leonard-Barton [39] also studied the concept of technology evolving over time to meet the changing needs of different user groups. Due to the lack of empirical data, this study focuses on gaining an in-depth understanding the implementation process in one organisation.

2.1.7 Sequential activities

Adoption-decision models claim that the implementation stage occurs sequentially after the completion of the decision stage [30]. In a start-up new venture like the B2B e-market, the implementation stage also occurs after the decision stage to go ahead with the innovation. However, the implementation stage is subject to constant feed-back loops and refinements that will match the requirements of the users of the product (B2B e-market) and will be subject to further redesign as the market demands over time. Extant literature does not provide adequate information on the sequence of implementation activities [14, 40, 41].

Arguably the *implementation of innovation process* follows a set of steps and each step is dependent on it being *evaluated and redesigned through feedback loops* in order to implement an innovation and perform implementation activities simultaneously rather than as a *linearly sequential*

chain of activities. This leads to the following working proposition.

WP₃: *The implementation of an innovation follows a set of sequential steps where each step interacts with the previous step through feedback loops, rather than a linearly sequential chain of activities.*

2.2 Participants

2.2.1 Direct and indirect impact of champions in networks

The network approach implies two theoretical extensions [8]. First, although the relationship between focal network participants is important (i.e., the relationship between the manufacturers or sellers of raw material and the business buyers), there are other participants that may influence the activities of those within the focal network. A direct relationship may consist of the manufacturer and its immediate suppliers and immediate business customers. A new process that may influence the activities of the buyer firms with its suppliers and business customers constitutes an indirect relationship. Indirect relationships are of importance because (a) given the strategic situation, they influence the direct relationship and (b) changes in the strategic situation can change the buyer's position with regard to both the direct and indirect relationships. As firms are increasingly outsourcing various functions to other firms, third party involvement is a powerful alternative to traditional vertically integrated firm structures; one that can affect the existence and strength of direct and indirect relationships [42]. Direct and indirect relationships are crucial in the context of innovation because participants in these relationships affect the creation process [8]. The second theoretical extension relates to the kind of relationships. This relates to firms having a certain position in a network that can be defined by (a) the function performed by the firm for other firms (b) the relative importance of the firm in the network (c) the strength of the relationship with other firms in the network and (d) the identity of the firms with which the focal firm has a direct relationship [8].

The concept of champion has been documented in the product innovation management literature and is defined as the person, not organisation, who is spirited, almost independent and fully capable and willing to pursue the risk of creating a new venture [43]. In the new venture creation process a number of champions are involved. New venture creation champions are those who are directly involved with the new venture at a management and entrepreneurial level. The implementation champion is characterised as the one who is intimately familiar with the aim of the new venture and has the required skill and experience of the technology and co-ordinates the activities between the new venture and the third parties to achieve fruition of the new venture. This review of literature suggests that in the primary task environment,

network champions may have a direct or positive relationship with third party participant firms, new venture champion and new venture implementation champion but an indirect or negative relationship with supplier and business buyer firms.

WP₄: *In a B2B e-market context (in contrast to EDI), network champions attempt to create direct relationships with new venture champions, product champions and third party participants rather than attempt to maintain direct relationships with suppliers and business buyers.*

2.2.2 Influence of champions on potential participants

A study on innovation reveals that champions influenced top management's acceptance of a project by making apparent the strategic importance of such projects [44]. Burgelman [44] mapped the activities involved in Internal Corporate Venturing (ICV) onto the process model above. While Burgelman's [44] work provides a good foundation to this research as it identifies the importance of product and organisational champions, the study is limiting as it evaluates conditions in one organisation rather than across organisations. Yet the process can occur across organisations, especially in a network environment [8].

This research adapts and extends Burgelman's [44] model by allowing it to (a) operate at an inter-organisational rather than an intra-organisational level of analysis and (b) include the impact of network champions on the process model. In particular, the concept of network champions extends the work on product champions and the organisational champion concept [44], although it is more closely related to the latter than it is to the former. The product champion is one who creates, defines or adopts an idea for a technological innovation and is willing to accept the risk, whilst an organisational champion is a decision-maker. According to Woodside [10, p54] "... network champions are likely to serve, in part, as marriage brokers and deal makers to bring about new relationships amongst enterprises at multiple levels who must interact for the adoption of new ET (electronic technologies) in a manufacturing process". Woodside and Wilson [9] admits that such conclusions are the result of preliminary exploratory study and that detailed description through in depth case study is required of specific networks that emerge in the adoption of new technology. Arguably, in a B2B e-market environment, a network champion works across firms in order to bring about new relationships amongst enterprises at multiple levels.

One can conclude that the *likely acceptance of an innovation* is dependent on *the involvement of network champions who can support potential participants to "buy into" the innovation.*

WP₅: *The involvement of network champions who persuade potential participants to "buy into" the innovation, results in the likely acceptance of the innovation.*

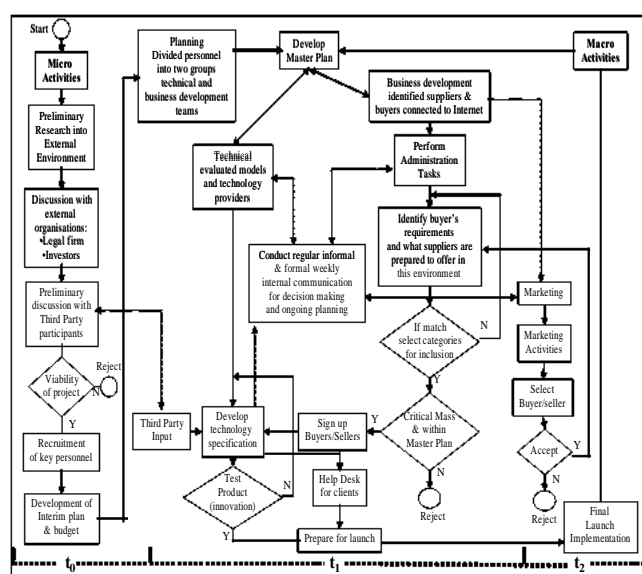

3. An example of operationalizing the first working proposition

Based on data captured during preliminary interviews an integrated flowchart (see Figure 2) was developed from the various functional areas. The integrated flowchart depicts the micro and macro activities over a longitudinal time frame. The concept of the master plan developed suggests that the functional areas used the master plan as a guide: "we had a very much integrated master plan where we basically managed the (creation) process.....we got together (weekly) and reviewed the objectives, strategies that we were developing". From the time of its conception to its final launch the objectives changed which was possible due to the flexible nature of the firm and is captured by the following extract: "the beauty of running a start up firm is that it's constant evaluation of alternatives.....the flexibility that a small agile company gives you, you (can) translate (this flexibility) directly into changes you require to meet the needs".

One can argue that the master plan was an integral part of the planning process and the macro and micro activities were a consultative process between the functional areas. Therefore, the formation of new venture B2B e-market firms is dependent on the consultative process of macro and micro activities in line with the master plan. In turn this master plan is dependent on it being flexible in order to meet the changing nature of the objective over time. The refined proposition to WP₁ is stated below:

P¹: *The formation of the new venture B2B e-market firm is dependent on a consultative process of macro and micro activities in line with a master plan that has the flexibility in changing the objective over time, rather than a sequence of unrelated events based on a static objective.*

Figure 2: Flowchart of process activities as interpreted from the CEO's interview

4. Future Direction and Limitations

Concerns of external validity will be traded off against opportunities to gain insights into a new phenomenon [44]. The caveats pertaining to field research described by Kimberly [45] will be taken into account. Further, a cross-site analysis process will be developed to compare data gathered from different sources in order to triangulate the findings.

New venture B2B e-markets have been widely touted as a revolutionary mechanism for more competitive and efficient operations of business marketing and procurement systems. Yet, many such B2B e-markets are experiencing start-up problems and slower than expected growth. This paper offers a set of working propositions that suggests how the creation, commercialisation, decision and implementation take place for such B2B e-markets. In addition, the working propositions suggest how several key classes of participants can facilitate particular aspects of e-market exchange structure and its acceptance as a technological and organisational innovation. These working propositions are subject to further refinement and development, which will be the focus of future research.

Preliminary observations and interviews offer tentative support although case study evidence in itself will not provide a definitive test of any of those theoretical propositions. It will, however, establish constructs and attributes and contribute to the refinement of theory in the literature on new ventures.

Consequences of e-Business Initiatives on Business Process Performance – A Model for Analysis

Dr. Ravi Seethamraju
School of Business, The University of Sydney
Australia
r.seethamraju@econ.usyd.edu.au

Abstract:

This paper discusses the consequences of implementing e-business initiatives on business process performance and proposes a model for further analysis. Integrating the operations management literature, diffusion theory and reengineering theories, this model attempts to hypothesize the consequences of implementing e-business strategies by way of redesigning and/or integrating the information, systems and processes and its impact on the business process performance attributes. Using an survey methodology, this study will attempt to measure the extent of implementing e-business initiatives in Australian manufacturing industry and the consequences of those initiatives on business process performance. Developing a theoretical framework/model will help in minimizing the uncertainty associated with such transitions, and explain the dynamic interactions between organizational factors, business process performance variables and information systems. In addition, it will make contribution to the theories dealing with the interface between information systems and operations management in e-business context.

1. Introduction and background:

Despite some initial failures and issues with regard to the implementation of associated changes, e-business is expanding in Australia. Understanding the specific impact of e-business initiatives as an IT innovation on processes and their relationships to other factors such as information systems, and organization are important to develop strategies for managing and improving the business processes. Considering the huge investments already made in these initiatives, and their overarching influence on business in general, it is important to understand the impact on business processes. Based on the literature from information systems and operations management fields, this paper analyses the consequences of implementing e-business initiatives on business process performance in manufacturing industry and proposes a theoretical model for analysis.

A report by National Office of Internet Economy (NOIE) in Australia [7] observed that the e-business readiness of Australia is ranked second only to USA.

According to this report, about 62% of Australian companies are now reporting cost savings of 1 to 5% achieved by online marketing and sales, and efficient online financial transactions. Though the number and value of electronic transactions between businesses, government and customers is steadily increasing, the current levels and volumes are not significant in Australia. At present, the B2C (Business-to-Consumer) and B2B (Business-to-Business) transactions are worth 0.17 per cent and 1.1% of the GDP respectively [7]. Generally, the manufacturing industry is observed to be lagging behind the finance, banking, insurance and other service sector in the introduction of e-business initiatives.

In spite of its advantages and potential benefits, implementing e-business initiatives often poses challenges to many businesses. Some of the challenges are back-end integration, transforming business processes, integrating information systems and IT applications, reliability of operational data, hierarchical and functionally oriented organisational structure, and performance measurement of e-business processes [4][10].

It is well recognized in the literature that adoption of information technology enables businesses to achieve competitive advantage. However, the consequences of adoption and their impact on the organizational performance are considered too complex to study. Generally, there are very limited studies on the consequences of technology adoption [7][6], though there are several studies that analysed the implementation and diffusion of technologies in different settings. Unlike other IT innovations, e-business initiatives are generally pushed into the organization and therefore does not involve the adoption component of the classical diffusion model by Rogers [9]. Because of the indirect and unanticipated consequences, and their complex cause and effect relationships, it is considered difficult to measure the consequences of IT innovations [9]. Even though it is difficult to measure impact in specific performance terms, many organizations, however, are able to achieve competitive advantage by using IT as an enabler, while others by deploying it as a tool in the redesign of business processes [8][11]. Software vendors and consultants who sponsor research on IT innovations generally assume that the consequences of such e-business initiatives are

positive. However, several IT innovations such as ERP systems, CRM and SCM softwares, and other applications are reported to have negative impacts and did not seem to realise the full benefits espoused by the vendors [3].

2. Model for analysis:

Taking some components of the Barnes et al [1] framework for the study of e-business in operations management literature, Rogers' diffusion theory and reengineering theories by Davenport from information systems literature, the following theoretical model is developed to analyse the impact of e-business initiatives on business process performance. Rather than studying them separately, this model helps to study the factors inherent in e-business initiatives, the impetus these factors give for initiating various organizational changes and their effects on business process performance variables such as cycle time, quality, flexibility and cost. In this context, based on the model proposed and presented at the end of the paper (figure 1), some hypotheses are formulated to be tested empirically in Australia.

In the theoretical framework developed (Figure 1), various e-business initiatives described in the literature are taken as the basis. These initiatives are expected to have an impact on the information systems, business processes and organisational factors. Moreover, the organisational changes as mentioned above can be analysed in conjunction with the attitude of the enterprise towards various e-business initiatives. The sequence of intra-organizational changes can be hypothesized to vary depending upon the sequence of events, whether the organisation took a pro-active approach or re-active approach [8]. In the pro-active approach to the adoption of these initiatives, it is expected that organization would change organizational structure and strategy, staff selection and training, and redesign/automation of business processes and information systems in that sequence. Similarly in the re-active mode, organizations are expected to change the business processes and information systems first and then follow with changes to staff skills, organizational structure and e-business strategy in that order. All these changes and effects are to be analyzed within the context of organizational variables such as structure, size and business model.

The type and motives of a particular e-business initiative(s) are influenced by the nature of customer, the path to the adoption, and the extent of changes to the business processes and information systems. Consequently, the performance of the business processes in generic sense are expected to be dependent upon the extent of this redesign and integration of business processes and information systems in the given organizational context (Barnes et al 2002). Thus, the

understanding of these aspects is important in developing new theories that include e-business initiatives and accompanying organizational changes as relevant variables, rather than studying them separately.

The term business process is very generic and encompasses a wide range of activities in the firm at both strategic and operational level. There are three levels of processes – manage processes, operate processes and support processes [2]. According to Childe et al [2], 'operate processes' are directly involved in producing value for the customer, 'manage processes' are those related with the strategy and business model, while 'support processes' generally support the other two types of processes. The proposed model focuses on the 'operate processes' in the manufacturing organizations that involves processes such as 'develop product, get order, fulfill order, and support product/customer'.

It is also expected that the social and technological issues that involve organisational culture, organisation size, skill levels of staff may become barriers to the implementation of e-business initiatives. For example, conservative nature of the organisation and/or industry, and the general resistance to technology, may pose problems for the transformation of organisational processes. In addition, inability to invest in technology, influence of major partners in the supply chain, lack of sound organisational strategies, and motives of organisations to select and adopt e-business strategies may influence the scope and outcomes of e-business initiatives. In addition, lack of industry standards and open systems, complexity and limitations of legacy systems are some of the technical barriers. While some companies want to lead the industry by adopting technological innovations, other companies are simply following their competitors with the hope of neutralising the competitive advantage of the leader. On the other hand, some organisations have clear objective of exploiting the full potential of e-business strategies and thereby achieve reduced costs, improved service and target specific niche markets.

3. Methodology:

Several studies in the past have tried to explain the e-business phenomenon, its potential advantages, the changes required in management and organization of the companies, and the possible business models. Most of these studies were exploratory in nature and mainly employed case study approaches [5]. Empirical studies that try not only to measure the nature and extent of implementing e-business initiatives, but also identify the way these measures impacted on various organizational changes, and their consequent effect on business process performance are necessary. As this research is measuring

the extent and consequences, a survey methodology is considered appropriate to collect data [12]. The questionnaires will be posted to the top 1000 companies in Australia in November 2003. This paper reports on the first stage of the research project that has helped develop a model for further analysis and empirical testing.

5. Conclusions:

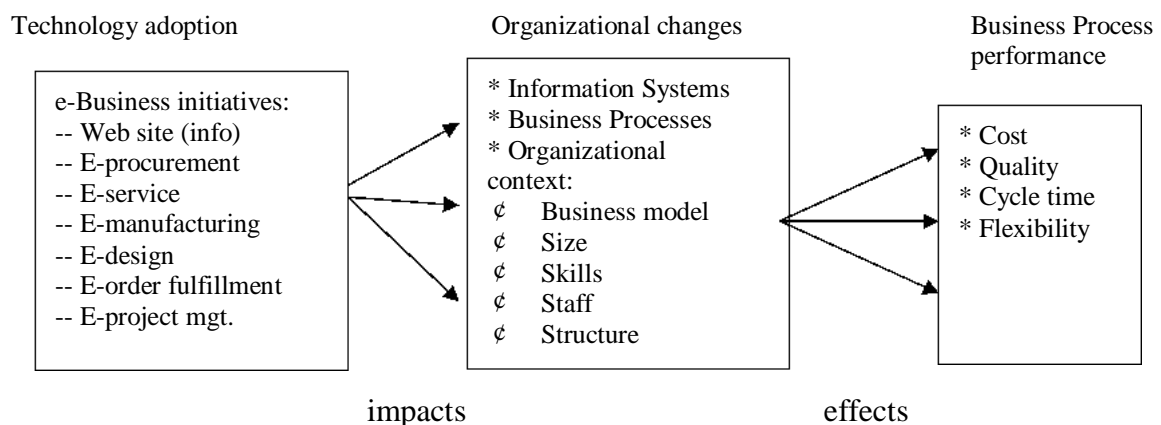

Manufacturing organizations which are traditionally behind the other organizations in services sector, in introducing IT related innovations, are not able to evolve beyond the most basic Internet-enabled applications such as e-mail. Some large manufacturing companies, however, have attempted to implement or have recently implemented ERP systems partially or fully with mixed results in Australia. Reports by NOIE also suggest that there is a need for manufacturing organizations to speed up the adoption of e-business initiatives and to understand the reasons behind this lagging [7]. Some of the reasons suggested include lack of framework within which the analysis of changes required to the processes and systems could be carried out, and difficulty of integration between 'bricks' and 'clicks' processes. Developing such framework will help in minimizing the uncertainty associated with such transitions, and explain the dynamic interactions between organizational factors, business process performance variables and information systems. In addition, it will make contribution to the theories dealing with the interface between information systems and operations management in e-business context.

Abstract

Empowerment has been an evolving construct for many years and is identified as one of the factors contributing to affective outcomes in the workplace such as increased worker effectiveness, satisfaction and performance. Prior research has generated considerable knowledge on empowerment from management and non-management perspectives. The adoption and implementation of integrated enterprise systems (commonly known as ERP systems), have resulted in dramatic changes in organisational processes. The implementation strategies focus on mapping processes and training end users in using the system but do not appear to focus on engaging the users in the change process. Perhaps the concepts of user empowerment as a focal point of the change management process could improve the successful use of such complex systems. This research program seeks to define the concepts of user empowerment, develop, measure and validate the constructs of user empowerment in an enterprise systems context. In addition, the program will study the correlation of user empowerment with enterprise systems success. The research alludes to several ways that user empowerment influences the enterprise systems success. Organisations need to understand that there are critical human factors involved in a successful implementation and thereby a successful Enterprise System.

1. Introduction

Of the many issues that merit research on enterprise resource planning systems (ERP) success, one of the least researched is the effect of enterprise user empowerment on Enterprise Systems Success (ESS). While some large companies have enjoyed significant gains, others have had to scale back their projects and accept compromised benefits, or even discard implementation of enterprise systems projects.

Conceivably the main cause for this is that the handful of large vendors of enterprise systems dominate the market, promote their products as best practice solutions. The adoption and implementation of integrated enterprise systems (commonly known as ERP systems), have resulted in dramatic changes in organisational processes. The implementation strategies focus on mapping processes and training end users in using the system but do not appear to focus on engaging the users in the change process. Although there have been several studies undertaken to measure manifestations and constructs of Enterprise Systems (ES) success, there is lack of empirical study on the effects of user empowerment on ES success. Perhaps the concepts of user empowerment as a focal point of the change management process during an ES implementation could improve the successful use of such complex systems.

This research program seeks to define the concepts of user empowerment, develop, measure and validate the constructs of user empowerment in an enterprise systems context. In addition, the program will study the correlation of user empowerment with ES success.

2. Literature Review

All ES vendors such as SAP, Portals, PeopleSoft, and Oracle are software packages that promise the seamless integration of all information flowing through a company, across all business processes including customer relationship, vendor management, accounting and finance, supply chain management, marketing, and human resources. ES have increased the ability of organizations to gather more information in greater detail and in real time, and widespread vertical and lateral dispersal of information throughout the organisations [1]. This expanded information makes the users more visible across the organisation and thus is viewed as a means of empowering the users [2]. It is on this potential relationship between ES Implementation and user empowerment that we will focus in the remainder of this paper.

Organisations using ES can be viewed under three distinct categories- those who have successfully

implemented ES; those who never succeeded; and those who are struggling in between the high-end successful organisations and the failures. The next section sets out to define empowerment and then understand the concept by studying its components.

3. Empowerment and Enterprise Systems Context

Empowerment of the employees has been a management goal since the 1980's [3] yet empowerment is an evolving construct and continues to attract management researchers and practitioners [4-12]. Empowerment has been interpreted across a wide spectrum of non-management disciplines such as healthcare, politics, women, minority groups, and education [13]. In management disciplines Conger and Kanungo were the pioneers in establishing a relationship between empowerment and workers' effort-performance expectancies [8, 14].

In the context of management disciplines, empowerment has been commonly perceived in terms of power and authority, rather than as a motivational process shaped by individual differences [4]. Organisations are constantly challenged to sustain and succeed in today's turbulent economic environment of fierce global competition, changing consumer needs, government regulations and globalisation. In such a climate of economic uncertainty organisations embrace change management initiatives in order to adapt and remain a performance driven business [2]. Empowerment is seen as one such practical solution to facilitate the change as it is often considered to be an integral part of a Business Process Re-engineering or Total Quality Management change initiatives [2]. Thus, empowerment is embraced as a management strategy by today's organisations, which aim at enhancing employee satisfaction and improve productivity of the enterprise, thereby contributing towards increased work effectiveness of the employees [15].

3.1. How does empowerment relate to Enterprise Systems?

Livermore and Ragowsky [16] highlight a number of challenges associated with ES implementations. The two key challenges as opposed to other systems are that ERP systems involve the whole organization and require a combination of technical and human expertise to select, develop and implement successfully. Secondly, ES involve re-engineering of the organisation's business processes thereby resulting in organisational cultural change. Given this argument, companies adopting ES need to focus on specific aspects of technical and human factors in order to translate

their efforts to anywhere close to an ES success.

The motivation to investigate empowerment is to understand the role of user empowerment as a predictor in ES success. This calls for an in-depth understanding of the user empowerment concept itself and its underlying constructs should be of paramount interest while studying the framework of user empowerment. The emphasis of the research program is to identify the relationship between the constructs of user empowerment and ES success measures. It is our belief that such an exploration will facilitate better understanding of the ES success' correlation with user empowerment. The next section examines the constructs in user empowerment.

3.2. The Paradigm of User Empowerment

Building on the work of Conger and Kanungo [4], Thomas and Velthouse [8] defined psychological empowerment as intrinsic motivation manifested in four cognitions reflecting an individual's orientation to his or her work role: meaning, competence, self-determination, and impact. Another conceptualisation of empowerment defines it as a pattern of experienced psychological states and argues that each dimension of empowerment adds a unique facet to an individual's experience of empowerment [8]. Conger and Kanungo's [4] definition of empowerment as, "a process of enhancing feelings of self-efficacy among organisational members through the identification of conditions that foster powerlessness" is now conceptualised broadly as a pattern of experienced psychological states [8, 17].

Psychological empowerment differs from the structural concept of user empowerment in that it focuses on intrinsic motivation [8] rather than the expanded discretion a user has over how his/her work is to be done in the immediate work environment [1]. Thomas and Velthouse [8] have explicated a comprehensive, cognitive model of "intrinsic task motivation" to describe the empowerment process in individuals. Cognitive variables, referred to as task assessments are impacted by empowerment. These tasks being an array of activities directed towards a goal. The four dimensions of task assessment are included as cognitive variables of intrinsic motivation. These are: impact, competence, meaningfulness, and choice. The model developed by Thomas and Velthouse provides a synthesis of Hackman and Oldham's [18] work on the motivation construct. Following Hackman and Oldham's propositions empowerment in workplace has been widely explored in relation to leadership behaviour [10, 12, 19-21], power and control as relational constructs [4, 22], power perspective in work groups [15], autonomy and decision-making empowerment [23], organisational downsizing [24, 25], and organisational culture [9, 26,

27].

Spreitzer [14] extended the work of Thomas and Velthouse [8] and hypothesised that a high level of four dimensions namely meaning, competence, self-determination and impact in an individual, result in a high level of empowerment. Further empirical research examined how these four dimensions of empowerment were differentially related to effectiveness, work satisfaction and reduced job related strain [11] but did not examine antecedents of empowerment [28] in context of organisation. The Spreitzer, Kizilos, and Nason's [11] study also was limited in that the researchers did not identify and test for outcomes that could appropriately serve as measures of success for the organisation because after all, the entire exercise of empowerment in workplace, is to gain strategic advantage in current turbulent economic environment [17]. Another area that remains left out of Spreitzer's outcomes of empowerment is lack of adequate measurement of effectiveness in terms of net compounded outcome emerging from empowered behaviours of employees.

The individual is the basic unit of analysis in this research on user empowerment. We pose the question on how this construct affects the organisation both as a process and as an independent variable. The user empowerment process must be embedded as part of design, training, and evaluation and must be an iterative process in itself. For an organisation to be empowered, information is a central component as Psionos et al. [2] state that employee decision making is critically dependent on the timely distribution of the right information in the cycle of various business processes. The logic here is that employees will be more understanding of the reasons for business decisions and as a result more committed to the organisation's action [3]. Simply informing employees via formal authority that they are now empowered, without providing training to develop needed skills and knowledge, will nearly always result in failure [29].

The characteristics of user empowerment within the ES context are: to encourage people to take a more active role in their learning with respect to the adopted ES; to take responsibility for self learning, and; to enable people's participation in demanding decision processes [30]. This latter aspect can be conceived as both self-initiated and initiated by others, making a commitment to common goals, taking risks and demonstrating initiative and creativity [31]. These characteristics suggest user empowerment to be a multidimensional concept similar to the empowerment construct [8, 11, 20, 28] and a dynamic phenomenon [32] that needs to be nurtured by the holistic organisational environment within which it operates [3].

User empowerment in ES context is in many

respects analogous with user involvement that has been widely studied in Information Systems (IS) implementation [33, 34]. User involvement is referred to participation in the IS system development process by representatives of the target group. Doll & Torkzadeh [34] report that end user satisfaction levels are significantly correlated with their involvement in the design of the system. Along similar lines, increased job satisfaction and systems usage are reported as being positively related to involvement in the development process by Lucas [35], or Baroudi et al. [36].

The next section develops and justifies the motivation for the research program and study by giving an overview of the perspectives on ESS and IS success models.

3.3. Justification for the Study

The value proposition of adopting ES from SAP, Baan, Oracle, PeopleSoft and their software packages enticed organisations to invest heavily in these systems. The key drivers in the increased trend to adopt these complex systems can be summarised as: fierce globalisation of business; legacy systems and Year 2000 system concerns; increasing national and international regulatory environment e.g. European Monetary Union; Business Process Reengineering (BPR) and the current focus on standardisation of processes e.g. ISO9000; scaleable and flexible emerging client/server infrastructures; and trend for collaboration among software vendors [37].

When an organisation decides in favour of a new Enterprise Systems, its implementation is a socio-technical process, affecting tasks, people, technology and structure [38]. Markus and Tanis [39] also identify this element and proposed the engagement of the users as a key variable. An organisational change process such as ES implementation may include many factors for success and one of the potential factors is empowering users. This logically follows from the fact that those affected by the change in technology (users of the ES) must be a part of the change. Workgroups and teams specifically, are more likely to be advantaged or disadvantaged by organisational change as compared to individuals. This clearly echoes AES CEO Roger Sant's philosophy on empowerment where he suggests empowerment makes decision making safer since the team feels it is fully accountable and will take more responsibility than if it feels that their manager is accountable [40]. Therefore it makes intuitive sense to consider a more collective measure of user empowerment such as workgroup and if it better facilitates ESS as compared to individual user empowerment. This latter aspect is a focal question of this research project.

Many authors identify change management as a critical success factor for enterprise system success, but fail to clearly articulate the means of engaging the user. Empowerment theory seen above may assist here.

Perspectives on ESS

Organisations have spent significant resources and many years implementing their ES and realised that it is an implementation that was extremely difficult and an expensive change to roll back [41-46]. Research points out that many high profile organisations failed in their ES projects implementation [41-46] [47-49]. The recent collapses and failure of such large scale complex ES implementations initiated several researchers to conduct ES implementation studies that implicitly and explicitly suggest the need to critically evaluate the risks and success factors of ESS [41-46].

Markus and Tanis [39] give a phased approach of an organisation's experience with an enterprise system, which Holland, Light and Gibson [50] echoed. The characteristics of an infused organisation appear to be related to the constructs of empowerment. Models of Information Systems success have been developed [51] and exploited in the Enterprise Systems success area [52] [53]. This research will use the established models as the dependent variable in the correlation study.

4. Empowerment Model

The four dimensions of meaning, competence, self-determination and impact, multiplicatively combine to create high psychological empowerment (see Figure 1) [54], which leads to the positive outcomes of effectiveness, work satisfaction and reduced job related strain. These terms are next detailed.

Meaning

According to the job characteristics model [18], the degree to which jobs are motivating can be measured through five core job characteristics: skill variety, task identity, task significance, autonomy, and job feedback. Hackman and Oldham's research led to the conclusion that "to the extent that a job contains these five characteristics, three psychological states are produced: experienced meaningfulness of the work, experienced responsibility for outcomes of the work, and knowledge of the actual results of the work activities. Spreitzer developed the above meaningfulness of work as the meaning dimension of empowerment. Meaning is believed to be a vital component of an individual's empowerment experience [17] since it acts as the fit between the requirements of one's work role and one's beliefs, values and behaviours [55].

Competence or self-efficacy, specific to one's work, is a belief in one's capability to perform work activities with skill [56]. An indicative outcome of competence would be self-confidence in one's ability to perform the task.

Self-Determination is a sense of choice in initiating and regulating one's actions and the ability to endorse one's actions at the highest level of reflection [57]. The self-determination theory evolved by Deci and Ryan [58] posits that self-determined individuals experience a sense of freedom to do what is interesting, personally important, and vitalizing.

Impact is a state of belief in individuals that they can influence the system, of which, they are an integral part of. Examples of indicative outcomes include *personal initiative* which is characterised by an individual's proactive attitude to work without prompting or direction from others [59]; *voice* which is a behaviour exhibited by group members making suggestions and speaking up in the interest of the company or group even when the group is not appreciative [60]; *taking charge* a discretionary behaviour where organisations motivate employees to go beyond the boundaries of their jobs to undertake constructive efforts that effect how work is executed [61]; *proactive coping* when individuals undertake proactive measures to avoid potential events that may cause stress [62]; and *empowerment* which is a direct result of a sense of belief that an individual's actions are influencing the system [14]. These elements are shown in the Figure 1 below.

4.1. The Research Scope, Questions and Aims

Although there have been extensive studies in ES implementation success, critical success factors of ES success [47] and measuring ES benefits [52, 63], there has been no prior significant research that links the user empowerment aspect of enterprise systems success. It is this gap in the research that this research program addresses.

The literature review to date has enabled understanding of existing models, theories and frameworks on empowerment in workplace. An in-depth analysis helped in clarifying the constructs of user empowerment and provided direction for identifying the research gap in the existing framework of the empowerment concept. Here the object of research is user empowerment and its strength in predicting ES success. The related investigative questions vary in their level of detail, purpose, and include:

- What constitutes user empowerment in an ES context?
- Is there a correlation between user empowerment

and ES success?

- Which factors assist or inhibit ES success?
- How can user empowerment be measured?
- What characteristics of user empowerment are vital to Enterprise System Success?

Thus, the specific aims of this user empowerment research are:

- to integrate measures of user empowerment extending Spreitzer's model and instrument;
- to assess the effects of user empowerment on change management practices in enterprise systems context, and;
- to develop and pilot an instrument for measuring user empowerment and correlate with ES implementation success.

4.2. Objectives of the program of research and investigation

This research project is a part of a larger program of research called Organisational Readiness for Enterprise Systems (ORES). There are three sub-researches embedded within: the affect of organisational culture; leadership and risk aversion issues; and user empowerment. Each of these studies are inter-dependent.

The proposed study will contribute to the parent project "Organisational readiness for enterprise systems" across several of its phases. It is further aligned with several objectives of the main study and will seek to validate several of its propositions. The direct contribution to subsequent phases of the parent study is likely, however dependent on further coordination of team efforts. The research questions listed under objectives of the program of research and investigation (*section 3.2*) have been developed in accordance with the above research aims and propositions.

5. The Research Methodology

The use of an appropriate methodology for a piece of academic research is fundamental to the research's success [64, 65]. The research uses both qualitative as

well as quantitative methods. A multiple case study method is applied. The research will progress in three stages namely pre-pilot in an organisation that has recently implemented an ES; a pilot study within government public sector agencies and; finally the main study across different industry sectors. A survey instrument will be designed and developed for quantitative analysis. The pre-pilot is being conducted to validate the user empowerment survey instrument and will facilitate in validating the instrument for the subsequent phases of the study. The case study methodology adopted can be justified as below: subsequent phases of the study. The case study methodology adopted can be justified as below:

As Yin [66] advocates, a case study method is best suited to a research if it poses "how" or "why" questions criteria, the investigator has minimal control or no control over events, and the focus is a contemporary set of events. The proposed research meets all three conditions i.e. the questions ask "how" and "why" the researcher will have no control of events within the selected organisations, and both user empowerment and ES are contemporary phenomena.

As demonstrated in the literature review, the essence of the research program is concerned with ES stakeholders' (users of the ES) perceptions of their system's development, implementation, and ultimate success. It is not the intention of this research to examine in detail *why* the users hold these views. Thus, the most appropriate philosophy for this research will follow the positivist approach described by Robson [67], i.e. the formulation and testing of hypotheses. Hypothesis testing involves the collection of quantitative data, which is then analysed for statistical significance, using an appropriate technique.

Figure 1. Partial Nomological Network of psychological empowerment in the work place [11]

Organisation Selection

A suitable number of organisations will be chosen from different sectors such as retail, higher education, banking, mining, defense and healthcare. The primary reason for choosing a cross section of sectors within the economy is to achieve a more generic implementation of ES picture across a diverse range of business processes. Another aspect to be considered while selecting these organisations will be the broad range of ES thus making the study generic for extended ES. The chosen organisations will all have implemented their ES (2-4 years ago) or will be in the implementation life cycle during the time when the case study will be conducted. In this time frame the ES success and the strength of user empowerment should be clearly evident for those who

have implemented ES. There are four categories of organisations that will be targeted in the data collection phase. These categories are:

1. Stalled adopters (organisations where the use of the ES has peaked or even stopped)
2. Adapters (organisations who adapt their business processes to suit the purchased ES)
3. Expanders (organisations who seek for additional business functionality)
4. Exploiters (organisations who seek strategic and innovative ways of deploying the ES technology)

Figure 2: Study progression and phases
Data Collection

Unit of Analysis

It is important to clearly define the units of analysis for measuring user empowerment and ESS and the possible correlation between them. Individual users will be the unit of analysis when measuring user empowerment.

Data will be collected via interviews, questionnaire and survey instruments. The selection of the instrument will be decided upon the nature of the variable being measured. The key informants who agree to participate through these instruments will be notified in advance about the ethical clearance, privacy and confidentiality issues regarding the data collected. The selection of target informants may vary within the range of users of the ES (i.e. senior managers, administrators, operational staff, and specialised staff such as payroll officers to

general users within various business processes of the organisation).

6. Conclusion and Outlook

This paper has presented initial framework of a study aimed at understanding and assessing user empowerment on ES success. The user empowerment constructs have been developed based on the work by [11, 14] and related empowerment literature in order to present a complete set of constructs that explain user empowerment in ES context. Further analysis will be done in relation to the measures of ESS [53] and user empowerment constructs. We are currently progressing with the pre-pilot study to be conducted within department of a large organisation that has implemented an ES. The rest of the study is as shown in figure 2 above.

The intended contributions of the research program are:

- To provide a definition of the construct user empowerment within the ES context.
- To develop, test and validate user empowerment instrument.

To Correlate user empowerment constructs and ESS constructs and finally to correlate user empowerment and ESS.

Abstract

In today's global marketplace, individual firms no longer compete as independent entities but rather as integral part of supply chain links. In order to cater for the increasing demand on collaboration between supply chain partners, the technology of intelligent agent has gained increased interest in supply chain management. However fewer researches have clearly investigated the mechanism about agent applications in this area. In this paper we are to study the way how to incorporate intelligent agents into supply chain management from the perspective of agent-oriented system analysis and design. A multi-agent framework for collaborative planning, forecasting and replenishment in supply chain management is developed, in which supply chain collaboration models are composed from software components that represent types of supply chain agent, their constituent control elements, and their interaction protocols.

1. Introduction

Supply chain management system is an integrated system of suppliers, factories, warehouses, distribution centers and retailers. In today's global marketplace, individual firms no longer compete as independent entities but rather as integral part of supply chain links, and there have been increasing attentions on the collaboration in supply chain management. With the increasing research work on collaboration in supply chain management systems, the technology of intelligent agent has been widely applied in this area. A supply chain can be looked as a network of autonomous or semiautonomous business entities collectively responsible for procurement, manufacturing and distribution activities associated with one or more families of related products [1]. There have been a number of researches exploring the agent application in supply chain management and collaboration. However, the approaches involved in most applications are somewhat special, and more efforts are needed to investigate the mechanisms how to incorporate multi-agent technology into supply chain management and collaboration.

In this paper, we will investigate the mechanism how to apply the technology of intelligent agents into the collaboration in supply chain management. The agent-oriented methodology is used for the analysis and design of agent-based systems for supply chain collaboration. In this multi-agent framework, we

propose a society of agent integrated with legacy supply chain systems to cater for the increasing demands on supply chain collaboration between partners and strategic adaptation to dynamic environment. Each agent carries out a specific function; they work together to perform tasks in supply chain collaboration in an autonomous and collaborative fashion. The rest of the paper is organized as the follows. Section 2 briefly reviews the relevant literature on supply chain collaboration and the application of agent technology in supply chain management. The methodology of agent oriented analysis and design is briefly introduced in section 3. Following this methodology, a multi-agent framework for supply chain collaboration is developed in section 4. Finally, some conclusions are addressed in section 5.

2. Literature review

2.1 Collaboration in SCM

Supply chain is a set of activities that span enterprise functions from ordering and receipt of a raw materials through the manufacturing of products and the distribution and delivery to the customers. In today's competitive environment, single enterprises acting alone can no longer provide maximum value to many of today's demanding customers. The new competitive realities are causing suppliers, manufacturers, wholesalers, and retailers alike to rethink their strategic initiatives with their supply chain partners [2]. In recent years, a number of collaborative-based initiatives are addressed for supply chain management. Vendor Managed Inventory (VMI) is probably the first trust-based business link between suppliers and customers. It is an arrangement where the supplier, not the customer, decides when and how much of the customer's stock is replenished. We can also see some similar trends such as Supplier Managed Inventory (SMI) or Joint Managed Inventor (JMI), which are different ways of looking at the same thing [3]. Today, the focus is shifting toward programs like Collaborative Planning, Forecasting and Replenishment (CPFR). CPFR is a collaborative initiative aimed at "making inventory management more efficient and cost-effective, while improving customer service, and leveraging technology to significantly improve profitability" [4]. Nowadays, CPFR has won the support of companies in the drug, grocery, general merchandise, and apparel industries.

2.2 Intelligent agents in SCM

Intelligent agents can be seen as software agents that enjoy such properties as autonomy, co-operativity, reactivity, pro-activity, and mobility. Actually, an agent is a computer system that is situated in some environment, and that is capable of autonomous action in order to meet its design objectives [5]. A generic agent has a set of goals, certain capabilities to perform actions, and some knowledge about its environment. To achieve its goals, an agent needs to reason about its environment (as well as behaviors of other agents), to generate plans and to execute these plans. In recent years, there has been considerable growth of interest in the design of a distributed, intelligent society of agents capable of dealing with complex and distributed problems, and vast amounts of information collaboratively. Software agents offer a convenient way of modeling processes that are distributed over spaces and time. They are good candidates for domains that require constant adaptation to changing environment or demands. Endowed with extended communication capabilities by the advances in network technologies, multi-agent systems are being used in an increasingly wide variety of applications involving inter-enterprise collaboration, extending the boundaries of strategic partnership to wherever the network technologies can reach.

A supply chain encompasses all activities associated with the flow and transformation of goods and services from the raw material stage, through to the end user, as well as the associated information flows. Intelligent agents with their cooperative properties are suitable candidates for collaborative activities in business organizations [6,7]. They can carry out intelligent such tasks as joint decision on orders, monitoring on product activities, and adjustment on replenishment policies, in an autonomous and collaborative way [8, 9]. The combination of supply chain process definitions with an advanced infrastructure in terms of multi-agent systems has the potential to make possible a real strategic competitive advantage for the entire supply chain and will enable new forms of business and work [10]. Nowadays there is an increasing number of researches exploring the agent application in supply chain management, in which the multi-agent paradigm is utilized for modeling and analysis of supply chains. However, the solutions involved in most applications are somewhat special, and more generic approach is needed to support agent application in supply chain management. Furthermore, more efforts are needed to clearly investigate the collaboration mechanisms and collaboration processes in supply chain management, especially at strategic level with respect to multi-agent technology.

3. Agent-oriented system analysis and design

Traditional software development techniques fail to adequately capture an agent's flexible, autonomous problem-solving behavior, the richness of an agent's

interactions, and the complexity of an agent system's organizational structures, and software engineering techniques are specially tailored for the analysis and design of agent-based systems based on agent-specific concepts [11]. The agent-oriented analysis and design process is concerned with how a society of agents cooperate to realize the system level goals, and what is required of each individual agent in order to do this.

In agent-oriented system analysis, we view an organization as a collection of roles, that stand in certain relationships to one another, and that take part in systematic, institutionalized patterns of interactions with other roles. Thus, the organization model is comprised of two further models, role model and interaction model. The *roles model* identifies the key roles in the system, and can be viewed as an abstract description of an entity's expected function. Such roles are characterized by some attributes, e.g. permissions/rights and responsibilities associated with the role. The inevitable dependencies and relationships between the various roles in a multi-agent organization are central to the way in which the system functions. Such links between roles are captured and represented in the *interaction model*, which consists of a set of protocols definitions, capturing the recurring patterns of inter-role interaction.

The design process involves generating three models followed. The *agent model* aggregate roles into agent types, and refine to form an agent type hierarchy, as well as document the instances of each agent type using instance annotations. The *services model* identifies the main services that will be associated with each agent type. For each service that may be performed by an agent, we can document its properties, such as inputs, outputs, pre-conditions, and post-conditions. The *acquaintance model* documents the acquaintances for each agent type; it defines the communication links that exist between agent types.

4. Agent-oriented collaboration in SCM

Based on the above methodology of agent-oriented analysis and design, we will investigate the mechanism how to apply the technology of intelligent agent into the collaboration of supply chain management. A multi-agent framework for collaborative planning, forecasting and replenishment in supply chain management is to be developed, in which supply chain collaboration models are composed from software components that represent types of supply chain agent, their constituent control elements, and their interaction protocols.

4.1 Domain analysis

In this paper, we focus on collaborative planning, forecasting and replenishment in supply chain management. With such collaboration, a customer sends data about sale activities and inventory status to a supplier, and the supplier then uses the data to generate replenishment forecast that will be shared with the customer before it is executed. The kind of

collaboration between suppliers and customers can be applied in different kinds of partnerships, such as component suppliers and product manufacturers, manufacturers and retailers (or distributors), distributors and retailers. For purpose of simplifying the discussion, we focus on the collaboration between manufacturers and retailers.

With the emergency of new telecommunications and computer technology, the way products are bought and distributed is dramatically affected. The collaboration between manufacturers and retailers can be web-based, EDI based or through other network technology, as shown in Figure 1. According to related issues about collaborative planning, forecasting and replenishment [3], the basic transactions in such collaboration process are outlined in the Figure 2. **Collaboration Planning**, the first step for collaboration, is to make a

collaboration plan, which may contain replenishment policy (e.g. inventory levels, fill rates), monitoring policy (e.g. critical inventory, shipment delay), performance measures (e.g. forecast accuracy rate, on-time delivery), communication process, and so on.

Product Activity Reporting is the backbone of collaborative supply chain management, in which the manufacturer's sale and inventory information is typically sent to the manufacturer on a scheduled basis. Based on the report of product activities, the manufacturer may perform **replenishment forecasting** and create order suggestions if necessary. The retailer can review the order suggestions and then determines if the order suggestions are proper or need modifications. Subsequently, an order may be generated based on such **joint decision** from both sides.

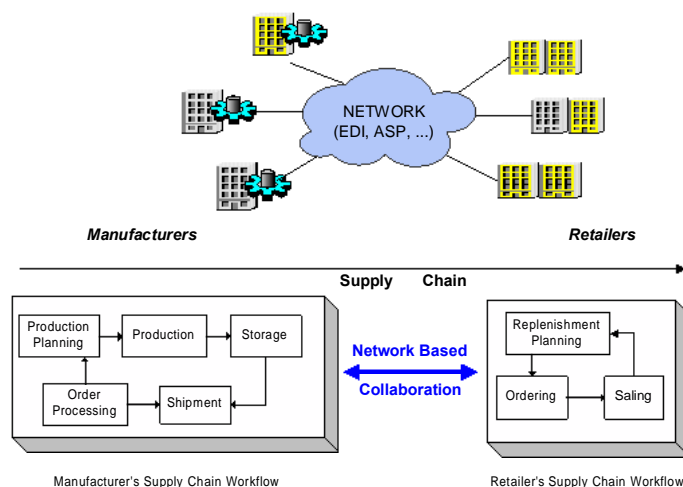

Figure 1. Network-based Collaboration in Supply Chain

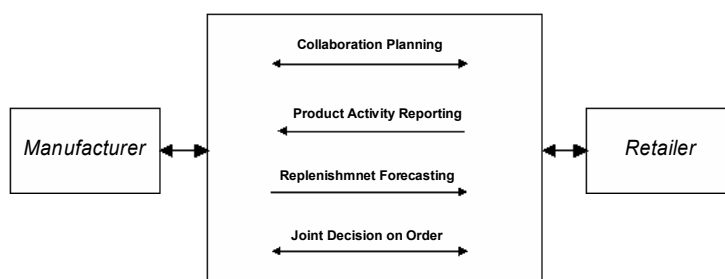

Figure 2: Transactions in the Collaboration Process

After an order is generated based on the consensus from both sides, the manufacturer will inform the retailer what product to expect from him. There are several kinds of message being used for this transaction. The *Validated Order* used as purchase order acknowledgment contains the product numbers and quantities ordered on the retailer's behalf. Then, the manufacturer picks and ships the order and transfers a *Shipment Notice* to tell the retailer exactly what is being sent and when it is shipping. When the shipment is received, the retailer transfers a *Receipt Advice* to tell

the manufacturer exactly what was received. The manufacturer can then match this to his purchase order to determine any potential problems and send out an *Invoice* to the retailer for payment.

4.2 Agent hierarchy

Moving from the above analysis on supply chain collaboration, we design the agent model and present it as agent hierarchy in Figure 3. We classify these agent roles into three classes, task agent, user agent and

information agent; each class contains several sub-

classes as the follows.

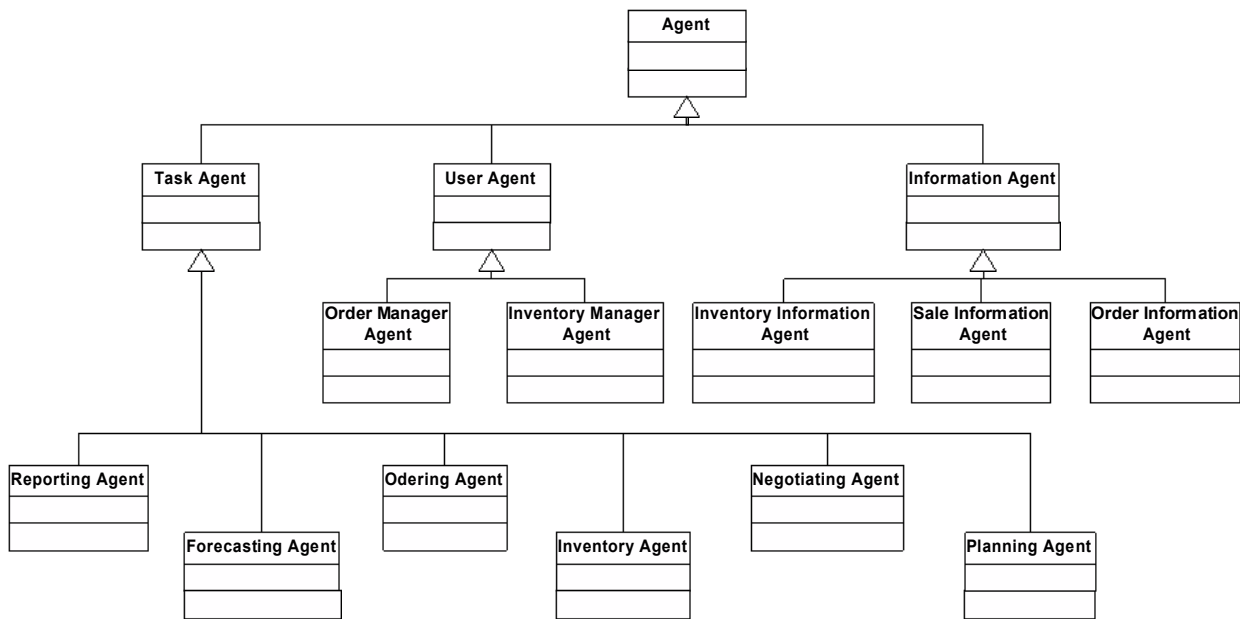

Figure 3. Agent hierarchy for supply chain collaboration

4.2.1 Task agent

Several kinds of task agent are proposed to carry out business operations involved in the supply chain collaboration.

- The **Reporting Agent** is to send the retailer's sale history file and current product activity reports to the Forecasting Agent of the manufacturer on a scheduled basis.
- The **Forecasting Agent** is responsible for conducting data analysis on retailer's sale history and current product activity reports to generate replenishment forecast or order suggestion. The order suggestion is made on the calculation of reorder point according to the replenishment agreement between partners.
- Once receiving an order suggestion from the Forecasting Agent, the **Ordering Agent** will ask the order manager for check and modification, and then send it to the Inventory Agent for review and confirmation. If the order quantity is over pre-defined limitation, the Inventory Agent will ask the inventory manager for validation. After validation, the order is sent back to the manufacturer side for confirmation and execution. Subsequently, the Ordering Agent will start to monitor the process and progress of this order.
- If the order suggestion is not accepted by the retailer side, a **Negotiating Agent** can be activated to guide both sides to make an online discussion in order to achieve some consensus for the joint decision. Also, the manager of both sides can start this agent for negotiation

on other issues, e.g. adjustment on collaboration plan.

- The **Inventory Agent** is charged with the inventory management for the retailer. Besides reviewing order suggestion from the manufacturer, this agent will keep track on inventory status, raw materials/components shipment and receiving. For example, if one kind of raw material in the inventory is detected in a critical status, the Inventory Agent will ask the Forecasting Agent to generate a replenishment order suggestion in a real time fashion.
- The **Planning Agent** is proposed to make collaboration plans for supply chain partners. It can also make suggestions about collaboration adjustment based on its planning knowledge and analysis on supply chain performance, and send it to managers for reference. When the managers decide to adjust the plan, the Planning Agent can help distribute the content of the adjustment to related agents. For example, the modified replenishment policy will be sent to the Forecasting Agent and Inventory Agent to adjust their activities.

4.2.2 User agent

User agents act as effective bridges between the users and the system in order to make the human-computer interface more intuitive. There are two kinds of user agent in this system; each represents a type of user who interacts with the system. The **Order Manager Agent** enables the order manager of the

manufacturer to read replenishment forecast, check order suggestions, validate orders, control progress of orders, and negotiate with the retailer through the help of several task agents. The **Inventory Manager Agent** enables the inventory manager of the retailer to review and validate order suggestions, check inventory status, negotiate with partners, and etc.

4.2.3 Information agent

Information agents are responsible for operations on multiple, heterogeneous and distributed information sources with a view to controlling resources of business processes. Although there is no need for centralized storage of all knowledge regarding supply chain collaboration, there could be consistent knowledge repositories that maintain and integrate all information related to collaboration tasks. In this way, the various agents that make up the system can exchange knowledge regarding entities involved and deal with supply chain management in a collaborative manner. In our system there are three types of information agent, **Order Information Agent**, **Inventory Information**

Agent, and **Sale Information Agent**, each responsible for access to the corresponding information resource. Moreover, such information resources may form an important base for agents' collaboration in supply chain.

4.3 Agent architecture

Based on the above description of various agents in the system, we are to design the internal structure and operations of each agent as its service model. Generally, the design of agent architecture considers an agent knowledge base, its operational facility and its external interface. Knowledge is required by each agent to perform its internal and external activities. It consists of resource status information, rules for particular tasks, information about other agents, and so on. The operational facility can execute different functions and provide collaboration with other agents. The external interface envelops an agent and provides access to it via a well-defined interface. It is also the primary conduit for communication between agents.

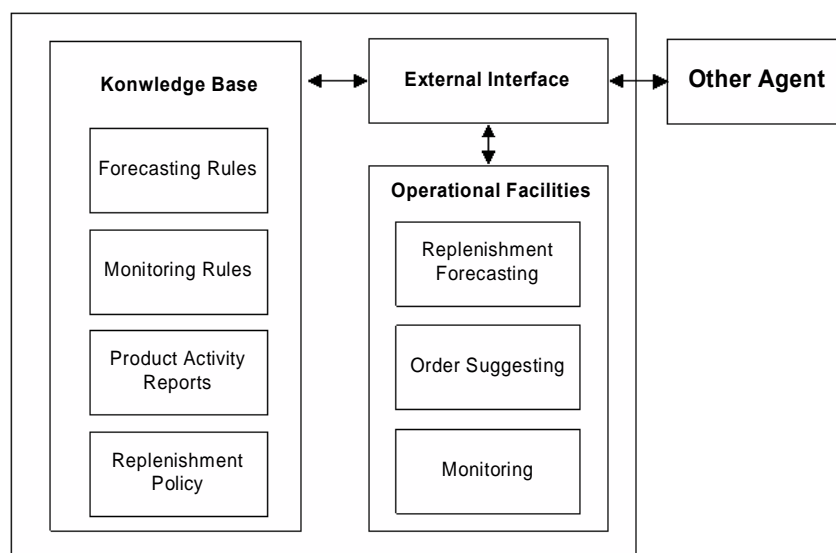

Figure 4. Architecture of a Forecasting Agent

In the interests of brevity, we only present the architecture of the Forecasting Agent as an example. As presented in Figure 4, the **external interface** enables the Forecasting Agent to communicate with outside, i.e. receiving product activity reports from the Reporting Agent and sending order suggestions to the Ordering Agent. The **operational facility** is represented by a set of functions followed. The replenishment forecasting function is responsible for conducting data analysis on current product activity reports as well as retailer's sale history to generate replenishment forecast. The order suggesting function works based on the calculation of reorder point specified in the replenishment policy, e.g. stock level, fill rate, and etc. The monitoring function is proposed to keep track on product or sale activities to detect unexpected events happened in the retailer side.

Knowledge is required by the Forecasting Agent to perform its internal and external activities. There are several types of knowledge for this agent to perform various tasks, including forecasting rules, monitoring rules, product activity reports, and so on. Furthermore, the Forecasting Agent can access the sale information through the Sale Information Agent to assist its forecasting activity.

4.4 Agent communication and collaboration

Interaction among agents, an important aspect on research of multi-agent system, is set up on the base of lower-level data communication that takes charge of transferring data without semantic from end to end. Unlike data communication, interaction among agents

is mainly control information with semantic and knowledge. KQML (Knowledge Query and Manipulation Language) is a language that is designed to support interaction among agents [12]. Message transferring with respect to information flows models the exchange of information and contributes to the collaborating processes between supply chain agents. For instance, after a purchase order is created based on the joint decision between the manufacturer and the retailer, several types of message may be transferred between the two sides, such as “validated order”, “shipment notice”, “receipt advice” and “invoice”. All the messages are structured documents based on KQML language, and can be dealt with by each agent

according to the event selection mechanism that is subject to some control rules such as first in first out (FIFO).

Our collaborative multi-agent environment is to provide the application independent framework to meet the infrastructure needs of everyone involved in supply chain collaboration. With the multi-agent environment, collaboration goes beyond the simple, serial exchange of information between varied disciplines or domains. It ensures that knowledge can be shared and used at the moments when it can best impact the work. The interaction and collaborations among agents in our system are described in Figure 5.

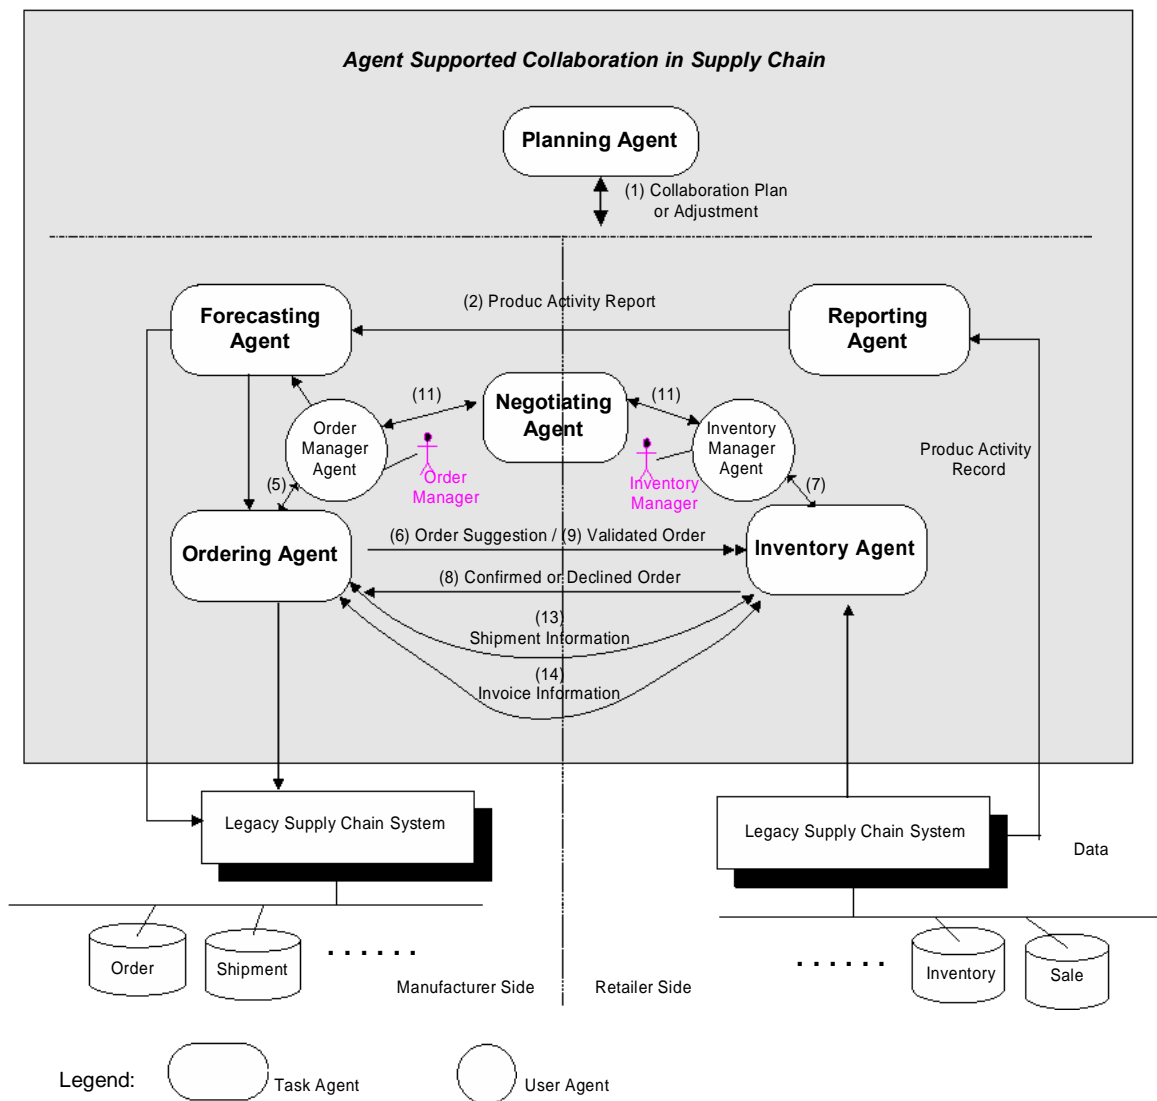

Figure 5. Agent interaction in supply chain collaboration

As shown in Figure 5, the first step for supply chain collaboration is to make a collaboration plan between partners, which may include replenishment policy, communication process, monitoring policy, performance measures, and etc. The managers can

submit the collaboration plan to the Planning Agent and let it distribute the plan to related agents to initiate their activities (1). The Reporting Agent sends current product activity reports to the manufacturer on a scheduled basis (2). Then, the Forecasting Agent

conducts data analysis on these reports and generates replenishment forecast (3) or order suggestions (4). After receiving an order suggestion from the Forecasting Agent, the Ordering Agent will ask the order manager to check or modify this suggestion (5) and send it to the Inventory Agent for automatic validation (6). If the order quantity is over pre-defined limitation, the Inventory Agent will ask the inventory manager for check and modification (7). After such process, the order is sent back to the manufacturer side (8) for confirmation (9) and execution (10). If the order suggestion is not accepted by the retailer side, a Negotiating Agent can be started to facilitate both sides to make a discussion for some consensus if possible (11). When the products are to be delivered to the retailer (12), the Ordering Agent will transfer a shipment notice to the Inventory Agent (13). Then, the Inventory Agent will check the matching of the product order and the shipment notice, and send receipt advice for payment while receiving the expected products (14).

5 Conclusions

In this paper, we applied the methodology of agent-oriented analysis and design to the system development of supply chain collaboration. Based on the analysis on supply chain collaboration paradigm, a multi-agent system framework is developed, in which various types of agents are proposed with their internal services and external interactions to perform collaborative activities in supply chain management. The key concepts in this methodology are agent roles, which have associated with them responsibilities, permissions, and can interact with one another in certain ways specified in the protocols of the respective roles. We believe this work is not only of pragmatic value for supply chain collaboration applications, but also assists a precise understanding of some concepts and terms in agent-oriented system development.

Strategic Learning and e-Business Solutions in a Pharmaceutical Organization.

Prof. Marjatta Maula, Dr. (Econ.), M. Sc.
Institute of Business Information Management
Tampere University of Technology
marjatta.maula@tut.fi

Abstract

This paper analyzes how e-business solutions facilitate strategic learning in a globally operating industrial organization. Because of confidentiality, the case company is called here The Pharmaceutical Company. The theoretical framework consists of strategic composition[®], an interpretation of autopoiesis theory (the theory of self-producing systems). The framework emphasizes both interaction with the business environment and self-referentiality to ensure efficient utilization of accumulated knowledge.

The Pharmaceutical Company is a healthcare company that manufactures and markets pharmaceutical products and services for certain illnesses. It is not only a world leader in the care of one serious illness but also has a leading position in some other pharmaceutical product areas.

The Pharmaceutical Company has created comprehensive web-based solutions that are centrally coordinated, locally maintained, and enable interactive communication between the company, consumers and professionals.

Development of these solutions has resulted in much of the tacit knowledge becoming explicit, thus facilitating organizational learning both at the coordinating and local levels. The Pharmaceutical Company's web solutions have also facilitated interaction with consumer and professional communities, as well as provided a medium for education. Many parties outside the company have thus become more firmly involved in the learning processes and have gained the opportunity to improve their knowledge.

Although many regulations prevent using the information produced by the system, even that information available within the limits of the regulations has remained underutilized. The Pharmaceutical Company has many potential opportunities to learn from the interaction offered by its web-based e-business solutions.

1. Introduction

1.1 E-business solutions as enablers for strategic learning and knowledge management

For many firms, the major motivation for implementing e-business solutions is to increase efficiency and service capability, and to enable new business processes. This paper assumes that e-business can also increase innovativeness, learning and a capacity for renewal that are increasingly important factors affecting the competitiveness of a firm.

However, it is not clear how firms utilize e-business solutions for learning, knowledge creation and renewal. Motivation, opportunities and methods to apply e-business solutions may vary widely across various businesses. The firms could learn from their customers and markets by tapping into potential information and knowledge that can be channeled through e-business solutions. They could also learn from each other, by sharing knowledge about their plans, progress, experiences, and best practices. Big corporations have relatively good opportunities to acquire knowledge about feasible solutions outside the firm, to test them and to invest in them.

The theoretical background and key concepts, such as autopoiesis theory, the living composition[®] model, major knowledge flows, boundary elements, e-business and knowledge management will be defined briefly in Appendix 1.

1.2 Research project

This paper is part of the research project "Strategic Management of Innovativeness, Renewal Capability and Knowledge, and the Role of e-Business", which aims to investigate three different internationally operating organizations that utilize e-business in their business relations. The project analyzes the following organizations:

- the case company of this paper is a globally operating pharmaceutical company that has developed a comprehensive and culturally sensitive business-to-consumer e-business solution. E-business solutions are also used to connect the firm with professionals.
- Metso Paper (part of Metso Corporation) is an example of a global corporation that is developing e-business solutions to support the

product life cycle of the paper machines supplied to customer firms.

- Outokumpu Copper Products OCP Europe - Electrical Power & Components Unit, has created a sophisticated business-to-business extranet solution for a relatively small number of customers. The customer relationships are based on long-term contracts, and interaction with them is complex by nature.

These companies were selected among internationally recognized innovators and frontrunners in the strategic application of e-business. The purpose is to create new knowledge and to facilitate benchmarking and learning from their experiences. They differ considerably from each other in the methods used to apply e-business.

The study applies a qualitative multiple-case study methodology, which can convey rich and dense data about complex, dynamic research phenomenon. Four persons were interviewed for this case study at Pharmaceutical Company eBusiness Department on June 7th 2002:

- Manager, eBusiness Department
- Project Manager, the communities' site
- Project Manager, the professionals' site
- Project Manager, an additional illness' site

The interviews were conducted in English, recorded and transcribed.

The research project has been financed by the Foundation for Economic Education, and later also by Seinäjoki Polytechnic. The project reports have been finalized at the Tampere University of Technology. The author extends a warm thanks to all persons and organizations that have contributed to this study.

1.3 Research question

It is not clear how firms utilize e-business solutions for their own learning and knowledge creation, and more importantly how they exploit e-business-enabled interaction with the customers and increased, more rapid access to new knowledge. Therefore, this study investigates two research questions:

How does The Pharmaceutical Company learn and create new knowledge by utilizing e-business solutions?

2. The Pharmaceutical Company

The Pharmaceutical Company is a healthcare company that manufactures and markets pharmaceutical products and services. It is a world leader in the care of a very

general illness, and also has a leading position in other product areas. The story of The Pharmaceutical Company started in the first decades of this century. The current company is a result of a merger. The company has production facilities in almost ten countries, and affiliates or offices in about 70 countries. The Pharmaceutical Company reaches out to almost 200 countries around the world. The company has about 20,000 employees.

The Pharmaceutical Company specializes in products and services for the treatment of a serious illness that can occur at all ages. The illness is becoming increasingly common in developed and developing countries.

3. E-Business Solutions at the Pharmaceutical Company

3.1 E-business strategy at Pharmaceutical Company

According to the manager of the eBusiness Department, the e-business strategy of The Pharmaceutical Company consists of three focus areas. One focus is corporate communication, which covers the corporate site and all the affiliates. The second area consists of websites that focus on patient communities and professionals, while the third area covers the products.

Although the content of Pharmaceutical Company's e-business solutions is basically local, it is based on shared structures and principles created at the eBusiness Department at the headquarters. The strong orientation towards localization allows for differences in culture and lifestyle, regulations, logistics, and other relevant aspects. In addition to the local pages, there is also an international version for the professionals' website.

We have the international one (version), yes. Because if we have people on the ground in each country we can include local events and local debate on the site, which we cannot do from the headquarters. Which is why we have the international one. But it needs some resources to maintain. And they are very expensive. (Project Manager)

The availability of Internet connections and the capability of the population to use it are improving, which has implications for the applications directed at consumers.

The challenge is Internet because most of the older people are not looking into the Internet today. But also that is changing. For example we can see that women in the age of 40 and up are looking into the Internet. Whereas the people over 60 years don't. But in the future people in that age will be familiar about the Internet and use it. (Manager)

The Pharmaceutical Company uses communities to increase the awareness of the company. The illness community is the largest one. ---. However, the representatives of Pharmaceutical Company emphasize that they are not allowed to collect information about the patients.

The heart of the e-business strategy is that the websites launched by Pharmaceutical Company are based on *a content management system*, which offers a useful user-friendly interface, where people can easily update the content if they have basic word-processing skills. The strategy also includes *local infomasters*. They are not technology specialists who do coding or maintain web services.

Local infomaster is responsible for moderating the community, making sure that there are always updated news on the front page and links to the interesting stories about local initiatives, facilitating the dialog and so on. That is a very important part of the site. And that's why don't call them the 'webmaster' which is the normal term, but an infomaster. We are more interested in a person with an information background or a journalist or something like that than a tech person. (Project Manager)

The website structure has become quite comprehensive, and the challenge is to ensure that consumers and professionals can find the right information.

We have been focusing on creating a lot of awareness and having a lot of sites in these areas and different countries. So right now we are in a situation where we have awful lot of sites. In each country they look similar and they got the same corporate visual identity (CVI). But now we are trying to re-think, because our corporate site has a lot of visitors. We have like 100.000 visitors a month. --- Right now I'm trying to focus on to find out how we can use what we have to get more traffic and to use all these sites in a better way, to link them together in a better way, so we can get our customers to the right places. So we are trying to re-think the portal or the corporate site and to use that as the main portal. (Manager)

The purpose is also to support the sales representatives in different countries where the regulations and cultures vary considerably.

3.2 Organizing e-Business Projects at The Pharmaceutical Company

The eBusiness Department is a part of international marketing. The department has 13 full-time employees and 7 student workers. It coordinates the development of websites globally and provides the strategy. There is also

a group of about six persons in the US because they have special needs. The objective is that there is one web coordinator in each affiliate, but this is not always the case.

We have a central hosting of the web pages. We have a strategy trying to align the technology so that we're not having different content management systems in different countries. We are coordinating, trying to have a central platform. And it is our job to control that they are to the CVI. (Manager)

It can take ten years to develop new pharmaceutical products. The development process includes many phases, such as clinical trials. The development of marketing materials starts about three years prior to product launch. Therefore, the market research department works very closely with R&D. The eBusiness Department joins the process about one year before the launching of a new product in order to conduct communication planning. Each country is responsible for the local sales and promotion of products in individual countries, and the local managers are responsible for the launches. It therefore also makes sense that they manage their own campaigns. The websites form part of that campaign.

The department provides support for all the sites, but in principle it does not pay for the content. However, because some of the affiliates lack sufficient resources, the department has been working with the content as well as providing support. When implementing new project development and IT development, the department uses different web vendors, including The Pharmaceutical Company's IT department.

Corporate communication has responsibility for the public corporate website. The manager sits on the steering committee to ensure that the department can influence decisions concerning strategy for the new portal and other matters related to web services.

3.3 Architecture and infrastructure

About 80 % of the Pharmaceutical Company's websites are based on Site Manager content management system, which is proprietary technology developed by a local software firm. The new development is taking place in a commercial system. Also other alternatives have been available. The content management market is not entirely mature market yet, and therefore The Pharmaceutical Company is working with several different systems. The purpose is to focus on off-the-shelf products that are supported by larger companies. The primary idea is that the system should be so easy to use that there is no need for technical persons but rather for journalists or communication person to work with the sites. (Project Manager)

3.4 The Pharmaceutical Company Websites for Patients and Patient Communities

The websites for patients are open to anyone in about 20 countries. The current version represents the third generation created since 1999. The eBusiness Department has developed a general platform or template and many different modules that the local affiliates can select and add on to their sites. All sites are published in the local language to enable local users to search and find information in their local language. There are also many cultural differences that have to be taken into account in the content of the webpages.

The websites do not include any recommendations for the patients. Instead, they provide patients with a tool to keep better track of their condition. All recommendations should come only from their own personal physician.

We are not collecting patient data, we only can use it to give the patient better information or better service. --- The person creating a profile (onto the website) has to explicitly tell if we can use the data. Otherwise the data is just locked and we cannot see it. But if we are allowed to look at the data we can check it to see how people use the site. --- We can use the patient's data for analysis and for developing new functionality of the site or whatever we find necessary. But today we don't use it. (Project Manager)

The webpages aim at creating user communities and facilitating interaction between The Pharmaceutical Company and the patients, as well as among the patients. The patients can be divided into two groups, each of which requires a different approach.

We are segmenting our consumers into groups, but mainly we have two groups. We have the **active patients** and typically they are people who are very active and do a lot of sports. They want to take care of their illness, they want to be able to perform. They also know about the illness. And they will go back to the doctor and try to influence and say "I have read about this product and this is something for me". And then you have another group, which is called the **more passive group**. (Manager)

The Pharmaceutical Company home page contains an '**I wish' theme**' with case stories about different patients from all over the world. They include statements such as "I wish no-one ever gets this illness again". The purpose is to demonstrate that the webpages are for the patients and that the company cares about patients and is involved in their stories, instead of just selling products.

The local front page typically contains much information, including a calendar of events, useful links, and

information about products and devices. The **library** (R&D) part of the site contains information about the illness.

Then you have a **dictionary**, the words people don't understand. The illness is quite complicated, there is a lot of complicated words and people can look at them here to see explanations for them. --- In this kind of site we have some **applications** as well. (Project Manager)

Users can create **personal profiles** and register information about themselves in order to use it in the interactive pages on the site. They can, for example, save their personal measurements in a **diary** and create a **scorecard**, as well as keep track of their doctors, specialists and all other persons involved in their health care. However, they only need to provide the information required to use or search that part of the site, in so far as it makes sense to ask information.

At this moment we are only providing graphs and so on, and the people have to do the conclusions about their illness themselves. (Project Manager)

All my values should be between certain values, within the green area. And if I have values below or over that, then I can see that this is not good. --- If the patients just use this tool as intended then they would be able to see some kind of development in their disease. --- This is part of the personal diary what we call the personal scorecard. The medical measures are interesting for the patients with this illness. And the patients can track this data. For instance they can set up a goal, and they can see how they are doing compared to that goal. If I get a "red traffic light" it means that I am in a high risk. We have some predetermined intervals where these values should be in according to the international diet lines to treatment of the illness. And if you are not between within these intervals then you would get these highlights, the red and yellow. (Project Manager)

As to the more **interactive parts** of the site, The Pharmaceutical Company has found that live chat is not easy to do when dealing with a relatively limited number of people. There is almost never anyone in the chat room. Therefore, the chat has been replaced by a moderated chat forum that is facilitated by the infomaster and the local affiliate.

Maybe the most successful module, especially in certain countries is '**ask the experts' sites**. In an affiliate, for example, 12 to 15 experts are connected to the sites as well as patients, doctors, nurses and all kinds of health care

professionals. And the users of the site can then ask whatever questions in life, and they send the questions to the site --- For example in one country the *infomaster* arranges a meeting with local specialists, and says that on Monday from 6 to 7 we have this chat with this person. And then people come and they discuss something with that person and they have questions and so on. But if we just have it as a local chat over time, then people drop in from time to time but there is never any real discussion. So it has to be a moderated chat with an interesting person. Otherwise it does not work. ... The other thing is the debate that it's separated into different topics. We have 'the café' and 'the children' and 'the young people' and 'the parents' at this moment. And then people just start discussions and share experiences and talk about their teenage kids and how they smoke and all the things they do that they should not be doing. --- People are interested in sharing their experiences and it just has to be started. (Project Manager)

Questions can be sent to the *expert panel*, with all questions being posted thereafter on the site together with their answers, since most of these questions can also be of interest to other users of the site. Thus, when submitting a question, users are always informed that all questions will be answered and all answers will be published on the website. The objective is to answer the questions within a week.

There are also many applications, such as a cookbook, that are useful for the patient.

I think we have a thousand recipes or something like that in English, approved by dietists and they can just take from these, have them translated locally and update. (Project Manager)

The web pages help in educating different types of patients. "We force the people to think themselves about their treatment, to improve their treatment".

And we have an interesting thing, it's a *quiz*, it's actually a *jeopardy about the illness*... and it's combining film and sport and music with topics related to the illness. And then it's a good way for teenagers and for young people interested in playing games to learn about the illness while playing. We have both a grown-up, a teen and a child version. (Project Manager)

The quiz is interrupted and I have a little *case story*. And based on this case I have to decide if I should take medicine, or should I exercise or whatever to get better. And then in this case I suggest that I need a little of juice. And then OK, that was right. And then I get back to the quiz. So at times the quiz is interrupted and you

have a case story where you have to decide something related to your therapy. (Project Manager)

This is a *game for smaller children*. ...And it's kind of based on the Tamaguchi idea. You have your own little Pet and you need to take care of it. You name it, so it is your own personal pet, it is called a Pet. And I can play with her, I can go roll skating. And there is a little game here. And all the time this Pet reacts, so I can always measure the indicators of her illness. I can go on the fridge. Now I give her some cheese and I measure again. And now it's better. ... And now the Pet is getting some of these symptoms of the illness. I can see the value is a way too high. And then I can give some medicine. So the Pet is taking some medicine. And this is basically a tool for the parents to play with the kids, basic things about taking medicine, doing other necessary things and a way to teach while you learn ... You also get emails from your Pet. And if you haven't been playing with your Pet for 10 days or something, you can get an email saying "I miss you, please come and play with me". (Project Manager)

In one country the site is focused on the *young people*. You can go in and there will be a movie about a guy – he is falling in love - how he is telling her he has this illness and so on. So, that's trying to focus with young people and how they live --- If you are a young person you know that you have to live with this for the rest of your life. It must be hard ... (Manager)

The '*Living with the illness*' sites contain lots of articles about the illness. The headquarters has made a basic pack of content for the site, and the local affiliate can add on to it.

In principle, the web pages do not include information about Pharmaceutical Company's products. Instead, they provide information about products in general.

And it is one of the core systems - CRM Customer Relationship Management systems - for the sales. We have learned from this that it is very hard job to sell things, that it is huge difference between marketing and sales. Because here the patient is not just buying books or cd's or things like that. Here they are buying things that they are putting into their own body. (Project Manager)

3.5 The Pharmaceutical Company's Websites for the Professionals

The "Illness information for the professionals" website is offered as a service from The Pharmaceutical Company

to health care professionals, such as physicians, nurses, pharmacists, and trainers. There is an international version, and a couple of national versions. The site contains professional information and research, such as up-to-date medical information, educational resources, and the latest research in the illness. An editor reads through medical journals and creates a short calendar describing events and current debate within the field. An abstract database allows physicians to search in journals for abstracts. An image bank provides images of body parts commonly affected by the illness. The site also includes an event calendar, praxis tools, and a monthly newsletter co-edited by an in-house doctor, a medical advisor who works for the website (but not as a 'netdoctor' directly serving patients).

And we don't get anything other in return than our corporate branding. There is no product branding in this service. The goal is to signal that The Pharmaceutical Company is "being there" and we actually do stuff for the doctors and not only for profit. And we try to improve the care of the illness. --- And I think actually that the project was launched to improve the care of the illness given our offering from our company to help patients. (Project Manager)

The US is a bit different because they have another way of looking at a disease. A different definition. (Project Manager)

Physicians are a difficult target group for a website, since the information should meet a high standard of quality and be highly relevant.

Actually most complicated aspect of this work is to find the right content and the right level. --- You have to put something relevant on the website for the doctors. If you put too much product information on this website it wouldn't look objective and then they wouldn't use it. --- If they click in a certain place they will get a screen that says "you are now leaving objective information and it's being product universe". So, the products are not far away, but they are not in the base all the time (Project Manager)

Education is one of the objectives of the site. Many guidelines already exist on topics such as how to treat the illness and how to educate the patients. The eBusiness Department does not write the content for such pages, because it is at such a high level, but rather hires opinion leaders to write the text.

We have some cooperation with some international organizations concerning the illness. We have people in house who have a lot of good contacts with these organizations. They prepared guidelines, which we have put on into the Internet for them as a service to the

organizations. --- We actually do not write the guidelines, it is the international organizations. So we actually just collaborate with them. They do the writing and we pay for some of the technical stuff. --- Then we use some vendors. A vendor in Holland produces news about the illness, and they have a panel of doctors who check out what is happening in the world of the illness. --- Then we have in some of our affiliates people hired to actually to write. They have journalistic background. (Project Manager)

It is very difficult to make a website like this because FDA - the US drug administration¹ - they have a very tight schema or rules of what you can tell or not tell. So, for example with this site in the US we have to be very focused on not mentioning our own products at all. But we can mention our competitors' products. (Project Manager)

Regulatory aspects are more difficult than the medical and legal aspects.

At the moment I am working together with the US affiliate and at the same time our IT department to get the US site up and running and to get the content on the site approved by our internal approval organ in the US. And there are so many regulations in the US, it's very long process. We have legal, medical and regulatory assistance. The regulatory people know what the FDA authorities in the US know and what their requirements are. So they tell that to me and say: "You have to do this and this and this". And they review this every time I come with something new and they have to review it. So that's one part of it, and another part is actually to get ideas for content. And that's very difficult because you work within this framework of rules and regulations. And then they of course check all that clinical stuff. (Project Manager)

3.6 Organizational Learning

The development and maintenance of the websites facilitate learning in several ways on both local and global levels. However, this capability is not fully utilized.

The most important part is that our *local affiliates* are learning about their customers from these questions. And we don't have any organizational rules or systems to handle this ... I mean saying as we probably don't have it when people take the phone and call into the company and ask questions about the product, then we

¹ Food and Drug Administration

don't collect this information to learn and to develop products in a better way and so on. This is of course something that we have to deal with. --- But it is on the local level. It is on informal and local level and it is not coordinated globally. And that is of course a challenge because we have to find out how we can utilize all the information we can get out of these sites ... all the different questions and all the contacts when people use the contact part of the site (Project Manager)

The professionals' site is primarily a tool to get in contact with professionals and opinion leaders. The Pharmaceutical Company gets a lot of organizational learning via the site.

And the doctor might give us his comments on some of the articles or something like that. But also at conventions we have used that site to get in contact with them. And in general we work together with people who write stuff on the site. That's a good way to collaborate with the opinion leaders. (Project Manager)

As to the eBusiness Department, one of the objectives is to develop "Web intelligence" and to improve the services offered to the target groups.

If you look at my department we could be much more learning about ... I think we are focusing on it but we are on the first step of learning and ...because we have been so much focusing on getting in out there, and now we want to see what we can get back from it. It hasn't been the main focus until this year. I think it is very important, also the *web intelligence*: how we can get the information back now. --- Is to make sure the effect of the internet sites, to get that information back and then to use that as an evaluation of how the sites are doing, and if the sites are used the right way or if we should change something. We also want to see how much we can collect some of all the information we get about the users. In some cases we do collect a bit because we ask people to register on some of the pages but also here there are a lot of regulations and country specific regulations, so we have to be really careful. (Manager)

Actually, we have invested in a statistics system which is more like a reporting system rather than an intelligent system, but still we can get some information about how many users, where they go, on which pages and so on. So we just evaluated a product site and found out that there was really a bit interest for the site, but they only look on the front page and then they lost the interest. We could see how they lost the interest and they didn't go to the right pages, where the

real product information was. --- So we have evaluated the sites and we made a proposal on how we could change the content and make it more relevant for the customers. (Manager)

Actually there has been one online survey. We asked about what they think about the website and what they would like to read there, and asked them to compare it to other websites, and general comments. We got a lot of frustration of that. And then we have made a focus group where I think there was 12 people trying the website together with one person getting their comments. (Project Manager)

4. Conclusions

This case study aimed at investigating the research question

How does The Pharmaceutical Company learn and create new knowledge by utilizing e-business solutions?

4.1 How Does the Company Learn and Create New Knowledge by Utilizing e-Business Solutions?

The Pharmaceutical Company is a knowledge-intensive company. The success of the company is based on the development and application of explicit scientific knowledge. The development of the products occurs through a long and complex procedure overseen by R&D specialists. The Pharmaceutical Company has also developed comprehensive and interactive websites that cover the most important partners: the consumers and the professionals.

4.2 Classification

According to Skyrme's classification [2001], The Pharmaceutical Company's internet-based e-business solutions can be classified as interactive solutions and partially as trading solutions. They are not 'brochureware'.

4.3 Learning through design and implementation

During the implementation of the web solutions, a large amount of knowledge that was previously in tacit form has now become explicit. This has facilitated organizational learning both at the coordinating and local levels. It is most likely that designing and maintaining the websites has promoted organizational learning and increased awareness of company stakeholders at The Pharmaceutical Company. For example, the creation of community sites has made the eBusiness Department and the affiliates more sensitive towards the different perspectives of the various customer groups and

professionals, and of the cultural and regulatory differences.

The Pharmaceutical Company's web solutions also facilitate interaction within the consumer and professionals' communities, and promote their educational aim. These solutions have thus allowed The Pharmaceutical Company to reach many parties outside the company, to more tightly connect them to the learning process, as well as provide these stakeholders with an opportunity to improve their knowledge.

4.4 Learning Through Continuous Utilization of the Websites; Websites as Boundary Elements

The sites provide access to an extensive amount of data that is, to a large extent, protected from access by legislation and regulations. However, the legally available data has great potential as a source of organizational learning on global and local levels for market analysis, product development and other learning purposes. This potential has remained underutilized at The Pharmaceutical Company mainly due to the absence of a shared explicit framework or concept of organizational learning. Such a framework would help to coordinate various parties, processes, knowledge resources and ICT systems to facilitate the learning process.

Through the web solutions, The Pharmaceutical Company has become aware of its business environment and of many changes occurring within this environment. The websites serve as interactive boundary elements that help to distribute knowledge between the firm, user communities and professionals, as well as to monitor and collect information. The solutions facilitate the utilization of experts and opinion leaders within and outside the company.

Many regulations prevent the firm from using the information and knowledge produced by the system. However, even that information which could be used within the confines of the regulations has not been very efficiently utilized. These unutilized opportunities would allow Pharmaceutical Company to learn from the interaction enabled by its web-based e-business solutions. For example, using CRM Customer Relationship tools would require screening of essential information from the data for learning, R&D and marketing purposes.

In general, the creation of interactive websites can also support the development of business strategies. They have opened up possibilities to improve customer, partner and supplier processes, as well as enable extended reach, coverage, and presence.

Other types of boundary elements may also exist at Pharmaceutical Company, but they are not studied in this paper.

5 Benefits of the Research Project

This research project will link e-business solutions to major knowledge flows and thus to organizational learning and renewal. This is a relevant approach because e-business solutions may facilitate innovativeness and learning. E-business may thereby become an increasingly central component in the innovativeness, renewal and underlying dynamics of the organization.

The research project contributes to the following areas:

- Strategic management, innovation capability and strategic learning.
- Knowledge and information management.
- Customer and market information management. 'Boundary' management.
- E-business, Internet technologies and interactive solutions.
- New organizational structures and processes. Digitalization of business processes.
- CAS Complex Adaptive Systems, self-producing systems and living organizations.

Moreover, the study helps to test and further develop the relatively new theoretical and methodological framework of strategic composition[®]. This project provides new evidence to support the use of autopoiesis theory (and Complex Adaptive Systems theories in general), a promising approach to organizational learning and renewal phenomena.

An earlier study (Maula, 1999) investigated four management consulting firms. This research project will introduce several new aspects, such as:

- Investigation of a manufacturing company.
- Focusing on openness, supported by interaction and knowledge flows, and linking it to learning and innovativeness
- Investigating openness in the light of e-business.
- Testing the generalizability of the existing theoretical and methodological framework.
- Focusing on selected strategic components, and especially e-business in the role of a boundary element.

In general, the study provides new empirical evidence on boundary elements, and especially on the role of e-business solutions for knowledge management and strategic learning.

APPENDIX 1

THEORETICAL BACKGROUND AND KEY CONCEPTS

Autopoiesis theory

The study is based on an interpretation of the *autopoiesis theory*, which combines general systems theory and complexity theory. The theory explains the properties and behavior of self-producing (autopoietic, living) systems ('auto'=self, 'poiesis, poein' = to produce, create; greek). The theory was developed originally by Humberto Maturana and Francisco Varela in the fields of neurophysiology and phenomenological biology [3], [4]. Autopoiesis theory and its implications have been described by Mingers [7]. It has been applied in the context of organizations, for example, by von Krogh and Roos [1], [2].

Living composition[®] model and major knowledge flows

The *living composition[®] model* is an interpretation of the autopoiesis theory in the organizational context [5], [6]. It provides a systematic, theoretically justified and empirically tested methodological framework for analyzing organizations as living systems. The main assumption is that living organizations are simultaneously open and closed (self-referential) systems. Living organizations are featured by two major knowledge flows:

- Knowledge flows that facilitate openness, innovativeness and interaction with the environment ('organizational senses').
- Knowledge flows that facilitate self-referentiality ('organizational memory') and enable efficiency.

In this study the focus is on 'organizational senses'. The main conclusion from the autopoiesis theory and living composition model is that knowledge-intensive organizations are *simultaneously open and closed* (self-referential) systems. The model explains how organizations can simultaneously operate both efficiently and innovatively if knowledge flows are organized properly [5], [6]. This means that the conventional dilemma between exploration (creativity, innovativeness) and exploitation (efficiency) can be re-framed in the light of the theory and model.

Boundary elements

An autopoietic system is a unity with identifiable boundaries and contained within and producing a boundary. The living composition[®] model identifies ten components that also include boundary elements. The boundary elements include various roles and functions that can be embedded not only in people but also in ICT

solutions (Maula, 1999, and forthcoming). The boundary elements have a central role in organizational renewal and learning capability. In a living organization, the connecting and absorbing boundary between a firm and its environment can provide new services for the customers, as well as new competences and learning capabilities for the firm itself.

E-business

E-business may have radical implications for the organizations' structures, business processes, products, services and knowledge flows among organizations and their customers and other parties. In this study, e-business is defined as electronic internal and external communication that can cover the whole value chain (business-to-business, business-to-consumer) and can also include the suppliers' and consumers' activities.

According to Skyrme [8, pp 42-43], internet-based e-business solutions undergo four phases on the way to becoming mature organizations:

1. *Brochureware* includes transferring marketing material onto the web.
2. *Interaction* means two-way information flow, however without any online integration into the firms' core systems.
3. *Trading* includes full e-commerce activities with online credit card payment processing, as well as good links to product and service information as well as non-competing specialist portals.
4. *Integration* means that the website is fully integrated with the organization's core computer systems including customer management, order fulfillment and finance systems. Web pages are customized and information flows seamlessly between the supporting systems.

By mid-2000, most of organizations were at the second or third stage on the e-business path.

E-business and knowledge management

Few organizations have fully integrated knowledge management into their main business processes and management decisions. Most organizations need to accelerate their progress along the e-business path in order to exploit the advantages of the Internet for capitalizing on their knowledge [8, pp. 25, 43]. However, even efficient utilization of the firm's own existing knowledge is not sufficient. A more general trend can be identified: the shift from inward looking perspective to an external one. Most knowledge initiatives aim at improving internal processes by utilizing existing knowledge. Thereafter, the focus shifts to knowledge creation and innovation, the creation of new and better products and services. The next logical move is to extend

the scope of knowledge management beyond the enterprise, which means that more information and knowledge flows across the boundary between an organization and its marketplace in both directions.

Abstract

The goal of this paper is to provide insight into the effectiveness of site customization. In the marketing context, the term customization is often used to refer to the tailoring of products and services to the individual customer's needs and wants. Online customization offers customers the opportunity to tailor a web site to their needs and wants. The customization of web sites can provide customers with added value but may also increase their switching costs. In this paper we will investigate the possible effects of site customization on individual customer perceptions and purchase behavior.

1. Introduction

During the last century, several developments have dominated marketing theory. From the production concept, focusing on efficient and low costs production facilities allowing products to be widely available, theory has evolved to the customer concept, where the focus is on shaping offers, services and messages to individual customers [15]. One of the main differences in these concepts is the role of information, especially individual customer information. Implementing the customer concept requires the availability of information about individual customers. For example, a direct marketing approach lets marketers identify needs and wants of individual customers and target customers based on these pre-identified preferences [14].

The focus on individual customers and forming a long-term relationship with these customers to mutual benefit is core to relationship marketing theory (e.g., [4], [21]). Creating products and services tailored to individuals needs and wants, creates long-term relationships and competitive advantage (e.g., [27], [7]). The combination of relationship marketing and mass-customized products and services has proven its worth [23]. Moreover, the availability of information technology allows customization of not only products and services, but also communication and distribution [25]. To initially customize these functions closest to the marketplace, that is the downstream functions, makes the most sense [16].

The tailoring of products and services to the needs and wants of individual customers, has received considerable

attention since the rise of relationship marketing. Web site customization is a new example of tailoring to the needs and wants of individual customers. Companies incorporate several interactive functions in their websites, ranging from customer-specific wish lists to MyCompany.com sites. Customization functions are found in many Web sites, both in business-to-business (B2B) markets and in business-to-consumer (B2C) markets. For example, Marshall Industries, an electronic distributor, offers customers the opportunity to search for parts by their own internal reference part number. Customers have to key in once which internal reference numbers correspond to which Marshall part numbers. At subsequent visits, customers are able to use their own internal numbers (www.marshall.com). Other well-documented examples are Dell in B2B markets, and Amazon, Musicblvd, and Yahoo in B2C markets. For instance, the Dell's password protected Premier Pages contain for each corporate customer only the products, prices, approval procedures, service and support information that is appropriate to that particular customer. Dell has developed more than 35,000 Premier Pages in 12 languages.

In the direct marketing literature the advantages of personalization are recognized and its importance is often stressed. Customization of Web sites, however, provides more opportunities to tailor information and services to the specific needs of individual customers. In practice, many companies are experimenting with customized sites, and in the business press one can find ample anecdotal evidence of their success. However, although the importance of site customization has been stressed in conceptual papers, to our knowledge no academic study provides empirical evidence for it.

The application of site customization leads to several questions. For instance, what are the consequences of customization in relation to product variety, advertising and promotions [20]? How does customization influence the satisfaction with the online channel [26]? How does the interaction with customized technology effect customer evaluations and behavior [18]? With this study we aim to provide insight into the effectiveness of web site customization. More specifically, we will answer the following four questions: What is web site customization? How can we determine the effect of site customization on customer attitudes and behavior? How can we measure

the extent to which customers are using site customization features? Using data about 900 customers of a national retailer who have used the company's site for at least one year, we will answer the final research question: to what extent can the hypothesized effects of site customization be shown in an empirical study?

The remainder of this article proceeds as follows. The second section discusses site customization and provides an answer to the question what it is. The third section discusses the effectiveness of site customization. That is, how the effect of site customization on customer evaluations and behavior should be determined. The fourth section discusses the data collection and analysis and provides an insight into the effect of site customization on customer evaluations and behavior. The fifth section concludes and identifies areas for future research.

2. Online Customization

There are many ways to customize (elements of) a product. The term product is used here in a broad sense, including both the primary product or service and supporting services, as well as the information communicated to customers about these elements and their use [30]. Most opportunities for customization exist for products that can be digitized. Digital products can be customized at almost zero marginal costs, examples include customized music cd's and sites that offer the opportunity to monitor your own portfolio of stocks. For non-digital products the mass customization literature offers a variety of cost-effective customization approaches. Many companies offer components (or modules) that customers can combine into 'tailor-made' products, well-known examples reach from pizzas and clothing to cars and personal computers. Dell customers can configure and evaluate multiple systems online with choices from hundreds of components and obtain instant price quotes, enabling them to select the best possible PC given their budget and performance requirements.

Customization of web sites, according to Srinivasan et al. [24] indicates the ability of an e-retailer to tailor products, services and the transactional environment to individual customers. Wind and Rangaswamy [29] offer an extended view with their theory of customerization, where a customized site is used to create a customized product or service. Angehrn and Meyer [1] describe online customization as the degree to which the Internet is used to provide individualized services to users. Rowley [22] also describes customization as the tailoring of web site and product offerings to suit specific customers, based on customer profiles. Thus, site customization refers to making a site tailor-made based upon information explicitly provided by the customer.

Besides site customization, the concept personalization is often referred to in an Internet setting. Hanson [9] uses the term personalization to describe a special form of product differentiation, transforming a

standard product or service into a specialized solution for an individual. The term personalization most likely originates from the direct marketing theory. In the DM theory, personalization implies tailoring a mailing to individual customers through for instance a personalized letter heading [10]. Site personalization can be considered as the collection of individual customer data in order to provide an individual online experience.

So, both site customization and personalization are focused on collecting and using individual customer data on customer preferences in order to make the site more customer-specific. The difference between both concepts is that site customization is initiated by the customer. The customer explicitly decides to provide the supplier with information about preferences needs and interests [12]. User names and passwords limit access to only the authorized customer, thus enabling suppliers to build extranets with specific customers. The provider initiates site personalization. Based on the information the supplier has collected about the customer, e.g. purchases or click stream data, the supplier adapts the contents of web pages to improve their relevancy for this customer. For example, if a customer searches for maintenance information the site can offer links to the maintenance of any available product or links to only those products that have been bought by that particular customer. This differentiation based on customer control was empirically tested by Burke [5]. His research indicates that customers prefer the one-to-one marketing options that give them control over acquisition, dissemination and use of their personal information.

The level of customer awareness and customer control in respect to the tailoring process characterizes site customization and personalization. Based on the awareness (customer and/or organization), Wallin [28] distinguishes between four types of customization, where the level of awareness is different for the parties involved. If the customer deludes the organization, i.e. through filtering, the customer has the highest level of awareness. When neither the organization nor the customer is aware, the filtering is performed by a third party and is referred to as censorship. The other two forms are the closest related to site customization and personalization as described. If an organization personalizes the information, the firm has the highest awareness and it can be considered as the provider deluding the customer. With site customization both parties should be aware of the tailoring process, referred to by Wallin [28] as collaboration between the organization and the customer.

Hanson [9] provides a similar distinction in relation to the level of customer control. If the customer controls the tailoring process, he refers to adaptive customization. The terms cosmetic and transparent customization are used to describe customization strategies where the organization is in control. Collaborative customization describes the strategy where both parties have some level of control. Table 1 provides an overview of the characteristics mentioned for both site customization and site

personalization and the corresponding strategies provided by Wallin [28] and Hanson [9].

Table 1. Characteristics of customization and personalization

	Web Site Customization	Web Site Personalization
Customer awareness	High	Low
Firm awareness	High	High
Wallin	Provider and customer collaborate	Provider deludes customer
Customer control	High	Low
Firm control	High	High
Hanson	Collaborative customization	Cosmetic or adaptive customization

Both forms of online tailoring, site customization and site personalization, have much in common. Both concepts have the objective to provide a tailored experience via the Internet. In order to achieve this experience, both concepts collect and apply personal information. Only with respect to the method of data collection there is a difference. In the case of site personalization, the supplier collects information based on expressed behavior online, which is less obvious to the customer. In the case of site customization, the supplier explicitly asks the customer to provide personal information in order to tailor the experience. Research has shown that combining site personalization with site customization increases the satisfaction with the personalization elements over which the customer has less control [19]. In this paper we will focus on site customization. However, given the close relationship with site personalization, much of what we will discuss, e.g., how to determine the effectiveness of site customization, will be relevant for personalization too.

3. Effectiveness of Web Site Customization

In order to provide tailored web site experiences suppliers collect and use personal information, where the method of collection can be either explicit (asking the customer for information) or implicit (through observing customer behavior). Site customization can have an effect on both customer evaluations and behavior [18]. Examples of customer evaluations include satisfaction and loyalty, while behavior can be related to the site visiting behavior or to purchases.

The customer evaluations can be related to the site or the organization. Site customization is expected to improve satisfaction and loyalty. The satisfaction can be related to the site, but might also be related to elements outside of the site. The same holds for loyalty, due to the

expectation that web site customization provides more value and therefore improves relationships (e.g., [17], [2]). In order to determine the effect of site customization on evaluations both aspects, i.e. evaluations with respect to the site as well as other elements of the organization, will be taken into account.

Customer behavior may be related to behavior in the web site, such as web site stickiness. Web site stickiness is characterized by the duration, the intensity and the frequency of web site visits. The concept reflects the overall attractiveness of a web site, portrayed in customer online behavior. However, behavior may also be related to the purchases customers make. These purchases can be made either online or offline. In cases where the site does not contain a transaction function, which is the case for most current web sites (e.g., [8], [11], [3], [6]), purchasing behavior only refers to offline purchases.

So, in order to define the effects of web site customization, we focus on the three main concepts, e.g. web sites stickiness, customer evaluations and customer purchases. We assume a direct influence on all three main concepts, e.g. web site customization has a direct influence on stickiness, customer evaluations and customer purchases. Assume that a web site uses customer profiles to customize the content and product suggestions. Then, it is conceivable that the tailored content will influence the attractiveness and the evaluation of the site and that the product suggestions will influence the evaluation of the organization and the purchases. Therefore, web site customization would have a direct effect on all three concepts, as presented in figure 2.

Figure 2. Conceptual models reflecting the effects of web site customization

Based on this model, hypotheses with respect to the effect of site customization on web site stickiness, customer evaluations and customer purchases can be formulated.

- H₁: Web site customization has a positive effect on web site stickiness.
- H₂: Web site customization has a positive effect on customer evaluations.
- H₃: Web site customization has a positive effect on customer purchases.

Besides these hypotheses, due to the exploratory nature of this type of research, the relations between the concepts will be investigated as well.

Until now we have considered site customization as a homogenous concept. In practice, however, there are various types of customization that can be distinguished. Firstly, for several site customization features the benefits are clear and customers can determine them beforehand, while with other customization features customers have to wait and see to what extent they will benefit from providing the supplier with personal information. Being able to determine the background color of a web site, allows the customer to instantaneously determine the benefits of the feature. Providing a web site with preferences implies that the customer will have to wait and see how well the supplier is able to provide product suggestions based on these preferences.

Secondly, the level of customer awareness also affects the effectiveness of customization. For instance, explicitly providing a site with preferences will make the customer aware of the process and will increase his/her expectations. If the customization is implicit, it is less obvious to a customer and will have a less direct effect on for instance customer evaluations and purchases.

Thirdly, it is possible to make the distinction between customization features, i.e. a shopping list, and customized features, i.e. product suggestions. Suppose a web site has both features: a shopping list and product suggestions based on provided preferences. A shopping list allows customers will most likely be tailored at each visit of the feature, for instance to add or remove products. Providing preferences is a feature, which is tailored once, that is, the preferences will most likely listed once. However, the page with the product suggestions, e.g. the customized feature, might be visited at each web site visit.

In our measure of the extent to which customers use site customization features we will take into account the different types of features with respect to the customer benefits, customer awareness and customization versus customized features. Moreover, when measuring the level of customization, the number of available and the number of used customization/customized features should be taken into account. A distinction between customization and customized features should also be made. A correction for the degree of page views and the degree of visits should also be incorporated.

In order to determine the effects of web site customization data is necessary on an individual customer level. It should also be possible to link all of the different measures to individual customers. That is, for each individual customer it should be known (1) what he/she does in terms of customization, (2) how intensive he/she visits the site, (3) what his/her evaluations are with respect of the site and the organization and (4) what purchases he/she has made.

4. Data Collection and Analysis

In our empirical study, we focused on the effect of the use of customization features of a non-transaction web site on the stickiness, perceptions and offline purchases of the customers of a large national retailer. Purchase data and site usage data of individual customers is available for a period of one year. After this year, the users of the web site completed an extensive online questionnaire. All the data can be linked on an individual customer level by means of customer ID card numbers.

The site mainly offers information and entertainment but also provides product suggestions based on information provided by the users. The site requires the customers to log on at every visit, providing a customized experience for each individual customer. The customization features the site offers, ranges from product suggestions based on information provided by the customer, to online address books with an online gift planner.

It was decided that only those users who had at least visited the web site four times were included in the analyses. Of these users only those were included who had completed the questionnaire. Eventually, this resulted in a sample size of 900 users.

So far, only some preliminary analyses, e.g. correlations, have been performed. We are still in the process of testing the model as presented in figure 2. The extent to which customers use the customization features had a direct relationship with the online satisfaction and the stickiness of the web site. We did not find a direct relationship between customization and offline purchases. So far, it seems that site customization has an influence on web visits, i.e. the duration, intensity and frequency of the visits, and the evaluation of the site.

5. Conclusions

With this study we aimed at determining the effectiveness of site customization. In order to do so, we have shown that conceptually site customization and site personalization do not differ that much. The difference between these concepts mainly lies in the method of collection of personal information. The objective, providing individual customers a tailored web site experience, and the use of the information, however, remain highly similar. The opportunities the Internet offers to customize products and services are extensive and provide ample opportunity to engage in true one-to-one relationships.

Moreover, Dell offers anecdotic evidence of the effects of site customization. Both personalization and customization are iterative processes that are beneficial to both parties: customers receive functions and offers that better match their needs and suppliers decrease waste and increase the customer's switching costs. Huizingh [13] found that customization of the Web site is an important determinant for Web site success.

The preliminary results of our empirical study indicate

that the extent to which customers use site customization features is only related to online perceptions and behavior. The effect on purchases made offline was not significant. So, it seems that the effects are limited to the environment where the customization of the communication takes place and is not extended to other channels in which the supplier and the customers interact. Further research into the relationships between the various possible effects of site customization should provide more insight into the structure of the chain of effects of web site customization.

An Algorithm for Warehouse Capacity and Replenishment Scheduling Decisions

Mark Goh

Abstract

In our paper, a Singapore chemical manufacturer procures a kind of raw material from Europe and the material arrives at a fixed quantity with a cycle of about two months according to their long term contract. The material can be stored for only one week in normal conditions. So the manufacturer has to rent a special warehouse to hold the material before it is transported into the workshop, which happens at the beginning of each week. But at that time the manufacturer cannot know the exact demands of its customers each week. So understock and overstock of the material may exist. The manufacturer has to decide the capacity of the special warehouse and the replenishment quantities to the workshop each week.

The total costs make up of three parts: the cost due to the warehouse capacity constraint, the cost due to the workshop inventory constraint and the inventory cost at the warehouse. Because the material is transported and stored in tanks, we build up a newsvendor model with discrete variables. And it is an integer quadratic programming with linear constraints. Then we convert this integer quadratic programming into a binary quadratic programming, and then into an integer linear programming. Thus, existent software, such as ILOG CPLEX can be used to solve the problem.

Keywords: stochastic lead time, discrete newsvendor model, binary integer linear programming

1. Introduction

In real life, due to the different supply contracts (lead time, order quantity etc.), different industrial requirements (emphasis on quick delivery or on transportation economy etc.) and different supplier-buyer relationship, logistic decision making may be complex

and diversified and the crucial decision variables may be completely different. Unlike usual papers, ours makes the decisions of the warehouse capacity and replenishment quantity to the workshop jointly.

In our project, a Singapore chemical manufacturer procures a kind of raw material from Europe and the material arrives at a fixed quantity with a cycle of about two months according to their long term contract. The manufacturer has a long term contract with its outside supplier to replenish the warehouse's inventory at a fixed quantity of two hundred tanks with a period of about two months (We have the distribution of the period's length. At the same time the manufacturer faces uncertain demands. And due to the operational complexity and related high costs, a Just-in-Time system is infeasible in this company and we can only replenish the workshop's inventory from the warehouse at the beginning of every week. A kind of special trucks with the capacity of only one tank is used for the transportation from the warehouse to the workshop. So the transportation fee from the warehouse to the workshop is unrelated to our decision.

2. Notations and Modeling

We assume that the manufacturer gives an order of fixed number to the warehouse at the beginning of the t^{th} week after the last replenishment, and the preplanned interval between two replenishments of the warehouse is T weeks and the fixed order quantity is R . As we mentioned above the trucks transporting containers from the warehouse to the factory's workshop has a capacity of one tank, so every T weeks a fixed number of R trucks are necessary and the transportation cost is fixed. Thus our decision will not change the transportation cost and

it can be ignored in our model. Since all the goods are packaged in tanks until being consumed in the factory and the left inventories in the factory after a week will be discarded, the demands in the factory at the t^{th} week can be modeled as discrete random variables D_t with the probability mass function $P(D_t = j) = p_j^t$, $\sum_{j=0}^{D_m} p_j^t = 1$. If the order quantity of the factory from the warehouse is too large, a holding cost of h_f per tank per week will occur. On the contrary, if the replenishment quantity at the factory is too small, the production will break and a penalty cost of p_f for the shortage per tank per week will occur. We should decide the proper quantities from the warehouse to the factory at the t^{th} week Q_t to optimize the total costs. We also need to decide the capacity of the warehouse due to the uncertainty of lead times from outside supplier and the factory's demands. If the warehouse is too large, a penalty cost of co per tank occurs (this cost is reasonable since the over capacity will last all the T weeks), and if it is too small, the company will have to rent other warehouse to hold the inventory and lead to an incremental cost is cu (this incremental cost may be the additional transportation cost from the temporary warehouse to the factory). The goods arrive at the warehouse i weeks ahead of the plan with a probability of p_i , and the inventory level of the warehouse at the end of t^{th} week is I_t if the replenishment arrives as plans. Define

Figure 1: Inventory Level of the Warehouse

$K(Q_w, Q_1, Q_2, \dots, Q_T) := \max\{k : I_m(k) \leq Q_w\}$ as the week of the warehouse's inventory clearance, then every T weeks, the costs caused by the capacity of

the warehouse is

$$co \sum_{i=0}^K (Q_w - I_m(i)) p_i + cu \sum_{i=K+1}^{L_m} (I_m(i) - Q_w) p_i,$$

the warehouse's inventory cost is

$$\sum_{t=1}^T I_t t h_w + R h_w \sum_{t=0}^T t p_t,$$

the second part is caused by the advance of the warehouse's replenishment and is irrelevant to our decision of $Q_w, Q_1, Q_2, \dots, Q_T$, so we can ignore it; in each week the costs caused by the imbalance of the factory's demand and the replenishment quantity is

$$p_f \sum_{D_i=Q_i+1}^{D_m} (D_i - Q_i) p_{D_i}^i + h_f \sum_{D_i=0}^{Q_i} (Q_i - D_i) p_{D_i}^i$$

so our problem is

$$\begin{aligned} \text{Min. } & co \sum_{i=0}^K (Q_w - I_m(i)) p_i + cu \sum_{i=K+1}^{L_m} (I_m(i) - Q_w) p_i + \\ & \sum_{t=1}^T I_t t h_w + \sum_{i=1}^T [h_f \sum_{D_i=0}^{Q_i} (Q_i - D_i) p_{D_i}^i \\ & + p_f \sum_{D_i=Q_i+1}^{D_m} (D_i - Q_i) p_{D_i}^i] \end{aligned}$$

s.t.

$$I_t = R - \sum_{i=1}^t Q_i, \quad (1)$$

$$\sum_{t=1}^T Q_t = R, \quad (2)$$

$$I_m(t) = R + I_{T-t} = 2R - \sum_{i=1}^{T-t} Q_i, \quad (3)$$

$$I_m(K) \leq Q_w < I_m(K+1) \quad (4)$$

$$Q_t \geq 0, t = 1, 2, \dots, T, Q_w \geq 0 \quad (5)$$

Constraint (1) expresses the relationship between the planned inventory level and the transportation quantity to the factory. Constraint (2) states that the replenishment of the warehouse is used for T weeks' demands for the factory. Constraint (3) is used for calculating the maximum inventory level at the warehouse if the replenishment arrives at the warehouse t weeks ahead of the schedule. Constraint (4) is the definition of the cutoff level K .

In order to express the sum of K (a random variable) variables in a convenient way, we make the following conversion. Define

$$x_t^{(K)} = \begin{cases} 1 & \text{if } t \leq K \\ 0 & \text{if } t > K \end{cases},$$

then $K = \sum_{t=1}^T x_t^{(K)}$,

$$x_t^{(T-K)} = \begin{cases} 1 & \text{if } t \leq T-K \\ 0 & \text{if } t > T-K \end{cases},$$

$T-K = \sum_{t=1}^T x_t^{(T-K)}$, and $x_t^{(K)}$ and $x_t^{(T-K)}$ have to satisfy the constraint (6) $x_{T+1-i}^{(T-K)} + x_i^{(K)} = 1, \forall i = 1, 2, \dots, T$

$$x_t^{(T-K-1)} = \begin{cases} 1 & \text{if } t \leq T-K-1 \\ 0 & \text{if } t > T-K-1 \end{cases},$$

$T-K-1 = \sum_{t=1}^T x_t^{(T-K-1)}$, and obviously, there is constraint (7) $\sum_{t=1}^T x_t^{(T-K-1)} + 1 = \sum_{t=1}^T x_t^{(T-K)}$

$$x_i^t = \begin{cases} 1 & \text{if } i \leq Q_t \\ 0 & \text{if } i > Q_t \end{cases},$$

then $Q_t = \sum_{i=1}^{Q_m} x_i^t$, the problem becomes:

$$\begin{aligned} & co \sum_{t=0}^T \left(\sum_{i=1}^M x_i^w - 2R + \sum_{i=1}^{T-t} \sum_{j=1}^{Q_m} x_j^i \right) p_t x_t^K + \\ & cu \sum_{t=0}^T \left(2R - \sum_{i=1}^{T-t} \sum_{j=1}^{Q_m} x_j^i - \sum_{i=1}^M x_i^w \right) p_t (1 - x_t^K) + \\ & \sum_{t=1}^T \left(R - \sum_{i=1}^t \sum_{j=1}^{Q_m} x_j^i \right) th_w + \sum_{t=1}^T [h_f \sum_{D_t=0}^{Q_m} \left(\sum_{j=1}^{Q_m} x_j^t - D_t \right) p_{D_t}^t x_{D_t}^t \\ & + p_f \sum_{D_t=0}^{Q_m} \left(D_t - \sum_{j=1}^{Q_m} x_j^t \right) p_{D_t}^t (1 - x_{D_t}^t)] \end{aligned}$$

s. t. constraints (6) and (7),

$$x_t^K, x_i^w, x_i^t = 0, \text{ or } 1, \forall i = 1, 2, \dots, Q_m, \forall j = 1, 2, \dots, M,$$

$$\forall t = 1, 2, \dots, T;$$

$$x_{i+1}^w \leq x_i^w, \forall i = 1, 2, \dots, M-1;$$

$$x_{i+1}^t \leq x_i^t, \forall t = 1, 2, \dots, M-1, \forall i = 1, 2, \dots, Q_m-1;$$

$$x_{t+1}^K \leq x_t^K, \forall t = 1, 2, \dots, L_m;$$

$$\sum_{t=1}^T \sum_{i=1}^{Q_m} x_i^t = R;$$

$$2R - \sum_{t=1}^T \left(\sum_{i=1}^{Q_m} x_i^t \right) x_t^{(T-K)} \leq \sum_{i=1}^M x_i^w;$$

$$\sum_{i=1}^M x_i^w < 2R - \sum_{t=1}^T \left(\sum_{i=1}^{Q_m} x_i^t \right) x_t^{(T-K-1)}.$$

This is a quadratic binary problem. In the following paragraph, we convert it to linear binary problem. When the two factors have the same subscription, such as x_i^t and x_j^t , it is easy to see that $x_i^t \cdot x_j^t = x_i^t$, if $i \leq j$. When the two factors have different subscription, we need the following theorem.

Theorem x, y are binary variables, then $x \cdot y$ is equivalent to the a variable and a group of constraints: z , subject to $z \leq x, z \leq y, z \geq x + y - 1, z \geq 0$.

The proof is easy from the following table,

Table 1: Convert Multiplication to Linear Constraints

x	0	0	1	1
y	0	1	0	1
$x + y - 1$	-1	0	0	1
$x \cdot y$	0	0	0	1
z	0	0	0	1

This theorem provides a general method to convert a quadratic binary programming to a linear programming. However, this conversion will increase the number of decision variables and constraints. So it is only suitable to small scale problems. Define

$$x_{it}^{wK} := x_i^w \cdot x_t^K,$$

$$x_{ijt}^{fK} := x_j^i \cdot x_t^K,$$

$$x_{tjD_t} := x_j^t \cdot x_{D_t}^t,$$

$$y_{ij} := x_i^{(K)} \cdot x_j^{(T-K)}$$

$$z_{ij} := x_i^{(K)} \cdot x_j^{(T-K-1)}$$

then,

$$\text{Min.}(co+cu) \sum_{t=0}^T \sum_{i=1}^M p_t x_{it}^{wK} - 2R(co+cu) \sum_{t=0}^T p_t x_t^K + (co+cu)$$

$$\sum_{t=0}^T \sum_{i=1}^{T-t} \sum_{j=1}^{Q_m} p_t x_{ijt}^{fK} + 2Rcu - cu \sum_{t=0}^T \sum_{i=1}^{T-t} \sum_{j=1}^{Q_m} p_t x_j^i$$

$$-cu \sum_{t=0}^T \sum_{i=1}^M x_i^w p_t + R \sum_{t=1}^T th_w - \sum_{t=1}^T \sum_{i=1}^t \sum_{j=1}^{Q_m} th_w x_j^i +$$

$$(h_f+p_f) \sum_{t=1}^T \sum_{D_t=0}^{Q_m} \sum_{j=1}^{D_t} p_{D_t}^t x_{D_t}^t + (h_f+p_f) \sum_{t=1}^T \sum_{D_t=0}^{Q_m} \sum_{j=D_t+1}^{Q_m} p_{D_t}^t x_j^t$$

$$\begin{aligned}
& -(p_f + h_f) \sum_{t=1}^T \sum_{D_t=0}^{Q_m} D_t p_{D_t}^t x_{D_t}^t - p_f \sum_{t=1}^T \sum_{D_t=1}^{Q_m} \sum_{j=1}^{Q_m} p_{D_t}^t x_j^t \\
& + p_f \sum_{t=1}^T \sum_{D_t=0}^{Q_m} D_t p_{D_t}^t
\end{aligned}$$

s. t. constraints (6) and (7),

$$x_{i+1}^w \leq x_i^w, \forall i = 1, 2, \dots, M-1;$$

$$x_{i+1}^t \leq x_i^t, \forall i = 1, 2, \dots, Q_m-1, \text{ and } t = 0, 1, 2, \dots, T;$$

$$x_{i+1}^K \leq x_i^K, \forall i = 1, 2, \dots, T-1;$$

$$x_{it}^{wK} \geq x_i^w + x_t^K - 1, \forall i = 1, 2, \dots, M, \text{ and } t = 1, 2, \dots, T;$$

$$x_{it}^{wK} \leq x_i^w, \forall i = 1, 2, \dots, M, \text{ and } t = 1, 2, \dots, T;$$

$$x_{it}^{wK} \leq x_i^K, \forall i = 1, 2, \dots, M, \text{ and } t = 1, 2, \dots, T;$$

$$x_{ijt}^{fK} \leq x_t^K + x_{ij} - 1, \forall i = 1, 2, \dots, T, j = 1, 2, \dots, Q_m,$$

$$\text{and } t = 1, 2, \dots, T;$$

$$x_{ijt}^{fK} \leq x_t^K, \forall i = 1, 2, \dots, T, j = 1, 2, \dots, Q_m,$$

$$\text{and } t = 1, 2, \dots, T;$$

$$x_{ijt}^{fK} \leq x_{ij}, \forall i = 1, 2, \dots, T, j = 1, 2, \dots, Q_m,$$

$$\text{and } t = 1, 2, \dots, T;$$

$$y_{ij} \leq x_i^{(K)} + x_j^{(T-K)} - 1, \forall i = 1, 2, \dots, T,$$

$$\text{and } \forall j = 1, 2, \dots, T;$$

$$y_{ij} \leq x_i^{(K)}, \forall i = 1, 2, \dots, T, \forall j = 1, 2, \dots, T;$$

$$y_{ij} \leq x_j^{(T-K)}, \forall i = 1, 2, \dots, T, \forall j = 1, 2, \dots, T;$$

$$z_{ij} \leq x_i^{(K)} + x_j^{(T-K-1)} - 1, \forall i = 1, 2, \dots, T,$$

$$\text{and } \forall j = 1, 2, \dots, T;$$

$$z_{ij} \leq x_i^{(K)}, \forall i = 1, 2, \dots, T, \forall j = 1, 2, \dots, T;$$

$$z_{ij} \leq x_j^{(T-K-1)}, \forall i = 1, 2, \dots, T, \forall j = 1, 2, \dots, T;$$

$$\sum_{t=1}^T \sum_{i=1}^{Q_m} x_i^t = R;$$

$$2R - \sum_{t=1}^T \sum_{j=1}^{Q_m} x z_{tj} \leq \sum_{i=1}^M x_i^w < 2R - \sum_{t=1}^T \sum_{j=1}^{Q_m} x z_{tj}.$$

This is a linear binary problem with $Q_m T^2 + Q_m^2 T + T^2 + T Q_m + T M + 3T + M$ variables and $3Q_m T^2 + 6T^2 + 3MT + Q_m T + M + T + 1$ constraints. Actually the problem could be much smaller because we can ignore many unreasonable values of decision variables if we have some historical data, so many x_i^t, x_{Kt} etc. can be replaced by 1s directly. In our project, the warehouse replenishes the inventory about per twenty weeks with a fixed

order quantity of $R = 200$, the factory does so per week with a delivery quantity of at most $Q_m = 20$. So the problem has 15960 binary decision variables and 45121 constraints. We use ILOG CPLEX 7.1 (Intel mobile CPU 1.6G, and 256M RAM) to solve this problem. After the preprocessing of CPLEX, there are 34422 rows and 11841 columns left and it spends about half an hour to get a solution within the 0.01% error of the optimal solution.

When the problem's scale becomes larger, we can get the solution iteratively. First we can split the domains of decision variables into several large intervals (just like in the above, we select 1 as the interval) and in the same method we can decide which interval should be selected to get the optimal solution. Then we can split the cutoff intervals into several smaller intervals with a proper number so that we can handle them, the same method is used for selection of these smaller intervals. Iterate these steps until we can shorten the intervals to 1. Then we can get the optimal solution.

4. A Numerical Example

pl=[0.3, 0.3, 0.2, 0.1, 0.05, 0.05, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]

Table 2: Values of Parameters

co	cu	hw	hr	p
0.9	0.5	0.3	0.9	1

0, 0, 0, 0, 0, 0]

pd[t, 21 - t] = 0.6, pd[t - 1, 21 - t] = pd[t + 1, 21 - t] = 0.2,

We can get $Q_w=200$, Cost=1488.32, and

$Q=[20, 20, 20, 20, 20, 20, 20, 20, 20, 9, 9, 2, 0, 0, 0, 0, 0, 0, 0, 0]$

3. Conclusions

In this project we met an unusual problem as common papers. We need to consider the warehouse capacity and the factory replenishment jointly. Due to the small scale and containerization of the problem, we build a discrete model. A method of solving quadratic binary programming is designed.

Abstract

In recent years, due to dynamic evolution of information and communication technologies (ICTs) and the increasing importance of ICT diffusion in the process of economic growth, there exists the need for a broad and systematic comparison of the ICT framework development of countries around the globe. The Information Age that is upon us holds out the promise of a new world of shared prosperity, a global renaissance. At the same time, it also holds out the danger of economic exploitation, societal devastation and a new era of imperialism and colonialism. It can be spurned if we can bridge the economic and development gap, the information and knowledge gap and the great divide within.

A key element to extending the information revolution is identification, development and utilization of information assets. Information and knowledge is the new fuel of the economy. In this information economy, economic development means harnessing the information and knowledge assets of a community to help local businesses succeed in the new environment.

1. Introduction

There are many economic, political and cultural issues wrapped up in the digital divide. The facts suggests that there is a wide gap in computer use between rich and poor countries, and between rich and poor within most countries, and this gap often is a reflection of religious, ethnic and racial distinctions that shadow economic divisions throughout the world.

This gap, the "digital divide", threatens to cut off populations and seize the chance to participate in the affairs of the broader society. For some citizens technology brings the promise of inclusion, opportunity and wealth; for others, greater isolation and increased poverty. Herein lays the present tragedy and the making of a future catastrophe. It urges the important need to probe relationships between the public, corporate, and nonprofit sectors to address the critical questions for democracy in the information age.

The task is not just about reviving the weak economy. Real sustainable economic growth will come from expanding the information revolution to all parts of society. It is evident that the value of a network increases exponentially in relation to the number of users and the same is true for markets and economic activity. By leaving some behind, we impoverish not only those individuals; we also impoverish ourselves.

Local knowledge and information assets can be drivers of that economic development activity by:

- Capturing and using that knowledge as an information product;
- Using local knowledge to identify new entrepreneurial opportunities; and
- Developing the local knowledge and social capital base to facilitate innovation.

There is a need to work on narrowing the digital divide as much as possible by allowing all to exploit the Internet revolution, with elaborate global coordination and cooperation. This paper focuses on the subjects that are responsible for this divide and possible renaissance of improved information society. The Internet may follow a pattern similar to the telecommunications revolution of the 19th and 20th centuries. The last decade has seen the developed countries benefit from the Internet far more than the emerging countries. Countries such as China and India can narrow this Internet digital divide by effectively exploiting the Internet in their countries.

2. Economic Development

Economic development and the digital divide go hand-in-hand for many reasons. Communities with tools and skills to compete in digital economy are at distinct advantage over communities that don't. A community with a well-educated, technology-literate population is more likely to attract and sustain new businesses, and which in turn attract well-educated, technology-literate people into the area. Conversely, a community that lacks reliable access to technology and the skills to use it is less likely to attract and sustain new businesses that could potentially serve as a catalyst to economic prosperity. Simply put, if communities are to remain competitive in attracting, retaining and developing businesses in today's economy, they must develop modern telecommunications facilities and cultivate a well-trained workforce to stay viable.

Two critical success factors for, that should be kept track of, transcending the digital divide is adequate funding and good planning. Although, it is too early to make any firm conclusions about the overall nature of a desired future digital society, as these subjects are in a constant state of definition, redefinition and evolution, present state of knowledge illustrates some important, basic, approaches.

- Social inclusion.
- Effective and efficient use of IT& human resources.
- Building services around citizens' choices
- Providing information responsibly

- Making government and its services more accessible online.

3. Some Facts

Electronic readiness of a country is another critical success factor for digital divide. E-readiness assessment is a major international assessment of countries' capacity to exploit the opportunities offered by ICTs and helps to map out the factors & the deficiencies that contribute to this capacity. Such assessments are momentous in the case of countries like India where statistics on one hand shows that Indian IT professionals are most sought after in the world and India is among the largest software solution providers whereas on the other hand, approx. 50 percent of the population has not even seen the computer. Over the past few years, a number of electronic readiness assessments have been carried out. In fact, India has been assessed 11 times at the global level. Some of them are given below:

- The July 2002 EIU ranking ranks India below Sri Lanka at 43rd out of 60 as E-business follower.
- The January 2001 IDC ranking found that 55 of the countries navigating the information Super highway account for 98 per cent of all IT in 150 countries. It ranked India at 54 and Pakistan at 55 among the group of elite 55.
- The May 2001, Mc-Connell ranking of EReadiness Assessment indicated that substantial improvements were needed in the area of Connectivity. Improvements are also required in the areas of E-Leadership, E-Business, Information security and Human Capital.
- The Global Information Technology report, 2002-03, ranked India 37, above China which is ranked 43rd, where as the 2001-02 report ranked India 54.

The enabling factors are constructed to reflect the preconditions for quality network infrastructure as well as future network proliferation and use in the country. The enabling factors are constituted of

- Information Infrastructure and Hardware and software support
- ICT policy of a country and Business & Economic Environment.
- Networked Society
- Networked Economy that is e-commerce, e-government and general infrastructure.

Networked society assesses quality of learning using information and communication technologies, the extent of their use and societal and demographic factors. Networked Economy considers the extent to which the public and private sectors are participating in the networked world.

4. Role of Private Sector

About using Knowledge Management as an approach for finding appropriate information in a work situation in Knowledge Intensive Industry is the ability to find appropriate information in a work situation is a

Knowledge Intensive activity that is relevant to Knowledge Management. Modern Knowledge Management increasingly adopts knowledge sharing approaches, such as communities of practice, commercial information technology that is to support knowledge management tends to draw on Electronic Service for knowledge management.

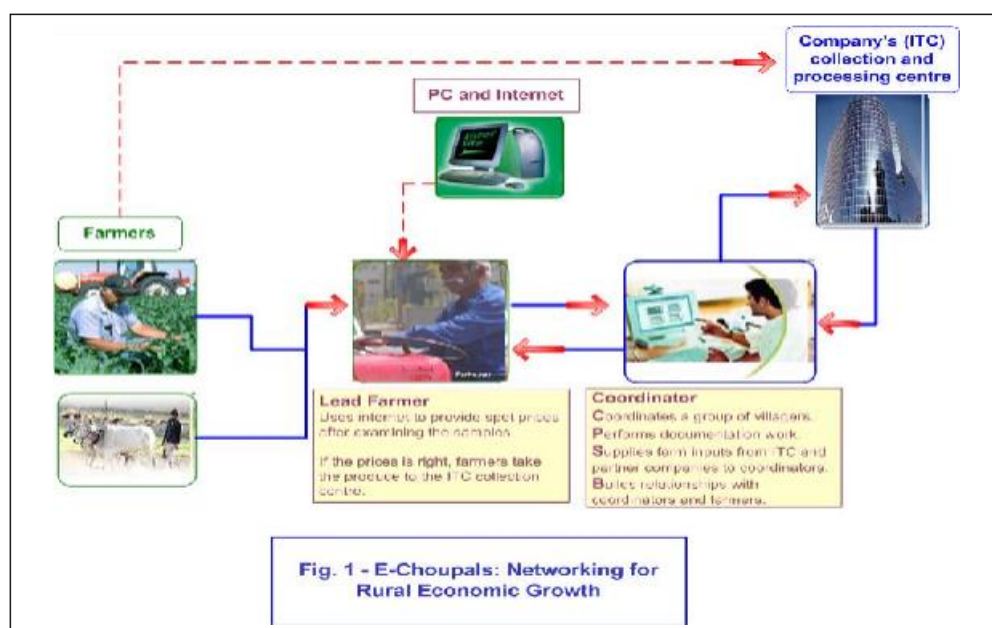

Organisations are incessantly looking for means to stimulate innovation and creativity, within and across work groups, functions and geographical boundaries. One of the ways to achieve this is through tacit knowledge exchanges in the form of sharing and transfer of knowledge by means of narratives, storytelling, reminders, best practices etc. At the same time, organisations are turning more towards information technology and seek ways of leveraging their investments in Information and Communication Technologies, Web technologies, in particular, to foster knowledge exchanges between individuals and work groups. The Web may be applied in new, innovative ways to draw dispersed community members together virtually and in particular, to promote tacit knowledge exchanges

The importance of industrial contribution can be reckoned by studying the case of an Indian company ITC's International Business Division, which in 6000 villages, creates e-choupals where they use computers and the internet to conduct their business. The target product is wheat and if ITC manages to capture the value of this wheat over next couple of months through these e-choupals, it will be a step closer to its dream of being India's largest agri-produce processor which services 100,000 villages covering 10 million farmers by 2007. The more audacious game plan of ITC is to create "An information superhighway to connect the rural economy". That means using the e-choupals as a single point of contact between farmers and a range of suppliers of agri-inputs and consumer goods – Monsanto, Eicher, Nagarjuna Fertilizers, *et al.*

To start with, choupal is a village square in north India where people gather to exchange gossip, to watch TV, talk work and the weather, etc. before they finally head home. These quaint trends are enabled with a PC, and provided an Internet access is termed as e-choupal with a business model build around. ITC started with these e-choupals to gain control over soyabean market and traded soyabean worth Rs 1600 million during last year. For its business models success, ITC created soya processing and collection centre. Then it started scouting villages around these centres for lead farmers to lead choupals. The computer was placed at this lead farmer's house and he was trained to use it. The information on daily prices was made available through Internet, at lead farmer's house. Information regarding best practices in farming and weather forecasts are also supplied. Co-ordinators were created who were responsible for market documentation, supplies farm inputs from ITC to lead farmers and build relations with and within lead farmers.

The concept is being picked out as evidence of how corporations can smartly fill institutional voids in emerging markets using power of Information Technology. This experiment creates enough communication capacity to connect with a market segment that is currently underserved but clearly has purchasing power. In the end, the rural India is the beneficiary by two ways, firstly by getting good yields for the crops and secondly knowing the power of IT and Internet. The concept is related rightly to the roots of those who till date were earning the least advantage of the ICTs.

This community-centric model of ITC (Fig. 1) not only instigates the rural economy through the means of Internet but paved the way for those who were lacking due to the unawareness of the use of Information super highway. Indirectly, this also creates inquisitiveness to learn more about the dominance of ICTs.

5. Conclusion

As a composite of the application of technology to government and bridge the digital gap, the solution falls beneath a large technological umbrella that includes:

- Instigating policies to promote private sector to participate and promote programmes that support the enlistment of digital society.
- The automation of public systems and the online delivery of services.
- The widespread adoption of network-based technologies and the migration to the Internet environment;
- the application of electronic capabilities and practices to governmental environments, to reduce costs and client fraud and to increase efficiency;
- The use of information and communication technologies (ICTs) to facilitate the conduct of business and foster economic growth;

- The fundamental reengineering and streamlining of the structures of government and the nature of public administration;
- The use of ICTs to foster new levels of democracy and citizen engagement, from electronic town halls to the online voting booth and new levels of political accountability.

B2B E-commerce and BPR for Establishing the Competitive Supply Chain

Hwan-Yann Su

Department of Asia-Pacific Industrial and Business Management
National University of Kaohsiung
Kaohsiung, Taiwan
h_su@nuk.edu.tw

Abstract

This paper deals with the problems frequently facing contemporary businesses including the problems of quality, lead times, quantity flexibility, customization, service and cost through supply chain management. To increase the competitiveness of the supply chain, the importance of increasing its velocity, variability visibility and value – 4vs - has been proposed. Understanding the importance of increasing competitive advantages through supply chain management, a referential model based on the 4vs is provided in detail. It is argued that B2B e-commerce and business process reengineering from the perspective of customers to create value are both important for the success of the proposed model and for establishing the competitive supply chain.

Key words: supply chain management, e-commerce, business process reengineering, competitive advantage

1. Introduction

E-commerce can be regarded as to carry out business activities over the informational network. There are four basic categories for these activities: the activities regarding Business to Business (B2B), Business to Consumer (B2C), Consumer to Business (C2B) and Consumer to Consumer (C2C). The B2B e-commerce can achieve for a business and its counterparts the elimination of repetitive data inputting because only one party has to input the needed data. The correctness of the data input is also enhanced for the same reason. The completeness of the data input is also improved because incomplete data will be automatically rejected. With the data regarding the items required being correctly and completely input, a business can strengthen its ability to fulfil the requirements of its customers and improve its quality. As Crosby [1] points out that “[i]nstead of thinking of quality in terms of goodness or desirability we are looking at it as a means of meeting requirements”.

The B2B e-commerce can also achieve for a business and its counterparts the reduction of lead times and the improvement of services. Instead of sending related data to each other through post or facsimile and ensuring their reception, they can be transmitted over the informational network in seconds and after office hours. Tremendous lead times can be saved and the service can be improved up to 24 hours a day. The partnership between a business and its counterparts can then be strengthened. The cost of labor and operation cost can also be considerably saved.

Business process reengineering (BPR) that is to re-think and re-design fundamentally and thoroughly the ways in which a corporate conducts its business in order to improve its performance dramatically [2-3], must be considered when implementing B2B e-commerce. To gain the best out of the co-operations from external counterparts such as customers by means of B2B e-commerce, a business should redesign its own business processes to remove unnecessary activities first. In addition, using information technology to facilitate BPR cannot be used in the way to simply speed up how a corporate used to conduct its business. A new way of conducting business must be sought out in advance and the new business processes can then be implemented by information technology.

Under severe global competition, ways of dealing with the problems of quality, lead times, quantity flexibility, customization, service and cost through supply chain management need further investigation. Incorporating B2B e-commerce and BPR, a referential model that intends to deal with these problems, is thus provided for establishing the competitive supply chain.

This paper will proceed as follows: section 2 will discuss the background of the research; section 3 will provide a referential model; section 4 will summarize the paper.

2. Background to the Research

2.1 Supply Chain Management

The Supply Chain Council (SSC) points out that supply chain management includes all the efforts made for transforming materials to finished products and distributing them to end customers and that the members of a supply chain range from suppliers to end customers. Severe global competition has forced the management of the supply chain to focus and compete simultaneously on quality improvement, lead time reduction, higher quantity flexibility, customization enrichment, service enhancement and cost reduction [4-9]. To increase the competitiveness of the supply chain, the importance of increasing its velocity, variability and visibility, has been proposed [10-13]. Velocity refers to the ability to quickly fulfil internal and external customer's demands. Variability refers to the ability to fulfil the fluctuated and changing customer's demands. Visibility refers to the ability to make transparent the status of resources.

To emphasize the customer orientation, this paper argues the importance of value. Each process and activity

should be carefully reviewed to ensure that it creates value for customers. As Seybold [14] points out that companies are so concentrated upon fine-tuning their own products that they fail to understand how their products fit into the real lives of their customers and how value can be delivered. Based on the 4vs – velocity, variability, visibility and value – the paper will investigate into the literature and propose a referential model to facilitate the establishment of the competitive supply chain.

2.2 Velocity

Due to the difficulties in accurately predicting the demand in the market and the depreciation of inventory within a short period of time, customers now days stop providing sales forecast for a business in advance. Instead, they give their orders to a business after they have taken orders from their own customers. This has forced a business to increase its ability to quickly fulfil its customers' demands under severe conditions such as "955" and "982". "955" and "982" refer to the severe due date conditions that 95% and 98% of ordered goods must delivered within 5 and 2 days respectively. To fulfil these requirements, all the processes of a business must be redesigned to eliminate unnecessary activities and to reduce all the lead times reducible. These processes include the processes of ordering, designing, procuring, manufacturing and distributing.

2.3 Visibility

The application of electronic commerce through the adoption of information technology to enabling rapid and effective intra-organizational and inter-organizational communication and coordination, to removing intra-organizational and inter-organizational barriers and to achieving customer satisfaction, has also been getting more and more emphasized [15-20]. In the area of intra-organizational communication, the use of information technology enables a business to have a clear picture of the availability of all its inventory resource, machinery resource and human resource in its factories, warehouses and branches around the world. This visibility provides a business with a foundation to calculate its ability to fulfil its customers' demands within due dates set by them and to figure out where the products ordered should be manufactured. This visibility also enables a business to minimize its inventory level, increase inventory turnover, and as a result, sell products with a small margin and lower its demand in capital.

In the area of inter-organizational customer communication, the development of Internet has provided a low-cost and yet rapid and boundaryless option because Internet is an open-structure environment that supports a variety of platforms and is compatible with existent facilities of a business. Internet enables instant information exchange and sharing too. In a traditional supply chain, the information such as product information or order information is exchanged between manufacturers and customers through mails or facsimiles. In addition, the

information such as production or inventory status is held by manufacturers and it takes a long process for manufacturers to share this kind of information with their customers. However, through Internet, information exchange and sharing can be instant.

2.4 Variability

In the modern world where customer's demands are getting more and more customized and cost reduction through inventory reduction has become an important consideration, make-to-order (MTO) strategy has been widely adopted. Generally speaking, there are three kinds of production strategies: make-to-stock (MTS), assemble-to-order (ATO) and make-to-order (MTO). MTS production strategy emphasizes on satisfying customer's unified demands through the inventory of finished products. Under this production strategy, finished products have been manufactured and manufacturing process has completed before customer's orders are issued. Therefore, the lead time for order fulfillment under this strategy is the shortest but its success depends on high level of costly finished product inventory. Its success also depends highly on accurate sales forecast because if the forecast goes wrong the inventory left will be costly finished product inventory.

ATO production strategy emphasizes on satisfying customer's differentiated demands through assembling pre-designed differentiated modules to finished products. Under this strategy, pre-designed differentiated modules have been manufactured before customer's orders are issued. Therefore, the lead time for order fulfillment under this strategy is still short (the time needed for assembling) but its success may be less dependent on costly finished product inventory. Its success is also less affected by sales forecast because if the forecast goes wrong, the inventory left will be less costly commonly usable modules for many differentiated products rather than costly and single purposed finished products. MTO production strategy emphasizes on satisfying customer's customized demands through designing and manufacturing according to customer's customized orders. In principle, manufacturing under this strategy cannot begin before the issuance of customer's orders. No finished products are stocked despite that sales forecast of finished products is still required for the procurement of materials needed. Therefore, the lead time for order fulfillment under this strategy is the longest but its success depends least on costly finished product inventory. Its success is also least affected by sales forecast because if the forecast goes wrong, the inventory left will be least costly materials rather than costly finished products. As a result of the growing importance of MTO for enhancing variability, this paper will particularly address the model proposed under this production strategy.

In addition to the customers' changing demands, their fluctuated demands also challenge a business' ability to manage its supply chain. Modularization and the same materials or components used in differentiated products are two strategies that can be adopted at the product

design stage to deal with the challenge. These two strategies enable a business to quickly re-allocate materials previously arranged when its customers change the products ordered because a considerable amount of materials can be used in or taken from other orders.

2.5 Value

Anderson and Narus [21] indicate that a growing number of businesses have drawn their attention to what their customers value to gain marketplace advantages over their less knowledgeable competitors. Lin and Su [22] also argue that transformation of better understanding of customers to long-term and promising customer relationships and formulating CRM strategies in this way can create valuable marketing opportunities, increase customer value and enhance customer satisfaction in the pursuit of business excellence. The value of products come from what customers want from them and why. Therefore, value creation should begin with a business' choice of who their customers are and its understanding of their priority regarding its branding, quality, due dates, quantity flexibility, product variety, service, price and innovation which as whole is the reason for their purchase. In this paper, supply chain management regards the chosen customers and their priority concerning its branding, quality, due dates, quantity flexibility, product variety, service, price and innovation as given from the function of marketing. Under this assumption, the task of supply chain management is then to redesign all the processes by means of BPR to make sure that unnecessary activities are removed and that the redesigned processes create values according to the list of priority as perceived by chosen customers.

3. The Proposed Supply Chain Integrative Model (SCIM)

Based on the importance of the velocity, visibility, variability and value factors mentioned above to the success of supply chain management, this paper proposes a model which enables the effective communication among the internal functions and external partners of a business for the successful implementation of the competitive supply chain. To reduce complication, this paper assumes the existence of certain management information systems which make visible and provide the following information: order information, customer-related information, production information, and shop floor status. Besides it also assumes that B2B e-commerce and BPR from the perspective of customers has been implemented to ensure the accessibility and acquirement of the above-mentioned information. To understand the model, the ideas of master production scheduling (MPS), material requirements planning (MRP) and capacity requirements planning (CRP) must be introduced.

3.1 MPS, MRP and CRP

Traditionally MPS is to decide what, when and how many end items will be manufactured and this decision is made under the consideration of a business' sales forecast, backorder, production capacity, material resource and production strategy. Material requirements planning (MRP) is to calculate the needed amount of materials and the needed procurement lead times of insufficient materials for master production schedules previously given. Therefore, accurate master production schedules can be used for MRP to calculate the right quantity of materials needed and coordinate the arrival of materials in order to reduce the material inventory level and procurement lead times. As American Production and Inventory Control Society (APICS) defines MPS as a representation of sales forecast, backorder, other demands, the quantity projected available and the quantity available to promise (ATP) and a representation of the planned production of different products of each product group and their quantity and schedule and how the facilities are arranged.

Accurate master production schedules can also dampen the utilization oscillation of production capacity. Inaccurate master production schedules may cause many problems. Without knowing exactly what, when and how many end items will be manufactured, production will be in chaos and production capacity will frequently swing between redundancy and insufficiency. Capacity requirements planning (CRP) is to decide and allocate the needed production capacity for master production schedules previously given. When production does not proceed according to schedule, MRP will be neglected because it will not matter so much if materials will arrive with the right quantity and at the scheduled time. When MRP is neglected, inventory levels of some items of materials or work-in-process (WIP) will go up on the one hand. However, on the other hand, inventory levels of some items of materials or WIP will be insufficient before production and chaotic production will be further postponed and procurement lead times will be increased. Inventory level of finished products will have to increase to deal with the immediate market demand because no one can estimate exactly what, when and how many finished products will be manufactured. Therefore, MPS is important for dampening the utilization oscillation of production capacity, reducing lead times, inventory levels of materials, WIP and finished products and coordinating the arrival of materials.

More importantly, a clear consideration of MRP and CRP is also very important before MPS can be finalized. Traditionally MPS, MRP and CRP are decided separately. Traditionally MPS is considered first and the decision regarding what, when and how many end items will be manufactured is made. Then MPS is taken as an input for MRP explosion. However, if the exploded MRP shows that materials will be unable to arrive with the right quantity or at the scheduled time or that production capacity will not be available for the time scheduled for production, there is no clear defined channel for modifying the MPS already made.

Therefore, this paper argues that it is necessary to integrate MPS with MRP and CRP. From the perspective of lead times and inventory level reduction and efficient utilization of production capacity for enhancing velocity, visibility, variability and value, a well-defined model for clearly integrating MPS with MRP and CRP is very important too. Thus, this paper will propose a model

considering MPS, MRP and CRP together with BPR from the perspective of customers implemented and certain management information systems already existent which provides the information mentioned above. The proposed internet-based Supply Chain Integrative Model (e-SCIM), as shown below in Figure 1, will be discussed in further detail in the following section.

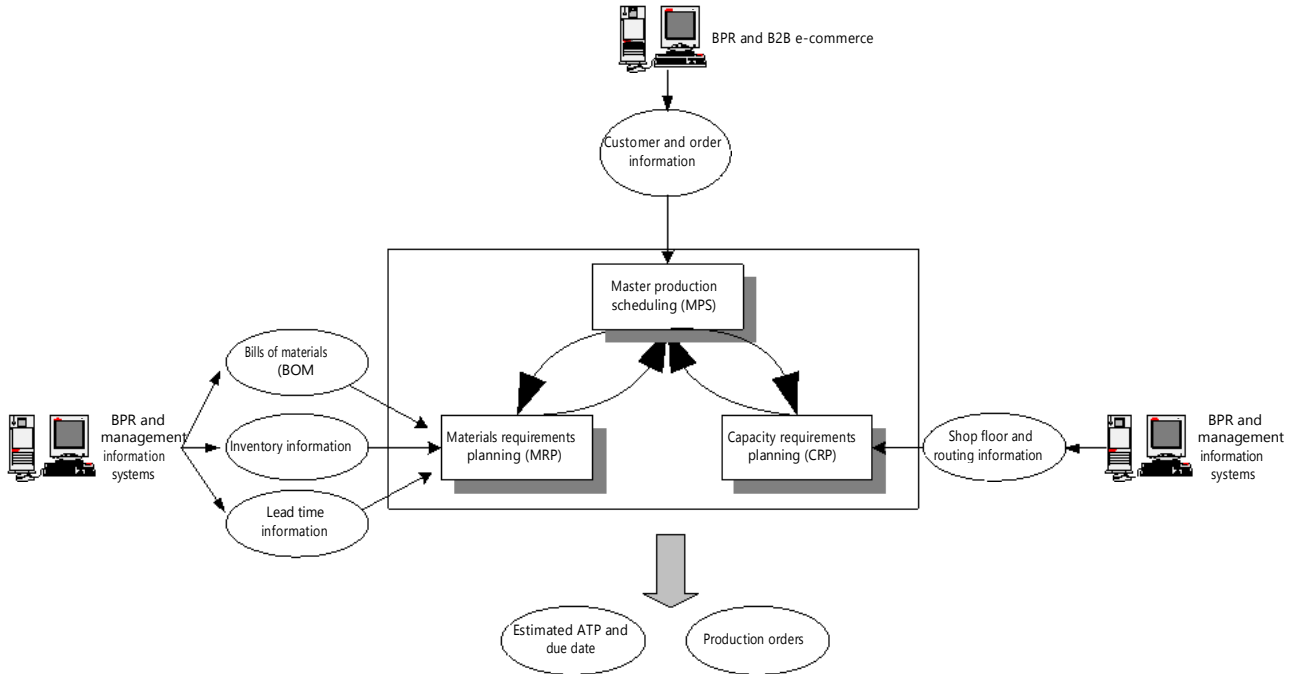

Figure 1: The informational inputs and the thorough consideration of MPS, MRP and CRP of the e-SCIM with BPR, B2B e-commerce and management information systems being implemented.

3.2 e-Supply Chain Integrative Model (e-SCIM)

In the proposed e-SCIM, the model needs the inputs of order information, customer-related information, production information, and shop floor status in order to determine the estimated due date and the quantity available to promise (ATP) and to generate production orders. Adopting the MTO strategy because of its growing importance, the e-SCIM considers the basic functions of MPS, MRP and CRP as a whole as depicted in Figure 2. The variables of the model are shown below in Table 1.

As shown below in Figure 2, the operating process of the model begin with customer's issuance of an order of a specific product that determines net demand $N(t)$ under MTO production strategy. Other products in the order may be processed later on in the same way. It is assumed here that the procurement of materials has been done according to sales forecast of that product. MPS is initiated and $M(t)$ is set to be equivalent to $N(t)$. That is, $M(t) = N(t)$. In addition, the net demand achievable $N_a(t)$ is also set to be equivalent to $N(t)$, i.e., $N_a(t) = N(t)$, assuming in the beginning that all the net demand can actually be satisfied at the interval t . Then Gross demand of item I_{mn} is determined by the explosion of $M(t)$ of finished product to the needed quantity of the n th item at level m according to the BOM. The value of I_{mn} projected available at interval t ,

$P(t)$, is the sum of I_{mn} projected available at the previous interval, $P(t-1)$, and the planned quantity of I_{mn} to be manufactured or received at this interval, $S(t)$, and the reduction of the gross demand of I_{mn} at interval t , $G(t)$. That is, $P(t) = P(t-1) + S(t) - G(t)$. If the $P(t)$ of item I_{mn} is no less than zero, which means the quantity of item I_{mn} is sufficient, there will be no arrangement of manufacturing or procurement of item I_{mn} . If all the items at level m are not fully exploded, the next item I_{mn+1} at level m is exploded and its $G(t)$ calculated. However, if all the items at level m are fully exploded and yet all the items at all levels are still not fully exploded, the first item at the next level $Im+1n$ is exploded and its $G(t)$ calculated. If all the items at level m are fully exploded and all the items at all levels are also fully exploded, the e-SCIM is arranged and completed. Then $ATP A(t) = M(t) = N_a(t) = N(t)$ and the estimated due date is the end of the interval t .

Table 1: Variables of the e-SCIM.

Notation	Variable	Detail description
$N(t)$: Net demand	In principle, the net demand is determined mainly by customer's orders under the MTO production strategy. However, net demand may be modified according the policy of a business. This variable is denoted by $N(t)$ in this model where t refers to the interval t .
$N_a(t)$: Net demand achievable	The net demand achievable refers to the demand that can actually be satisfied at the interval t .
$M(t)$: MPS	$M(t)$ here refers to the quantity of finished product to be manufactured at the interval t . Under the MTO strategy, $M(t) = N(t)$ in principle.
I_{mn}	: The n th item at level m	The n th item at level m (a material or WIP) according to the BOM of a particular finished product
$G(t)$: Gross demand of item	Gross demand of item I_{mn} is determined by the explosion of $M(t)$ of finished product to the needed quantity of the n th item at level m according to the BOM.
$S(t)$: Planned quantity of item to be manufactured or received	The originally planned quantity of item I_{mn} to be manufactured or received through procurement. When the quantity of item I_{mn} is not sufficient, this value needs to be adjusted.
$\Delta S(t)$: Insufficient quantity of item to be manufactured or received	When the quantity of item I_{mn} is not sufficient, additional quantity to be manufactured or received needs to be arranged.
$P(t)$: Item projected available	Item projected available refers to the projected quantity of I_{mn} available at a particular interval.
$PdL(t)$: Production lead time available for item	Production lead time available refers to the available manufacturing quantity (transformed from production lead time including queue, setup and run time) for I_{mn} at a particular interval.
$\Delta PdL_i(t)$: Production lead time unavailable for item	Production lead time unavailable for item refers to the insufficient manufacturing quantity (transformed from production lead time including queue, setup and run time) for I_{mn} at a particular interval.
$\Delta PdL_r(t)$: Production lead time unavailable for finished product	Production lead time unavailable for finished product refers to the transformed insufficient quantity of finished product $\Delta PdL_r(t)$ from the insufficient quantity of item $\Delta PdL_i(t)$ at a particular interval due to the unavailability of production lead time.
$C(t)$: Capacity available for item	Capacity available refers to the available manufacturing quantity (transformed from capacity) for I_{mn} at a particular interval.
$\Delta C_i(t)$: Capacity unavailable for item	Capacity unavailable for item refers to the insufficient manufacturing quantity (transformed from capacity) for I_{mn} at a particular interval.
$\Delta C_r(t)$: Capacity unavailable for finished product	Capacity unavailable for finished product refers to the transformed insufficient quantity of finished product $\Delta C_r(t)$ from the insufficient quantity of item $\Delta C_i(t)$ at a particular interval due to the unavailability of product capacity.
$\Delta PcL_i(t)$: Procurement lead time unavailable for item	Procurement lead time unavailable for item refers to the insufficient quantity that cannot be procured in time for item I_{mn} to be received at a particular interval.
$\Delta PcL_r(t)$: Procurement lead time unavailable for finished product	Procurement lead time unavailable for finished product refers to the transformed insufficient quantity of finished product $\Delta PcL_r(t)$ from the insufficient quantity of item $\Delta PcL_i(t)$ at a particular interval due to the unavailability of procurement lead time.
$A(t)$: Available to promise	Available to promise (ATP) here refers to the accumulative quantity of finished product that is stocked or is planned to be manufactured and that has not been promised to any customer.

However, if the $P(t)$ of item I_{mn} is less than zero, which means the quantity of item I_{mn} is not sufficient, the insufficient quantity of item I_{mn} to be manufactured or received through purchasing $\Delta S(t)$ needs to be arranged. Ideally $\Delta S(t)$ should be set to the value to make $P(t)$ equal zero. That is, ideally $\Delta S(t) = G(t) - P(t-1) - S(t)$. On the one hand, if item I_{mn} needs to be manufactured, the production lead time has to be considered. If the production lead time available $PdC(t) - \Delta S(t) > 0$, the production lead time is sufficient for additional production of item I_{mn} .

The production capacity has to be considered next. If the capacity available $C(t) - \Delta S(t) > 0$, which means the production capacity is sufficient for additional production of item I_{mn} , the question regarding if all the level m items are fully exploded is similarly considered and the rest processes are process 8, 9, 10 or 11 (see the numbered arrow in Figure 2) as mentioned above. On the other hand, if item I_{mn} needs to be procured, the lead time for procurement has to be considered. If the latest date when procurement must be done is later than the date when planning is made, which means time is still sufficient for

additional procurement of item I_{mn} , the question regarding if all the items at level m are fully exploded is similarly considered. The rest processes are process 8, 9, 10 or 11 (see the numbered arrow in Figure 2) as mentioned above. If production lead time unavailability, capacity unavailability or procurement lead time unavailability does not happen after all the items at all levels are fully exploded, the e-SCIM is arranged and completed. Then $ATP A(t) = M(t) = N_a(t) = N(t)$ and the estimated due date is the end of the interval t .

However, if the $P(t)$ of item I_{mn} is less than zero, which means the quantity of item I_{mn} is not sufficient, the insufficient quantity of item I_{mn} to be manufactured or received through purchasing $\Delta S(t)$ needs to be arranged. Ideally $\Delta S(t)$ should be set to the value to make $P(t)$ equal zero. That is, ideally $\Delta S(t) = G(t) - P(t-1) - S(t)$. On the one hand, if item I_{mn} needs to be manufactured, the production lead time has to be considered. If the production lead time available $PdC(t) - \Delta S(t) > 0$, the production lead time is sufficient for additional production of item I_{mn} .

The production capacity has to be considered next. If the capacity available $C(t) - \Delta S(t) > 0$, which means the production capacity is sufficient for additional production of item I_{mn} , the question regarding if all the level m items are fully exploded is similarly considered and the rest processes are process 8, 9, 10 or 11 (see the numbered arrow in Figure 2) as mentioned above. On the other hand, if item I_{mn} needs to be procured, the lead time for procurement has to be considered. If the latest date when procurement must be done is later than the date when planning is made, which means time is still sufficient for additional procurement of item I_{mn} , the question regarding if all the items at level m are fully exploded is similarly considered. The rest processes are process 8, 9, 10 or 11 (see the numbered arrow in Figure 2) as mentioned above. If production lead time unavailability, capacity unavailability or procurement lead time unavailability does not happen after all the items at all levels are fully exploded, the e-SCIM is arranged and completed. Then $ATP A(t) = M(t) = N_a(t) = N(t)$ and the estimated due date is the end of the interval t .

However, if the item I_{mn} needs to be manufactured and its $PdL(t)$ (Production lead time available) $-\Delta S(t) < 0$, which means the production lead time is insufficient for additional production of item I_{mn} , Production lead time unavailable for item $\Delta PdL_i(t) = \Delta S(t) - PdL(t)$. Thus, Production lead time unavailable for finished product $\Delta PdL_f(t)$ may be obtained through transforming the insufficient quantity of item $\Delta PdL_i(t)$ via calculating how many finished products cannot be manufactured at the particular interval t due to the unavailability of production lead time. Then MPS is rearranged and $M(t)$ is reduced to $M(t) - \Delta PdL_f(t)$ and the whole processes restarts.

If production lead time is sufficient but $C(t)$ (capacity available) $-\Delta S(t) < 0$, which means the production capacity is insufficient for additional production of item I_{mn} , Capacity unavailable for item $\Delta C_i(t) = \Delta S(t) - C(t)$. Thus, Capacity unavailable for finished product $\Delta C_f(t)$ may be obtained through transforming the insufficient quantity of item $\Delta C_i(t)$ via calculating how many finished products cannot be manufactured at the particular interval t due to the unavailability of production capacity. Then MPS is rearranged and $M(t)$ is reduced to $M(t) - \Delta C_f(t)$ and the whole processes restarts.

If item I_{mn} needs to be procured and the latest date when procurement must be done is earlier than the date when planning is made, which means time is insufficient for additional procurement of item I_{mn} , $\Delta PcL_i(t) = \Delta S(t)$. Thus, Procurement lead time unavailable for finished product $\Delta PcL_f(t)$ may be obtained through transforming the insufficient quantity of item $\Delta PcL_i(t)$ via calculating how many finished products cannot be manufactured at the particular interval t due to the unavailability of procurement lead time. Then MPS is rearranged and $M(t)$ is reduced to $M(t) - \Delta PcL_f(t)$ and the whole processes restarts.

When production lead time unavailability, capacity

unavailability or procurement lead time unavailability happen(s), the finalized $M(t)$ will be less than net demand available $N_a(t)$ after all the items at all levels are fully exploded. The difference between $N_a(t)$ and $M(t)$ will be arranged for MPS at the next interval $t+1$. That is, $M(t+1) = N_a(t) - M(t) = N_a(t+1)$. In addition, $N_a(t)$ is reduced to $M(t)$. The whole processes begin again until at a particular interval $t+x$ the arranged MPS $M(t+x)$ equals $N_a(t+x)$. Then the e-SCIM is arranged and completed. As can be seen in Table 2 below, the estimated due date is the end of the interval $t+x$. Assuming the due date required by the customer is at interval $t+y$. In this situation, if $t+y1 \geq t+x$, $ATP A(t+y) = N(t) = A(t+x)$ and due date is the end of interval $t+x$. If $t+y2 < t+x$, $ATP A(t+y) = N(t) - \sum_{i=1}^{y-1} N(t+i) + N_a(t+y2) + \dots + N_a(t+x) = A(t+y2)$ and due date is the end of interval $t+y2$. When this happens, the order will undergo a different process. Manual intervention as to consider working overtime, partial shipment, alternative materials and processes, or outsourcing and to negotiate with customers, will take place to ensure that the order can be fulfilled as negotiated.

Table 2: The related intervals, net demand, MPS, net demand achievable, due date and ATP in a planning horizon T.

Planning horizon T	z intervals										
	Interval	t	t + 1	...	t + y ₂	...	t + x	...	t + y ₁	...	t + z - 1
Net demand N(t)	N(t)										
MPS M(t)	M(t)	M(t+1)		M(t+ y ₂)		M(t+x)					
Net demand achievable N _a (t)	N _a (t)	N _a (t+1)		N _a (t+ y ₂)		N _a (t+x)					
Due date				Customer's due date t+ y ₂		Estimated due date t+x		Estimated due date t+x			
ATP A(t)				A(t+ y ₂)		A(t+x)		A(t+x)			

4. Discussion and Concluding Remarks

B2B e-commerce and BPR from the perspective of customers will reduce the manual and iterative operations and improve communication among the customers and the sales department and the production department of a business. This is done through the elimination of repetitive data input, the correctness and completeness of data input, and as a result a business will have a stronger ability of to fulfil the requirements of its customers and improve its quality. B2B e-commerce and BPR from the perspective of customers can also achieve for a business and its counterparts the reduction of lead times and the improvement of services and thus contribute to its velocity, visibility and value regarding quality. Through the proposed e-SCIM and the corresponding BPR and information systems needed to implement the model, it is expected that the manufacturing lead times can be reduced. The reason for manufacturing lead times reduction is that unnecessary queuing for production capacity availability can be eliminated when production schedules became

accurate. In the situation when production schedules is not accurate, it is very likely that production capacity is still not available when all the materials, components, assemblies or WIP needed for production are ready. This will contribute to a business' ability to enhance its velocity. Through the adoption of MTO, modulization and multiple-purpose materials and components strategies, it is expected the variability of a business can be improved. Variability is also improved when a business is able to communicate quickly with its customers and its internal functions can communicate quickly among themselves through the enhancement of its velocity. It is also expected that the procurement lead times, on-time shipping rate and inventory cost can be reduced. The procurement lead times can be reduced because all the materials needed will arrive at the specified dates when production schedules become accurate, material requirements can be well planned and the production process will not postpone for the lack of few materials. On-time shipping rate can be increased because of accurate production schedules and due date estimation. The material, WIP and finished product inventory cost can be reduced because all kinds of the inventory can be less stocked when production schedules and estimated due date become accurate. These can contribute to the enhancement of a business' velocity and value regarding due dates and cost. It has also been considered to adopt the advantage of customization and inventory level reduction of the MTO strategy and to improve its difficulties in inaccurate due date estimation, long due dates, the calculation of ATP, the management of production capacity constraints and no finished products stocked for dealing with production uncertainty.

Therefore, the proposed e-SCIM enables a business to compete on quality improvement, lead time reduction, higher quantity flexibility, customization enrichment, service enhancement and cost reduction. It is demonstrated that the ability to improve velocity, visibility, variability and value of the supply chain can be enhanced effectively by means of the e-SCIM, which considers the basic functions of MPS, MRP and CRP as a whole, and through the deployment of the modern IT via connecting the business with the information systems of its internal functions and with its customers over B2B e-commerce. The author has been involved in many e-business projects and the proposed model has been being implemented in a real world environment. The initial result demonstrates B2B e-commerce and BPR from the perspective of customers to create value are both important for the success of the proposed model and for establishing the competitive supply chain.

Abstract

As the knowledge-based economy time comes, the core of business process is transforming financial intensive into technology intensive and knowledge intensive gradually. However, the value of knowledge itself can't be measured easily. We must evaluate and investigate the performance of knowledge management through activities of knowledge management process. During the performance evaluation process, many uncertain factors must be considered. It is also involved ambiguity occurred by human subjective judgment. Therefore, a performance evaluation model of knowledge management is proposed in this paper by combining Fuzzy Delphi with Fuzzy AHP. Finally, a numerical example is given to demonstrate the procedure for the proposed method at the end of this paper.

Keyword: Knowledge Management, Measuring Performance, Fuzzy Delphi, Fuzzy AHP

1. Introduction

When the knowledge becomes the key resource of the enterprise, how to apply knowledge appropriately to produce new knowledge and value is an important issue for business management.

Drucker[8] indicated that knowledge will become the most important sources for promoting business advantage. However, lacks of the effective measurement tool, knowledge cannot be exploited sufficiently. In recent years, many businesses have realized that knowledge management is the most important issue to increase their competitiveness. Therefore, the performance evaluation and measurement become a key point of promoting knowledge management plan successfully. However, the evaluation process of knowledge management must consider many uncertain factors such as attitude of employee, professional ability, and the subjective judgment of managers. Thus, it is difficult to evaluate the performance of knowledge management easily. Therefore, an evaluation model of knowledge management is proposed in this paper by combining fuzzy set theory with analytic hierarchy process (AHP).

2. Literature review

2.1 Knowledge Management

Liebowitz and Beckman[15] identified that knowledge management contains the following definitions.

- (1) The knowledge management is a systematic process that creates knowledge clearly. Raise the relevant knowledge in business with applying avail knowledge.
- (2) The knowledge management uses the experience, knowledge and expert knowledge to create new ability. It makes the business possesses the excellent performance, encourages innovation and increases the value of customers.

Papows[17] proposed seven reasons of implementing the knowledge management.

- (1) Globalization. If Organizations all around world own an important competitive advantage, namely it can share experiences and resources effectively.
- (2) Speed. As of the business shortens the lead time and obtain the valid business operations, we must get the information and the knowledge valuable quickly.
- (3) Service orientation. If attaining quick response, all essential information and related operations must make the employee work on-line in any time and change the action procedure.
- (4) Saturation of workers. Employees have higher turnover at knowledge age. We usually need a set of system to keep the knowledge of the worker and reuse them.
- (5) More close relation of business. The WWW is also a resource that learns the new information. Each organization must integrate it in usual learning processes.
- (6) Technique. Advanced information system, group software and WWW assembly together provide technique foundation of knowledge management for the company.
- (7) Competition. The organization regards its intelligent capital as the force and promotes the competitive advantage of the organization systematically.

Sarvary[18] identified the knowledge management is the integration of the business flow via creation of business and using a process of collective knowledge. This process includes three flows as follows.

- (1) Organization learning. The company acquires the process of the information or knowledge.
- (2) Generalize knowledge. It is a process that information

is converted and integrated knowledge. The knowledge can resolve the problem of the commerce.

(3) Propagation knowledge. Making organization members can acquire and use the process of company community knowledge.

Synthesize above the viewpoints of the knowledge management, knowledge management is a process for business to increase the competitiveness by creation, transformation, diffusion and deposition of knowledge.

2.2 Knowledge management activities

The knowledge management flow indicates the different attitudes of knowledge management in business management process. The definition of knowledge management flows includes knowledge creation, knowledge transformation, knowledge diffusion and knowledge storage. Some illustrations of knowledge management activities are shown in Table 1.

2.3 Performance evaluation

The performance evaluation in nature is the control function in the business management activities. Being able to generate influences or take action in before the event or activities steering by the establishment of the performance evaluation system. The appraisal must depend on the reasonable and valid performance indicators and reach to the object of performance evaluation. Concretely, the performance evaluation has four objects[19] :

- (1) The object of the fulfillment to weigh the extent of success.
- (2) Providing the suggestion or correct amendments to the organization redevelopment.
- (3) Providing the feedback mechanism to manager.
- (4) Evaluating the internal input and output.

Because knowledge management flow of business and its performance evaluation have the subjective recognition, and is seen as problems of multi criteria, we can use many appraisable theories of multi criteria to reach reasonable performance evaluation. Therefore, this paper uses the linguistic variables to represent the subjective judgment of decision makers, and combine Fuzzy Delphi method with Fuzzy Analytic Hierarchy Process method (Fuzzy AHP) to propose a performance evaluation model of knowledge management.

3. Fuzzy Theory

3.1 Triangular fuzzy number and linguistic variable

The original concept of fuzzy sets in the pioneering

paper of Zadeh was introduced as an extension of usual sets, by enlarging the truth value set of grade of membership from the two value set $\{0, 1\}$ to the unit interval $[0, 1]$ of real numbers[20].

3.1.1 Triangular fuzzy number

Triangular fuzzy number can be defined by a triplet $\tilde{T} = (l, m, u)$ and $a \leq b \leq c$ (shown as Fig 1). The fuzzy number is the so-called triangular fuzzy number with its characteristic member function written as[1, 12] :

$$\mu_{\tilde{M}}(x) = \begin{cases} \frac{x-a}{b-a}, & a \leq x \leq b \\ \frac{c-x}{c-b}, & b \leq x \leq c \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

3.1.2 Linguistic variable

A linguistic variable is a variable whose values are linguistic terms [21]. The concept of linguistic variable is very useful in dealing with the situations are too complex to be reasonably described in quantitative expressions [21]. For example, the membership functions of the term set {Very Unimportant (VU), Unimportant (U), Medium (M), Important (I), Very Important (VI)} for representing weights of the importance of knowledge management. The linguistic values can also be represented via triangular fuzzy numbers.

3.1.3 Distance measurement

Let $\tilde{M}_1 = (a_1, b_1, c_1)$ and $\tilde{M}_2 = (a_2, b_2, c_2)$ be two triangular fuzzy numbers, then the vertex method is defined to calculate the distance between them as[5]:

$$d(\tilde{M}_1, \tilde{M}_2) = \sqrt{\frac{1}{3}[(a_1 - a_2)^2 + (b_1 - b_2)^2 + (c_1 - c_2)^2]} \quad (2)$$

3.2 Fuzzy Delphi Method

This paper adopts Fuzzy Delphi Method to select the evaluation indicators. The Fuzzy Delphi Method is one of the specialist forecasts, its main object lies in obtaining the consensus of specialists, looking for to the opinion of the uniformity of the particular object [7].

The traditional Delphi method is one effective method, which enables forecasting by converge a possibility value through the feedback mechanism of the result of questionnaires, based on experts' judgments. However, the weakness of the traditional Delphi is that it requires repetitive surveys of the experts to allow the forecast values to converge. Therefore, Fuzzy Delphi Method uses Linguistic variable to express opinions of each expert, acquiring better integrative results [11, 13].

The Fuzzy Delphi Method is applied in this paper to find out the evaluation indicators. The steps are described as follows :

Step1. The expression of the specialist opinion

Each expert makes use of the Linguistic variable representing the importance weights of the decision criteria (shown as the Table 2).

Step2. Integrate fuzzy evaluative values of experts

Using Fuzzy Delphi Method to integrate fuzzy evaluative values of all experts in this step. If the l th expert judges the importance of the k th indicator is shown denoted by $\tilde{W}_{lk} = (a_{lk}, b_{lk}, c_{lk})$, the fuzzy weight \tilde{W}_k of the k th indicator, then \tilde{W}_k can be calculated as:

$$\tilde{W}_k = (a_k, b_k, c_k) \quad , \quad k = 1, 2, \dots, n \quad (3)$$

$$a_k = \min_l \{ a_{lk} \}, b_k = \frac{1}{m} \sum_{l=1}^m b_{lk}, c_k = \max_l \{ c_{lk} \}$$

Step3. Selecting evaluative indicators

Using Centroid Method to transform fuzzy weight of each indicator \tilde{W}_k into single value. S_k [14]. It can be calculated as:

$$S_k = \frac{a_k + b_k + c_k}{3} \quad (4)$$

Set a threshold value as t and select a suitable evaluative indicator. The rule of selection is described as follows:

- (a) If $S_k \geq t$, then accept the k th initial indicator as evaluative indicator.
- (b) If $S_k < t$, then delete k th initial indicator.

3.3 Fuzzy Analytic Hierarchy Process Method (Fuzzy AHP)

Buckley[2, 3] proposed that AHP method on the criteria's appraisal can't present appraisal subjective judgment and criteria in real situations. Therefore, Fuzzy AHP is proposed by combining fuzzy set theory with AHP to reflect true environment decision analysis suffers of subject. Making use of the Fuzzy AHP undertaking appraisal step justification as follows:

Step1. Based on features decomposed by each attribute to

create the hierarchy levels.

Step2. Calculate fuzzy positive reciprocal matrix. Converting the linguistic evaluation into triangular fuzzy numbers to construct the fuzzy decision matrix and determine the fuzzy weight of each criterion.

Step3. Calculate fuzzy weight. According to Lambda-Max method, we can calculate the fuzzy weight value [6].

4. Performance Evaluation Model

The knowledge management activities are divided into knowledge creation, knowledge diffusion, knowledge transformation, and knowledge storage in this paper. The performance evaluation framework of knowledge management is shown as Fig. 2.

The processes of knowledge management performance evaluation model is described as follows:

Step1. Calculate the fuzzy weight value of the evaluative dimension.

- (1) Each expert use linguistic variable of the Table 3 to calculate the KM performance of each dimension. And give a linguistic variable to represent the relative importance in two dimensions [2]. Giving comparative and important evaluation of extent in pair-wise comparisons.
- (2) Using Fuzzy AHP to calculate the fuzzy weight as \tilde{W}_i^p of each expert.
- (3) Using Average Method to integrate fuzzy weight value of each expert with regard to each dimension into \tilde{W}_i .

$$\tilde{W}_i = 1/p (\tilde{W}_i^1 \oplus \tilde{W}_i^2 \oplus \dots \oplus \tilde{W}_i^p) \quad (5)$$

Step2. Calculating evaluative value of each dimension

- (1) Each expert use linguistic variable of the Table 3 to calculate evaluative values and weight values of evaluative indicators within each evaluative dimension.
- (2) Using Weighted Average Method to integrate all of fuzzy evaluative value of all experts within each evaluative dimension. It can be computed as:

$$\tilde{X}_{ij} = \frac{1}{p} \{ (\tilde{X}_{ij1} \otimes \tilde{W}_{ij1}) \oplus (\tilde{X}_{ij2} \otimes \tilde{W}_{ij2}) \oplus \dots \oplus (\tilde{X}_{ijp} \otimes \tilde{W}_{ijp}) \} \quad (6)$$

Where \tilde{X}_{ij} is the j th indicator's fuzzy evaluative value within i th dimension after the integration of all experts. \tilde{X}_{ijp} is the j th evaluative indicator's fuzzy evaluative value of the p th decision-maker within the i th dimension. \tilde{W}_{ijp} is the j th indicator's fuzzy weight value of the p th expert within the i th dimension.

- (3) Calculating fuzzy evaluative value in each dimension

as:

$$\tilde{X}_i = \frac{1}{n_i} \{ \tilde{X}_{i1} \oplus \tilde{X}_{i2} \oplus \dots \oplus \tilde{X}_{in_i} \}, i=1,2,\dots,m \quad (7)$$

where \tilde{X}_i is the fuzzy evaluative value of the i th dimension. n_i is the evaluative indicator's numbers of the i th dimension.

(4) According to the fuzzy weight value and fuzzy evaluative value of each dimension, calculating comprehensive fuzzy evaluative value as:

$$\tilde{P} = \frac{1}{m} \sum_{i=1}^m (\tilde{X}_i \otimes W_i) \quad (8)$$

where \tilde{P} is the comprehensive fuzzy evaluative value, and m is the numbers of dimensions.

(5) Calculating the distance value of comprehensive fuzzy evaluative value \tilde{P} and the linguistic variable L_i of each evaluative value (shown in Table 4). Distance measurement is computed as:

$$d(\tilde{P}, L_i) = \sqrt{\frac{1}{3} [(P_1 - l_{i1})^2 + (P_2 - l_{i2})^2 + (P_3 - l_{i3})^2]} \quad (9)$$

where $\tilde{P} = (p_1, p_2, p_3)$ is the comprehensive fuzzy evaluative value. $L_i = (l_{i1}, l_{i2}, l_{i3}), i=1,2,3,4,5$ is the linguistic variable of evaluative value.

(6) If the distance between comprehensive fuzzy evaluative value \tilde{P} and the linguistic variable L_i is the minimum value, it represents that L_i is the integral evaluative value of KM activities.

5. Example Description

According to the business knowledge management performance evaluation framework (shown as Fig. 2) in this paper. Suppose there are three experts to evaluate the performance of KM. The step is described as follows:

Step1. The hypothesis makes the pair-wise comparison matrix by the three expert's important extent to each evaluative dimension as follows:

$$\begin{aligned} \tilde{T}_1 &= \begin{bmatrix} (1,1,1) & (7,8,9) & (1,2,3) & (7,9,9) \\ (0.11,0.12,0.14) & (1,1,1) & (0.14,0.2,0.33) & (1,3,5) \\ (0.33,0.5,1) & (3,5,7) & (1,1,1) & (5,7,9) \\ (0.11,0.11,0.14) & (0.2,0.33,1) & (0.11,0.14,0.2) & (1,1,1) \end{bmatrix} \\ \tilde{T}_2 &= \begin{bmatrix} (1,1,1) & (1,3,5) & (3,4,5) & (7,9,9) \\ (0.2,0.33,1) & (1,1,1) & (1,3,5) & (7,9,9) \\ (0.2,0.25,0.33) & (0.2,0.33,1) & (1,1,1) & (5,7,9) \\ (0.11,0.11,0.14) & (0.11,0.11,0.14) & (0.11,0.14,0.2) & (1,1,1) \end{bmatrix} \\ \tilde{T}_3 &= \begin{bmatrix} (1,1,1) & (3,5,7) & (3,4,5) & (5,7,9) \\ (0.14,0.2,0.33) & (1,1,1) & (0.2,0.33,1) & (5,6,7) \\ (0.2,0.25,0.33) & (1,3,5) & (1,1,1) & (3,4,5) \\ (0.11,0.14,0.2) & (0.14,0.16,0.2) & (0.2,0.25,0.33) & (1,1,1) \end{bmatrix} \end{aligned}$$

Step2. Calculating fuzzy weight value of each decision-maker within dimension via Fuzzy AHP as :

$$\begin{aligned} \tilde{W}_1^1 &= (0.45, 0.06, 0.25, 0.04) \\ \tilde{W}_1^2 &= (0.3, 0.16, 0.11, 0.03) \\ \tilde{W}_1^3 &= (0.48, 0.14, 0.16, 0.05) \\ \tilde{W}_2^1 &= (0.55, 0.09, 0.32, 0.04) \\ \tilde{W}_2^2 &= (0.54, 0.28, 0.15, 0.03) \\ \tilde{W}_2^3 &= (0.58, 0.14, 0.23, 0.05) \\ \tilde{W}_3^1 &= (0.55, 0.22, 0.39, 0.06) \\ \tilde{W}_3^2 &= (0.54, 0.33, 0.16, 0.13) \\ \tilde{W}_3^3 &= (0.58, 0.15, 0.25, 0.05) \end{aligned}$$

Therefore, integrates the fuzzy weight value of each decision-maker within evaluative dimension as:

$$\begin{aligned} \tilde{W}_1 &= (1.23, 0.36, 0.52, 0.12) \\ \tilde{W}_2 &= (1.67, 0.51, 0.7, 0.12) \\ \tilde{W}_3 &= (1.67, 0.7, 0.8, 0.24) \end{aligned}$$

$$W_1 = 0.52, \quad W_2 = 0.18, \quad W_3 = 0.22, \quad W_4 = 0.08$$

Step3. Decision-makers use linguistic variable (shown as Table 5 and 6) to give their assessment value. According to data of Table 4. The first dimension value can be computed as:

$$\begin{aligned} \tilde{x}_{11} &= \frac{1}{3} \{ [0.5, 0.6, 0.7] \otimes [0.7, 0.8, 0.9] \oplus \\ &\quad [0.5, 0.6, 0.7] \otimes [0.3, 0.5, 0.7] \oplus \\ &\quad [0.5, 0.6, 0.7] \otimes [0.7, 0.8, 0.9] \} \\ &= (0.28, 0.42, 0.58) \end{aligned}$$

Step4. Calculating evaluative value of each dimension as:

$$\begin{aligned} \tilde{x}_1 &= (0.16, 0.25, 0.35) \\ \tilde{x}_2 &= (0.07, 0.14, 0.25) \\ \tilde{x}_3 &= (0.18, 0.28, 0.36) \end{aligned}$$

Step5. Calculating fuzzy evaluative value of comprehensive effects according to the weight value of each dimension is $\tilde{P} = (0.28, 0.46, 0.63)$.

Step6. Calculating the distance value of comprehensive fuzzy evaluative value and the linguistic variable of each evaluative value via distance measurement as:

$$d(\tilde{P}, \tilde{F}) = \sqrt{\frac{1}{3}[(0.28-0.7)^2 + (0.46-0.9)^2 + (0.63-0.9)^2]} = 0.38(\text{VG})$$

$$d(\tilde{P}, \tilde{B}) = 0.35(\text{G})$$

$$d(\tilde{P}, \tilde{E}) = 0.25(\text{MG})$$

$$d(\tilde{P}, \tilde{D}) = 0.15(\text{F})$$

$$d(\tilde{P}, \tilde{C}) = 0.01(\text{MP})$$

$$d(\tilde{P}, \tilde{H}) = 0.08(\text{P})$$

$$d(\tilde{P}, \tilde{V}) = 0.16(\text{VP})$$

$$d(\tilde{P}, \tilde{R}) = 0.26(\text{CP})$$

$$d(\tilde{P}, \tilde{G}) = 0.95(\text{CG})$$

Step7. If the distance value is the minimal, it's represented the whole performance evaluative value as namely the corresponding linguistic variables is [Medium poor].

According to the foregoing results, the knowledge management performance of this business belongs to "Medium Poor".

6. Conclusion

From the viewpoint of the business, knowledge management is based on the knowledge embedded in the process and allowed that business to operate profitably in providing attractive products and services to customers. The knowledge has become the most important practical factor. To demonstrate a business benefit, knowledge must be measured.

In general, business must reach a balance between intangible and tangible assets. The proposed model provides business systematic processes to measure the business performances evaluation in knowledge management. Using the linguistic variable and fuzzy Delphi method, managers can evaluate and understand the overall performance in knowledge management easily and effectively.

Table 1 Activities and contents of knowledge management

Knowledge management activities	Contents
Knowledge creation [16]	Organizational knowledge creation involves five main steps : (1) Sharing tacit knowledge (2) Creating concepts (3) Justifying concepts (4) Building a prototype (5) Cross-leveling knowledge.
Knowledge transformation [16]	Knowledge Spiral brings up knowledge creation having four paths included from tacit to tacit(Originating-sharing tacit knowledge between individuals), from tacit to explicit(Conversing-having group conversations to form concepts), from explicit to explicit(Documenting-converting knowledge into explicit forms), from explicit to tacit(Internalizing-making explicit knowledge tacit once more). It is mainly aimed at the interaction of tacit and explicit knowledge to show the path of the knowledge management removal at the same time, by the criterion knowledge oneself whether be easy to be explicit, and then aimed at the knowledge to be easy to be explicit or not, depend on the different path to design the more likely knowledge removal mechanism.
Knowledge diffusion [9]	Knowledge diffusion suffers the impact of common knowledge in employee easily, containing common language, common symbol, collective expertise, consciousness that share, know the individual knowledge realm.
Knowledge storage[4]	The business is considering how to store knowledge resource. It can adopt the knowledge to extract, the knowledge diffusion, structured etc.

Abstract

In this paper, we propose a model to study influence of pricing and deteriorating rate on the supply chain level net profit and total inventory where genetic algorithm is used for determine the optimal solution. A one-vendor and multi-retailer supply chain for a single deteriorating finished product and raw materials is analyzed. Under the proposed strategy, the vendor buys a non-deteriorating materials to vendor a deteriorating finished product, delivers the finished product to all retailers by common replenishment periods based on VMI (vendor managed inventory) being implemented. All retailers who buy the finished product sell the finished product on their markets. In all of these markets, the finished product in different markets has substitution each other since consumers may have opportunity to buy the finished product from different retailer and Cobb-Douglas demand function is introduced to describe this market attribute. After developing an integrated product-inventory-marketing model for deteriorating product, genetic algorithm is conducted to calculate the optimal pricing and inventory policies. Finally we present the results of a detailed numerical study that analyses the market and deteriorating rate related parameters influence on the supply chain level net profit and inventory level.

1. Introduction

A lot of research efforts have been made and several integrated inventory models have emerged in order to minimize the inventory cost of deteriorating products for both vendor and buyers. Goyal (1977) [6] proposes a joint economic lot size (JELS) model where the objective is to minimize the total relevant costs for a single vendor, single buyer system. Banerjee (1986) [1] generalizes Goyal's model by incorporating a finite production rate for the vendor and gives the optimal joint production or order quantity. Goyal (1988) [8] extends Banerjee's model again by relaxing the lot-for-lot production assumption and argues that the economic production quantity will be an integer multiple of the buyer's purchase quantity and shows that its model provides a lower or equal joint total relevant cost as compared to Banerjee's model. Kohli and Park (1994) [12] investigate joint ordering policies as a method to reduce transaction costs between a single vendor and a homogeneous group of buyers. They present expressions for optimal joint order quantities assuming all products are ordered in each joint order. Lu (1995) [15] considers a one-vendor multi-buyer integrated inventory

model and gave a heuristic approach for joint replenishment policy. Banerjee and Banerjee (1992) [2] consider an EDI-based vendor-managed inventory (VMI) system in which the vendor makes all replenishment decisions for his/her buyers to improve the joint inventory cost. But most of these previous works on integrated vendor-buyer inventory systems do not consider raw material procurement decisions except for the work by Woo, Hsu, and Wu (2001) [22]. Their model is extended to become a three-level supply chain in which one raw material is considered. However, they do not consider marketing policies and deteriorating products in VMI Vendor Managed Inventory.

Several researchers have integrated marketing policies and deteriorating products into inventory decisions for infinite time horizon. Kotler (1971) [13] first incorporates marketing policies into inventory decisions and discussed the relationship between economic ordering quantity and price decisions. Ladany and Sternleib (1974) [14] study the effect of price variations on demand and consequently on EOQ (economic order quantity). Goyal and Gunasekaran (1995) [10] extend the previous work considering perishable goods in a multi-stage inventory model. Although both of the advertisement and price are considered in their papers, they are treated as input parameters and the impacts of advertisement and price are only analyzed by sensitive analysis in their numerical example, without considering the substitution of finished products where Cobb-Douglas demand function is considered. Moreover, they do not consider supply chain context, only limited to a vendor or manufacturer. However, in reality, there are significant differences between deteriorating rates among raw materials, and between finished products. In such circumstances, the raw materials' deteriorating rates can be neglected when compared with that of the finished product. However, this issue has not yet been widely considered in previous VMI works. Moreover, it has been a challenge to calculate the optimal solution for deteriorating product as reported in the literature. Both Goyal and Gunasekaran (1995) [10] develop a computer program for finding their optimal solution by using an exhaustive search method and consume a large amount of computer resources. Fortunately genetic algorithms have been demonstrated successful in providing good solutions to many complex optimization problems and thus received increasing attentions. Their uses have been well documented in the literatures, such as that of Goldberg (1989) [5], Michalewicz (1994) [16] and Fogel (1994) [4], for a wide

variety of optimization problems. GA (genetic algorithm) has also been applied to supply chain optimization.

In this paper, we propose a model to study the influence of pricing and deteriorating rate on the net profit and total inventory cost of the supply chain. GA is used for determining the optimal solution from the proposed model. A one-vendor and multi-retailer supply chain for a single deteriorating finished product is analyzed, also considering the raw materials. Under the proposed strategy, the vendor buys non-deteriorating materials for producing deteriorating finished products, and delivers the finished product to all retailers by common replenishment periods based on VMI (vendor managed inventory). All retailers who buy the finished product sell the finished product on the markets. In the markets, the finished product sold by different retailers has substitution each other since consumers may have opportunity to buy the finished product from different retailers and Cobb-Douglas demand function is introduced to describe this market attribute. After developing an integrated product-inventory-marketing model for deteriorating product, genetic algorithm is conducted to calculate the optimal pricing and inventory policies.

This paper will be organized as follows. Section 2 introduces assumptions and notation. In Section 3, we analyze the system and develop an integrated product-inventory -marketing model for deteriorating product. Section 4 presents a genetic algorithm for calculating the optimal pricing and inventory policies. Section 5 gives a detailed numerical study to analyze the influence of parameters such as market and deteriorating rate on the net profit and inventory level of the supply chain. Section 6 concludes the paper by closing remarks.

2. Assumptions and Notations

The supply chain system considered in this paper includes only one vendor and only one type of finished product are considered. This vendor provides the finished product to multiple retailers and buys multiple raw materials in order to produce the product.

2.1 Assumptions

The following assumptions are used to derive the mathematical model:

- (1) Demand rate is determined by the retail price and the attributes of the markets and is a function of the retail price and a concave function with respect to each retail price; finished products in different retailer have substitution each other since the product is procured from the same vendor. And the units from the raw materials are immediately available.
- (2) Common replenishment cycle is performed by the vendor and all retailers in the supply chain based on VMI.
- (3) Deteriorating rate for the finished product is deterministic and deteriorated finished product is replaced and repaired.
- (4) The deteriorating cost per unit is different when they are in the different owner. For the deteriorating finished

product occurred in retailer i , the deteriorating cost for each finished product is its retail price. However, the deteriorating cost for the vendor is its production price.

2.2 Notations

M	Number of retailers considered;
$i=1,2,\dots,m$	Index of retailers;
p_i	A decision variable, retail price for retailer i (\$/unit);
D_i	Demand for retailer i per unit time, a function of p_i , (\$/unit/time);
a_i	A positive number which is determined by retailer i 's market;
β_{ij}	Substitution elasticity for retailer i 's demand with respect to retailer j 's price;
α_i	Price elasticity;
H_{bi}	Holding cost of the finished product for retailer i , (\$/unit/time);
ζ_i	Transportation cost for retailer i (\$/unit);
p_0	Production and raw material cost per unit finished product (\$/unit);
C	A decision variable, Common replenishment cycle for the vendor and all retailers;
n	Integral number of production batches per raw materials procurement cycle, which is a decision variable, and $n>1$;
A	Ordering cost per raw materials order for the vendor;
S	Fixed cost for the vendor per common replenishment cycle;
T_i	Ordering cost for per retailer i 's order;
M	Usage rate of raw material for producing each finished product;
P	Production rate for the vendor, which is a known constant;
H_{vm}	Holding cost per unit finished product;
t_{vi}	Production time for the vendor to satisfy the requirements of retailer i in the common replenishment cycle;
H_{vp}	Holding cost of the finished product for the vendor, (\$/unit/time);
θ	Deteriorating rate of the finished product;(percentage/units/time)
Q_i	Lot size for retailer i ;
TC_{bi}	Total inventory cost for retailer i ; per unit time, (\$/time);
H_p	Holding cost of the finished product for the vendor in the common replenishment cycle C , (\$);
TC_{vp}	Total inventory cost of the finished product for the vendor per unit time, (\$/time);
HC_{vm}	Holding cost of the raw material for the vendor in the common replenishment cycle C , (\$);
TC_{vm}	Total inventory cost of the raw material for the vendor per unit time, (\$/time);

JTC	Joint total inventory cost for the supply chain system per unit time, (\$/time);
π	Total net profit per unit time, (\$/time).

3. Model

The net profit of the supply chain level that we studied is equal to the net revenue minus the total inventory cost. In this section, firstly we calculate the net revenue; secondly the total inventory cost is put forward; and lastly the integrated model is proposed.

3.1 Net Revenue

The product demand D_i for retailer i is a general function of (p_1, p_2, \dots, p_m) and downward sloping with respect to its own price p_i . That is

$$\frac{\partial D_i}{\partial p_i} < 0. \quad (1)$$

Since all retailers offer the substitutable products, the other retailer's retail price will influence the demand volume of retailer i , we assume that

$$\frac{\partial D_i}{\partial p_j} > 0 \quad i=1, \dots, m \text{ and } j \neq i. \quad (2)$$

This represents a common definition of substitutable products, which goes back to Samuelson (1947) [19] and see also Vives (1990) [21]. In other words, each retailer can expect its sales volume to go up, whenever one of another retailer increases its price.

Assume product demand rate for each retailer at the retail price p has a Cobb-Douglas form (Nicholson, 1989) [17], that is

$$D_i(p) = a_i p_i^{-\alpha_i} \prod_{j \neq i} p_j^{\beta_{ij}} \quad i=1, \dots, m, \quad (3)$$

where $p = [p_1, p_2, \dots, p_m]^T$, $\alpha_i > 1$, $a_i > 0$, $\beta_{ij} \geq 0$ for all i and $i \neq j$.

The product is sold by the system at the retail price p_i per unit, which yields net revenue of:

$$\text{net revenue} = \sum_{i=1}^m D_i \cdot (p_i - p_0 - \zeta_i) \quad (4)$$

3.2 Total Inventory Cost

In our model, we assume that the vendor purchases raw material outside to produce its finished product. The procurement lot size of raw material is assumed to be an integral multiple of the usage of each production batch. This policy has also been considered in some previous works by Goyal (1977) [7], Goyal and Deshmukh (1992) [9] and Goldberg (1989) [5] etc, which are more general than the lot-for-lot procurement policy adopted in other works such as that of Sarker and Parija (1994) [20] and Nori and Sarker (1996) [18]. The product is then delivered to multiple retailers at a common replenishment cycle. We assume that all enterprises to cooperate the supply chain wide profit function.

In this section we calculate the joint total inventory

cost for the vendor and all retailers. The inventory levels for all retailers and vendor are shown in Fig 1.

The change of inventory level for retailer i , notified by $I_i(t)$, during common order cycle C can be described by the following equations:

$$I_i'(t) = -\theta I_i(t) - D \quad 0 \leq t \leq C \quad (5)$$

with the boundary conditions

$$I_i(C) = 0. \quad (6)$$

The solution of the differential equation of Equation (5) - (6) is

$$I_i(t) = \frac{D_i}{\theta} (e^{\theta(C-t)} - 1) \quad 0 \leq t \leq C. \quad (7)$$

For retailer i , the maximal inventory level, that is, the order quantity of retailer i , is

$$Q_i = I_i(0) = \frac{D_i}{\theta} (e^{\theta C} - 1). \quad (8)$$

So in the common replenishment cycle C the retailer i 's total inventory cost is given as

$$\begin{aligned} \int_0^C H_{bi} I_i(t) dt &= \int_0^C H_{bi} \frac{D_i}{\theta} (e^{\theta(C-t)} - 1) dt \\ &= \frac{D_i H_{bi}}{\theta^2} (e^{\theta C} - 1) - \frac{D_i H_{bi} C}{\theta}, \end{aligned} \quad (9)$$

and total deteriorating cost is

$$p_i(Q_i - D_i C). \quad (10)$$

The retailer i 's total inventory cost is given as

$$TC_{bi} = \frac{1}{C} [T_i + \frac{D_i H_{bi}}{\theta^2} (e^{\theta C} - 1) - \frac{D_i H_{bi} C}{\theta} + p_i(Q_i - D_i C)]. \quad (11)$$

From Fig.1., it can be seen that the finished product inventory level notified by $I_{vi}(t)$ for the vendor follows the differential equation:

$$I_{vi}'(t) = P - \theta I_{vi}(t) \quad 0 \leq t \leq t_{vi}, \quad (12)$$

with boundary conditions:

$$I_{vi}(0) = 0. \quad (13)$$

From Equations (12)-(13), we have

$$I_{vi}(t) = \frac{P}{\theta} (1 - e^{-\theta t}) \quad 0 \leq t \leq t_{vi}, \quad (14)$$

where t_{vi} is determined by $I_{vi}(t_{vi}) = Q_i$. The solution is

$$t_{vi} = -\frac{1}{\theta} \ln[1 - \frac{D_i}{P} (e^{\theta C} - 1)] \quad (15)$$

Then, the vendor's holding cost for the finished product in the common replenishment cycle C is

$$\begin{aligned} H_p &= \int_0^{t_{vi}} H_{vp} I_{vi}(t) dt = \int_0^{t_{vi}} H_{vp} \frac{P}{\theta} (1 - e^{-\theta t}) dt \\ &= \frac{H_{vp} P}{\theta^2} (\theta t_{vi} + e^{-\theta t_{vi}} - 1) \end{aligned} \quad (16)$$

And the vendor's decaying cost for the finished product in the common replenishment cycle C is

$$p_0(P \sum_{i=1}^m t_{vi} - \sum_{i=1}^m Q_i) \quad (17)$$

Now the total inventory cost per unit time of the vendor is

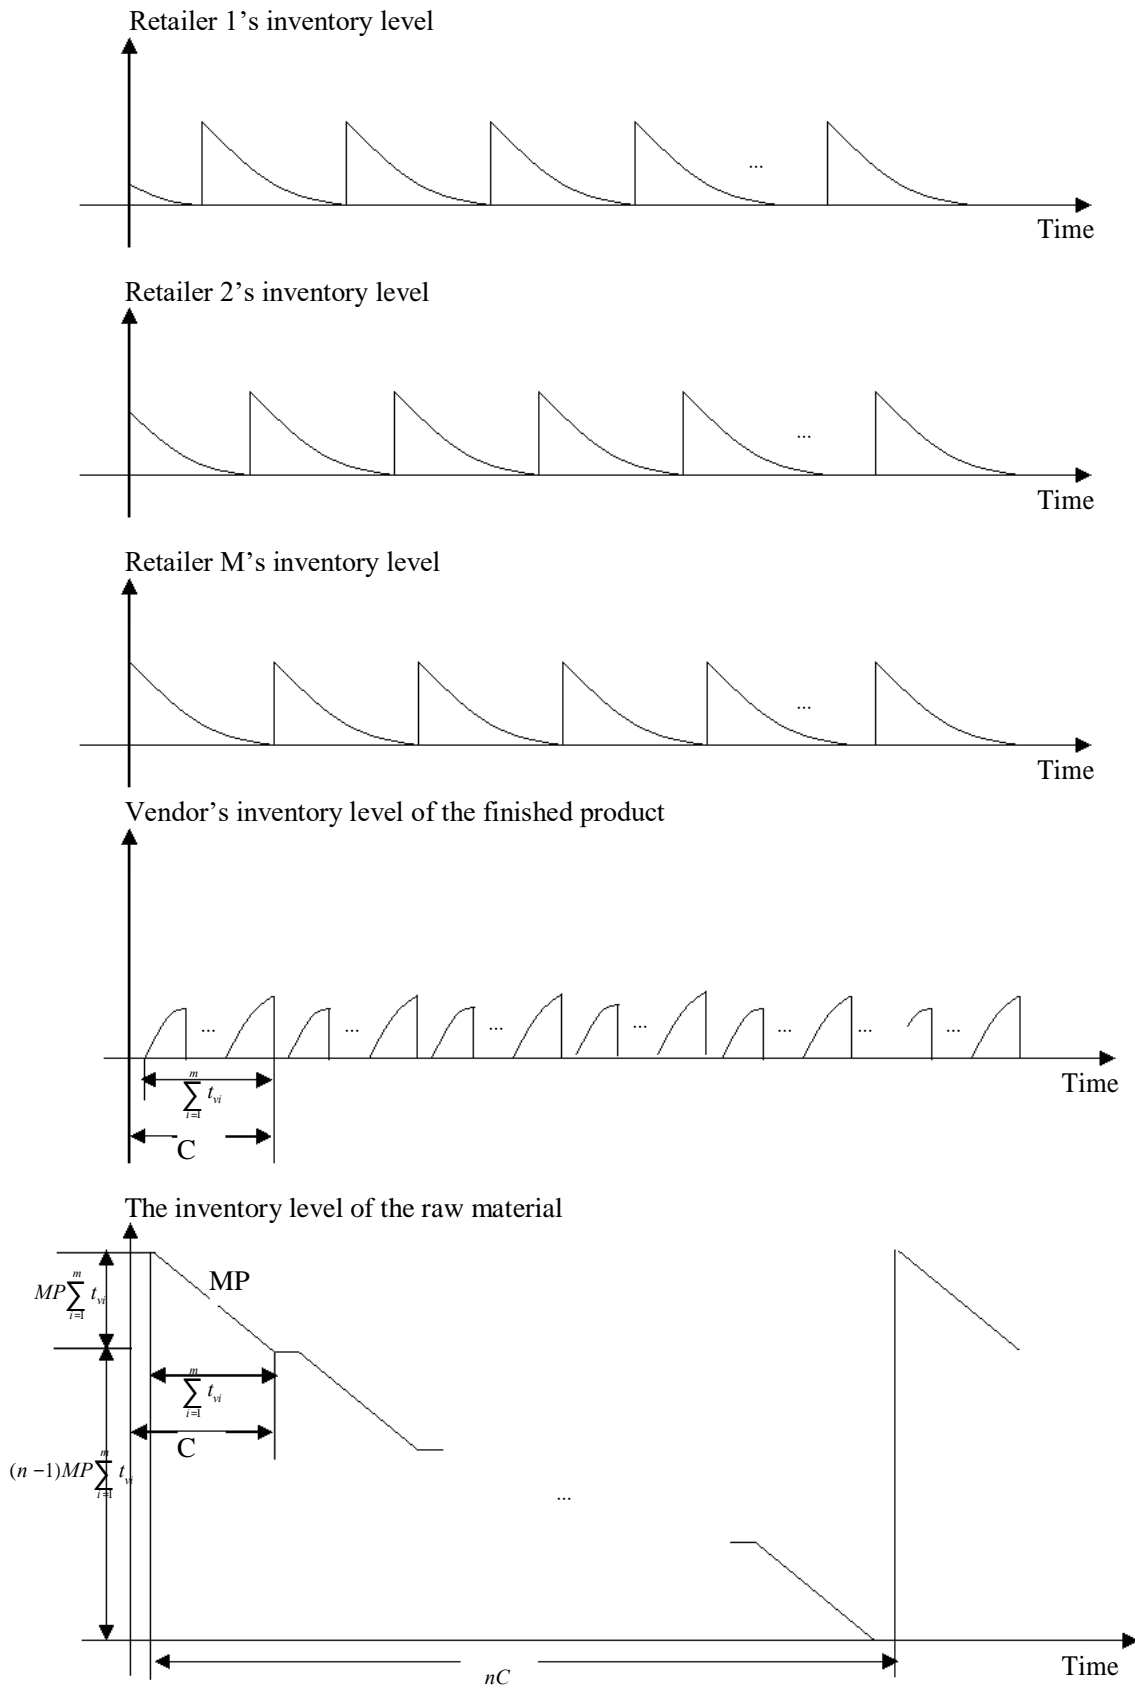

Fig. 1. The inventory level for all retailers and the vendor

$$TC_{vp} = \frac{1}{C} [S + \sum_{i=1}^m \frac{H_{vp} P}{\theta^2} (\theta t_{vi} + e^{-\theta t_{vi}} - 1) + p_0 (P \sum_{i=1}^m t_{vi} - \sum_{i=1}^m Q_i)] \quad (18)$$

Assume that the raw material's replenishment cycle for the vendor is integral multiple of the finished product's replenishment cycle. The holding cost of the vendor in its replenishment cycle nC is

$$HC_{vm} = H_{vm} \left[\frac{n}{2} \sum_{i=1}^m \sum_{j=1}^m (MPt_{vi}) + \sum_{j=1}^{n-1} (jC \sum_{i=1}^m (MPt_{vi})) \right] \\ = \frac{nMPH_{vm}}{2} (\sum_{i=1}^m t_{vi})^2 + \frac{n(n-1)CMPH_{vm}}{2} \sum_{i=1}^m t_{vi} \quad (19)$$

The total inventory cost per unit time of the raw material for the vendor is

$$TC_{vm} = \frac{1}{nC} (A + HC_{vm}) \quad (20)$$

Therefore, the joint total inventory cost for the vendor and all retailers per unit time is

$$JTC = TC_{vm} + TC_{vp} + \sum_{i=1}^m TC_{bi} \quad (21)$$

3.3 Supply Chain Level Net Profit

From the above analysis, by the net revenue described in Equation (4) minus the total inventory cost described in Equation (21), we can get the following model, notified by SCLNP.

$$\pi = \sum_{i=1}^m D_i p_i - \sum_{i=1}^m D_i p_0 - \sum_{i=1}^m D_i \zeta_i - JTC \\ = \sum_{i=1}^m D_i p_i - \sum_{i=1}^m D_i p_0 - \sum_{i=1}^m D_i \zeta_i - \frac{1}{C} \left\{ \frac{A}{n} + S + \sum_{i=1}^m T_i \right. \\ + \frac{(n-1)CMPH_{vm}}{2} \sum_{i=1}^m t_{vi} + \frac{MPH_{vm}}{2} (\sum_{i=1}^m t_{vi})^2 \\ + \sum_{i=1}^m \frac{H_{vp} P}{\theta^2} (\theta t_{vi} + e^{-\theta t_{vi}} - 1) + \sum_{i=1}^m \left[\frac{D_i H_{bi}}{\theta^2} (e^{\theta C} - 1) - \frac{D_i H_{bi} C}{\theta} \right] \\ + p_0 (P \sum_{i=1}^m t_{vi} - \sum_{i=1}^m Q_i) + \sum_{i=1}^m p_i (Q_i - D_i C) \} \quad (22)$$

$$\text{and } \sum_{i=1}^m t_{vi} \leq P \quad (\text{capacity constraint}), \quad (23)$$

where Q_i , D_i and t_{vi} are determined by Equations (8), (15) and (3) respectively.

In the integrated inventory model, the decision variables are retail price $(p_1 \ p_2 \ \dots \ p_m)$, common replenishment cycle C , the integral multiple number n to maximize the net profit π . A closed form analytical solution cannot be obtained for the objective function to calculate the optimal decision variables. So to this kind of function, both Goyal and Gunasekaran in 1995 and Luo in 1997 are to develop a computer program for finding their optimal solution by using an exhaustive search method. In their method, for all each possible

combination of decision variables is calculated and this may consume a large amount of computer resources since there are much more continuous variables $(p_{b_1} \ p_{b_2} \ \dots \ p_{b_m})$ in our model. So the genetic algorithm for the model is developed in the following section.

4. Genetic Algorithm

Genetic algorithms have demonstrated a considerable success in providing good solutions to many complex optimization problems and received more and more attentions. They have been well documented by numerous pieces of literature, such as that of Goldberg (1989) [5], Michalewicz (1994) [16] and Fogel (1994) [4], and applied to a wide variety of optimization problems. In this section, a genetic algorithm for solving the optimal solution for model SCLNP to maximize the supply chain level profit is designed as follows:

- Step 0: Input parameters pop-size, pm, pc, pr, M, and N, where pm, pc and pr is the percentage of mutation, crossover and reproduction respectively.
- Step 1: Initialize pop-size chromosomes (the first generation).
- Step 2: Evaluate the pop-size chromosomes by fitness function.
- Step 3: Selection.
- Step 4: Alter the chromosomes by crossover and mutation operations.
- Step 5: Evaluate the pop-size chromosomes by fitness function.
- Step 6: Selection.
- Step 7: Repeat the 2nd to 6th steps till the third termination condition is satisfied.
- Step 8: Report the best chromosome as the optimal solution.

5. Numerical Example

This section presents a numerical example for model SCLNP. The related input parameters are given in Table 1. As an illustration, the case of $m=3$ are discussed. The unit time is one year and the monetary unit is U.S. dollar. The optimal decisions for all retailers and the vendor are shown in Table 2 and the sensitivity analysis for the parameters that associate with market and deteriorating, i.e., a_i , α_i , β_{ij} and θ are shown from Table 3-6.

Table 1: Input parameters

Parameters	Value	Parameters	Value
P	60000	M	0.95
p_0	40	θ	0.02
A	5000	ζ_i	3
S	2000	α_i	1.45
T_i	1000	a_i	20000000
H_{bi}	80	H_{vm}	15
H_{vp}	40	β_{ij}	0.01

Table 2: optimal decisions of the base example

(p_1, p_2, p_3)	$\sum_{i=1}^3 D_i$	N	C	JTC	π
(154.95, 154.95, 154.95)	44276.81	3	0.04771	279384.71	4677414.84

The parameter a_i represents the attribute of customer markets of retailer i ; in which the larger of a_i , the larger of demand volume of customer i . From Table 3, it can be seen that with the increasing of a_i , the demand of the vendor which is the sum of the demands of its retailers is increasing constantly. The demand volume increases from 10205.57 at $a_i=0.5$ to 59968.11 at $a_i=3.5$ by 487 %. P_1, P_2 and P_3 decrease at first when the capacity of the vendor is full before $a_i \leq 2.5$. However when the capacity of the vendor is used up after $a_i \geq 3$, with the increasing of a_i , all prices begin to go up and

JTC increases by 2.67 from 1251180.68 at $a_i=0.5$ to 334708.00 at $a_i=3.5$ whereas π increases by 7.39 from 1109766.82 at $a_i=0.5$ to 8202461 at $a_i=3.5$. When the replenishment cycle of the finished product decreases constantly since when the demand of the vendor goes up rapidly with the increase of a_i before $a_i \leq 2.5$. With the increase of a_i after $a_i \geq 3$ where the capacity of the vendor is used up, the increasing of the retail price deduces the penalty of the deteriorating cost per unit finished product goes up and such the replenishment cycle of the common replenishment cycle decrease too.

Table 3: Sensitivity analysis where a_i is changed

a_i (107)	(p_1, p_2, p_3)	$\sum_{i=1}^3 D_i$	n	C	JTC	π

1.35	186.70, 186.70, 186.70	57216.98	3	0.04089	325475.18	7896685.77
1.45	154.95, 154.95, 154.95	44276.81	3	0.04771	279384.71	4677414.84
1.55	135.74, 135.75, 135.75	32750.91	2	0.06385	234812.22	2801737.00
1.65	122.90, 122.90, 122.90	23559.22	2	0.07696	195104.79	1687361.87
1.8	110.82, 110.82, 110.82	13763.88	2	0.10289	145784.39	787662.38

a_i represents the elasticity of markets of retailer i ; in which the larger a_i is, the more price sensitivity for the market of retailer i . From Table 4, it can be seen that with the increasing of a_i , the price of the finished product

reduced rapidly; the price is 451.92 at $\alpha_i=1.15$ whereas the price is 110.28 at $\alpha_i=1.15$ by 341.10. Accordingly $n, \sum_{i=1}^3 D_i, JTC$ and π reduce and the

finished product replenishment cycle C is increasing.

From Table 5, with the increasing of β_{ij} , P_1 , P_2 , P_3 , $\sum_{i=1}^3 D_i$, JTC and π go up while C decreases and n keeps unchanged. Something needs to be noted that when β_{ij} is equal to 0.05 P_3 becomes Infinity. Likewise, when β_{ij} is equal to 0.08, P_2 and P_3 both become Infinity. The

infinity price of P_i means D_i becomes zero, which leads to the decreasing of retailers. It can be seen that when β_{ij} is equal to 0.08 the prices of three retailers are 547.78, Infinity and Infinity respectively. That is, only one retailer should be left while another two should be canceled.

Table 5: Sensitivity analysis where β_{ij} is changed

β_{ij}	(P_1, P_2, P_3)	$\sum_{i=1}^3 D_i$	N	C	JTC	π
0	150.33,150.33,150.33	41819.58	3	0.0493	270253.37	4218795.06
0.001	150.78,150.78,150.78	42063.13	3	0.04822	271165.11	4262479.02
0.005	152.60,152.60,152.60	43037.41	3	0.04852	274797.88	4441961.47
0.01	154.95,154.95,154.95	44276.81	3	0.04771	279384.71	4677414.84
0.03	165.65,165.65,165.65	49369.98	3	0.04481	297877.96	5757515.32
0.05	170.45,170.45,Infinity*	59967.47	3	0.03565	315691.32	7328893.33
0.08	547.78,Infinity,Infinity	59967.47	3	0.02734	310124.20	29533606.3

*When the optimal P_i calculated by GA is larger than 10^9 we give Infinity to P_i there.

From Table 6, with the increasing of θ , JTC arises to 513343.84 at $\theta = 2$ by 86.15% comparing with that of by from 275764.28 at $\theta = 0.001$, and π is decreased by 5.19% from 4680974.66 at $\theta = 0.001$ to 37037420.10 at $\theta = 2$. The decrease of π by 5.19% is relatively small comparing with the increase of the joint inventory cost JTC , 86.15% since in this example the inventory cost is relatively small compare with π . With the increase of θ , at first, the demand of the vendor

$\sum_{i=1}^3 D_i$ rises and all retailers' prices goes down before $\theta = 1$, but then both of them drop down from $\theta = 1$ to $\theta = 2$. C and n increase constantly with the increase of deteriorating rate θ ; which means that with the increase of the deteriorating volume for the finished product and the decrease of the demand of the vendor the common replenishment cycle C will be ascended and the replenishment cycle for the raw material increases too since there is no deterioration for the raw material.

Table 6: Sensitivity analysis where θ is changed

θ	(P_1, P_2, P_3)	$\sum_{i=1}^3 D_i$	N	C	JTC	π
0.0001	155.00,155.00,155.00	44259.98	3	0.04843	275764.28	4680974.66

6. Conclusion

In this paper, an integrated model for a one-vendor, multi-buyer supply chain where the Cobb-Douglas demand function is modeled. The vendor and all buyers to place the replenishment orders at common replenishment cycle based on vendor management inventory. The vendor buys raw material that is no decay to produce a finished product by a finite production rate and transport them to its retailers. All retailers sell the finished product in its market and customers can buy the product from different retailers. So the finished product sold by different retailers has the attribute of substitution. The

problem of determining the optimal the common replenishment cycle for the finished product, the replenishment cycle for raw materials and all retailer's price and be modeled as an integrated model in our paper. After modeling the problem, a genetic algorithm is proposed to give the optimal decisions. An extensive numerical study was conducted to understand the influence of various parameters related to market and deteriorating rate. The numerical study revealed that the decrease of the deteriorating rate θ and the increase of the elasticity of its own price α_i and substitution elasticity β_{ij} contribute to the net profit of the supply chain and vice versa. And Here that should be noted from

our integrated model that with the increase of the β_{ij} , the whole market is improved, and even the β_{ij} is better enough the number of the retailers may be decreased.

Abstract

One of our recent studies revisited Nolan's stages theory on IT growth in the context of Chinese companies and concluded that IT spending and learning with regard to IT management are not as tightly linked as is implied in Nolan's stages theory. The study also revealed that aggregate IT spending can be better explained by a technology diffusion process on the population level. Based on the findings, in this paper, we re-consider Chinese companies' IT spending growth pattern, and in turn, their IT application history over the past 20 years from a perspective of IT diffusion stages, highlighting the special characteristics of the network/Internet era. We project that the IT diffusion process in China's Network Era would experience four stages and has currently reached the third. Also, we propose some important issues to be further addressed.

Keywords

IT management, Stages theory, Diffusion of innovation, IT spending, Chinese companies.

1. Introduction

Both practitioners and academics have been concerned with the process of IT diffusion and absorption in enterprises since late 1960's. Former research has produced various models to describe the IT growth processes in different organizations during different periods of the history of IT development. Nolan's stages theory, as a well-known model regarding the link between IS management and IT spending in organizations, has shown its practical usefulness and intuitive plausibility while continuing to appeal to practitioners and consultants.

Nolan's theory was based on observations of US organizations. But application of information technology in China started much later and research on IT strategy and IT growth here is also weaker than in the West. Meanwhile, the context of using IT in China, including social, historical, technical, cultural, and management characteristics, is greatly different from that in other

countries. In other words, there must be something special about IT growth processes in Chinese enterprises.

On the other hand, empirical studies of various organizations over years have revealed mixed results in different countries and under different contexts. Therefore, there are good reasons to re-assess Nolan's classical theory in the light of new data from Chinese companies and find out in which ways this concept may be a useful guide for IT management decisions, and then may serve as a framework to interpret the IT growth process in China's Network/Internet Era.

Thus, we conducted a survey study to further develop Nolan's stages theory, as well as to analyze the IT growth process of Chinese companies. Based on data collected from 94 Chinese companies, we revisited Nolan's stages theory and concluded that aggregate IT spending can be better explained by a technology diffusion process on the population level. With such findings, we re-considered Chinese companies' IT spending growth pattern, and in turn, their IT application history over the past 20 years, highlighting the special characteristics of the network/Internet era.

2. The survey

In our questionnaire, we asked IT managers to provide absolute values of their organization's annual IT budgets for the period between 1989 and 2001, as well as additional information about company size, ownership structure, profitability, industry, and the year in which they began to use new technologies such as LANs and the Internet. From two rounds of survey, we have in total received 94 answers usable for data analysis after eliminating incomplete or obviously invalid responses. The results of these data collection methods can be seen in Table 1.

The sample characteristics can be seen from Table 2. Manufacturing companies clearly dominate in our sample. This corresponds to the percentage of manufacturing companies among all Chinese companies, which is 44% [15]. Also, the sample is dominated by State-owned firms while privately held firms come second. Thus, our sample can be characterized as predominantly consisting of Chinese firms. Regarding firm size, the sample is rather

evenly distributed among the four size categories indicating that small, medium, and large companies are

about equally represented in our sample.

Table 1 Data collection methods

Round	Method	Enterprises	%
1st (March 2002)	Questionnaire	21	22.34%
2nd (April-June 2002)	Interview + Questionnaire	40	42.55%

3. Revisiting Nolan's stages theory

Nolan proposes that companies progress through a series of well-defined stages, labeled Initiation, Contagion, Control, and Integration, as they learn to absorb new information technologies. According to this 'stages theory', companies have to start a new learning cycle with each major innovation in the field of information technologies as has happened with the mainframe computer, the micro computer and the Internet (ushering in the so-called Data Processing, Micro and Network Eras respectively). In each learning cycle, IT budget growth curve would display an S-shape, which is tightly linked to companies' learning curve regarding the management and use of (successive waves of new) information technology (see Figure 1). Also, Nolan has specified a number of dimensions (called growth processes), or benchmark variables, along which learning must take place such as the application portfolio, technology characteristics, user awareness, and management techniques [19].

Initially proposed in 1973, the stages theory has itself evolved considerably over 20 years driven by both Nolan and others [7][16][17][18]. Some empirical studies also found support for the stage concept in this theory [21][11][9]. Some other studies, however, have provided negative evidence for the stages theory [12][1][10][13][5]. Generally, most of the critiques come down to two basic

questions. Namely, does the S-shaped IT-budget (or spending) curve really hold for Chinese companies, both on population and company level? And furthermore, if the curve does hold, is it tightly linked to the organizational learning process regarding IT management, as Nolan has addressed?

Our first effort was to clarify the above ambiguities and further develop Nolan stages theory (details of this study are specified in another working paper). Based on data collected, we found that aggregate spending behavior of these companies follows an S-shaped growth curve, as would be predicted by Nolan's stages theory, while patterns of individual companies appeared to be differing. A further investigation with a 'del' test for the cross-classification data indicated that such aggregate behavior of company spending could be better accounted for by a population-level diffusion process, rather than a company-level learning process, which is implied in Nolan's stages theory.

Thus, we concluded that IT spending and IT management learning are not as tightly linked as is stated in Nolan's stages theory. But on the population level, as well as for large companies, the stages theory could still provide an insightful framework from a diffusion perspective. In these cases IT spending curves could serve as an indicator of the diffusion process, along which a series of diffusion variables could be specified and

aligned in the light of the context studied, so as to evaluate and predict the overall trends of innovative technology

applications.

Figure 1 Nolan's stages theory

4. IT Diffusion Stages in the Network Era of Chinese Companies

A few years ago, we conducted a survey study about Chinese companies, comparing the characteristics of these organizations' IT application processes with those of US organizations featured in Nolan's stages theory and highlighting some of the key factors that affect the IT growth and management of IT in China [2]. Due to limitation of survey extent, many important issues were left untouched. Besides, in that study we have followed the concepts and terminology of the 'learning' stages model Nolan proposed. But the above discussion indicates

that the 'learning' explanation does not hold the promise as a good framework for interpreting such processes. Based on the above findings, it seems warranted to re-consider Chinese companies' IT growth process from a perspective of IT diffusion.

The aggregate IT spending curve for our sample is shown in Figure 2. Visual inspection clearly indicates that this curve follows an S-shape which has been manually fitted on the data in this figure too. To confirm this impression, we have statistically fitted several functional specifications on our data. With the results of the tests, we conclude that our data can indeed be best described as following an S-shaped growth pattern on the aggregate level.

Figure 2 Aggregate IT spending growth in sample companies

It was not until 1992 had Internet been introduced into China [3], so we assume that the Network of Chinese companies started around 1992. To link the IT spending growth with diffusion stages, we first plotted the adoption frequency of Internet in companies against time, as

illustrated in Figure 3. To confirm this impression, we have statistically fitted several functional specifications on our data. With the results of the tests, we conclude that our data can indeed be best described as following an S-shaped growth pattern on the aggregate level.

Figure 3 Adoption frequency of Internet in sample companies

The diagram displays a bell shape, which is indicative of a diffusion process on the population level [20], resulting from adoption being spread across time and companies, with a few companies (usually called innovators) leading the adoption of a new technology, followed by the majority of their peers (often separated into the early and late majorities) and a few companies adopting the technology late relative to their peers (usually called laggards). By combining the IT spending growth curve and the Internet adoption frequency pattern,

the IT diffusion stages in the Network Era of Chinese companies can be roughly distinguished. As illustrated in Figure 4 (these smoothed curves are generated by Microsoft Excel, based on real data of 1992 through 2001, as has been used in Figure 2 and Figure 3, and predicted data of 2002 through 2006, as shown with the shadowed area), we project that the IT diffusion process in China's network era would experience four stages and has currently reached the third.

Figure 4 IT Diffusion Stages in the Network Era of Chinese Companies

In Nolan's stages theory, the terminology used to describe individual stages seems to be derived from both company level learning and aggregate level diffusion explanations. Specifically, the terms 'Initiation' and

'Contagion' are indicative of an explanation referring to an epidemic process while the terms 'Control' and 'Integration' seem to refer to a management-level learning process. Such mixture brings confusion into the

framework and restricts it from better describing the diffusion process on the aggregate level. In fact, learning is an individual behavior and can not be explained on the aggregate level. For better description, we suggest the usage of “cooling” and “permeation” for Stage III and Stage IV.

4.1 Stage I: Initiation (1993-1995)

Between late 1992 and early 1993, the Internet came into being in China. In 1994, the first backbone network was built and connected to the Internet [3]. Activated by the “Golden Bridge” Project of the Chinese central government and influenced by the “Information Highway” of the US, Chinese enterprises noticed the great future of business networks and the Internet. Some enterprises went on building local area networks and a few started trying emails. These companies acted as the innovators. But generally speaking, the emphasis of Chinese enterprises’ IT application was still on how to control and integrate microcomputers. So it is reasonable to say that between 1993 and 1994, Chinese enterprises’ IT diffusion process was in the ending period of Micro Era and also the initiation stage of the Network Era.

From the second half of 1994 onwards, development of the Internet in China took off. The most significant achievements during that period were the construction of ChinaNet and CERNET [3]. In a very short period, all kinds of Internet services came forth and the influence of the Internet expanded continuously. Meanwhile, microcomputer applications in enterprises matured. Most enterprises actually benefited from the value that IT brought to business. Thereupon, more and more enterprises turned their eyes to the Internet, started to build network applications, and became early adopters of the Internet technology. By 1995, the adoption of the Internet technology had reached a critical mass, which is significant for technologies strongly subject to network externalities [14], and preparation for network expansion was generally finished.

It is worth noting that the initiation stage of the Network Era in China is rather short comparing to the corresponding stage of the Micro Era. In the study of Chen and Jiang [2], the initiation stage (the study treated it as two related stages, namely initiation and penetration, partly because of its long time-span) of the Micro Era lasted all through 1980s.

There are three possible reasons for this observation. First, having experienced the Micro Era, managers of Chinese enterprises had realized the strategic importance of information technology and paid active attention to IS application and IT development. In this situation, when companies moved on into the Network Era, Chinese enterprises proactively embraced the new technology and started to apply it immediately. In contrast, the beginning stages of the Micro Era are much longer because, at that moment, IT application in Chinese enterprises was almost non-existent and it took a relatively much longer period to prepare for expansion.

Secondly, from 1992 the reformation and opening policy in China was further quickened. Driven by the government’s economic policies, enterprises were eagerly searching for development opportunities. When looking back to the Micro Era, we find that in the first half of the 1980s economic reforms were tentative and just beginning while most enterprises were still taking their bearings. In this atmosphere, initiation and penetration in the Micro Era could not be quick.

The third reason for the “quick-in” characteristic of Network Era is related to the Internet, the most important technology of this era. The IT growth processes of Chinese enterprises in the Network Era resemble that of the Internet in China. The speed of application and development of the Internet significantly exceed those of microcomputers.

4.2 Stage II: Contagion (1995-2000)

Late in 1995, the contagion stage of the Network Era began. Majority of the companies became adopters and the aggregate IT spending started rising remarkably. Surrounded by the atmosphere of global networks, encouragement from governments, seduction of firms, and the prospect of magnificent new products, many enterprises augmented their network applications in a hurry and the phenomena of expansion without planning once experience in the Micro Era were repeated. Redundant projects and waste of resources were rather common phenomena in those years.

In 1997 and the years thereafter, the emergence and flourishing of e-commerce pushed the “leaping” pattern to its climax. The tide of e-commerce firstly hit the foreign trade industry before sweeping across various industries. Still, the accelerating forces from governments could not be ignored during this period. It was not until 1999 that the “Network Economy” began cooling down. With the collapse of the “Internet bubbles”, more and more enterprises sat down to consider the actual importance of networking and e-commerce for their long term business plans of IT applications. The contagion stage of the Network Era was coming to an end and the cooling stage, labeled as few adopters and limited spending growth, set in.

4.3 Stage III: Cooling (2000-2004)

The majority of the companies would have adopted the networking technology and only a few laggards would become adopters in this stage. Most of the companies that have adopted the new technology shift their focuses to better control of IT applications and start to ponder upon the real value that IT might bring. Since the year 2000, “Reengineering” has been popular in Chinese enterprises. Adjustment of business processes and improvement of IT applications have been complementing each other [4]. Through BPR and Information Resource Planning, the enterprises tried to obtain highly centralized control of IT applications and

stroved to get beyond the redundant projects and isolated information islands left behind by the expansion. Meanwhile, IT strategic consulting played an increasingly important part in IT application and some famous consulting firms strengthened their presence in China's IT consulting market. Many of the enterprises in our survey cut down budgets for IT implementation and increased budgets for IT consulting. Overall, the cooling stage lasted for nearly three years and may well carry on into 2004.

4.4 Stage IV: Permeation (2004-?)

Judging from the patterns of the aggregate IT spending curve and the adoption frequency diagram, the last stage of the Network Era may start around 2004. By then, most Chinese companies would have adopted the Internet technology and generally few would-be adopters would still be left. It is a stage in which the technology completely penetrates and the adopters gradually development their applications. Meanwhile, a new major innovation may bring the next technology era, and the IT diffusion process would step into the initiation stage of that era. We think that the technology which will dominate the next era might be M-Commerce or business intelligence. However, it is quite possible that the innovation is still to appear in the coming years.

5. Issues and discussions

We feel that our findings may arouse some worthwhile endeavors and re-open the discussion of some important issues on IT management, especially the issue of introducing new IT into organizations.

First, we have shown that IT spending curves could serve as an indicator of the diffusion process. Therefore, along the aggregate IT spending curves, a series of diffusion variables could be specified and aligned in the light of the context studied, so as to evaluate and predict the overall trends of innovative technology applications. In a review, Fichman discussed 18 empirical studies of innovation diffusion theory and provided a framework mapping two classes of technology (low knowledge burden, low user interdependencies, versus high knowledge burden, high user interdependencies) against locus of adoption (individual versus organizational) and resulting in four IT adoption contexts [6]. We feel that this classification seems meaningful also to the stages analysis. It would be worthwhile that these specifications of contexts are incorporated into the aggregate level stages theory and some variables are borrowed from that framework.

Second, we have stated that the company-level IT spending curves do not commonly follow an S-shape and cannot be directly regarded as indication of organizational learning, but our survey has revealed that many large companies' IT spending indeed display an S-shape on the company level. We think that the S-shaped spending

pattern of large companies could itself be the result of a diffusion process on the company level. A learning process is about the behavior of an individual, while a diffusion process is about an aggregation. From this point of view, large companies are special because they incorporate the characteristics of the two levels. On the one hand, they are individual companies and would follow a learning path to effectively managing IT; on the other hand, large companies are themselves aggregations of a number of smaller units and therefore diffusion processes are likely to take place inside the bodies. The classification of Fichman [6] on locus of adoption also implied the importance of paying attention to the diffusion inside an individual company body, as well as in a body of many companies.

The difference between a company- and a population-level diffusion process is that, on the company level, diffusion is relatively more constrained and, to some extent, determined by the level of the company's IT management. Briefly, the company level diffusion process could be, on the same level, tightly linked to the company's learning process regarding IT management. Also, we note that Nolan's stages theory was originally proposed based upon observations on some large US companies [16]. Therefore, it may be reasonable to say that the S-shaped spending growth pattern is indicative of and caused by company level learning for, and only for, large companies.

The third issue of further interest is the different IT spending growth patterns of different sectors of companies. As mentioned, in our survey, we divided the companies into 6 major sectors, namely headquarters of groups, IT and electronic, traditional manufacturer, commerce and trade, service, and agriculture. IT spending growth curves for these sectors are illustrated in Figure 5. For better comparison, we have normalized the resulting data by taking the number of 1992 as the base.

Visual inspection reveals that although 3 of these 6 curves follow a clear S-shape, patterns of different sectors vary significantly. Furthermore, the IT spending curve of commerce and trade sector is very special. There is a significant oscillation with a clear peak and trough in the growth process of this sector. Thus, it can be inferred that each sector has its own characteristics which significant affect the diffusion process. In an early stages model introduced by Greiner [8], it was stated that companies in different industries of different growth rate would take different paths of organizational development. This implies that industry growth rate may be taken as one of the factors that determine the IT diffusion process on the sector level. However, such a variable seems inadequate to explain the IT spending curve of commerce and trade sector shown in Figure 5. There must be some other characteristic factors whose effects should be taken into considerations.

Figure 5 IT spending growth curves of different sectors

A Case Study of VMI using TOC

Fu-Kwun Wang

Department of Industrial Engineering and Management

National Taipei University of Technology

E-mail: fukwun@ntut.edu.tw

Abstract

A vendor managed inventory (VMI) is a process whereby a supplier maintains an inventory for a retailer by generating orders for the retailer based on its demand information. In this relationship, the supplier is responsible for maintaining the retailers' inventory levels and transportation and transaction costs. The performance measurements that are associated with the theory of constraints (TOC) have been widely advocated as a mechanism of linking operational objectives to the global goals of an organization. In this paper, we use a case study of the Procter & Gamble to illustrate the application of TOC in VMI. The results show that the quality of service and the inventory level can be improved.

1. Introduction

Supply chain management (SCM) has become an important topic in many disciplines. The core objective of the SCM is to minimize system-wide costs while satisfying service requirements. Note that the supply chain is a dynamic relationship which includes all of the activities – i.e. manufacturing and assembly, warehousing and inventory control, distribution, and customer service – that are involved in delivering products or services from raw material providers to customers. Supply chain management (SCM) then coordinates and integrates all of these activities into a

seamless process. With increasing global competition and the emergence of e-business, supply chain management is considered to be a powerful approach to cutting costs and increasing profits.

Marient [1] identifies strategic alliances as among the key supply chain enablers. Strategic alliances concern how external companies (customers, suppliers, and logistic-service providers) are selected as business allies and how inter-company relationships are built and managed whereby a supply chain links all of the chain partners, including departments within an organization, and the external partners, including suppliers and third party providers. A successful alliance enables managers in companies across the supply chain to take an interest in the success of other companies and to work together to make the whole supply chain competitive. Strategic partnerships typically lead to long-term strategic benefits for both partners.

However, demand forecasting is one of the most difficult tasks for both retailers and suppliers in a supply chain, especially when the product life cycle is short and made-to-order requests are common. In addition, the demand variation of suppliers is much greater than the variation of retailers due to the bullwhip effect [2]. Regardless of these difficulties and uncertainties, enterprises must still rely on forecasted demand to make managerial decisions, e.g. resource allocation, capacity planning, production planning, and cost control, etc. [3]. Thus, to achieve the congruent supply chain goal, it makes sense to create cooperative partnerships between

suppliers and retailers to leverage the knowledge of both parties. Simchi-Levi et al. [4] state that various types of retailer-supplier partnerships (RSPs) can be placed on a continuum. The lowest degree of partnership (on the far left) is information sharing, whereby the vendor plans the demand based on limited information provided by the retailers, and at the other end (the far right) is a consignment scheme, whereby the vendor completely manages and owns the inventory until the retailer sells it. This partnership is implemented by the strategy known as vendor-managed inventory (VMI). VMI is a planning and management system that is not directly tied to inventory ownership. Under VMI, instead of the customer (the retailer) monitoring its sales and inventory for the purpose of placing replenishment orders, the vendor (the supplier) assumes the responsibility for these activities. In the past, many suppliers operated vendor-stocking programs whereby a representative visited a customer a few times in a month and restocked its supplies to an agreed-upon level. As popularized by Wal-Mart, VMI replaces these visits with information gathered from cash registers and transmitted directly to a supplier's computer system via Electronic Data Interchange (EDI). Suppliers can now directly monitor sales of their products and decide when to initiate the replenishment process. However, VMI is an expensive proposition for suppliers. Investments must be made in new systems, software, and employee training. This brings us back to the question of whether there is a payoff.

Over the last few years a number of semiconductor companies have implemented shop-floor control procedures based on the theory of constraints (TOC), which was developed by Goldratt [5] and focuses on constraining resources, subordinating the remainder of the plant to keeping the bottleneck work centers running at their maximum capacity, and simultaneously working on elevating the bottleneck to

improve its performance. The TOC is a problem-solving approach that can be applied to many business areas. The five steps of the TOC are: (1) identifying system constraints; (2) deciding how to exploit the system constraints; (3) subordinating everything else to that decision; (4) elevating the system constraints; and (5) if in the previous steps the constraints have been broken, then returning to step 1, but not letting inertia become a system constraint. The concepts of TOC have been used to develop production-scheduling rules that are collectively known as optimized production technology [3]. The TOC has been implemented in many different areas, such as operations, finance and measures projects, distribution and supply chains, marketing, sales, managing people [6], job-shop manufacturing [7], the service industry [8], project management [9], among others. Moreover, the performance measurement system in the TOC has been recognized as the global goal of many organizations, and it is profitable. We apply TOC to VMI to improve the quality of service and reduce the inventory level among suppliers and retailers. The remainder of this paper is organized as follows. Section 2 discusses related works on the development of VMI, and section 3 focuses on VMI adoption. Section 4 discusses the applications of the TOC in VMI, and section 5 provides a case study. Section 6 draws conclusions and provides suggestions for further research.

2. The development of VMI

VMI, which is sometimes called the continuous replenishment program [10], is a pulling replenishing practice that is designed to enable vendors to respond to demand by obtaining actual consumption data with additional forecasts from the retailer. In the retailer-supplier partnership (RSP) continuum, VMI is the highest degree of cooperation, and vendors make the

primary decisions about placing orders and inventory control. The vendor is entitled to view every item that the retailer carries, as well as point of sale (POS) data. In VMI, the supplier decides the appropriate inventory levels of their products (within previously agreed-upon bounds), and the appropriate replenishment policies to maintain those levels. Holmstrom [11] reported that the demand variability for the vendor was reduced from 75% to 26% in the pilot implementation. Total stock was down 30% and the order/delivery lead-time was cut from 48 to 10 hours.

The history of VMI can be traced back to the early development of quick response (QR) between general merchandise retailers and their suppliers. Due to intense competition in the textile industry, leaders in U.S. apparel manufacture formed the Crafted With Pride in the U.S.A Council in 1984 [11]. The Council commissioned a supply chain analysis, and the results showed that the delivery time for the apparel supply chain was 66 weeks from raw materials to consumers, 40 weeks of which were spent in warehouses or in transit. To reduce the lead-time and inventory cost, the report proposed a QR strategy. A QR strategy is a partnership wherein retailers and suppliers work together by sharing information so that they can quickly respond to consumer needs. Under this strategy, suppliers receive POS data from retailers and use it to synchronize their production and inventory control with actual sales at the retailer. However, the retailer still makes the decision to generate orders and the supplier must improve demand forecasting and production scheduling by using POS data alone. Milliken and Company, a textile and chemicals firm, was one of the first to adopt QR, which reduced lead-time from 18 to 3 weeks [12].

Similar to the textile industry, a group of grocery industry leaders created a joint industry task force called the efficient consumer response (ECR) working group in 1992. The group appointed Kurt Salmon Associates Inc.

[13] to examine the grocery supply chain to identify opportunities to increase competitiveness. The subsequent report identified a set of best practices, which if implemented could substantially improve overall performance. Kurt Salmon and Associates found that “by expediting the quick and accurate flow of information up the supply chain, ECR enables distributors and suppliers to anticipate future demand far more accurately than the current system allows”.

A further development from ECR was the continuous replenishment program (CRP). CRP is a move away from pushing products from inventory holding areas to grocery shelves based on consumer demand [10]. In a CRP strategy, which is sometimes called rapid replenishment, vendors receive POS data and use it to prepare shipments. In an advanced form of CRP, suppliers may gradually decrease inventory levels at the retail store or distribution center as long as the service level is met [14]. Thus, inventory levels are continuously lowered. Other topics in inventory replenishment are discussed by Waller et al. [15], Cetinkaya and Lee [16], and Chaouch [17].

In the history and development of RSP, one phenomenon stands out. That is, RSP was driven by competitors as they strove for survival and success. Such competition allowed the progressive development of RSP strategies and the establishment of industry standards through the joint efforts of companies that were originally at loggerheads. This implies that the partnership was extended from a single supply chain to multiple yet integrated supply chains. The implementation of RSP benefited both retailers and suppliers, and eventually the end-consumer. The RSP strategies are summarized in Table 1. When partnership moves from one level to the next on the RSP continuum, new skills should be learned and employed by the vendor.

3. The Adoption of VMI

Many success stories from various industries have been told of VMI. Examples include the Wal-Mart/P&G arrangement, Fasson MPD (which is a division of Avery-Dennison) and Worsleys (the only inter-merchant paper trader from the U.K. in continental Europe), Baxter International and a large number of hospital customers in North America, and YCH in Singapore [18]. Moreover, Stundza [19] showed that the application of supply alliances such as VMI could cut costs and reduce inventories in metal industries. Kaipia et al. [20] presented a time-based analysis for measuring the benefits of VMI in different circumstances. The results revealed that VMI was a much more efficient solution for low volume items. The motivation behind RSP and VMI strategy is that both parties work together to maximize the competitiveness of the supply chain. However, the most obvious benefits of VMI are the inventory cost reduction for retailers and total cost reduction for suppliers that arise from coordinated production and distribution with better demand forecasts. The identified benefits of VMI program can be found in the Simchi-Livi et al. [4] and Vendor Managed Inventory [18] studies.

Despite the numerous benefits of VMI, some concerns need to be taken into account. In the Aichlymayr [21] survey of VMI implementations, the concerns were as follows. (1) Vendors' administrative costs increased, as did their responsibilities and the amount of work that needed to be done. (2) The implementation time was long due to the trial and error approach. (3) The system was hard to use with volume discounts and special pricing – alternate pricing strategies were sometimes necessary. (4) In the short run the system was complicated because the roles of employees, vendors and customers could be unclear upon implementation. (5) Retailers risked losing control and flexibility, especially when the adopted

procedures were innovative. (6) There was potential for arguments about the handling of over-stocked or obsolete goods, and specific agreements were needed between manufacturers and retailers.

To implement VMI, three enablers are essential: organization infrastructure, information technology, and training [4]. VMI strategy involves a high degree of partnership between retailers and suppliers, and it changes fundamental ways of doing business. The commitment from the senior executives of both parties is the first attribute of organizational infrastructure that will ensure the success of a VMI program. The feeding of previously confidential sales and inventory data to suppliers necessitates determination and commitment from very high levels. A certain degree of mutual trust and a regular review scheme must be in place to maintain the alliance. Moreover, the introduction of VMI may also shift power from one group to another within an organization. This is because suppliers need to collect more information online and the daily contact with retailers moves from sales and marketing departments to logistic departments. This organizational change must be considered in the re-structured scheme, and job responsibilities have to be re-assigned.

Information technology, including the technology itself and integrated production systems, is another important enabler in VMI. Forms of technology such as bar codes are essential to accelerating the data input and maintaining data accuracy. Electronic data interchange (EDI) or Internet technology (such as XML) is also useful in creating direct links between retailers and suppliers. Note that a direct link can avoid entry errors and diminish data transfer time. Once real time data are available, an integrated enterprise system such as enterprise resource planning (ERP) [11] can be used to incorporate planning, inventory, production, and distribution into a fully implemented VMI strategy.

Beside organizational change and technological adoption, suppliers also need to adopt new skills and practices such as forecasting, inventory control, supply chain management, and retail management, etc, into their operations. Therefore, a comprehensive training program is important for the relevant managers and operators. The Simchi-Livi et al. [4] and Vendor Managed Inventory [18] studies provide a systematic approach to VMI system adoption in 5 stages.

Stage 1. Present & Align: The first stage covers the concepts, benefits, and requirements of VMI, and requires the participation of senior managers. These managers must commit to the possible costs involved, the human resources needed for establishment/ maintenance, and the concept of having someone else managing their inventory. They need to ensure that all employees who will be conducting the relevant activities into the VMI concept. Moreover, they must align the firm's objectives with those of its supplier, define the scope of the partnership, and formulate the contractual terms of the agreement. This should include decisions about ownership, credit terms, ordering responsibility, and performance measures.

Stage 2. VMI system design: A steering committee is formed to take control of the project. It defines the project schedule and scoreboard to assess feasibility against VMI requirements. Information is defined and logistic processes are established. The necessary information systems are identified and acquired. EDI formats are defined and EDI transmission testing is conducted before a VMI training program is implemented.

Stage 3. Pilot Run: The process is validated by user acceptance testing. Problems are identified and the process is refined.

Stage 4. Implementation: Dual systems (VMI and the original system) are run according to a transition plan. Then, VMI goes live if the system adoption works smoothly.

Stage 5. Monitor and review: The scoreboard is updated. Problems and improvement areas are identified and acted upon to achieve targets.

This implementation approach provides a general reference. Any stage can be modified to fit individual VMI program needs.

4. Applying TOC to VMI

As suggested by Goldratt and Fox [22], three new measures can be added to the traditional measures such as net profit, return on investment (ROI), and cash flow. They are (1) throughput – the rate at which the system generates money through sales; (2) inventory – the money that the system invests in purchasing things to sell; and (3) operating expenses – the money that the system spends to turn inventory into throughput. Goldratt and Fox also presented a relationship among the global performance measures. That is, if throughput increases while inventory and operating expenses decrease, then net profit, ROI, and cash flow will increase. In contrast, if throughput decreases while inventory and operating expenses increase, then net profit, ROI, and cash flow will decrease. Based on the TOC performance measurement, throughput is equal to the final net sales rather than shipments or any other measures that are commonly used. Moreover, inventory is valued at the cost of raw materials rather than on a cost accumulation basis. Operation expenses take in all other costs. For example, all overhead costs that are traditionally allocated to inventory as it migrates through the production process are considered as operating expenses. The direct labor of employees is considered as part of these expenses. Thus, the TOC changes the accounting scheme for performance measures. Here, the

TOC performance measures will be used to relate functional measures to the performance of VMI. In addition, the repetitive TOC steps, i.e. identifying system constraints, exploiting system constraints, subordinating the firm's operations to those constraints, elevating the system constraints, and returning to the first step, are used for continuous improvement in VMI. Managers can also use "thinking system" techniques, such as evaporating clouds and effect-cause-effect diagrams, to facilitate their decision making [22]. These techniques help managers to challenge conventional thinking and to find the root causes of the problems that they face. A detailed application of TOC is described in the following case study.

5. Case study

As mentioned earlier, consumer demand drives replenishment orders and shipping in CRP. This process can be distributor managed, supplier managed, or third party managed (by an agent or outside service). The most common CRP is Vendor Managed Inventory (VMI), in which the vendor manages its customer's inventory and ensures that the replenishment process optimises the customer's warehouses or retail stores. The vendor must receive regular sales off-take and inventory data from the retailer, and forecast demand and deliver the required quantity to the retailer. VMI can operate at either the retailer's warehouse or store level, depending on the sophistication of business operations and information technology adoption. In implementation, the retailer's warehouse transmits daily inventory levels and off-take or store order data to the vendor; and the vendor is responsible for creating orders to ensure that the warehouse can meet the retailer's product need. In this paper, we use the VMI piloting program between Procter & Gamble (P&G) and Wellcome, a CRP software package called the Key Account Replenishment System (KARS), as

the case study. The main function of KARS is to generate suggested order quantities based on retailers' off-take and inventory information. The logic behind the KARS calculation of order quantity is illustrated below.

A key factor in the success of VMI operation is the demand projection to cater for both normal demand and abnormal demand that arises from promotions, new product introductions, out of stock products, or seasonal variations. Other than demand projection, factors such as order calculation (considering the current stock level, order to delivery lead time, and others), safety stock requirements, and delivery optimization in terms of pallet and truck loads are important. In KARS, there is a built-in forecasting model for estimating daily demand off-take at a distribution centre (DC). The rationale behind the forecast calculation is to predict the amount of products that the will DC required according to sales off-take in the past 8 weeks. Note that the formula for demand forecasting considers the 8-week-averaged sales off-take as well as customer service level. The past 8 weeks off-take divided by the achieved customer service level is the base for future demand projection. The customer service level has been incorporated in this calculation to minimize the chances of underestimating future demand when products have been out of stock (OOS) in the previous sales period. Demand projection is converted into a suggested order by taking into account the stock requirement and delivery optimization. Stock requirement is determined by stock-on-hand, safety stock for demand variation, order frequency, and lead-time. Here, the safety stock requirement is based on the standard deviation of the past 8 weeks off-take. The delivery optimisation minimizes order sizes and determines pallet size and truck loads.

In this case study, non-cosmetic products (88 stock keeping units (SKUs)) are chosen to evaluate the performance of a VMI. The results of the key performance indicators are shown in Table 2, and are grouped into 2 categories: (1) success criteria, or the direct measurement of the degree to which VMI objectives have been achieved, e.g. reduction in inventory and increase in service quality; and (2) the process performance that is related to monitoring process efficiency and effectiveness, e.g. the line fill rate and on time delivery. Significant improvement after VMI implementation in phase I (from September, 1998 to April, 1999) led to an inventory reduction from 24 to 13 days, which was already very close to the target of 10 days. However, some areas demanded further improvements, such as the high occurrence of overrides (which are considered as constraints in the TOC). Manual intervention, in particular the modification of purchase order quantities by the retailer, occurred frequently and had an adverse effect on the automation process. Several potential causes of overrides were identified: demand created by new channel openings, manual input for promotional items, and manual input for new products. In phase II (May, 1999 to November, 1999), with the adoption of the five TOC steps, we ascertained the override quantity on how much inventory should be maintained was identified. The key performance measurement for inventory was the turnover rate (step 2 in the TOC). The performance measurement aspects of throughput, inventory, and operating expenses were used for internal management decisions. The management also used the effect-cause-effect and cloud decision-making techniques, and was trained in the use of underlying performance measurement methods. For override analysis, the occurrences were first compared against different causes of overrides. The objective was to identify the percentage of overrides that were caused

by different factors, namely data related issues and the handling of promotional orders and new products. Special attention was needed to observe any override clustering among certain product categories, brands, or SKUs (step 3). Moreover, the success rates of both KARS suggested quantity and Wellcome override quantity were measured and compared to reflect the necessity and accountability of the override process. The formula to measure success in the proposed order quantity and override order quantity was as follows (step 4):

$$\text{Success} = \frac{\text{inventory on hand} + \text{replenishment quantity} - \text{Wellcome DC off-take}}{\text{KARS suggested order quantity}}$$

The KARS suggested order quantity and Wellcome's override quantity were considered to be successful when the actual Wellcome DC off-take was less than the quantity that was recommended by either party plus inventory on hand. This implies that order quantity can fulfil actual DC demand. After applying TOC to VMI, the results of the performance indicators can be improved (step 5, see the last column in Table 2). This case study can aid in the understanding of how VMI implementation can be more effective and efficient.

6. Conclusions

VMI can help companies to (1) eliminate repetitive purchasing activities, (2) lower the cost of processing claims, (3) reduce inventory, (4) increase inventory turnover, and (5) solidify the supplier-retailer relationship. By implementing VMI, suppliers and retailers can focus on the same issue – how to sell the right products to the end customer at the right time. This changes the supplier's focus from encouraging the retailer to buy more to helping the retailer to sell more. Moreover, when the TOC is applied in VMI, its benefits increase. VMI is not a new concept – automated inventory replenishment by suppliers has been an issue

in the retailing world for more than 30 years. However, as shown in our case study, VMI can be utilized through integration with TOC, information technology, and other elements. Similar trends, such as supplier management inventory (SMI) or joint managed inventory (JMI), are merely different ways of looking at the same thing.

Abstract

Branding in cyberspace, cyberbranding, digital branding or e-branding is attracting the attention of many corporate executives in both traditional and internet companies. Branding as a marketing concept is universally known. Branding is the effort of a company to evoke a particular response in the end user/consumer's mind about a particular product or service.

The brand is not only that product or service, but also all of the emotions, perceptions, and impressions experienced by the person buying or using that product or service. Companies spend trillions of dollars each year in efforts to brand their company, their products, and their services. But at the end of the day, brand managers can't actually dictate what a brand really is. They can try everything possible to convey a certain message about their brand, but it is still the impressions left in the mind of the end user that dictate the success or failure of the brand.

What is cyberbranding? How is it different from traditional branding? What are the major cultural issues in cyberbranding? What is cyberbrand equity? How should a manager create and grow strong brands in a digital environment? How should one deal with merging brand entities? These important questions are addressed in this article. The article also suggests that marketers should view cyberbranding not in isolation, but alongside traditional branding while extending some enduring principles generally associated with traditional branding.

1. Introduction

When Philip Morris acquired Kraft several years ago, it paid six times the value of Kraft's physical net assets. The Philip Morris CEO indicated that his company needed a portfolio of brands that had strong customer relationships that could be leveraged to enable the tobacco company to diversify itself, especially in the retail food industry [1]. In other words, Philip Morris was prepared to pay billions of dollars for a set of customer

and trade brand relationships and the anticipated support such relationships would provide.

What then is a brand? One official definition by Interbrand, the London-based brand consulting firm, is "a mixture of tangible and intangible attributes, symbolized in a trademark, which, if properly managed, creates influence and generates value" [2]. Brand is therefore the sum of visual, emotional, rational, and cultural images associated with a company or a product that set them apart from their competitors. The brand Volvo, may conjure images of safety. When consumers think Nike, they might think of Michael Jordan or the Nike slogan "Just Do It." Brand recall accompanied by positive associations with a brand makes a customer's product selection easier and enhances the value and satisfaction gained from the product.

While Brand X cola or even Pepsi-Cola may win blind taste tests over Coca Cola, the fact is that more people buy Coke than any other cola and, most importantly, they enjoy the experience of buying and drinking Coca Cola. The fond memories of childhood and refreshment that people have when they drink Coke is often more important than a little bit better cola taste. It is this emotional relationship with brands that make them so powerful [1].

2. What Makes Up a Brand Identity?

A brand comprises three things: what a company sells, what a company does, and what a company is. Invariably, a brand represents a set of promises. These promises include implied trust, consistency and a set of defined expectations. Strong brands occupy a position in the mind of the customer that is unique to that brand. Brand identity includes brand names, logos, positioning, brand associations, and brand personality. A good brand name gives a good first impression and evokes positive associations with the brand. A positioning statement tells, in one sentence, what business the company is in, what benefits it provides and why it is better than the competition. Imagine you're in an elevator and you have 30 seconds to answer the question, "What business are

you in?" Brand personality adds emotion, culture and myth to the brand identity by the use of a famous spokesperson (Bill Cosby - Jello), a character (the Pink Panther), an animal (the Merrill Lynch bull) or an image (You're in good hands with Allstate) [3, 17].

Brand associations are the attributes that customers think of when they hear or see the brand name. McDonalds television commercials are a series of one brand association after another, starting with the yellow arches in the lower right corner of the screen and following with associations of Big Mac, Ronald McDonald, kids, Happy Meal, consistent food quality, etc. [1]

Branding is more than just ensuring that customers recognize a logo or product name. Branding means creating an emotional association (such as the feeling of success, happiness, or relief) that customers form with the product, service, or company. There are two basic techniques for branding: direct experience and indirect messaging. With direct-experience branding, users attribute emotions directly. For example, when customers test drive a car or eat a restaurant meal, their direct experience influences their feelings toward that vehicle or establishment [1].

However, marketers can't give users a direct experience for most products and services, so they need to use indirect messaging for their branding. For example, Nike sponsors sporting events to encourage the attendees to associate Nike products with the fun and excitement of the sport. Companies also create slogans ("Avis: We Try Harder," or "Built Ford Tough") and use them everywhere. TV commercials, magazine ads, and billboards are all indirect messaging. But this form of branding needs repeated exposure —conventional advertising wisdom says that a message isn't effective until the customer has received it at least 10 times [1].

3. What is Cyberbranding?

According to Deidre Breakenridge(19xx), If you take a logo, a company, a promise and a full set of values and expectations and mix them all together, what you get is the traditional meaning of a brand. However, if you have the same mixture of elements and put them on the Internet, they do not make up all the components of a cyberbrand. The Internet Breakenridge argues allows the brand to move into a new realm, and makes it possible for consumers to experience the brand on an interactive level.

Branding in cyberspace is no different than traditional branding. Huberman spent some time discussing the issue of branding in Cyberspace. First he provides a simple definition of a brand: a simple encoding of the attributes and reputation of an individual or firm. The purpose of a brand is to solve the problem of having to

search a large space or to choose from many options. Huberman goes on to say that in cyberspace, many firms can easily offer the same service to the same markets. These brands interact either as substitutes (competitors) or as complements in what is known as umbrella branding, in which complementary brands are associated in the consumer's mind [4].

The Internet continues to innovate new paradigms that allow manufacturers and service providers to link directly to their target customers. These paradigms are likely to change the nature of commerce. However, in an increasingly globalized economy, the Internet now can also affect the value of the brands in which companies have invested so much time and capital. Daily, companies launch new media campaigns, many of which incorporate today's interactive technologies, to keep their products and brand names visible amid the myriad choices facing today's consumers around the world. But they may fail to consider how these campaigns will affect their brands' value and reputation in the long run. Consumers desperately need a tool to cull the many suitors for their pocketbooks. Thus, reinforcement of a consistent, trustworthy brand message across many media is an important means of promoting product awareness and loyalty in a bewilderingly cluttered marketplace [5].

Though the internet revolution has put many companies on the defensive in protecting their names and reputations, the Internet can also help promote a brand's name and image in new markets in a variety of ways. Naturally, the Internet provides a forum for disgruntled consumers to broadcast their resentment of a brand across the world to millions of potential readers and customers alike, undermining the consumer trust and reputation for quality upon which brands depend. Thus, companies need to understand the factors that contribute to a brand's equity and the ways in which the Internet and the global economy can affect it.

4. The Difference between Cyberbranding and Traditional Branding

Organizations of all types, including privately held and publicly traded companies, non-profit associations, and even cities, countries and individuals are recognizing the value of using their brands to improve performance and build deep relationships with their customers. The reason for this rush to branding is simple. Intense market place competition and the ease of product duplication means that brands are the defacto means of simplifying the decision-making process for buyers and users. If managed properly, brands create difference, relevance and affinity. Branding on the internet is not that much different than traditional branding [6].

The combination of the brand and the technology that communicates its message is a powerful combination.

With each combination comes what Breakenridge refers to as a *differentiating factor*. Print and broadcast media for instance had positive brand factors in their early days. Print media's instant credibility and broadcast media's opening up consumer's ears and eyes to audio and visual entertainment were unique to the two media. With each factor came the opportunity for the brand to be more persuasive to evoke consumer action [7,15].

The Internet and the Cyberbrand entice consumer action with several differentiating factors. The Internet is the one place where a consumer can interact with a brand for hours prior to an actual purchase. Because of technological enhancements, the consumers interaction with the brand can be in the form of audio, video, or 3D animation. The bond between the consumer and the brand is enhanced as a result of constant one-to-one communication. Chat sessions, message boards and the ability of the consumer to request information or make a service inquiry are all various forms of the two-way communication that results from a cyberbrand relationship [7].

5. Global & Cultural Issues in Cyberbranding

The concept of branding is universally known. Only countries have borders; brands do not, as long as they are respectful of global issues. Brands travel across global boundaries and impact different nations in various ways. Global marketers strive to achieve a balance between art and science. The art of branding has its creative meaning that is universally accepted by all. Global brands are capable of enlightening scores of populations, bringing experience and fulfillment of expectations. The science is the careful research and development of the global brand, the precise method of communication, and the calculated timing of its message. When the balance of art and science is achieved, it doesn't matter if Coke is bought in a store in the United States or on the roadside in Mongolia. Either way, the Coke brand evokes a refreshing experience and a "good time" feeling [7].

The debate continues about whether the global branding paradigm is applicable to all brands and all product and service categories. The increasing availability of information via the Internet, both in breadth and depth, and increasing commercial globalization have helped expedite an answer. If companies do not globalize brand images, then consumers who encounter dissonant brand images, intended for different regional audiences, will become dissatisfied when they see an image that differs from the one they have entrusted the brand to maintain. Thus, not only does global branding reduce marketing budgets, but it is necessary to maintain long-earned equity in all markets entering the information age [5].

The World Wide Web not only delocalizes a company's customer base, but it is also the technology by which a

company can most easily introduce interactivity into its marketing and customer service activities. The age of interactivity will obviate mass-market technology. Companies will have to design products and services to meet the specific needs of individual consumers: Custom products beat standard ones 100% of the time. Though the range of variations may be narrow, the dialogue between the company and the consumer must empower the customer [5].

Inconsistencies are taboos in brand management. Consumer research suggests that consumers unconsciously perceive an incongruous representation of a brand—through its name, advertising, and packaging, experience dissonance, and subsequently switch brands. Companies wishing to establish a presence in cyberspace should do so carefully. Web sites should provide the same feel, format, and images that have proved successful in advertising campaigns. The Internet is primarily a tool to strengthen existing equity, not to establish it (except for a few niche industries that have their foundation in the Internet, such as Internet gambling, pornography, and book distribution) [5].

Another ongoing challenge for marketers according to Deirdre Brekenridge is to realize that worldwide brands carry the burden of cultural intricacies. As a matter of fact, in Asia-Pacific regions, "a common Chinese idiom describes Asia as an area of great treasures but a place filled with hidden dragons and tigers," may sum up the obfuscation marketers face when promoting global products. With language and culture posing the biggest threats, western marketers need a thorough understanding and appreciation of a region before introducing a brand in that region. Research is always imperative in a global effort. Common mistakes made by marketers include lack of research in the translation of names and spelling. Not verifying translation in the Asia-Pacific region can be the downfall of a brand. It is therefore no coincidence that Pepsi-Cola means "a hundred happy things" in Chinese, and is considered a lucky name [7].

6. Creating & Growing Brands in a Digital Environment

Consumers have different values, lifestyles, and resources, which guide their purchasing decisions. Consumers also prefer different advertising styles and content and use media representations in different ways to appraise a brand. Some consumers respond well to endorsements from "trusted" professionals, whereas others don't. Some people want detailed product information, whereas others want their purchasing decisions to be as simple as possible. Understanding a brand's target consumer through psychographic profiles is an excellent way to ensure that advertising through print and broadcast media presents the brand image and "attitude" appropriately. The Internet's increased interactivity and selectivity for loyal customers make

psychographically integrated marketing even more important in cyberspace [1,13].

Regardless of the clear advantage, many companies are likely to make some common mistakes in relation to their brands in cyberspace. They may adopt a one size fit all approach in handling both their Internet users and traditional channel users alike. One reason for this assumption may be the similarity of the demographic composition of both user groups. However, Internet users have significant attitudinal differences. Companies may also erroneously assume that the Internet is just another channel of distribution for their product and/or service. In reality, the Internet is far more than that. It is a new category with much broader one-to-one reach. Therefore, the Internet must be seen in proper context and used effectively to strengthen the brand [6].

7. Merging Brand Entities

Co-branding is the practice of placing a company's logo or content on someone else's Web site. It could be a clothing, toy or fragrance label on a department store site. It could even be a comic strip on a news site [8,12].

The fundamental value of co-branding arrangements is that an asset of one party -its brand and image- is acting as a magnet to draw surfers onto the Web site of another party. Ideally, this is a win-win situation. The Web site benefits by the increased traffic. The brand owner enhances its image and brand strength by associating with a wider range of products or services, as well as possibly an alternate distribution channel for its own products or services [18].

In addition to increasing traffic and boosting brand awareness, co-branding generates the following advantages: an expanded base of users and shoppers; diversified content; integrated clicks, bricks-and-mortar operations; additional sources of revenue; and a virtual alternative to a merger or acquisition [14].

But co-branding can do more than add value and drive traffic to lesser-known e-tail sites. If not properly structured and monitored, they can weaken or dilute a brand. In order to protect the integrity of everyone's brand and realize the desired benefits of co-branding, agreements need to be ironed out addressing the myriad issues that can result from the relationship [8].

8. Implications of Cyberbranding for Marketing & Management

With the Internet revolution sweeping the globe, firms are struggling to understand how to leverage this new opportunity. Many small and medium enterprises view the Internet as an unique vehicle to help them compete on an even basis with larger firms"[9]

Moore and Andradi (1996) reviewed the "key competitive dimensions which will determine who dominates in the future development of business on the Internet" and proposed that "the winners on the WWW will be leading brands, big access providers and firms with existing relationships with customers." Moore and Andradi's proposition is based on the four competitive dimensions of (1) access, (2) brands, (3) content and (4) relationships – areas in which they argue, large firms have the advantage. Nevertheless, they suggest that co-branding with leading companies, short-burst advertising on leading service providers, and being a specialist player are the means by which small firms can compete in the digital environment with their larger competitors [9]. They argue that small and "less well known" brands can leverage their brand value and add credibility – a challenge to marketers on the Internet) – to their company through strategies such as co-branding and strategic alliances with larger, more established brands on the Internet (5).

In cyberspace, marketing is more than just finding a catchy way to get the masses to buy a product. There are myriad factors a brand considers when jockeying for position in a competitive industry--among them the speed of the Internet, the sheer number of users online at any given time and the relative inexpensiveness of creating a website.

To say traditional, offline branding tactics--such as TV advertising's demographic targeting--don't necessarily translate well online and that companies, especially in a heated market such as telecom, must find new ways to reach and retain customers might be stating the obvious. But, according to Rob Frankel, president of robfrankel.com, a Los Angeles-based brand consulting firm, it's surprising how little so-called marketing experts know about the Internet [10].

So although cyberbranding and offline branding aren't exactly apples and oranges, they don't grow on the same tree, either. There are particulars that should be considered carefully when attempting to create a credible brand--or maintain an existing one--online. Attention to a few details can save time, money and headaches, not to mention achieve the goal of a strong brand and customer loyalty[11].

9. Conclusion

According to Breakenridge, the best brands have stood the test of time. They are the brands in our history that have been nurtured, supported and communicated effectively and have adapted over time to socio-technological changes. One hundred years from now, Coke, Pepsi, Heinz and Campbell's and many other well known brands will still capture a remembered feeling or positive experience (whatever the brand means to the user). These brands occupy a position in the consumer's

mind and heart. They have overcome adversities and challenges. If brands such as Yahoo!, Amazon, MSN, AOL and eBay continue to brand with the constant speed and strategy that has been exhibited so far, one hundred years from now they too will maintain their powerful brand presences.

Undoubtedly, the Internet represents an opportunity and challenge for existing brands as well as start-ups. It is now evident that the ease of establishing a brand and the significance of branding in cyberspace is more difficult and more important than previously thought. Nevertheless, the justification for building a brand and the process and discipline in managing one have been tested in the brick and mortar environment over the long term. It is arguable that the existing brands are at an advantage in migrating to the internet because they already understand the power of brands, and have brands.

Key Problems to be solved in Supply Chain Collaboration Management

Bin Ding, Guoshun Gong, Xiaojian Chen

dinbin@vip.163.com

Abstract

Supply chain members of independent enterprises are different from each other in strategies. Conflict in benefits is inevitable. The supply chain management system (SCMS) based on information system usually emphasizes on the function of the information technology. To achieve collaboration management, four main problems must be solved: 1) Belief among supply chain members, 2) Motivations of supply chain members, 3) Allocation of interests among supply chain members, 4) Integration of supply chain information system. This paper intends to analyze these key problems, and put forward some resolutions.

Key words: Supply Chain Management, SCM, SCMS

1. Introduction

With the entering of the 21st century, the trend of social information, economic globalization and electronic business accelerates increasingly, and the enterprises face more vigorous market competition than ever. The competition among single firms is gradually turning to competition among supply chains.

In order to enhance the competition ability of the supply chain, it is most important to intensify the cooperation among members of the supply chain, through which we can make the operation of supply chain among members as smoothly as the operation of a business enterprise to meet final customers' needs with high speed and low cost. Numerous researches and practice on supply chain management indicate that it needs to establish a mechanism of credibility and cooperation among enterprises and a cross organization supply chain management information system to plan in collaboration, in order to realize supply chain collaboration management.

However, because the supply chain members are independent enterprises, and the strategy of each

enterprise is different from another, there must be inevitable conflict in benefits. But the supply chain management system (SCMS) based on information system usually emphasizes the function of the information technology, and neglects the further analysis of members' benefits, therefore, it often suffers from the boycotting of members in application. To achieve safe and perfect collaboration management, many problems need to be solved. Mainly there are four problems as following:

- 1) Belief among supply chain members
- 2) Motivations of supply chain members
- 3) Allocation of interests among supply chain members
- 4) Integration of supply chain information system

This paper intends to analyze these key problems, and put forward some resolutions.

2. Belief among supply chain members

Belief is the foundation of successful cooperation, and supply chain particularly emphasize belief among all members. According to game theory, if your partner distrusts you, and your best choice must be distrust. When all partners trust each other, the game process can have the best solution. If you trust others excessively, but others misuse your trust, it is easy to cause damage or loss to you. It is a long process from distrust to trust, which demands all the member's efforts.

In the real life, there are many distrustful phenomenon, for example, mutual blockade of market and technique information between enterprises; deceitful information to cheat others to acquire the advantageous position in negotiation, and make use of the loophole in the contract to coerce the other party. Once these phenomenon occur, the distrust atmosphere spreads everywhere as a plague does, which becomes the obstacle of cooperation of supply chain.

The reasons for distrust among members are different.

First, the law environment is an important reason. Under the morbid environment of law, management with credibility cannot get the protection from laws, therefore, a lot of enterprises adopt accurate measures, and it is difficult to establish trust. Second, the ideas of social moral ethics decide the trustful relation of the social members, and also affect that of enterprises. In a society with credibility, if someone presumes to breach the credit principle, he must suffer the rebuke from the social members. Finally, quality of leaders is an important factor. If the leaders have received good education, have strong sense of responsibility, and put the credit principle to an important position, thus it is easy to establish the relationship of trust.

It is not only the enterprises' duty to resolve the problem of trust, but also the duty of all society. To make laws perfect is a way to establish the moral standard of credibility. As a member of the supply chain, while cooperating with other members, on one hand it is necessary to establish a credit evaluation system, only cooperate with enterprises with high degree of credibility; on the other hand, it is necessary to implement the credit principle actively to influence cooperation partners.

3.Motivations of supply chain members

Motivation decides behavior and further affects result. As the partners belong to different benefit corpuses with different strategy and operation mode, they also take different position in the supply chain. With the differences in management background, motivation and foundation, the partners in the supply chain show different behavior. The demand to participate in the supply chain needs to be deeply analyzed.

Every member in a supply chain must look after its own interests and its shareholders first and foremost. That is the fundamental nature of free enterprise, and the source of its strength. Then it is the interests of supply chain as a whole. It is impossible to request the member to abandon its own interests, but to obey the whole interests of the supply chain.

According to the position, members in the supply chain mostly have the following motivations:

Core enterprise. Each supply chain has a core business enterprise as a leader that contributes most values to the

supply chain, and it's usually the supply chain's organizer, planer and coordinator. At the same time, the core business enterprise is also an independent enterprise, which has its own goal of development. Because of its special position in the supply chain, it is easily self-centered, and tries to consolidate the position as group leader, and control the decision-making right of product and pricing. For achieving this purpose, it may try to baffle information circulation among members, and make use of the information's dissymmetry to control the whole supply chain.

Upstream supplier. Upstream suppliers' scales are quite different. The small-scale suppliers are usually in the subordinate position in the supply chains, expressing the obedience to the core business enterprise, extending the scale hard, and strengthening themselves in order to increase their own positions. For avoiding being controlled by a certain manufacturer, they serve many manufacturers at the same time to increase the selectivity of sales; therefore they would not like to build a very deep alliance with a certain manufacturer, preventing being abandoned by other manufacturers. As for large-scale suppliers (like the raw material producers), they supply many supply chains for mutually competing at the same time. Each supply chain's demand is not large enough to account for a very big portion. These suppliers care most about the demand change of the final consumers; therefore it is not easy to establish a close cooperation with manufacturers.

Downstream distributor. For the distributor, the consumer resources and the understanding of consumer requirements are its advantage in bargaining with manufacturer in the supply chain. Similar to the upstream supplier, the small-scale distributor is in subordinate position, but the large-scale retailer usually own its brand, a good image in the consumer mind, while its own strategy usually become an important baffling factor for its supply chain cooperation.

The motivation's influence on the supply chain cooperation is objective. It requires that members in the supply chain should pursue common goal with great similarity as well as few differences. If the targets differ from each other greatly, such enterprises cannot stay in a particular supply chain over a long period of time. At the

same time, the core enterprise should not regard itself as center, and take much care about general situation of the supply chain. The core enterprise should have the leader's bosom, concern and forgive, and set an example for its members as to benefit the development of the supply chain.

4.Allocation of interests among supply chain members

The supply chain is a value-added chain. It is a continuously value-adding process of raw materials through supplier, manufacturer, and distributor to final consumer, creating value for customer. Each member contributes to the increased value and the contribution is the member's input. As reward, members deal with certain price and allocate the profits. Under the traditional mode of operation, relation among members is only simply trading. Price is set by market competition. But under the environment of supply chain management, the members' relationship is cooperative and common developing relationship, creating customer value. Price is set by much more complicated factors which include inner cooperation factor of current supply chain, the market competition factor, and the problem of the whole benefits and partial benefits.

First, the internal benefits allocation of supply chain has no sound basis. Whole supply chain creates the value through collaboration. It is hard to distinguish how much an activity contributes; therefore the allocation of the added value(deal of price among members) has no scientific standard. Usually supply chain members set a market basis according to certain market rule, i.e. reasonable profits under normal operation. For the excess profits brought by cooperation (the cooperation makes cost lower, and should have excess profits), according to the both parties certain role, they set certain percentage of allocation. Under real circumstance, some supply chain members (particularly a leader of alliance) usually thinks they played a more important role in the value-added process, therefore, they hope to monopolize the exceeding profits, which easily causes the other members' dissatisfaction.

Second, the unreasonable allocation can result in the collapse of the supply chain. The principle of market

competition is the basic principle for business enterprises. There exists a problem. If the supply chain members compete fully and set certain price through negotiation, it is against the intention of the supply chain cooperation, and makes the small and medium enterprises in the disadvantageous position due to their position and information dissymmetry. This may force some members to turn to the other supply chain, and become the rivals.

Finally, the allocation of interests results a new problem of whether sacrificing the partial benefits to protect the whole benefits of the supply chain. For example, if the final consumer brings up a new demand, and the demand may represent the future development of the supply chainproducts. Therefore, the whole supply chain shouldpositivelydevelopnewproductstomeetthe needs of the future markets. However, in the process of new product development, members' investments may differ greatly, but the future benefits do not have big differences. There exits risk in the success of the new products development, and the performance of the product in the future market is not determined. For the members of big investment, whether to sacrifice theirpartialbenefitsandcreatebenefitsforthe whole supply chain becomes crucial.

5.Integration of supply chain information systems

The thoughtof supplychain managementdevelops with information technology, and it's an achievementofthe informationages. Supplychain management system(SCMS) is a bridge connecting the supply chain members, as were a platform of communication, and a necessary tool for supply chain collaboration management.

Supply chain management the system (SCMS) derives from the basis of Enterprise Resource Planning (ERP). ERP is used for the management of a single enterprise, with functions of planning, purchasing, stocking, manufacturing, selling and finance. It tries to optimism the resources of business. After entering the ages of supply chain management, collaboration of Ultra-firms becomes

an important content of the supply chain, which cannot be realized in ERP systems. There comes the SCM software, used for the collaborative planning among business enterprises. Some business enterprises adopt the ERP systems, the others may use MIS or MRPII, then appeared several solutions:

The first is electronic commerce based on EDI. This method aims at the processing of ordering and purchasing, transforming information through EDI or Internet. The management scope is limited. The information of SCMS and enterprise inner management systems cannot link together well. EDI is the initial stage of supply chain management.

The second is ERP plus SCM. The members apply ERP system to manage internal business, and apply SCM to integrate the ordering, planning, purchasing and service with other members. The advantage of this method is that each business's internal management is not influenced, and the initial investment can be protected. The disadvantage is that data exchange between SCM and ERP is comparatively difficult in real time processing.

The third solution is the complete adoption of SCM. Each member adopts the same platform to share data completely. This method can realize supply chain collaboration management. The disadvantage is the limitation of functions, and only close members can use this solution.

Ultra-firms SCM needs to resolve the problems of shared information, communication, and integration with internal systems of enterprises. No ideal solution is available at present time. Because of the above-mentioned problems of trust among enterprises, motivations and benefits allocation, some members do not prefer the integration of information, they even boycott the SCM application. Therefore, each supply chain partner need to set reasonable goals for system construction, and adopt its own methods to realize integration of information system according to their distinguished circumstances.

6. Conclusion

The future competition is the competition among supply chains. We must utilize the whole function of the supply chain to realize management collaboration. In the

process of management collaboration, there are protruding problems of trust, motivation, allocation of interests and integration of information systems. Only by solving these problems can we make supply chain meet customers' needs better, create values for customers, and maximize interests of all members.

1. Research objectives and aims of the projects

This paper deals with changes in working principles and communication environments during the introduction of computer-mediated information and communication in companies. Our findings indicate that social consequences (e.g. decrease of hierarchical barriers, self-organization, self-responsibility) are interrelated to organizational (e.g. management of change), technological (e.g. infrastructure, implementation) and personal dimensions (e.g. experiences with media use, gender, position). Figure 1 illustrates the assumed interdependencies.

Figure 1 The “ETO-triangle” as a frame of research

In other words: technologies do not determine their use by itself. Their integration in companies’ structures and operations seems to be a complex matter. Success of organizational changes is driven by the acceptance of social and working environment. Especially learning-by-doing processes, activities for teambuilding (“empowerment”) and the employees capability to create

companywide rules of practice can be interpreted as success factors. Additionally our results suggest that the direct integration of outsiders (e.g. suppliers, customers, retailers) is less a technological fact, it rather seems a question of business culture (e.g. leadership) and mental factors (e.g. employees open-mindedness, managerial attitude). The findings focus experiences with working in projects or teams, job satisfaction, mental work load and well-being. Also the use of computer-mediated communication and social consequences (e.g. bypassing, e-mail overload, information push and pull phenomena) are analysed.

The outlined aspects are elaborated in two ongoing scientific projects at the University of Trier. Both studies will likely be finished at the end of the year 2003 (for further details see www.ceb-trier.de/spirit and www.uni-trier.de/~comm). The project SPIRIT is merely concerned with 9 case studies in Germany and California. About 290 employees filled out a standardized questionnaire within this project. Furthermore explorative interviews have been conducted. This research is funded by the German Federal Ministry for Education and Research (BMBF). The second project (Trier communication study) is based on quantitative surveys in more than twenty german organizations (n=500 employees). The presented results will provide actual information about the use of new technologies and the challenge of implementing new organizational structures.

In chapters 2 and 3 the field of organizational change is drafted as well as characteristics of “digital” communication. The related social consequences for users and organizations are often vague and discussed in the sense of future scenarios. In view of that the outlined phenomena are contrasted with first findings of the above mentioned empirical studies (see chapter 4).

2. From “analog” to “digital”: Changes in communication patterns

„Markets are conversations [and] conversations among human beings sound human. They are conducted in a human voice [and] people recognize each other as such from the sound of this voice. The Internet is enabling

conversations among human beings that were simply not possible in the era of mass media.“ [7, p. 16] This description of the future of communication draws attention towards a phenomenon that is often associated with the use of new communication technologies in organizations. New media enable direct communication and decrease the impact of gatekeepers or hierarchical barriers. It is possible to establish “digital bridges” regardless of hierarchical levels. Concepts like virtual or modular organizations are feasible particularly because of computer-mediated communication. The implementation of such new structures is often accompanied by a decline of face-to-face-contacts. Telephone and e-mail replace personal meetings and enforce the virtualization of communication. As a consequence facial expressions and gestures are not available as resources of additional information. Referring to Watzlawick et al.: There is no „analog“ communication [9]. This leads to the question, how employees deal with this changing quality of communication. Possibly new rules are established around „digital“ communication (in terms of Watzlawick et al.). Additionally employees’ motivation and trust in the relative advantage of new technologies have strong influence on the efficiency of new organizational structures.

3. Technology and redefining organizational structures

Production concepts like partly autonomous (production-) teams or the “modular firm” need new administrative structures and an integrated use of information and communication technologies. These new networks lead to a change of working conditions and opportunities. Temporal and spatial restrictions are becoming more and more obsolete and enable various concepts of flexibility. For example, companies with telework-projects more often have access to new media than others. In 2001, 84% of US-companies having experiences with telework also had e-mail-access for the major part of their employees, whereas only 52% of the firms without telecommuters. Compared to Germany and other European countries this gap in e-mail access is remarkable (difference in Germany 21%, in Finland 24,2%, in United Kingdom 29,8%) [2, p. 71]. But the quality of organizational communication and the efficiency of organizational processes is not only a technological matter. If new and direct connections between departments or workgroups emerge, ways of coordination and consultation, especially of positions not involved in these networks, become necessary. Too much information is dysfunctional, but no information as well. Or in the words of Katz and Kahn: “[...] unrestricted communication produces noise in the system. Without patterning, without pauses, without precision, there is sound but no music. Without structure, without spacing, without specifications, there is a Babel of tongues but no meaning.” [6, p. 226] Modern technologies play a key role in organizing labour. Nevertheless actors, technology and context have to be considered not as distinct entities studied separately, but

rather as elements constantly interacting. For this a wellknown position of organization science has to be remembered: “To speak of organization is to speak of communication.” There is a need for concepts of social integration to prevent processes of exclusion. In 1977 Beard already stated: „The success of an organization is determined by how well its members perform, and the success of organizational communication is a function of how effectively organizational members communicate. The ways in which individuals receive, interpret, and transmit messages and the ways in which those messages affect the individuals’ motivations are therefore the factors central to organizational communication.“ [1, p. 33] This seems still to be true.

4. New forms of responsibility and experiences with organizational changes: First results of empirical studies

By implementing „self-services“ (e.g. document management, groupware) access to a variety of information is made possible, but self-organization on the individual level is required as well. Employees and management staff have to take more responsibility for receiving information and installing communication flows to prevent delays in decision making. Digital communication alone will not guarantee an efficient bridge between levels and positions involved. The availability of information does not substitute the need for processing it and drawing conclusions. This means that leadership, hierarchy and face-to-face still seems to be important dimensions.

First results of SPIRIT research indicate that market orientated objectives are central for implementing so called e-business projects in Germany. For example, speed-up business processes, integration of customers demands, lower costs or better competitiveness are expected. The industrial work organization seems to imply inflexibility (e.g. span of control, long decision processes). Therefore companies make use of internal project teams or special task forces and try to reduce hierarchical division of labor. As a consequence Webers’ (1864-1920) [10, p. 128] bureaucratic and “rational” way of organizing decisions competes more and more against the approach of new, flexible team structures in administrative operations. In view of that the majority of senior or middle management (62%) attain explicitly the goal of promoting team-work while integrating new technologies. According to own statements 54% did not achieve this strategic objective so far. Consequently one might pose the legitimate and provocative question (with reference to [11], p. 99): Is dynamic team-work “the heart of a lean” company? Some answers should be discussed in this paper.

Figure 2 illustrates findings concerning experiences with team and project work. Participants answers were collected on the basis of a six-point scale (1=strongly disagree up to 6=strongly agree). For example, the majority (53%) of employees who participate in teams partly or strongly stated longer times to reach common

decisions. But answers vary with the number of members involved in the team-work activities. Especially those who usually work closely together with 8 or more employees reported such impressions (average: 3,75). In contrast workers with less number of colleagues more frequent denied this statement (average: 2,93).

Figure 2 Experiences with team and project work (mean values, SPIRIT project)

More generally our research indicates new kinds of freerider-problems or of bystander-phenomenons like diffusion of responsibility while distributing management functions among team members. Furthermore unclear responsibilities (e.g. fixing deadlines, authority as a spokesman), complicated documenting work (e.g. saving of different versions, formalization of procedures) or a decline of motivation in case of higher-educated staff may come along with “anti-tayloristic” team-structures. That is why the ideal of more autonomy in companies’ decision processes and new concepts of employees participation sometimes seem to be valued as an unpracticable or less attractive alternative, especially from members in leading positions. Or in the words of a young Vice President of a Start-Up-Company in the Silicon Valley who has been interviewed within the SPIRIT project: „A company cannot be run as a democracy.“

Communication and the access to information can be seen as a main resource of organizational power. When e-mail and new communication and information technologies enable direct communication, the positions of formerly gatekeepers will be threatened. The results of the Trier communication study, which focus the impact of new media on organizational structures and processes, indicate that e-mail use lead to a decrease of hierarchical influences in organizational communication (see figure 3). Nevertheless the bypassing-phenomenon – passing over of persons which have to be involved according to formal rules of the organization – seems to be no direct consequence of technology itself [8, p. 94].

Figure 2: Consequences of e-mail use (Trier communication study)

The experiences of the employees on the one hand and the organizational culture and structure on the other hand define the impact of new media as well. The findings of the study show that employees use e-mail for informal communication only by and by (for further details see [5]). A private use of computer-mediated communication enforces an informal e-mail use. Even when it comes to consequences of e-mail use for social life in the enterprise, the results indicates that perception of e-mail changes in the course of time. For example, the “short-time-users” noticed more often a decrease of social contacts by the use of e-mail than the “long-time-users”.

However new companywide rules of communication can only emerge when a homogeneous perception is given. In our project, the employees in lower hierarchical positions had longer experiences with e-mail as those in higher positions. Moreover the management perceive new media less dominant for daily work. According to Goecke, this result may not surprise [4, p. 53 et sqq.]. Anyhow this can lead to heterogeneous media-skills (“digital-divide”) in organizations which will make it difficult to elaborate new (shared) communication rules. Therefore the attitude toward a decreasing influence of hierarchy on organizational communication patterns is often very different. In consequence of different tasks, different intraorganizational media-skills will be inevitable.

5. Production and Administration: Integration or Coexistence

These different media skills and uses could be an obstacle for implementing integrated information systems as well. For example the efficiency of electronic bulletin boards or even “employee-self-service”-systems is strongly related to the “internet-readiness” of users. Whereas the daily work in administrative departments is dominated by computer activities, employees in the field of production seldom have access to companies’ digital network. A possible consequence of this intraorganizational “digital divide” could be a coexistence of incompatible structures.

For example the use of digital and analogue information and communication systems for the same purpose (e.g. forms, newsletter) might happen. The efficiency of electronic workflow systems is reduced. Nevertheless the vision of “e-manufacturing” includes new concepts of production management. Flexibility of former on-site activities or services increases (e.g. the internet-technology allows maintenance services without the personal presence of workers). As a consequence, models of flexible work will emerge even in the production sector. Volkswagen for instance generated a system with more than 160 modes of flexible work. But an asynchrony of working hours may dissolve and recombine existing formal as well as informal groups. Different working hours may cause changing line-ups in workgroups. In this way, it could be difficult to establish or preserve personal relationships. When co-workers constantly change, informal structures will be weakened. In this sense personal access to new media cannot only be seen as a benefit for formal exchange but as a channel for informal structures as well. E-mail for example allows asynchronous communication between dislocated workers and “keeps people talking and juices flowing. E-Mail in workplace encourages communication.” [3, p. 3]

The “cluetrain manifesto”, an interactive elaborated internet-book which describes the new rules of markets in the internet-economy, outlines the dialogue between customer and worker as an alternative for the marketing activities of the enterprise [7, p. 25]. Maybe today this view seems to be too euphoric. But it points out that for an integration of all workers in e-business concepts of companies a direct and unrestricted access is favorable. Currently the most part of blue-collar workers cannot walk across digital bridges. Whereas in the production part access often is only given for the head of the department the majority of the administrative staff is working on the “digital highway”. For this reason a decline of hierarchical structures in the administrative part of organizations can be observed, while the hierarchy in the production part is still unchanged. To ensure a successful organizational change, the described digital gap has to be prevented or even closed. One possibility could be the installation of so called “kiosk-systems”, that is computer terminals in non-computer related workplaces. This enforces an integration in new digital networks. The results of our project indicate that private use during breaks might have a beneficial effect. On the one hand closing the gap will improve the efficiency of implemented electronic information systems. On the other hand it could result in similar forms of information flows in administrative and production parts. In other words: the access to new media might build the missing bridges that enable the next step in organizational change.

6. Summary

The outlined phenomenon of intraorganizational gaps are obstacles in the process of organizational change. Especially the “digital divide” of production and administrative part has to be changed. For a consequent

e-business reorientation of the company this separation has to be reduced by implementing electronic bridges. However, to find a common speech is not only a technological matter. The results of our both projects indicate that the emergence of new communication rules has to be seen as a bargaining process. Or in other words: In the ‘electronic babel of tongues’ it has to be found a new common language for the whole organization.

Abstract

Successful selling over the Internet involves organizing the entire value chain around the Internet and determines where they can exploit technology to add value. Such conversion in small and medium size enterprises (SMEs) is still at its infant stage; knowing on the large enterprises' experiences, this enlarges the non-empirical qualitative learning and possibilities for empirically testable theories to come up with a well-structured framework for such conversion. Based on theories from technological innovation literature, this paper presents an integrated model for T2E (Traditional to Electronic) business conversion for SME. Our novel T2E model makes use of a 3-layers hybrid approach: which unifies the technique of IDEF [Integrated Computer-Aided Manufacturing (ICAM) DEFinition] to assist in business process design; the concept of Business Process Reengineering (BPR) for business structure re-organization; and Innovation Diffusion (ID) theory for progressive introduction of new e-business functions. Our model is intended to minimize the impact of operational and cultural changes on SMEs while taken the critical successful factors of e-business projects in consideration. The feasibility of our conceptual framework is testified by a case study SME - Valentino World Fashion (VW), Inc.

Keywords: T2E (Tradition to Electronic) Business conversion; Business process reengineering; Innovation Diffusion; Integrated Computer-Aided Manufacturing; Critical successful factors

1. Introduction

Today, SMEs could not afford to fall behind in taking e-Business initiatives to reach customers, to collaborate with

Corresponding author Tel.: +852-2616-8090;
fax: +852-2892-2442.
E-mail address: drikwan@ln.edu.hk

business partners and to keep pace with competitors. Large enterprises had now found difficulties to promote their use of e-Business product and serve the highly segmented market, which on one end of the spectrum are multinationals and top-level domestic corporation while the other end are SMEs that are not yet ready to upgrade and transform their system. Many software vendors claim to provide SMEs extending from front office Customer Relationship Management (CRM) to back office Enterprise Resources Planning (ERP) applications and platform infrastructure. However, the e-Commerce initiative is believed to have more social-managerial issues to resolve than technical issues no matter how small is the company. It is clear that there is much changing drivers in management strategies, working culture and marketing plan between e-business and conventional business [5, 10, 15] besides the dramatic changes in its intra and extra-organizational processes.

When enterprises manage the impact of changes imposed by e-business, they typically proceed with Business Process Reengineering (BPR). T2E conversion in business need a detail but flexible, careful but innovative planning from the start, that integrated re-engineering process for dynamic strategic, managerial and technical consideration which interact and influence among each other constantly within an enterprise. This axiom supports the argument of Fixed Point Theorem [18, 19]. We concluded that speedy conversion from T2E would never catch up with the dynamic market changes. The key issue of e-business is process, process that inter-connect enterprise's individual business processes into a dynamic e-business network that open to authorized suppliers and potential customers. So this network should be flexible. This research proposes a novel dynamic T2E framework, which takes into consideration of changes and proactively adapt to the anticipated changes.

1.1 The e-Business System Life Cycle

Electronic stores need a strategic plan that react and adapt to changes, to survive and sustain profitability, to leverage investment in IT and to capitalize on knowledge through organizational learning. Disruptive technology (technology that replaces process) and creative technology (technology that enhance process) can cause a dichotomy in how organization operate and embrace IT-enabled change [13], we therefore regard that developing e-Business application should not constrain business possibilities under the limitation of computing technologies, but rather puts business sense into IT by developing each e-Business process that is business-focused and customer-centered. We recognize e-Business project should focus on business processes re-organization that adopts IT to enhance their connectivity and functionality for value adding. Hence, set up business vision and requirements are always the critical first step. The e-Business application development system life cycle provides us the foundation to construct our T2E

framework: the initial phase in the cycle involves the BPR for core business functions transformation into a series of conceptually defined web-based processes. This involves requirements acquisition and analysis that yields a corporate requirement document regarding the e-business set up.

1.2 E-Business Adoption Barriers for Traditional Business

The main barriers of their IS adoption and to develop a Web presence are simply the concern of knowledge deficiencies, lack of financial budget or slack resources, unconfident that the Web would not lead to more efficiency or lower costs [26, 27]. We have therefore identified from our literatures and case studies search that the critical success factors to adopt e-business in SMEs are as follows:

- $\frac{3}{4}$ It is important to have innovative and E-Business knowledgeable CEO.
- $\frac{3}{4}$ The SME must possess adequate financial resources and E-business knowledgeable employees.
- $\frac{3}{4}$ The E-Business must offer a better alternative to existing practices in the SME.
- $\frac{3}{4}$ The E-business system must be secure, easy to use and to understand.
- $\frac{3}{4}$ The E-Business system must be scalable, able to react and adaptive to changes.

The first two factors regards to human and organization issues of SME. The last three factors focus on the system design and implementation model. Our model also attempts to resolve the primary barriers of unfamiliarity with web and lack of guidance to start the T2E conversion process, by employing the theory of diffusion in our model.

2. From Traditional Business to e-Business

The T2E business transformation involves both the conversion of necessary legacy processes to web-enable applets and the integration of new enhanced modules to enable a value chains system. We propose to unify the concept of BPR for re-engineering the existing processes via organizational learning; Innovation Diffusion (ID) Theory for enhancing change management in new integration; and IDEF method as the modeling standard for design documentation in our T2E methodology. The hybrid use of these techniques and concepts accordingly should combine the advantages in providing a total solution.

2.1 Architecture of a B2C Web site

The typical architecture of a B2C e-store includes two tiers: the external tier is a web system that manages the customer ordering information; and the internal tier is an enterprise resource planning system.

External Tier Architecture - External tier architecture includes four typical subsystems: (1) a product management system, (2) a customer management system, (3) an ordering management system and (4) a payment management system.

The external tier is typically a web system. It is important to ensure that each of the following four major business processes corresponded to a web-enabled sub-systems.

- (1) **Product management system** - manages its stock with a workflow merchant for the products return and replenishment.
- (2) **Customer Management System** - offer customers the ability to update their profile, review their orders and payment history.
- (3) **Ordering Management System** - manages sales transactions and customer details, which includes capturing the transaction information.
- (4) **Payment Management System** - manages payment data, includes definition of preferences such as billing address, ship-to address and its verification.

Internal Tier Architecture - The Internal tier architecture typically includes an Enterprise Resources Planning (ERP) system in a company of medium scale or above.

2.2 An Introduction to IDEF

IDEF (Integrated Computer-Aided Manufacturing (ICAM) DEFinition) methodology [3, 21] is the successful end-result from the planning work of American Air Force-ICAM. The objective of ICAM is to upgrade manufacturing production by applying systematization of IT. It is a structural method for manufacturing using computer technology, and through this, it enables managers to understand the context of manufacture production more easily. The ICAM plan had developed an IDEF method that stated properties about manufacturing, then inter related the properties of statement and abstract them into graphics, to enhance communication.

2.3 Business Process Reengineering (BPR)

To perform T2E business transformation, we have extended the concept of BPR to our Total BPR that revise the integrated business processes via constant organizational learning for better system adaptability. Three important elements of context in Total BPR with organizational learning efforts: Vision, dialogue, and system thinking. The bottom line of system thinking is leverage seeing where actions and changes in structures can lead to significant, enduring improvement [22]. As much bigger payoffs are expected by revising the basic nature of the work performed rather than by just improving the source code itself that support the business process, we propose to integrate BPR actions with T2E organizational learning efforts as the solid building block of our

methodology. Total BPR procedure is not a one time process for T2E conversion, it is expected to be constant practices that carry out in the physical organization whenever there is new business vision and dialogue are formally identified. New business process could than be abstracted by corresponding conceptual e-business process and plug into the existing e-business system. Therefore, the principle of “High Cohesion and Low Coupling” (HCLC) is applied in the modular design with Total BPR approach for e-business application development. The challenge in our Total BPR is to restructure or structural transform the SME traditional business through e-Business, to determine whether the company should focus on core competencies or seek vertical and forward integration to provide integrated services so as to develop a single web-platform for the SME’s market. Our Total BPR attempts to abstract traditional and visionaries potential e-business changes conceptually by representing the pre-state and post-state of change after BPR in terms of As-Is and To-Be Models.

2.4 Building e-stores progressively

We therefore deploy the Innovation Diffusion (ID) Theory of Rogers [25] in of model to ensure thorough consideration in quality of service requirements in terms of sufficient knowledge on site architecture, network capacity and system software structure are all acquired before system implementation.; we have deployed his theory and relabeled them with our unique T2E activities. Our BPR

model is complement to the innovation diffusion view of implementing Enterprise Resource Planning (ERP) systems of Rajagopal [24] which consists of similar stages of Initiation, Adoption, Adaptation, Acceptance, Routinization and Infusion. The original ID theory of Roger is thus proven to be also feasible in application of e-Business development other than ERP implementation. We have built our T2E conversion activities base on the ID Theory of Rogers, who regards a new product or concept adoption can be classified into five stages: (1) Perception; (2) Interesting; (3) Evaluation; (4) Trial; (5) Adopt.

3. The T2E Business Conversion Methodology

The methodology framework is classified into five stages: (1) introducing management model, (2) choosing management model and channel thinking, (3) process analysis, (4) process simulation and (5) system establishment.

3.1 The Methodology Framework

The complete conceptual framework for successful e-Business transformation is presented in the following Figure 1. Our model is complement to the IS Adoption Model for small business [26] in conceptual term. Our model has also recommended specific tools; approach and techniques to enable these considering factors are taken care of in our model:

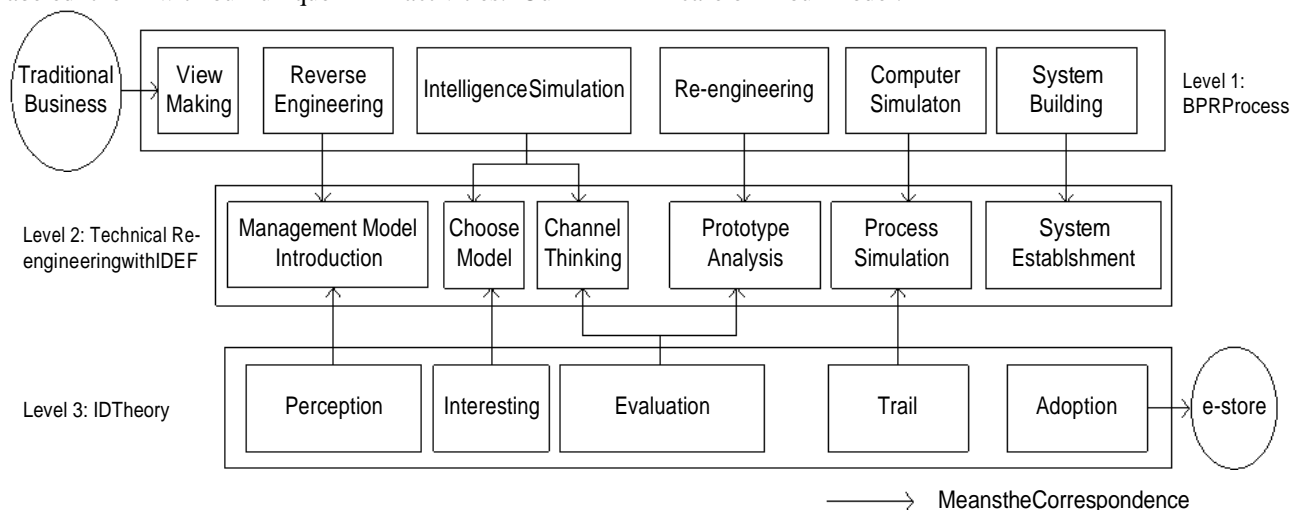

Figure 1: The conceptual framework for T2E process.

Stage1: Management model introduction.

The first stage uniquely declares the difference between the conventional stores and e-stores using an AS-IS (what the enterprise is currently doing) model and a TO-BE (what enterprise will do) model to ensure that the organization recognizes the changes and its impacts to business. Management support is important at this stage.

Stage2: Choosing a management model and Channel thinking.

Upon Stage 1, a management model could be decided for designing the e-Business plan.

Choosing an appropriate management model

The management model of *traditional stores* could be broadly classified into three types: (1) General stores, e.g. an independent shop; (2) Direct / Multiple store, e.g. Chain of retail stores and (3) Department

store. Whereas the management model of *e-stores* can be classified into another three models: (1) Single store; (2) Monopoly store and (3) Mall. Management could select an appropriate management style above by modeling the differences in processes, logistic and cash flow by AS-IS Model for current traditional business and by TO-BE Model for e-Business.

Channel thinking for building e-stores

McNaughton regarded that marketing activity could occur through three types of channels: distribution, transaction, and communication [16].

• Communication Channel

- ¾ Organizing and communicating interactively between customer and company [20].
- ¾ Acquire customers' information and comments on new products [7, 11, 12].

• Transaction Channel

- ¾ Improve transaction visibility [17].
- ¾ Improve revenues by exploiting cross-selling opportunities [9].
- ¾ Streamline transaction processing, thereby reducing task complexity, paper works and transaction cost [1, 14].
- ¾ Practice customization [12].

• Distribution Channel

- ¾ Eliminate large inventories and practice on Just In Time (JIT) business [4].
- ¾ Shorten supply chain and reduce commission and operating cost [8].
- ¾ Reduce delivery cost and ensure instant delivery of e-product/service.

Stage 3: Process Analysis for Building e-stores

e-Business has further caused changes on logistics flow, transitive cash flow and information flow [6]. This stage proposes to design operational process with the principle of HCLC to enable flexibilities in coping with changes. Coupling or association among and between processes as well as cohesion of functions within a process could be more easily identified by examining the AS-IS (traditional business) and built the TO-BE model (e-business) with power users before the confirmation of investment commitment for the new system is sought from management.

3.2 The Logistic Process Analysis

Business logic are analyzed and represented by IDEF chart for better communication among design team. We focused on the three arenas: Logistic Flow, Cash Flow and Information Flow.

3.3 The Cash Flow Process Analysis

Figure 2 below abstracts the differences of these cash flow processes in the AS-IS model and the To-BE model respectively:

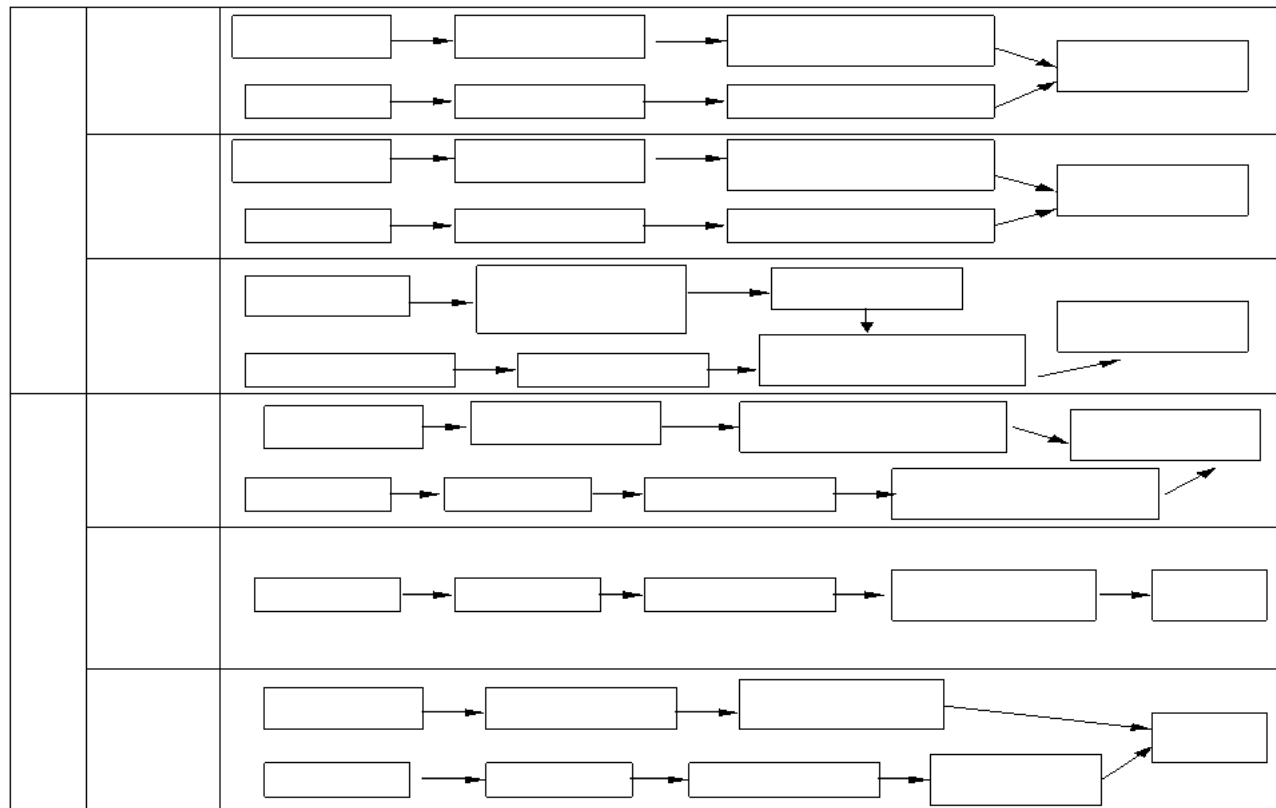

Figure 2: Comparison of cash flow between AS-IS model and TO-BE model.

3.4 Information Flow Process Analysis

This step works on the integration of local information flow among departments within the organization for a complete values chain concept. As such, information flows from upstream to downstream or vice versa is dramatically redeveloped to keep pace with the organizational changes.

By comparing the above As-Is and To-Be models, the SME could then determine on how to use its traditional assets flows and integrate Internet initiatives into its e-Business strategy to create sustainable competitive advantages.

Stage 4: Process simulation.

Simulating models ensure the development team to design a scalable system.

We recommend to deploy the CASE tool AIOWIN [2] to design the IDEF0 model which is the work flow diagrams of an e-store. We then used the Modeling Tool, ProSIM, [23] to convert the IDEF0 model with more design details ready for the simulation software WITNESS [28], to simulate the model. We highlight the five steps of simulation process in our model as follows:

Step1: Building an activity:

The basic concept is to define what is required to control and measure in a model.

Step 2: Building a structure of overall logistics:

Expand and refine the model of step 1 with more detail, in terms of what should be accomplished under its structure and who should be responsible for which activities.

Step 3: A transformation of AIOWIN design to ProSIM for modeling:

When the transformation is completed, the ProSIM system could then transform the input output of AIOWIN into an entity of ProSIM.

Step 4: Build the process arrangement, information flow and status for ProSIM system:

ProSIM establishes the procedural order and inter-relationship of the processes.

Step 5: Transformation from ProSIM system to WITNESS system:

After establishing the process flow, entering the variables in each process in ProSIM system to establish a simulation model (IDEF3), WITNESS [28] is applied in our prototype, to simulate each process of the e-store model by adjusting the variable's value to simulate different scenario. The optimum model (IDEF2) could then be selected.

Stage 5: System establishment.

We have deploy a hybrid approach that unify a combination of knowledge and concepts (BPR, IDEF, ID Theory) as well as techniques and software tools (AIOWIN, ProSIM and WITNESS) to come up with a

Corresponding author Tel.: +852-2616-8090;

fax: +852-2892-2442.

E-mail address: drikwan@ln.edu.hk

complete and novel T2E business design suite which have taken the consideration of the major e-Business successful factors identified in section 1.2 above.

4. Case study

A case study approach is applied as our empirical study on Valentino World Fashion (VW), Inc., a SME on clothing agent in Taiwan, to evaluate our model for T2E business transformation. While developing an e-store for VW Inc. (i.e. ValentinoWorld.com) based on our T2E methodology framework, we have observed and experienced the successful business conversion.

The VW Company was set up in 1977 with over 20 branches in Taiwan. The company was aiming for business growth and has decided to go for e-Business initiative for more market share.

4.1 Effect of Introducing EC

As the VW targeted for full control of information process built upon a value chain concept, direct transformation of the existing business processes do not map the desired e-operations. We have performed Total BPR on the original business process model of the company. The following e-store processes were identified and implemented:

- On-line stock information: from the stock web database, sales information was made openly available on the net for possible on-line order.
- Pick up/ get / return/ exchange operations: customers could directly handle their necessary information online for order delivery, receiving invoices/receipts for their payments.
- Keep track of customers' information: maintain e-CRM on-line customer information; offer the customers with information of their order status, profile and other information of their individual preferences and interests.

After the T2E business conversion, two additional e-functions and various corresponding information flows were successfully introduced into the system.

4.2 Learning from the T2E Conversion

Our learning from the VW Company experience:

- (1) Traditional stores must identify their strengths and weaknesses before kick off the e-Business initiative. Recognize that additional e-processes are for value adding and not merely for follow the trend in industry is an important start.
- (2) The management may choose from different management models for e-store conversion, but must select a complementary management style with their existing one to minimize impacts of changes in terms of working procedure and culture.

- (3) If cost is a major constraint of the business, the e-business could start by participating in monopoly stores by joining the main portal of the same industry as an affiliation.
- (4) For e-store to grow and be competitive in the e-market, the features of a customer-centered and business-focused e-store to attract Internet traffic are necessary.
- (5) Information: an informative yet simple Graphic User Interface (GUI), a multi-lingual search engine (e.g. both Chinese and English, specific for Taiwan and Mainland China e-Market), rich database, effective store plan, good e-CRM and Internet marketing are important. The bottom line is that the e-customer should be able to come to the web site and complete an e-service process from the beginning to the end in a user-friendly, sensible and intuitively correct manner.
 - Logistics: the e-store itself must have an optimal logistic structure. The bottom line is a complete values chain from order through payment to delivery with a simplest format in fastest time span.
 - Cash flow: secure and safe payment methods that are convincing and reliable. The bottom line is to trade with maximum flexibility and security on Internet.

5. Conclusions

This paper presents a three-layer with five-stage framework as the solution of T2E business model conversion within an SME using a hybrid concept of ID theory, Total BPR and IDEF standard. It is then empirically tested using a case study approach. We have demonstrated the practical feasibility of our model through a case study SME – VW. To the best of our knowledge, the T2E model emphasize the importance of initial management support, organizational learning, and change management as well as simulation before the e-store construction, with the primary objective to minimize the impact of cultural and procedural changes within an organization, is one of the first rigorous studies that examined T2E conversion in SMEs, from a theoretical and empirical perspective.

Future research could build on and extend the proposed T2E model by including potential variables to establish benchmark for measuring the degree of success of e-business conversion in SMEs. Finally, the limitation of this studies is (1) the Asian experience in SME T2E conversion, that might not be general enough to represent a generic model; (2) Quantitative data to empirically measure the effectiveness of our T2E model is not available for publish due to confidentiality. As such, the research method employed in our empirical studies was qualitative. (3) Difficulties to put a commercial web site in a lab setting for evaluation of its quality. Future research could

Corresponding author Tel.: +852-2616-8090;
 fax: +852-2892-2442.
 E-mail address: drikwan@ln.edu.hk

examine these possibilities. Notwithstanding these limitations, this paper has proposed and tested aT2E model for T2E business conversion for SMEs, in Asia perspective.

Abstract

This paper aims at developing a 3-tier inter-universities data warehouse prototype for the Egyptian universities. The implementation scope is restricted to the student enrollment process. The bottom-up approach and the multi-tier (3-tier) client/server architecture were used to implement the proposed prototype. The implementation required a number of steps to be undertaken. First, a star schema data warehouse was built based on an operational database of a public university. Second, another star schema data warehouse was built based on an operational database of a private university. Third, data from the two warehouses were abstracted to formulate the inter-universities data warehouse (tier 3). Hence, a data cube based on the resulting inter-universities data warehouse was developed using an OLAP server (tier 2). The data cube is then accessed by a client tool (tier 1) for the purpose of query and analysis. Although two universities were used to implement the inter-universities data warehouse, this scenario could be applied with any number of universities in a quite similar way. This inter-universities prototype is scalable and flexible to retain more than two universities regardless of the size of the operational databases. The inter-

universities prototype fosters the coordination between participating universities and supports the decision making process. The proposed system could be used to generate a variety of strategic reports.

1 Introduction

Data warehousing is gaining popularity as organizations realize the benefits of being able to perform sophisticated analyses of their data [31]. The quality of data and the variations in its form are the toughest obstacle to building good data warehouses [8]. Organizations moving toward the approach of adopting data warehouse should discuss and answer the following questions: What to put in that data warehouse? The principal task will be determining: what to extract from data sources, how to extract it, transform it, and invariably, clean it. Then, where will the data be stored? How the information is delivered to end-users? There are many different approaches, of course, and they need not be mutually exclusive [2].

2 Data warehouse (DW) definition

Several definitions have been proposed by [17], [34], [3], [24], [2], [4], [7], [1], [33], [13], [23]. Inmon and Hackathorn [17] defined

DW as a subject-oriented, integrated, time-variant, and non-volatile collection of data used in support of management's decision making process. Devlin [7] said that a DW is simply a single, complete, and consistent store of data obtained from a variety of sources and made available to end users in a way they can understand and use in a business context. Adamson and Venerable [1] defined it as a design aimed at getting data out; it is all about getting answers to business questions. Marakas [23] said that the data warehouse contains a copy of the transactions which should not be updated or changed later by the data warehouse but could be updated by the transaction system from which the DW was originated. According to Marakas [23] and Inmon [16] there are four main characteristics that generally describe a DW. Those are Time-variant, Non-volatile, Subject-oriented, and Integrated.

3 DW architectures

The data warehouse application is a client/server application. The role of the client in all the variations generally includes managing the user interaction and formatting and reporting data retrieved from the data warehouse [8]. There are two basic architectures for building a data warehouse. The two-tier data warehouse architecture consists of front-end client components and back-end server components. The two-tier architecture utilizes existing legacy systems as database servers for the data warehouse (tier 2), while LAN-based workstations perform all complex calculations and summaries that go beyond the capabilities of the data warehouse's DBMS (tier 1) [8]. The two-tier architecture is not scalable and does not support large numbers of on-line end users. It encourages the development of *fat-client* front-end systems, in which excessive application processing is allocated to desktop workstations [26]. The multi-tier (*three-tier*) data warehouse architecture or as sometimes called the *thin-client* model, handles the scalability and flexibility problems through the use of an application server between the data warehouse

server and the client. The application server manages the interaction with the data warehouse, performs data filtering, summarization, and aggregation, and sends the results to the client. A variation in the three-tier architecture is the use of a multi-dimensional database (MDD) server that stores the data in a special structure designed to facilitate dimensional analysis. The client remains responsible for managing the user interaction and formatting and reporting resulting data, but requires less processing power due to the reduced calculations and database server interaction [9], [8], [3].

4 The star schema architecture

The best way to build the DW database is by using the Star Schema structure (sometimes referred to as multi-dimensional data modeling). The Star Schema captures the measurements of importance to the business and the parameters by which the business measurements are broken down. It is a direct reflection of how business processes happen. The measurements are referred to as FACTS, whilst the parameters by which a measurement can be viewed are called DIMENSIONS [30], [1], [18].

5 OLAP

OLAP is a common use of a data warehouse that involves real-time access and analysis of multi-dimensional information [32]. OLAP always involves interactive querying of data, following a thread of analysis through multiple passes [27], [29], [14]. There are three major architectures for OLAP systems [6]:

- 1) Multi-dimensional databases OLAP, (MOLAP). MOLAP uses multi-dimensional databases to provide analyses.
- 2) Relational OLAP, (ROLAP). ROLAP uses data directly from relational databases using either a star or snowflake database schema.
- 3) Hybrid OLAP, (HOLAP). In this type, some summarized or aggregated data are stored in a multi-dimensional database,

while other data, such as detailed transaction data, is stored in related relational databases. The user can navigate the multi-dimensional database analyzing the summary (aggregate) data, but if the user requires data that is not stored in the multi-dimensional database, the system automatically generates SQL to retrieve the data from the back-end relational database and then loads that data into the multi-dimensional database, which is referred to as drill-through [6].

6 Inter-organizations data warehouse

An inter-organizations data warehouse can be established between two or more organizations whenever they agree to share data. The separate organizations have separate technologies, IT staffs, data elements, and administrative routines. What ties these diverse entities together is a strong desire to share data for the purpose of producing coordinated overall results. An inter-organizations DW does not come out because a group of organizations just want to share data. Significant planning and arrangement must take place before an inter-organizations DW can go live. All organizations participating in the DW must accept a centralized agreement. The members of the DW agree to the following [19]:

- 1) To define and use conformed dimensions. For instance, all members will use the ITEM dimension in a retail chain. All must agree on the definition of attributes in this dimension so that a compatible set of values from separate dimension tables can be combined together.
- 2) To define and use conformed facts. For instance, all members must agree on the definition of the "revenue" measure in the DW so that separate revenue measurements coming from separate fact tables can be combined mathematically. Whenever conformed dimensions and conformed facts are arranged correctly, the separate organizational members of

the DW are quite free to develop their databases independently.

7 Foundations and significance of research

This research is based on recommendations made by many scholars including: [5], [10], [12]. These recommendations suggest the establishment of an Inter-Organizations Data Warehouse. Inter-organizations data warehouse can be established between two or more organizations for the purpose of producing coordinated overall results, whenever they agree to: share data, use conformed dimensions, and use conformed facts. Inter-organizations data warehouse can help member organizations to enhance their business understanding and accordingly the decision quality [19].

8 Research objectives

- 1) Developing an Inter-Universities Data Warehouse prototype for the Egyptian Universities;
- 2) Support the decision makers by generating some reports based on the Inter-Universities Data Warehouse.

9 Methodology

The adopted methodology consists of the following components together with their respective mechanisms:

- 1) The bottom-up approach for DW development will be used, and
- 2) A multi-tier (three-tier) client/server architecture will be employed.

The bottom-up approach for DW development will be used as follows. First, a Star Schema Data Warehouse is built on the operational database of a Public University. Second, another Star Schema Data Warehouse is built on the operational database of a Private University. Third, data from the two warehouses is abstracted to form the Inter-Universities DW, as shown in Fig. 1. The multi-tier (three-tier) client/server architecture is deployed as follows. A *data cube* based on

the resulting Inter-Universities DW (tier 3) will be developed and run by an OLAP server (tier 2). The data cube can be accessed by the client's tool (tier 1) for query and analysis as needed. Fig. 1. Bottom-Up Approach for Building Inter-Universities DW

9.1 Data sources

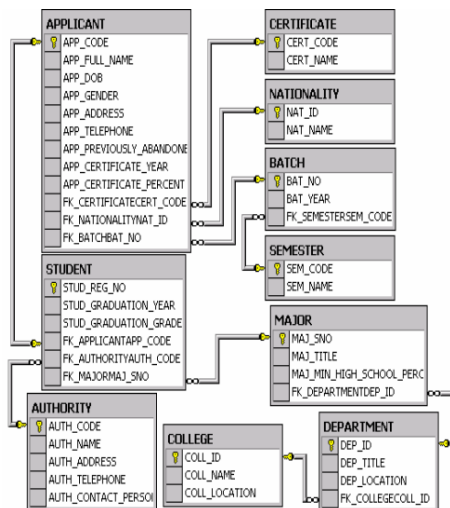

Fig. 2. ER Diagram of the 'Public University' Database

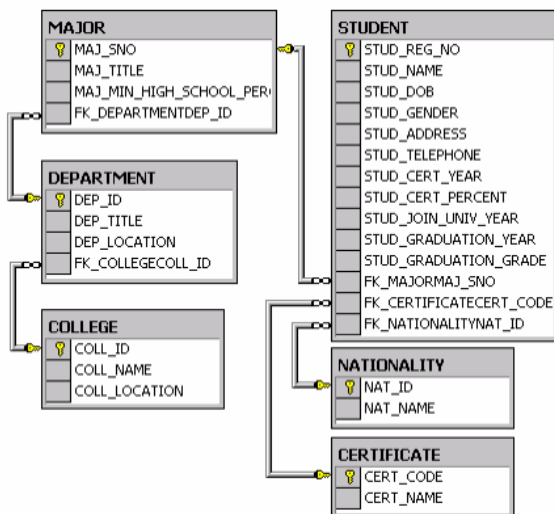

Fig. 3. ER Diagram of the 'Private University' Database

The following sections present a description of the proposed operational databases of the 'Public University' and the 'Private University'. This is done within the scope of student enrollment.

9.2 The public university database

This data source represents any of the Public Universities. An ER diagram of the Public University database, within the scope of student enrollment, is shown in Fig. 2. This database is a downscale of the Admission and Registration database in [12]. The database consists of the following entities: STUDENT, CERTIFICATE, NATIONALITY, MAJOR, DEPARTMENT, and COLLEGE.

9.3 The private university database

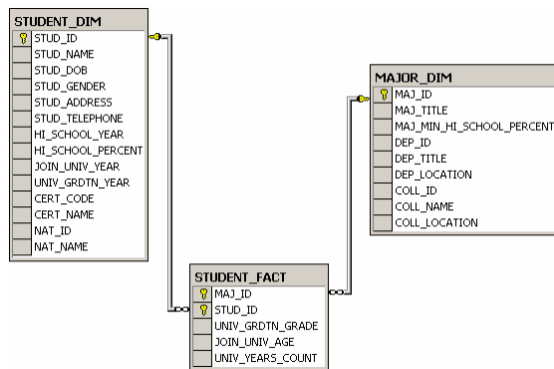

This data source represents any of the Private Universities. An ER diagram of the Private University database, within the scope of student enrollment, is shown in Fig. 3. This database is a downscale of the Admission and Registration database in [12]. The database consists of the following entities: APPLICANT, BATCH, SEMESTER, STUDENT, AUTHORITY, CERTIFICATE, NATIONALITY, MAJOR, DEPARTMENT, and COLLEGE.

9.4 Design of the star schema DW

In the following sections, the steps of designing the Star Schema DW for each university, based on its operational database, are presented. The design steps of a Star Schema DW include determining the grain of the fact table, the dimensional tables, and the measured facts. Then, the design of the Inter-Universities Data Warehouse is presented.

9.5 Design of the public university star schema DW

The Public University Star Schema DW is based on the Public University operational database, presented earlier. Since the proposed Star Schema DW concerns with the process of

student enrollment, the grain of the fact table has been chosen to be the individual *student*. Two dimensions were used: the *Major* (named as MAJOR_DIM), and the *Student* (named as STUDENT_DIM), as shown next.

- **MAJOR_DIM.** It was built by de-normalizing the tables: MAJOR, DEPARTMENT, and COLLEGE.
- **STUDENT_DIM.** It was built by de-normalizing the tables: STUDENT, CERTIFICATE, and NATIONALITY.

The following measured facts of a student were chosen: *university graduation grade*, *age at joining the university*, and *count of years in university*. An ER diagram of the Public University Star Schema structure, within the scope of student enrollment, is shown in Fig.4.

Fig. 4. ER Diagram of the ‘Public University’ Star Schema

9.6 Design of the private university star schema DW

The Private University Star Schema DW is based on the Private University operational database, presented earlier. Since the proposed Star Schema DW concerns with the process of *student enrollment*, the grain of the fact table has been chosen to be the individual *student*. Three dimensions were used: the *Applicant* (named as APP_DIM), the *Major* (named as MAJOR_DIM), and the *Student* (named as STUDENT_DIM), as shown next.

- **APP_DIM.** It was built by de-normalizing the tables: APPLICANT, CERTIFICATE, NATIONALITY, and BATCH.

- **MAJOR_DIM.** It was built by de-normalizing the tables: MAJOR, DEPARTMENT, and COLLEGE.
- **STUDENT_DIM.** It was built by de-normalizing the tables: STUDENT, and AUTHORITY.

The following measured facts of a student were chosen: *university graduation grade*, *age at joining the university*, and *count of years in university*. An ER diagram of the Private University Star Schema structure, within the scope of student enrollment, is shown in Fig. 5.

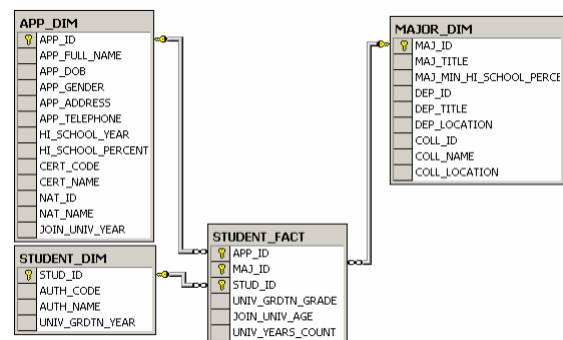

Fig. 5. ER Diagram of the ‘Private University’ Star Schema

10 Design of the inter-universities star schema DW

The Inter-Universities Star Schema DW is based on the two data warehouses: the Public University DW and the Private University DW. By abstracting data of the conformed dimensions and facts from the two data warehouses, the Inter-Universities DW can be built. The conformed dimensions that have been chosen are: the *major* and the *student*. Not all attributes of the two dimensions have been taken. The conformed facts of a student that have been chosen are: *university graduation grade* and *count of years in university* (also, not all of them have been taken). An ER diagram of the Inter-Universities Star Schema structure, within the scope of student enrollment, is shown in Fig. 6.

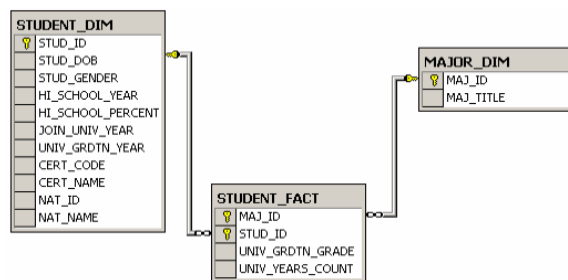

Fig. 6. ER Diagram of the 'Inter-Universities' Star Schema

11 Implementation tools

As mentioned earlier, the bottom-up approach was used for building the Inter-Universities DW, on which a data cube was developed using an OLAP server, to be accessed by the end user. This is referred to as multi-tier (3-tier) client/server architecture. Next, the tools used to implement each tier are presented. The back-end tier is the Inter-Universities DW, and was built using Microsoft® SQL Server™ 2000. The middle tier is the data cube, and was developed and managed by Microsoft® SQL Server™ 2000 Analysis Services. The front-end tier is the end user (client), and uses Microsoft® Excel™ 2000 to access the data cube and generate the required reports. Microsoft® Excel™ 2000 provides a client-based PivotTable® Service component which receives meta data with data from the server in response to a query. PivotTable Service shares much of the same functionality as the server, enabling it to bring the server's multidimensional calculation engine, caching features, and query management directly to the client computer. This client/server data management model optimizes performance and minimizes network traffic [25].

12 Building the star schema data warehouses

Building the back-end tier—the 'Inter-Universities' Star Schema DW—is based on both the 'Public University' Star Schema DW and the 'Private University' Star Schema DW. The Star Schema Data Warehouses were built using the tools delivered with Microsoft® SQL

Server™ 2000 as will be shown. Building each Star Schema Data Warehouse includes two main steps: loading the Star Schema dimensions, and loading the Star Schema fact tables. To load one or more of the Star Schema dimensions and fact tables, it is needed to build a Data Transformation Services (DTS) Package using the DTS Designer delivered with Microsoft® SQL Server™ 2000. The DTS Designer is a graphically oriented tool for building a number of connections and a number of data transformation flows (also known as data pumps) to run between the connections. The DTS Package also serves for mapping operational data model to data warehouse data model. Before creating the required DTS Packages, it is needed to create the Star Schema database structure for each DW and all the tables in it including keys and other constraints.

13 Building the inter-universities star schema data warehouse

The required DTS Package was created with three connections. The first connection to the Public University star schema, the second connection to the Private University star schema, and the third connection to the Inter-Universities star schema.

14 Developing the data cube

The data cube (or as sometimes called OLAP cube) was developed and managed by Microsoft® SQL Server™ 2000 Analysis Services, based on the Inter-Universities DW built above. The MOLAP storage mode (or as sometimes called multidimensional structure) was chosen for creating the proposed data cube. Microsoft® SQL Server™ 2000 Analysis Services system provides PivotTable® Service, which is OLE DB compliant provider. The data cube built above can be accessed for data query and analysis by Microsoft® Excel™ 2000 through Microsoft® OLE DB Provider for OLAP interface. Microsoft® Excel™ 2000 provides the ability to build PivotTable and PivotChart reports based on this interface. Thus, a wide variety of

reports can be generated to fulfill the requirements of various user communities.

15 Sample reports

The following sections present sample reports that are generated as a result of using a random data sample of 1900 records. The data sample contains some personal information about the students joining the university, and some other information about admission, majors, graduation grades, etc.

15.1 Student' high school scores Vs. average university graduation grades

Fig. 7 shows the average university graduation grades of the students against their high school scores in different majors for the university-members of the Inter-Universities DW.

15.2 University demand curve

This report shows the demand curve for education in the universities represented by the number of students joining the universities each year. This report can help the decision maker to arrange the required resources to fulfill the potential demand either on the major level or the university level.

15.3 Graduate students count Vs. University years count

This report shows how many students spent how many years in the university for the different majors. The report helps to show the distribution of graduate students by their university year's count.

Fig. 7. Students' High School Scores vs. Average University Graduation Grades

16 Conclusions

In this paper the bottom-up approach and the multi-tier (3-tier) client/server architecture were used to develop the Inter-Universities DW. The back-end tier (the Star Schema DW) was built using Microsoft® SQL Server™ 2000 and tools delivered with it. All transformations have been done without changing the operational databases at all. The middle tier (the OLAP data cube) was developed and managed by Microsoft® SQL Server™ 2000 Analysis Services. Analysis Services system provides PivotTable® Service, which is OLE DB compliant provider, to be used by applications from diverse vendors to retrieve data from the server and present it to the user. The front-end tier (end user) uses Microsoft® Excel™ 2000 to access the data cube and generate the required reports. Microsoft® Excel™ 2000 provides a client-based PivotTable® Service component which shares much of the same functionality as the server.

Two universities were used to show how to apply this scenario, but it could be applied with any number of universities in a quite similar way, no matter how big is the size of the operational database since the conformed dimensions and facts have been defined. The proposed system can be used to generate a

wide variety of reports showing overall and detailed information about the evolution of education in universities.

A Study of Traditional Versus e-Government Service Channels in The UK

**Professor David Gilbert, Professor in Marketing, School of Management, University of Surrey,
Guildford, UK , email d.gilbert@surrey.ac.uk**

Darren Littleboy, Principal Consultant, Detica Ltd., Surrey Research Park, Guildford, GU2 7YP, UK.

Abstract

This paper examines the reasons individuals would choose electronic self-service delivery methods, more specifically that of the Internet, over more traditional methods of service delivery for government services. The approach taken was based upon a combination of attitudinal technology adoption models and the service quality concept, with data gathered via a questionnaire. Trust, financial security, information quality (all adoption barriers), time and money (both adoption benefits) were found to predict potential usage. The results obtained demonstrated that the current approaches are limited in that they only consider the benefits of technology adoption, they do not consider the barriers to adoption, which is particularly important for electronic public service delivery as a new offering. The results are significant to public service managers if they are to develop plans to increase the take-up of their electronic services.

1 Introduction

In response to increasing consumer power, many organisations have sought to move to Customer Relationship Management (CRM). The core principle behind CRM is for organisations to better understand the needs of each customer, in order that they may personalise their offerings and so increase customer satisfaction, which is believed to develop customer loyalty and increase customer retention Kotler [1]. The Internet has become an important component of the overall CRM approach in that it can be used as an extension to the traditional methods of business.

However, whilst customer retention in e-services is particularly important because of the ease of utilising another provider due to low switching costs, little is known about how consumers perceive and evaluate electronic service delivery. This is of particular managerial importance in the public sector, where all government organisations have to deliver all services electronically by 2005 [2]. Without an understanding of why UK citizens would use electronic service delivery channels over more traditional service delivery methods, government organisations cannot take the necessary strategic actions to meet their citizen adoption targets for

these channels. Therefore, the aim of this paper is to investigate how individuals evaluate electronic channels, more specifically the Internet, for the delivery of government services, and to predict future usage intentions.

2 Literature Review

The consumer decision-making process model [1] is used as the framework to investigate how individuals evaluate on-line self-service delivery options. Thus the assumption is made that the consumer is at the 'evaluation of alternatives' stage where the consumer choice is not between different brands, but between methods of service delivery for a single organisation.

Previous research can be described as varying along a continuum from applying existing theories in a technology context to the development of specific technology adoption approaches. This adoption led approach is applicable since a consumer choosing an electronic service delivery mechanism over more traditional means can be considered as an issue regarding technology adoption. The three main approaches repeatedly used that have sound theoretical and empirical bases, and that are considered in this review are:

- **New theory:** Diffusion of Innovation theory [3, 4] indicates that there are three main factors that are most supported by empirical studies, namely relative advantage, compatibility and complexity. However, these studies all apply to the adoption of technology to information systems for performing job roles, such as the use of spreadsheets [5], and as such may not be as valid when applied to consumers.
- **Extension of existing theory to technology:** Technology Acceptance Model [6] showed that beliefs influence attitudes about information technology, which lead to intentions and subsequently behaviours of actual technology usage. Extensions to the TAM have been thus proposed, predominantly in the area of subjective norms, which are a key part to the theory of reasoned action (TRA), but were not included within the TAM. Venkatesh and Davis [7] acknowledged that there is a need to account for social factors and updated the Technology Acceptance Model (TAM2) by

integrating subjective norms. However, this model still accounted for only 50% of the variance in technology usage intention according to Legris et al. [8], indicating that there are other significant factors not yet identified. Attitudes towards technology have been found to influence Internet usage but the more formalised approach provided by TAM has not been widely adopted in Internet research. In what was found to be one of the first applications of the TAM to the use of the Internet by consumers, O'Cass and Fenech [9] investigated attitudes towards on-line retail purchases.

- **Application of existing framework to technology:** Service Quality (for example, see Dabholkar [10]). The two previous models (Diffusion of Innovation and Technology Acceptance Model) focused specifically upon consumer perceptions of technology and their effect on the intention to use that technology. Recently, another marketing concept that incorporates consumer intentions has been applied to service delivery via technology, namely service quality. Being considered as a differentiator between organisations, it is here being used as a differentiator between service delivery methods of a *single organisation*. In the service quality literature, perceptions relate to post-consumption evaluation of service performance, whereas in the previous two models the approach to perceptions are pre-determined beliefs that lead to attitudes about the product or service. The major issues that are immediately apparent are that the delivery of service via electronic means is still a relatively new concept so that many consumers will not have experienced or interacted with it. It must be also noted that although there is an increasing proportion of the United Kingdom population who use the Internet, this proportion represents still only 50% of the related population. Furthermore, according to Ofcom there is an unequal distribution of the diffusion of the Internet in the UK population: heavier users tend to be younger to middle age groups, larger households and higher income groups [11]. Therefore empirical studies may have to be based upon consumer *expectations* of service quality. The results of the Dabholkar study [10] demonstrated that speed of delivery, ease of use, reliability, enjoyment and control were all significant factors in determining expected service quality. However, the implementation of these attributes can be questioned because the study was aiming to compare consumer decision-making between traditional and technology based service delivery, whereas the instrument questions used these attributes in an *absolute* sense (about the technology), rather than a *comparative* sense.

Discussion

The literature review has highlighted areas where either the approach or the previous applications, have

limitations that may be reduced by combining all three approaches. The attitude-based methods are strong because they are supported by accepted behavioural theory linking perceptions to usage intentions. However, the primary drawback appears to be concerning the antecedents that affect the perceptions towards technology. As mentioned earlier, Legris et al. [8] described how the initial list of factors that affect technology adoption were simplified under the TAM and accounted for only 50% of the variance in technology usage intention.

For the service quality work, the attributes that are important in determining expectations have been well researched through various models, such as SERVQUAL, SERVPERF and the technical/functional model. The specific service quality dimensions have to be modified for the electronic service delivery consideration [12, 13]. However, these models are weaker in the area of linking service quality to customer satisfaction and usage (or re-usage) intentions. Therefore, the proposition is that by combining the attitude-based and service quality based approaches, the theory linking attitudes to behaviours can be exploited (DOI, TAM), with the service quality literature being used to help identify the antecedents that affect these attitudes. However, the antecedents of attitude towards technology adoption have to be defined, placing the onus on both the factors affecting consumer intentions to adopt an online service channel (considered in a comparative manner, i.e. relative benefits) and the factors representing a barrier to adopt the same.

3 Methodology

The analysis is conducted in two stages: the first as an exploratory study to identify the factors that may predict technology usage; the second to test the following hypothesis.

H₁: Each identified factor does not predict the intention to use the technology service delivery option

Whilst many of the principles from the reviewed studies can be used, the following reasons justify the modified approach taken in this research:

- The context here is a publicly available service, not one within the workplace; Whilst people are aware of the Internet, they are unlikely to have received training on how to use it or received direct marketing encouraging them to use it in general, this contrasts with potential users in a work environment; While the use of the Internet for service delivery has increased dramatically, the delivery of government services via the Internet is relatively new, so there are few people who have actually used it.

Thus, rather than questioning individuals on their perceptions developed from actual system usage, and relating this to whether they are actually intending to use it further, the study investigates the importance of the

candidate benefit-barrier factors relating to potential *willingness to use*. That is, the study does not measure actual perceptions, but investigates the factors that individuals consider important in evaluating whether or not to use the service. These factors are important to the service providers (government departments) because they contribute towards the development of attitudes in making the delivery of public services on-line more acceptable.

A self-administered postal questionnaire incorporating 5-point Likert scales was developed. The questionnaire contained 3 parts with parts B & C based upon the literature as indicated in Appendices 1 and 2:

- Part A: factual questions (demographics and previous Internet experience).
- Part B: attitude questions relating to the candidate benefit (Time, personalization, avoid personal interaction, cost, convenience, control) and barrier (visual appeal, safe, reliable, enjoyable, easy to use, confidential) factors.
- Part C: question for 'willingness to use' on-line public service delivery.

Stratified random sampling was performed in Guildford in which 50 streets were selected at random from the list of all streets, using the SPSS random selection facility. Individual addresses in each street selected were also chosen randomly using the same. A pilot study was carried out and consisted of 50 questionnaires distributed

through postal services within 10 streets randomly selected from the list developed. 9 responses were elicited.

Based upon the response rate of 18% from the pilot study, 555 questionnaires were then distributed. A follow-up visit to selected non-respondents was performed in order to increase response rates and finally 111 completed questionnaires were returned.

The reliability of the scales was calculated using Cronbach alpha whereby the scale items in the pilot for benefits and barriers were .75 and .72 respectively and for the final survey these were .83 and .8 respectively. However the reliability may indicate that together the questions measure benefits and barriers, but there was a question that they may not group under the 12 factors proposed as individually the items might not be robust. Therefore, factor analysis was used to identify the underlying constructs that characterise the data response and to investigate the convergent and discriminant validity of the emerging factors.

4 Analysis and Results

Compared to the UK total population census data [14], age range 25-34 and 55+, and people not working full-time were respectively over-represented and under-represented in the sample (Table 1).

Table 1: Comparison of demographic data

Category	Response	Study response (%)	1991 census (%)
Age	18-24	14	13
	25-34	42	20
	35-54	35	33
	55+	9	34
Work status	Full-time	89	46
	Not full-time	11	54

Source: Fieldwork and LGA (2000)

The following table contains the means and standard deviations (SD) for each construct. Each construct is grouped according to the relative benefit and barrier factors.

Table 2: Descriptive Statistics attributed to Construct

Construct	Mean	Standard Deviation
<u>Perceived Benefits</u>		
Avoid Personal Interaction	3.60	0.94
<i>Control</i>	4.20	0.76
<i>Convenience</i>	3.96	0.96
<i>Cost</i>	3.17	1.10
<i>Personalisation</i>	3.55	1.00
<i>Time</i>	4.15	0.80
<u>Perceived Barriers</u>		
Confidential	4.80	0.54
<i>Easy to use</i>	4.34	0.64
<i>Enjoyable</i>	3.46	1.00
<i>Reliable</i>	4.55	0.62
<i>Safe</i>	4.57	0.61
<i>Visual Appeal</i>	3.81	0.89

Source: Fieldwork

The constructs with the largest means (5 = “Strongly Agree” and 1 = “Strongly Disagree”) are those that the respondents have deemed to be the most important. Of

the largest 5 means, only 1 of them is a construct from the ‘relative benefits’ factors (relating to time), which provides an initial indication that, currently, people are more concerned about the risks than the potential benefits. This may be due to the current immaturity of the offering and the lack of exposure that the general public has to government services on-line.

The largest means are those relating to safety, confidentiality and reliability. This is a potentially important observation given that the only potential barrier included within the attitude based models is the ease of use of the technology option. It is interesting to note that a question (“prepared to pay for the online service”, 2.05) within the cost construct has the lowest mean for all questions across constructs, indicating that people certainly would not expect to pay for electronic service delivery even if the level of service exceeded other methods.

Factor Analysis

Exploratory factor analysis was used to identify the constructs that characterise the attitudes towards the on-line delivery of public services. To identify the number of key (also called principal) factors that explain the majority of the variance within the data and satisfying the assumptions of the test the principal component method was used [15]. Tables 3 and 4 summarize the results.

Table 3: Results of factor analysis for 9 extracted factors

Table 4: New constructs and corresponding reliabilities

	Factor	Reliability
Relative benefits	Avoid interaction	0.52
	Cost	0.66
	Time	0.62
Barriers	Experience	0.78
	Information quality	0.67
	Financial Security	0.70
	Low stress	0.68
	Trust	0.79
	Visual appeal	0.67

Source: Fieldwork

As per Table 3 above, 9 factors were identified (High factor loadings (>0.5) have been highlighted in bold, while moderate loadings (>0.3) have been highlighted in light grey boxes), 4 of which are original factors, and 5 are new factors. Whilst the relative benefit factors of avoid interaction, cost and time remained, the individual factors for convenience, control and personalisation no longer existed. This result does not agree with the studies that have identified these very factors, potentially because of the different application, that is government services over the Internet.

Within the barriers factors, easy to use, security, confidential, reliable and enjoyable have all been replaced with factors that are a combination of the items within the original factors. This is a significant result, since the attitude-based models (such as the Technology Acceptance Model) all have 'easy to use' as the single barrier to adoption. Here, easy to use was not found to be a factor used in evaluating such technology options, but there were five other barrier factors: experience, financial security, information quality, low stress and trust.

An important observation is that the reduction in factors has come from the relative benefits side, rather than the barriers, indicating again that the barriers to use are especially important in determining whether people will adopt public sector on-line service delivery.

Table 4 indicates acceptable reliability (above 0.6) and thus the results are representing people's attitudes although the 'avoid interaction' factor requires further validation through future research. Since the items that load onto each factor (loading > 0.3) do not load onto any other factors (loadings all < 0.3), then both convergent validity (items yield comparable results) and discriminant validity (items do not 'characterise' other constructs) can be inferred [16].

Hypotheses Testing

Whilst the nature of the data is ordinal (use of likert scale for each statement considered on their own), the use of parametric tests is warranted, in line with previous research reviewed earlier in this paper and with the behavioural sciences in general, as the underlying scale is continuous for each construct [17]. The assumptions of the tests used, namely linearity, homoscedasticity (the latter two assumptions were checked after generating scatterplots), random sample, normality and independence of observations are here all satisfied. Pearson linear correlation and multiple linear regression were performed below to test the research hypotheses.

Result Hypothesis H1

H₁: Each identified factor does not predict the intention to use the technology service delivery option

Before testing whether there is actual dependency between the 9 factors and willingness to use, it is useful to investigate whether there is any potential relationship by considering the correlation between each of the factors and 'willingness to use'. Pearson Product-Moment Correlation was used for that purpose (Table 5).

Table 5: Correlation between new factors and 'willingness to use'

Factor	r	r²	Sig. (2-tailed)
Avoid interaction	0.182	0.033	0.061
Cost	0.478	0.229	0.014
Time	0.763	0.582	0.000
Visual appeal	0.328	0.108	0.042
Experience	0.363	0.132	0.002
Financial security	0.651	0.424	0.001
Information quality	0.525	0.276	0.021
Low stress	0.307	0.094	0.033
Trust	0.614	0.377	0.000

Source: Fieldwork n=111

All results were reported as statistically significant at the 95% confidence level except for the 'avoid interaction' factor. Therefore it indicates that there is a relationship between willingness to use and each of the factors identified except for the 'avoid interaction' factor.

More specifically there is a strong correlation ($r \geq 0.5$) between time, financial security, trust, information quality and willingness to use the government online service, and a medium correlation between cost, experience, visual appeal, low stress and willingness to use the government online service. This is reflected in the variance shared by the variables (r^2), with time helping to explain 58% of the variance in respondents' scores on the willingness to use scale, with financial security at 42%, trust at 38%, information quality at 28%

and cost at 23%. The other factors only have an explained variance of 15% or lower.

Since the correlation analysis demonstrated a relationship between some of the constructs, a multiple linear regression analysis was performed to investigate whether any of the factors actually predict willingness to use the technology and see which variables have the greatest effect. Table 6 shows the results obtained.

Table 6: Results of multiple linear regression

	Sum of Squares	df	Mean Square	F	Sig.
Regression	53.377	9	5.931	40.923	0.015
Residual	18.695	101	0.145		
Total	72.072	110			

R	R²
0.566	0.320

	Unstandardized Coefficients	Std. Error	Standardized Coefficients	t	Sig.
	B		Beta		
(Constant)	-2.293	0.429		-5.35	0.000
Avoid interaction	0.040	0.032	0.061	-1.24	0.216
Cost	0.039	0.014	0.160	2.77	0.006
Time	0.168	0.019	0.519	8.96	0.000
Visual appeal	0.030	0.025	0.065	-1.21	0.228
Experience	0.001	0.016	0.002	0.04	0.970
Financial Security	0.097	0.027	0.233	3.53	0.001
Information quality	0.038	0.044	0.191	3.09	0.004
Low stress	0.013	0.027	0.026	0.46	0.645
Trust	0.072	0.023	0.200	3.18	0.002

The interpretation of the results in Table 6 is that the linear combination of the factors was significantly related to the willingness to use the technology self-service option, accounting for approximately 32% of the variance ($F(9,101) = 40.923$, $p < 0.05$).

It can be seen that the strongest significant predictors of willingness to use the technology at the 95% confidence level, are: Time, Financial Security, Trust, Information quality and Cost. In other words the hypothesis is rejected for these factors and accepted for the factors of avoid interaction, visual appeal, low stress and experience.

5 Discussion and Conclusion

The present research identified nine factors that are shown to be reliable measures for characterising the attitudes towards on-line public service delivery. These nine factors were either slight modifications of the original factors ensued from previous studies, or totally new factors; 3 of which were relative benefits (time, cost and avoiding interaction) and 6 of which were barriers to adoption (experience, information quality, financial security, low stress, trust and visual appeal).

The test results showed that all factors except avoid interaction, correlated with a willingness to use electronic government services; time, cost, financial security, trust and information quality were the significant predictors of usage. This result indicates that the previous models are restricted in that they do not consider the barriers to adoption, and that the benefits of usage will never be realised if these concerns are not addressed. This supports the results obtained for the attitude models in previous research that only capture 50% of the usage intention [7], and that success modifications have only increased this percentage incrementally [8]. It is proposed here that those models already capture the majority of the usage intention from the benefits perspective, but that significant advances will not be achieved unless the barriers to adoption are incorporated.

Furthermore, the results differ from some of the published literature in that ease of use and some of the perceived usefulness aspects did not emerge as important from the results. This may be because of previous applications [6, 4] which were predominantly applied in the work environment to technologies introduced for employees, rather than to the Internet.

This research can significantly help public sector managers in better understanding why individuals may choose to receive public services via online channels rather than by more traditional means, and help them to draw strategies for enticing people to use such channels.

Thus, from a marketing perspective, the factors identified that predict a willingness to use on-line service delivery could form the basis of a promotion campaign. Guildford Borough Council [18] has recently distributed information about the convenience benefits of their council tax website. However, within this research convenience was not found to be one of these factors; the literature could focus more on giving assurances to address the concerns of trust, financial security and information quality, in addition to highlighting the benefits of saving time and money (if appropriate).

There are aspects of the research that may limit the interpretation of the results. Firstly, the data were collected solely in Guildford, which is not necessarily representative of the UK population. The sampling method used in this research, namely stratified random

sampling, may however reinforce the validity of the results obtained here.

Further study is recommended to both validate the current scales identified in this research and to investigate whether other factors emerge. The current study could thus be extended to incorporate additional factors such as in own ability [23] to explain more of the variance in the willingness to use the technology.

Appendix 1: Relative benefit factors sources

Factor	Source references	Notes
Avoid personal interaction (no necessity to interact)	Forman and Ven (1991) Hansen (1995) Meuter et al (2000) Prendergast and Marr (1994)	
Control (ability to exert more control)	Cabinet Office (1998) Dabholkar (1996) Liao and Cheung (2002) Zhu et al (2002)	This can be expressed as giving empowerment to the individual
Convenience (ability to receive service how and when required)	Cabinet Office (1998) Meuter et al (2000) Szymanski and Hyse (2000) Zhu et al (2002)	This factor relates to the electronic service being more accessible and available
Cost (ability to save money)	Liao and Cheung (2002)	Includes savings to both the individual and the organisation providing the service
Personalisation (ability to tailor to the individual)	Van Riel et al. (2001)	Includes the technical aspect of being able to customise a public sector website.
Time (ability to save time with the service)	Berkley and Gupta (1994) Dabholkar (1996) Hansen (1995) Liao and Cheung (2001, 02) Meuter et al (2000)	Includes the time spent queuing at government offices or on the phone and also includes the responsiveness of the service delivery.

IT literacy [19], prior experience of using online commercial services [20, 21], culture [22] and confidence

Appendix 2: Barrier factors

Factor	Reference	Notes
Confidentiality (Personal data kept private)	Cabinet Office (1998) Van Riel et al (2001) Zhu et al (2002)	Relates to 'Assurance' SERVQUAL dimension
Easy to use (delivery mechanism has to be easy to use)	Agarwal and Prasad (1998) Dabholkar (1996) Lederer et al (2000) Meuter et al (2000)	
Enjoyable (experience of use should be enjoyable)	Dabholkar (1996) Davis et al (1989) Liao and Cheung (2001)	
Reliable (has to have required and trusted services)	Berkley and Gupta (1994) Evans and Brown (1988) Hansen (1995) Zhu et al (2002)	This factor also includes accuracy and currency (up-to-date) of the information on the website. Direct relationship with 'Reliability' SERVQUAL dimension
Safe (secure with respect to entering financial details)	Cabinet Office (1998) Berkley and Gupta (1994) Evans and Brown (1988) Szymanski and Hyse (2000) Liao and Cheung (2001, 2002)	
Visual appeal (website should look good)	Lederer et al (2000) O'Cass and Fenech (2003)	A technical attribute of the website itself, and can be considered as a technical service quality attribute

Abstract

The historical links of a web site include the URLs invalidated due to web site reorganization, document removal, renaming or relocation, or links to document snapshots, which are defined as the document's contents as of a specific point in time. Tracking historical links will allow users to use out-of-date URLs, retrieve removed documents and document snapshots. This paper presents a logging and archiving scheme to track a document's history of changes, and a Temporal URL scheme for users to submit a URL with temporal requirements. With the proposed schemes, a web site is able to track its historical links and provide better searching and information for its users.

1. Introduction

A web site is a system of integrated web documents embedded with links to reference related documents. At any given time, a Uniform Resource Locator (URL) uniquely identifies a document on the Internet. All URLs have the same format: <protocol>://<host>/path-to-document. The <protocol> specifies the method to be used by the browser to communicate with the web server. Common protocols include http, ftp, gopher, etc. The host name is the web server that stores the document. The path to the document is a sequence of directory names and the document name. URLs are also known as the addresses, or paths, of documents on the Internet.

URLs are temporal and exist only for a limited period of time. There are many causes that will render a URL invalid: the host may cease to exist; the host may reorganize by changing its directory structure, hence changing the path to a document; a document may be renamed, deleted, or moved to a different directory. The document may no longer exist or have a new URL.

URLs are published information that may be out-of-date. Internet users gather the URLs of their interests from many sources such as references in books and documents, web page hyperlinks, results of searching with search engines, etc. Very often those published URLs may already be invalid. Requesting a document with an invalid URL may cause a file-not-found error (HTTP 404). Some websites do not handle this error and simply let the browser display the error code. Some web sites redirect users to a default error-handling page typically equipped with search tools. Searching takes

time and may not be successful. Searching web sites storing a large amount of documents is particularly tedious and unfruitful. It may produce a large number of relevant documents but may not pinpoint the document requested by users.

The file-not-found error may be triggered by many causes such as: 1. The document may have never existed in the web site. 2. The document may be deleted. 3. The document may be renamed or relocated to another directory. Rather than simply displaying a file-not-found message, a web site will improve its services by handling each cause separately. For the first case, returning a message such as "file never exists" is more informative. For the second case, returning a message such as "file no longer supported" is appropriate. For the third case, the web site can redirect users to the document's new URL.

Even valid URLs don't necessarily retrieve the user's desired document. A URL may point to a document that is different from the one it pointed to earlier. This may happen because of the renaming of documents and directories. For instance, a document A may be renamed to C and another document B may be renamed to A; hence the URL originally pointing to A is now point to a different document. It may also happen when a web site removes a URL but later reinstates the URL for another document. Users submitting such a URL may get an unwanted document.

A document may have gone through several changes. A URL typically retrieves the current version of a document and its contents may be different from the last download. There are times when users would like to see the previous versions of a document. These previous versions are snapshots of a document. A document snapshot is defined as the document's contents as of a specific point in time. Studying a document's snapshots may help users identify trends and patterns of changes in a document.

Together, the URLs invalidated by a web site due to reorganization, document removal, renaming, or relocation, plus the links to document snapshots are a web site's historical links. Tracking historical links basically means recording the time and the type of changes that occurred to a document and its URL. It enables a web site to retrieve the document associated with an out-of-date URL submitted by users, deleted documents, and document's snapshots. This will improve

Web Document

	Added	No change	Relocated/ Renamed	Modified	Deleted
No change	New URL	URL current	Old URL invalid/ New URL	URL current/ Archive snapshot	Old URL invalid/ Archive
Reorganized	Old URL invalid/ New URL	Old URL invalid/ New URL	Old URL invalid/ New URL	Old URL invalid/ New URL/ Archive snapshot	

Figure 1: Effects of web site reorganization and web document changes.

a web site's searching ability and provide better information for users.

Tracking changes has been the research topic in many areas such as managing database snapshots [1], materialized views [4], and document versions [6]. Those researches may focus on tracking the changes (deltas) [5] or tracking document's snapshots. Using a log to record changes [2] [3] and archiving the many versions of a document are typical methods in tracking changes. This research proposes a logging and archiving scheme for tracking historical links and proposes a Temporal URL scheme to retrieve document snapshots. The objectives of this scheme are: 1. For an invalid URL the scheme will be able to distinguish if the document is non-existent, or no longer supported, or it has a new URL so that appropriate action can be taken. 2. For a valid URL the scheme will allow users to retrieve the document snapshots. 3. For a valid URL that retrieves an incorrect document, the scheme will allow users to resubmit the URL and inform the web site to process the URL as a historical link.

An analysis of the problem and the designs of solutions are presented in Section 2. The temporal URL scheme and algorithms for processing historical links are presented in Section 3. Section 4 is a summary.

2. Problem Analysis and Solution Designs

2.1 Problem analysis

Figure 1 summarizes the effects of web site reorganization and change to a document on its URL. When a web site reorganizes its directory structure, all affected documents will have a new URL. Similarly, when a web document is renamed or relocated to other directory, it will have a new URL as well. When a document is modified, its URL will not change and the old version before the modification becomes the document's snapshot between the previous and the current modification. In order to retrieve the snapshot, either the difference between the old and the current version needs to be recorded so that the snapshot can be reconstructed, or the old version is archived. Tracking the difference between two unstructured documents such

as web documents is not easy. Here, archiving is assumed. A deleted document is archived as well for later retrieval.

Figure 2 illustrates the progression of a web site. T_0 is the time when the web site is initiated, and T_i denotes a point in time when its contents change. Period i is the interval of time between T_i and T_{i+1} . Assuming the path of a valid URL is unique within the web site, a valid path leads to a document currently published. In the sequel, paths and URLs are used interchangeably. There are two sets of paths in period i : VP_i , a set of all valid paths, and HP_i , a set of paths becoming historical at T_i . Note that HP_0 is null. In Figure 2, paths that produce two dotted arrow lines such as P_1 in period 0, and P_4 and P_5 in period 3 represent documents that are renamed or relocated. In this case, only the document's path has changed but the document has not changed. Therefore, there is no need to archive any documents, but it is necessary to chain the old path to the new path in order to track the change. Paths that produce two solid arrow lines such as P_3 in period 1, and P_3 and P_5 in period 2 represent documents that are modified. In this case, the path is still valid but the document before the change needs to be archived as the document's snapshot. Paths that produce one solid arrow line, such as P_2 in period 1 and P_3 in period 3, represent documents that have been deleted. Those documents must be archived.

A path in HP_i may be repeated in HP_j , just as P_3 is repeated in HP_2 and HP_3 . To make a historical link unique, the time the path was published is added to the path. Hence P_3 in HP_2 is identified as $P_3 + T_1$ and P_3 in HP_3 is identified as $P_3 + T_2$. Similarly, a current path may duplicate a path in the historical links, as is the case of P_1 . By adding its published time, $P_1 + T_3$ is distinguishable from the historical link $P_1 + T_0$. The historical links of a web site before T_i are the union of sets HP_0 to HP_{i-1} , ($HP_0 \cup HP_1 \cup \dots \cup HP_{i-1}$). Assuming T_i is the last time the web site changed then the web site's historical links are the unions of sets HP_0 to HP_i , and the current links are VP_i . The union of historical links and the current links represents all the paths that are currently in use or have been used in the past. Every link in the union is uniquely identified by the value (path + path published time). This composite value is an example of a

Figure 2: An example of the progression of a web site with changes since its creation.

Temporal URL (discussed in Section 3). For any path P_x published at time T , the temporal URL ($P_x + T$) uniquely identifies a document that is currently or was once associated with P_x at time T .

2.2 Solution Designs

This section explains the scheme to track the historical links. The scheme has two major components: logging the changes to web documents and archiving deleted documents including document snapshots. The log, named TemporalURLLog, is designed to keep the history of changes to web documents. It has four fields: URL, PublishDate, ExpireDate, and NewURL. The URL field records a document's path; the PublishDate records the time the document is published; the ExpireDate field records the time this URL becomes invalid; should the change create a new URL for the document, the NewURL field records the document's new URL and serves as a link to chain all log entries related to the same document together. This log has a composite key of URL + PublishDate. The value of URL + PublishDate uniquely identifies a document in a web site's history. The Archive is a directory that stores deleted files and document snapshots. Those archived files are saved in the Archive using URL + PublishDate as file name. The log is maintained according to the log maintenance algorithm described below:

TemporalURLLog maintenance algorithm Changes to web documents are recorded in the log by the following rules:

New document: When a new document is added to the web site, a new entry is entered with its path and the time the document is published. The ExpireDate and the NewURL are set to null. Hence, log entries with a null ExpireDate are current document entries. Initially, all current documents have an entry in the log with null ExpireDate and null NewURL.

Deleted document: The log entry associated with the document is the entry of which the URL equals the document's URL with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time the document is deleted. Then, it saves the deleted document in the Archive with URL + PublishDate as file name.

Modified document: When a document is modified, its old version becomes a snapshot and its new version is treated as a new document. The log entry associated with the document is the entry of which the URL equals the document's URL with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time the document is modified. Then, it saves the old version in the Archive with URL + PublishDate as file name. Then, it adds a new entry with the same URL and the PublishDate is set to the time the document is modified. The ExpireDate and NewURL are set to null.

Consequently log entries with a non-null ExpireDate and a null NewURL may be related to snapshots or deleted documents. For such an entry, if there exists another entry with the same URL and its PublishDate equals to this entry's ExpireDate then this entry is a snapshot entry and the snapshot it associates with can be retrieved from the Archive using URL + PublishDate as its file name. The snapshot is valid from the PublishDate to the ExpireDate. Otherwise, the entry is associated with a deleted document which can be retrieved from the Archive using URL + PublishDate as its file name.

Relocated or renamed page: When a document is relocated or renamed, its old URL is expired and a new URL is created. The log entry associated with the document is an entry with the URL equal to the document's URL and with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time the document is relocated or renamed and changes its NewURL field to the document's new URL. Then, it adds a new entry with the new URL and the PublishDate is set to the time the document is relocated or renamed.

Hence, log entries with non-null NewURL field help chaining a document's log entries.

Using this log maintenance algorithm for the changes described in figure 2, the contents of the TemporalURLLog are shown in Figure 3, and there are five files in the Archive: P2T₀, P3T₀, P3T₂, P5T₁, and P3T₃.

URL	PublishDate	ExpireDate	NewURL
P1	T ₀	T ₁	P4
P2	T ₀	T ₂	Null
P3	T ₀	T ₂	Null
P4	T ₁	T ₄	P8
P5	T ₁	T ₃	Null
P3	T ₂	T ₃	Null
P3	T ₃	T ₄	Null
P5	T ₃	T ₄	P7
P6	T ₃	Null	Null
P1	T ₃	Null	Null
P8	T ₄	Null	Null
P7	T ₄	Null	Null

Figure 3: The contents of TemporalURLLog based on changes described in Figure 2.

3. Searching with TemporalURLLog

With the TemporalURLLog, a web server is capable of processing historical links involving deleted documents, out of date URLs, and document snapshots. For instance, using the log in Figure 3, it is possible to determine that:

- . A URL P2 valid between T₀ and T₁ is deleted, and the document it pointed to is in the Archive with the name P2T₀.
- . A URL P3 has been modified repeatedly and is eventually deleted. All documents associated with P3 can be found in the Archive.
- . An old URL P5 is now renamed to P7. It has been modified on T₃, and a copy of its snapshot can be found in the Archive with the name P5T₁.
- . The log is able to determine that a historical line P1 is now renamed to P8.
- . A URL P12 has never existed in the web site.

This section presents a Temporal URL scheme and algorithms for searching documents associated with historical links.

Requesting historical documents with temporal URL

A temporal URL is a URL submitted with temporal requirements of which the documents associated with the URL must meet. A typical way to submit additional information with a URL is through query strings. A query string is a set of name=value pairs appended to a URL. It is created by adding a question mark (?) immediately after a URL followed by name=value pairs

separated by ampersands (&). Two types of temporal URLs are designed:

1. The URL is not current: When the URL is not current, a keyword IsHistorical can be appended to the URL to indicate users are searching for documents associated with a historical link. The query string is:

?IsHistorical

2. The URL is current: The document associated with the URL may have gone through modifications. There are situations where users may need to access a document's snapshots at different points of time. Special keywords can be created for users to specify temporal requirements for snapshots. Some typical keywords are:

?SnapshotAsOf=date

?SnapshotsBefore=date

?SnapshotsAfter=date

?SnapshotsBetween=date1&And=date2

The ?SnapshotAsOf=date query string will retrieve a document's snapshot at the specified date; others will retrieve all snapshots that meet the date criteria. A web site may choose to implement the types of temporal query strings to fit its needs.

Algorithms for processing temporal URL are presented below.

Forward search to locate documents associated with a historical link

This algorithm processes the ?IsHistorical temporal query string submitted with a URL Px and searches the TemporalURLLog to locate all the documents related to a historical link. In the TemporalURLLog, entries for a URL may have three patterns of changes: 1. If a URL has a log entry with a non-null PublishDate and null ExpireDate field then it is a current URL; such as P6 in figure 3. 2. If all entries of a URL have a non-null PublishDate, ExpireDate and null NewURL field, then this URL is deleted from the web site; such as P3 in Figure 3. 3. If a URL has a log entry with a non-null NewURL field, then it has been renamed, and the log entries for the new URL may again have these three patterns of changes. Because a URL may be used several times in the life of a web site, such as P1, this algorithm will locate all documents associated with the historical link.

In the algorithm, SetPx is a set of records where URL equals Px. If SetPx is null then Px never existed. Otherwise, a loop is used to study change pattern. It applies a forward search that will trace down all related entries until reaching the last entry. To move forward, an entry's successor can be found and processed by the following rules:

1. If the entry has a null NewURL then its successor must have the same URL and the successor's PublishDate

Algorithm Forward Search

Inputs: TemporalURLLog, historical link Px

Outputs: Links to all documents related to Px

```

SetPx = { Select * From TemporalURLLog Where URL = Px And Not ExpireDate = Null
          Order By PublishDate }

If SetPx isNull Then
    Return Message: Document never exists
Else
    For Each Record R in SetPx
        If R.NextURL Is Null Then
            If Not Exist {Select * From TemporalURLLog Where
                          URL = R.URL And PublishDate = R.ExpireDate} Then
                Return LinkArchive(R.URL + R.PublishDate)
            End if
        Else
            PxLink = R.NextURL
            Do
                SetPxLink = { Select * From TemporalURLLog Where URL = PxLink
                              Order By PublishDate }
                NextLoop = False
                For Each Record R in SetPxLink
                    If R.ExpireDate isNull Then
                        Return LinkDocument(R.URL)
                    Exit Do
                Else
                    If R.NewURL IsNull Then
                        If Not Exist {Select * From TemporalURLLog Where
                                      URL = R.URL And PublishDate = R.ExpireDate} Then
                            Return LinkArchive(R.URL + R.PublishDate)
                        Exit Do
                    End if
                Else
                    PxLink = R.NewURL
                    NextLoop = True
                    Exit For
                End if
            End if
        End if
    Next
    If NextLoop = False Then
        Exit Do
    End if
Loop
End if
Next
End if

```

must equal the entry's ExpireDate. If no such successor is found, then this entry must have been generated due to a deletion and its archive name is created with this entry's URL and PublishDate. This algorithm returns a link referencing the archived document.

2. If the entry has a non-null NewURL then it must have a successor with a URL equal to the NewURL and the PublishDate equals to the entry's ExpireDate. Renaming or relocation must have generated the successor. When such a successor is found, a new loop is started to trace down the changes in the new URL. Although Px is not current, this new URL can be current if there exists an entry with the new URL and a null ExpireDate; a link referencing the new document is

returned. Otherwise, the new URL eventually is deleted and the algorithm returns a link referencing the archived document.

To illustrate, if P5?IsHistorical is submitted, initially SetPx contains two entries: (P5, T₁, T₃, Null), (P5, T₃, T₄, P7). The first entry's NewURL is null but the next entry's PublishDate equals the first entry's ExpireDate indicating that this is a modification. The second has a non-null NewURL indicating that it has been renamed. After processing the second entry, a new loop is started using the NewURL P7 to search. In the second loop, SetPx contains: (P7, T₄, Null, Null). Since its ExpireDate is null, this is a current URL and P7 is returned.

Algorithm Backward Search

Inputs: TemporalURLLog, valid URL Px, snapshot time T

Output: Px's snapshot at time T

```
CurrentEntry = {Select PublishDate From TemporalURLLog Where URL = Px and ExpireDate = Null}
```

```
If CurrentEntry.PublishDate <= T Then
```

```
    Return Document(URL)
```

```
Else
```

```
    Candidate.URL=CurrentEntry.URL
```

```
    Candidate.PublishDate=CurrentEntry.PublishDate
```

```
    Candidate.ExpireDate=Null
```

```
    PD=CurrentEntry.PublishDate
```

```
    Do
```

```
        PreviousEntry={Select * From TemporalURLLog Where URL=Px And ExpireDate=PD}
```

```
        If PreviousEntry Exists Then
```

```
            Candidate.URL=PreviousEntry.URL
```

```
            Candidate.PublishDate=PD
```

```
            Candidate.ExpireDate=PreviousEntry.ExpireDate
```

```
            PD=PreviousEntry.PublishDate
```

```
            If PD < =T Then
```

```
                Return Archive(Candidate.URL + Candidate.PublishDate)
```

```
            Exit Do
```

```
        End if
```

```
    Else
```

```
        PreviousEntry={Select * From TemporalURLLog Where NewURL=Px And  
                        ExpireDate=PD}
```

```
        If PreviousEntry Exists Then
```

```
            PD=PreviousEntry.PublishDate
```

```
            IF PD < =T Then
```

```
                If Candidate.ExpireDate=Null Then
```

```
                    Return Document(Candidate.URL)
```

```
                Else
```

```
                    Return Archive(Candidate.URL+ candidate.PublishDate)
```

```
                End if
```

```
            Exit Do
```

```
        Else
```

```
            Px = PreviousEntry.URL
```

```
        End if
```

```
    Else
```

```
        If PD > T Then
```

```
            Return Message: Snapshot Does not exist at T
```

```
        Else
```

```
            If Candidate.ExpireDate=Null Then
```

```
                Return Document(Candidate.URL)
```

```
            Else
```

```
                Return Archive(Candidate.URL+ candidate.PublishDate)
```

```
            End if
```

```
        End if
```

```
    Exit Do
```

```
End if
```

```
End if
```

```
Loop
```

```
End if
```

If P1?IsHistorical is submitted, initially SetPx contains only one entry: (P1, T₀, T₁, P4). Since its NewURL is non-null, a new loop is started and SetPxLink is created using P4 to search; SetPxLink contains one entry: (P4, T₁, T₄, P8). Because this entry's NewURL is non-null, a new loop is started to create a new SetPxLink with one entry: (P8, T₄, Null, Null). This indicates P8 is current and a reference to it is returned.

Backward search for a document's snapshot at a specific date. This algorithm processes the query string ?SnapshotAsOf=T submitted with a URL Px and searches for the snapshot based on the specified date T. It assumes Px is a current URL to simulate a scenario in which users who are viewing a current document would like to view the document's snapshot at a point in time. The algorithm is briefly explained below.

It processes log entries backward starting from a document's current entry to trace back its changes in order to locate the snapshot. If the current URL's PublishDate is less than T, then the current document itself is its snapshot at T. Otherwise the backward search starts. To trace back, an entry's predecessor has one of the following properties:

1. Its URL equals the current entry's URL and its ExpireDate equals the current entry's PublishDate. This indicates the predecessor is an old version of the document and it is the document's snapshot from the predecessor's PublishDate to its ExpireDate.

2. Its NewURL equals the current entry's URL and the ExpireDate equals the current entry's PublishDate. This indicates the predecessor has been renamed or relocated.

Initially, the current document is treated as a candidate for the snapshot. Before reaching past time T, whenever an old version is found it becomes the new candidate for the snapshot. Note that an old document's life may span beyond its PublishDate. If a document Y is originally derived from a document X through a series of renaming or relocation, then this document's life span is from document X's PublishDate to document Y's ExpireDate. The search reaches the last entry when its PublishDate is before T or it no longer has a predecessor. If the last entry's PublishDate is greater than T then snapshot does not exist at T.

To illustrate, if a request $P7?SnapshotAsOf=T_2$ is submitted, the backward search will pick up three entries: (P7, T₄, Null, Null), (P5, T₃, T₄, P7), and (P5, T₁, T₃, Null). They show that the document associated with P7 has been unchanged since T₃ and was originally associated with P5 and renamed to P7 at T₄. The document has been modified at T₃. Therefore, the algorithm returns Archive(P5 + T₁) as snapshot. If $P7?SnapshotAsOf=T_3$ is submitted, the backward search will pick up two entries: (P7, T₄, Null, Null) and (P5, T₃, T₄, P7) and return Document(P7) as snapshot.

If a request $P8?SnapshotAsOf=T_0$ is submitted, the backward search will pick up three entries: (P8, T₄, Null, Null), (P4, T₁, T₄, P8) and (P1, T₀, T₁, P4). These show that the document associated with P8 has been renamed at T₁ and T₄. It has not been modified since T₀. The algorithm will return Document(P8) as snapshot.

This algorithm can be modified to process ?SnapshotsBefore=date, ?SnapshotsAfter=date, and ?SnapshotsBetween=date1&And=date2 temporal query strings by modifying the temporal conditions in the algorithm.

4. Summary

The historical links of a web site include the URLs invalidated due to web site reorganization, documents' removal, renaming or relocation, plus links to document snapshots. Tracking historical links will allow users to use out-of-date URL and retrieve removed documents and snapshots. This paper has two contributions: 1. It presents a logging and archiving scheme to track a document's history of changes. These changes include a document's creation, modifications, web site reorganizations, and deletion, which are recorded in a log. The log records a URL's publication date, expiration date, and the new URL it is assigned to, if applicable. Document snapshots and deleted documents are archived to support users who need historical documents. 2. It presents a temporal URL scheme for users to submit a URL with temporal requirements of which the documents associated with the URL must meet. A URL will retrieve a current document by default. With the temporal URL users may inform the web server to treat the URL as a historical link, or request the document's snapshots. Algorithms for processing the log and the temporal URL are also presented. With the proposed schemes, a web site is able to track its historical links and provide better searching and information for its users.

E-Governments: Utilizing Customer Relationship Management (CRM) Platforms to Serve Citizens

Satya P. Chattopadhyay
Arthur J. Kania School of Management
The University of Scranton
Scranton, PA 18510, USA
spc354@scranton.edu

Abstract

In a democracy, elected governments are expected to meet the needs of their various constituencies in order to have an opportunity to continue in power. “Citizen” or “constituent” is legitimate stand-in for the letter “C” in Customer Relationship Management, accepted in the world of business. Currently, many CRM companies are prospecting the public sector organizations to market their products. The government markets, globally, are the fastest growing market for CRM systems in the upcoming years. This paper describes the goals of e-Government implementations and applications that characterize the nature of citizen service delivery initiatives in the public sector. The paper examines the differences between applying CRM in public and private sector. The paper goes on to discuss the application of four E-Commerce based CRM implementation strategies in the public sector and their outcomes in selected cases. The second part of the paper uses publicly available empirical data to investigate scope, extent and impact of global e-Government implementations.

1. Introduction

As democracy takes hold in more of the world's nations, governments feel more compelled to recognize their ultimate accountability to the citizens. Even benevolent autocracies, and one party governments have realized that citizen satisfaction is vital to remain in power. The move to e-Government has gathered momentum as a viable platform to make progress in that direction. Using advanced information and communication technology (ICT) and the capabilities of the world wide web (WWW) governments try to implement high level of service orientation to citizens and effectively managing relationships between them and the government personnel to minimize frustration and dissatisfaction.

SAP, a leading provider of enterprise management systems to organizations identifies the e-Government market as one characterized by the need for a “integrated solution... that empowers public administrators to better communicate and collaborate with its people and employees, while facilitating cost-efficient processes.”[SAP] This focus has been characterized as the paradigm of complex and one directional systems that broadcast information to citizen customers. A complementary approach, the paradigm of “interactivity”

is the focus of administrators in Europe [EDEN]. The goal is thus to streamline the delivery of citizen services on one hand, and on the other, make the services widely available in spite of barriers imposed by location, demographics, and ability to pay [Nigeria], and make them friendly, convenient, transparent and inexpensive[World Bank].

An internet search of case studies of e-Government implementations show a tremendous diversity in scope and characteristics [Chatt and Pratt] as well as degree of success [Prattapati and Chatt].

The next section will lay out the definition of E-Government as it diverges from that of e-Commerce and also establish a framework for evaluating its scope, extent and success.

2. e-Government: Definitions

E-Government refers to the use by government agencies of information technologies that have the ability to transform relations with citizens, businesses, and other arms of government [World Bank]. E-G differs from E-Commerce and E-Business in that the former does not focus on volume, revenue or profit maximization, but instead seeks improved governance procedures to connect better with and within civil society [Nigeria].

The direct conceptual benefits that are expected outcomes of E-G implementation are: a. Re-affirming the citizen centric organization of the government, b. Deliver citizen services where they are needed/sought rather than locating them only in government agency offices, c. Making it possible to access citizen services with seamless integration rather than requiring multiple points of contact, d. Transparency and ease of access to government information, e. Ability to complete remote transactions with government agencies.

The operational tasks that can accomplish these goals are described as: a. Handling all forms of customer contact, including telephone, face to face, e-mail and internet, b. Systems integration within and across agencies that serve citizens, c. Improvement in quality, efficiency and effectiveness of service delivery, d. Unified and updated access to full citizen contact history, e. Provides single point of enquiry for all citizen, f. Empowering staff to act to resolve issues, after backing them up with all necessary information [Aniteps]. Implementation of E-G must also consider adopting appropriate open source technologies that can support diverse operating platforms and

communications equipment that may be in use.

From the citizens' perspective, the outcomes of E-G will be demonstrated through: a. Ease of access to information about governance policies, b. Timely access to information regarding safety and security from threats both natural and otherwise, c. Ease of completion of transactions with government agencies, such as registration of events, voter registration, passport application, tax filing, exercising voting rights, registration of motor vehicles, and obtaining permits/licenses for personal and business reasons, among other things.

3. Impediments to E-Government

The sustained push toward E-G notwithstanding, the results have been mixed so far. Some citizens have been "turned off" by E-G. A study conducted by the UK government found information on the system to be inaccurate and out of date. Low usage by targeted citizens pointed to the inadequacy of the implementation and inability of the system to satisfy citizens' needs. A blue ribbon commission pointed out that to be successful, the E-G had to be more than simply moving existing operations to the internet [UK MP Report].

The primary impediments to implementing E-B have been characterized as a. Institutional weakness, b. Inadequate human resource capability, c. Lack of funding for infra-structural expenditures, d. Lack of facilities and institutions to flesh out the multi-layered system of vendors and technical support necessary to keep the system running, and e. Uncertainty over the choice of competing technology (hardware and software) that will maximize citizen acceptance [UNPAN]. From the citizens' perspective, apart from ease of access and usability, the over-riding concern is with security of transactions and integrity of system in preserving privacy of participants.

As more E-G systems come online, they seek to deal with the citizens' issues with increasingly sophisticated technology and improved business processes. However, addressing the macro impediments have been more difficult in a depressed global economic environment.

4. Impact of E-Government Initiatives

The impact of E-G implementation spans participative governance, economic efficiency and social responsibility. In addition, the promise of real time availability of information is expected to benefit the cause of transparency in government affairs and decrease perceived corruption.

The UNPAN 2001 benchmark study found the following status of its member states as shown in Figure 1.

Figure 1. E-Government status of UN members [UNPAN]

UN member states (total)	190
Some govt. web presence	169
National govt. website	84

Single entry portals	36
Sub-national govt. website	84
On-line transaction capacity	17

Using an index of E-G, [UNPAN] captures the member states relative sophistication in creating a platform to deliver information and services to all sections of its society. The researchers then assigned the member states to five hierarchical stages of E-G implementation.

In the "emerging" category are states that have been able to incorporate some information content in published web pages at some point. Information in the form of notices, some downloadable forms and possibly e-mail contact is published over the web. There are no procedures in place to keep the information updated. Syria, Cyprus and Mali fall into this category.

In the category of "enhanced" E-G, the countries show increased diversity and quality of on-line content, but the focus is more on political and public affairs rather than citizen services in the areas such as health care, education, environment etc. Georgia, Nigeria and Monaco are in this category.

In the "interactive" category, the citizens are not passive recipients but instead determine the content they seek, and also may choose the time and place to some degree in actually obtaining the same. Countries such as Argentina, Israel and Thailand are in this category, providing its citizens with a wide array of quality published information on demand and at their convenience.

The "transactional" category signifies ability to support not only information needs but also the secure completion of transactions involving payments and information products. In one case, a transaction over the web is sufficient to secure an electronic visa for border crossing at a later date. Australia, Norway and Singapore are examples of this group.

The "seamless" customer -centric system where all aspects of the government's functions are virtually organized to provide integrated one stop system customized to respond to the unique needs of the querying citizen-customer. This has not happened. The CAPPS system proposed by the Department of Homeland Security to process security of airline passengers proposes such integration, and has been subject of much controversy related to privacy and proper use of information.

The stages, characteristics and distribution of the 169 member countries with some form of E-G is shown in Figure 2.

Figure 2. Stages of E-Government of UN members

Stage	Characteristics	Members
Emerging	Limited basic information presented in static views, at the initiative of individuals	32
Enhanced	Regularly updated content	65

Interactive	Possible to download content and request services interactively	55
Transactional	Ability to complete payment transactions	17
Seamless	Integration across agencies to complete one-stop shop for most if not all citizen service requests	0

World Markets Research Center and Brown University reported a Global E-Government Survey in 2001, which noted an interesting phenomenon: 72 % of the E-Gs used the English language as at least one language of use. 45% of the sites were multilingual. This indicates a definite consideration of the global integration in today's world. The same study also provided an assessment of content type provided by E-Gs. It appeared that contact information (for follow up and possible resolution of enquiry) was the most common, with many sites providing links to databases or other sites to assist with the enquiry. The main findings are provided in Figure 3.

Figure 4. WMRC Findings

Characteristic	%
Websites with one stop or govt. portal	6
Websites with online execution capability	8
Websites with Links to database	41
Websites with Access to Publications	71
Websites with Privacy policies	6
Websites with Security policy	3
Websites with disability access	2

The findings indicate that even among the high end implementers of E-G, there is significant lack of assurance to public as to the security and integrity of the query and or transactions that are even possible. The perceived safety of using on-line access to government is a factor that effects the usage of such services by the citizens.

Another area of interest to the policy makers, particularly in the context of global economic development and poverty alleviation has to do with the "digital divide." The availability of government sites providing on-line services shows a very clear geographical bias. The prosperous regions of N. America and Europe stand in sharp contrast to the poorer regions of the world.

The next section of the study is going to look at some empirical data from published sources to examine the

following relationships:

1. Citizen use of E-G and Population Internet Usage
2. Citizen use of E-G and Human Development Index (provided by UNDP)
3. Citizen use of E-G and Perceived Safety of Transaction
4. Citizen use of E-G and E-Govt. Index Provided by UNPAN
5. Citizen use of E-G and Geographic Location
6. Citizen use of E-G and Perceived Corruption Level
7. E-Government Index and Perceived Corruption Level

5. Methodology

The data for the empirical analysis was obtained from published sources.

1. Taylor Nelson Sofres (2001) report a Government On-line study that surveyed respondents from 28 countries, querying a. levels of e-government usage, b. safety issues as a barrier to internet use.
2. UNPAN (2001) conducted a global survey of E-Government that developed an E-Government index and also examined the scope and extent of E-Government implementation.
3. World Markets Research Center (2001) also conducted a Global E-Government Study that focused on the contents of national government websites.

6. Analysis of Empirical Data

The results of the analysis will be reported at the conference.

7. Implications of Study and Recommendations for Policy and Future Research

The results of the analysis will be reported at the conference.

Towards an Electronic Commerce Growth Stage Model

Changsu Kim

School of Management & Social Sciences, Tongmyong University of Information Technology, Yongdang-dong, Busan, 608-711, Korea, E-mail:ckim@tit.ac.kr

Abstract

The advent of the digital economy and Electronic Commerce (EC) can be seen not as the development of existing commerce but rather as a new commerce pattern caused by Internet technology. There are many possible definitions of EC, but in this research we consider the definition of EC as the buying and selling of information, products, and services via Internet. The application of EC is diffusing into various areas such as merchandising, finance, education, advertising, entertainment and government. To better understand the shaping process of EC and to predict the direction of further diffusion, the growth stage model of EC is required.

It is difficult to find a growth stage model in relation to EC. Therefore, in this study, we divide the EC into a series of phases, then develop a model explaining the shaping process of EC, regarding major domains of EC such as economic, social, political and technical. To provide a theoretical basis for the growth stage model of the EC, we consider existing literatures about information systems, organization and industry life cycle and then suggest a growth stage model reflecting major characteristics of EC. The growth stage model of EC developed in this research can not only predict the direction of EC growth, but can also provide a useful model as guideline to organizations in planning EC.

Key Words: Digital Economy, Electronic Commerce Growth Stage Model, Shaping Process, EC Planning

1. Introduction

The advent of Electronic Commerce (EC) can be seen not as development of existing commerce, but rather as a new commerce pattern brought about by information technology, telecommunication network infrastructure, and Internet technology [31; 24; 9]. The definition of EC may be regarded in different ways but Kalakota & Whinston [21] defined it as buying and selling goods via network. Considering the application of EC diffusing into such various areas as company, merchandising, finance, education, advertising, entertainment and government, in this research, we define EC as all kinds of commerce activities in cyber space on the network of information communication technology (ICT) with a wide viewpoint. To understand the various areas of EC and to predict the

direction of the EC diffusion, the systematic framework is required [34].

The growth theory divides the growth stage, direction and diffusion aspects into some phases suggested by the peculiar characteristics. There are familiar growth stage theories such as Nolan's growth stage model [29], Utterback's organization innovation process model [37], McFarlan and Mckenney's technology diffusion model [27], Levitt's product life cycle theory [25] and Hofer's [15] and Grant's [13] industry life cycle model. However, among the various models of growth stage theory suggested by many researchers, it is difficult to find one that applies to EC. Therefore, in this study, we define EC into a series of phases and then develop a model explaining the shaping process of EC. To provide a theoretical basis for the growth stage model of EC, we consider existing literature about information systems, organization and industry life cycle, and then suggest a growth stage model reflecting the characteristics of EC. The growth stage model of EC developed in this research can not only predict the direction of EC growth but can also provide a useful framework as guideline to organizations in planning EC.

2. Theoretical Background

2.1 Review of Previous Research

This study review previous studies relevant to the growth stage models of information systems, organization, and industry to provide the theoretical background for an EC growth stage model. The most familiar growth stage model in IS is Nolan's Growth Stage Model [29]. Nolan's Growth Stage Model is the theory explaining the unique characteristics of each phase when an information system (IS) is adopted by an organization, being diffused. This is significant in allowing each organization to predict direction and then establish guidelines about IS planning and management. Nolan's Growth Stage Model is illustrated in Figure 1.

As can be seen in Figure 1, the growth stage of IS is divided into four stages namely: initiation, expansion, formalization and maturity. In the initiation stage, the organization introduces a computer to reduce cost in functional areas. In the expansion stage, electronic data processing (EDP) facilities are connected to a wide

variety of applications. EDP function is also expanded widely and the EDP managers' responsibility is increased. In the formalization stage, organizational control is used to regulate the growth of the computer use and the rising cost. To reduce the scope of cost rising, the organization

starts to strictly control the information system. In the maturity stage, information technology is diffused and integrated into various areas. Organization and information technology become combined, and the short-term supply and the long-term investment are balanced.

Figure1. Nolan's Growth Stage Model

Utterback [37] suggested a theory dividing the innovation process of organization into three phases: idea generation, problem solving, and implementation and diffusion. The idea generation phase is the integration of information about the consumer's need and technical methods to reduce the gap between the idea and the technical suggestions. The developing process of new products is started by acknowledging the development possibility of technology, and from this, new ideas and concepts are advanced. The problem solving phase is the process of analyzing the technical problems given in the idea generation step. In this step, the information for problem solving has to be instantly usable, and other research and development activity is required. The implementation and diffusion phase is the process of using new processes for manufacturing, the shipping of new products into the markets and the delivering of information for innovation to make economical influence. On the basis of Utterback's model, the adoption of information communication technology can be understood as being shaped through serious steps such as the general innovation process.

McFarlan and Mckenney [27] suggested a different four-step model to analyze the diffusion of new

technology in an organization. First is the technology identification and investment step. In this step, a new technology with potential profits is identified, and capital for the technology application is raised. Second is the learning and adaptation step of the technology. In this step, the user share their ideas about previous problem with the technology application. The user's experimentation in various areas is also encouraged. Third is the rationalization and management step. In this step, many techniques are developed through the effective application of the new technology to guarantee the confidence and permanency of investing in new skills. Fourth is the widespread technology transfer step. In this step the effectiveness and experience of the new technology is spread and technical basis is affirmed. The learning of the technology is also finished and the long-term strategy is established.

The product life cycle theory is generally accepted as the model that echos the human cycle being born, growing, maturing and declining, at last arriving at natural death [25]. As each product has its life cycle, industry too has also a life cycle [15], as can be seen in Figure 2.

Figure 2. Industry Life Cycle

An industry grows through the initiation period. In the growth period, once a product is known to markets, the demand of the product has a tendency to rapidly increase. In the maturity period, the demand increase is slow-moving and diminishes. As it declines, the industry becomes a so-called 'decaying industry', with its scope constantly reducing. Major forces deriving industry life cycle is the pattern of demand increased. The demand

increase itself is regarded as the diffusion process of knowledge about the product. According to the progress of the industry life cycle, the demand is popularized from the high-income bracket, and the technology also becomes standardized [38]. Although, in the early stage, the product design is frequently changeable, the design becomes oriented for cost and durability, and then the difference disappears as standardization progresses.

Moreover, in the aspect of the production and distribution, at the early stage, the production is small scale. On entering the growth period, production scale becomes insufficient, but in the maturation and decaying period, over-production can cause a problem. The industry is usually a monopoly and oligopoly system of a few enterprises at the early stage. Gradually many new enterprises enter into the competition making it keen, and eventually, through the competition in price, many businesses withdraw. The major elements for the success

of each industry phase are different according to each step. For instance, in the early stage, product innovation is the major element. However, through the growth and maturation period, cost and process innovation becomes important. In the decaying period, cost reduction, the rationalization of industry facilities and the role of distribution and brand are important to take into account. On the basis of this review, Table 1 provides a summary of the previous research of the life cycle in terms of its strengths and weaknesses.

Table 1. Summary of Previous Research

Division Stage Model	Strength	Weakness
Nolan's Growth Stage Model [29]	<ul style="list-style-type: none"> ñEase of information planning ñEffective management and control of system ñPresentation of direction for MIS growth 	<ul style="list-style-type: none"> ñShortage of logical linkage between each stage ñDifficulty of verification Model limitation for the electronic commerce system
MaFarlan's Information Diffusion Model [27]	<ul style="list-style-type: none"> ñSupports long term information system planning ñEffective information planning for the whole organization 	<ul style="list-style-type: none"> ñRigidity of information system planning ñGap immanence in the adoption of information technology to organization
Utterback's Innovation Process of Organization [37]	<ul style="list-style-type: none"> ñComprehensive model for organization innovation 	<ul style="list-style-type: none"> ñShortage of detailed characteristics at each stage of innovation
Industry Life Cycle Theory [15]	<ul style="list-style-type: none"> ñIndustry change based on life cycle ñArrangement of the development of industry structure and competition 	<ul style="list-style-type: none"> ñDifferent concepts for applying to whole ICT

2.2 Previous Research of Electronic Commerce Model

This section shows the theoretical background for identifying the characteristics of EC and developing the growth stage model through a literature review about the EC model.

Nissen [28] suggested the integrated EC model. This model divides commercial activity between purchaser and seller into five functions, which are used as a framework showing the relationship in the functional process between product, information, and payment. The model describes the five functions as 1) need definition, 2) resource finding, 3) negotiation, 4) purchase, and 5) use and maintenance in the purchaser's aspect, as well as 1) the arrangement, 2) the customer finding, 3) the negotiation, 4) the order execution, and 5) customer support in the seller's aspect. Nissen's business model proposes a conceptual model focusing on the commerce process between purchaser and seller, therefore, it is somewhat limited to explain the global scope of EC.

Information Infrastructure Task Force [18] provides a global EC framework which explains the principle and policy in the aspects of the economic, legal, and business issues. The detailed explanation is as follows. First, it divides economic issue into 1) customer and tax, and 2) electronic payment systems. Second, in the legal issue, there are 3) the unified business code for EC on the Internet, 4) copyright, 5) privacy, and 6) preservation.

Finally, the business issue includes 7) network infrastructure, 8) content, and 9) technical standard. This framework divides the issue related to the EC into three aspects such as the economic issue, the legal issue, and the business issue. However, it is a limitation that this framework disregards the technical aspect, which is one of the major issues of EC.

Zwass [39] suggested a three level structure model to facilitate the complex system and the development of EC. He defined hardware, software, database, and communication technology as the infrastructure level; classified message, transmission, searching, negotiation, an agreement as the service level; finally, customers and business partners, information sharing and cooperation, and electronic markets are defined as the product and structure level. This model is meaningful for the hierarchical classification of EC in terms of the system aspect. However, it does not explain the relationship between the hierarchical levels.

Kalakota and Whinston [21] proposed an EC framework consisting of legal and public policy, standardization and protocol, the information super highway, network infrastructure, general business service infrastructure, and EC application technology. However, this framework is likely to focus on the technical aspects among the several EC elements, and does not provide major characteristics about each element.

The US government proposed a global EC framework to promote global commerce on the Internet [36]. The

framework divided the principle to guide policy development and the guidelines of essential issue about EC, and a road map for international commerce into the financial, legal, and market access issues. It sets taxes and customs, and electronic payment in the financial issue; EC code in the legal issue; information technology, communication infra, contents, and technology standards in the market access issue. This framework has tried to explain comprehensively the relevant part of EC. However, the technical issues that should be considered as important factors in the EC domain are not categorized as a separate issue.

3. EC Growth Stage Model

3.1.1 Social Aspect

In e-commerce diffusion, the most important aspect is the social aspect. Generally, people prefer business in the market place so it is necessary to expand their understanding and experience about cyber business through networking. Moreover, it is only recently that the Internet is diffused and used in various social fields. Therefore, social members' recognition and reliance on cyber business based on networks such as the Internet have a major effect on the diffusion of EC. In addition, there is social risks in the barriers to the diffusion of EC. For example, the consumer's protection, contract completion, identification problems, counterfeiting of electronic payments, personal information protection and so on. Therefore how to handle effectively the various risks from transaction through EC is a major factor for the diffusion of EC.

3.1.2 Economic Aspect

EC changes the structures and the transactions of business, the organization, market and industry. Therefore, we need to examine the influence of the economic aspect within EC diffusion. That is, it is necessary to consider the usage of electronic payment, the reduction of product circulation process [6], the curtailment of distribution process [5], and the reduction of transaction cost. Without an intermediary such as the middle distribution process, direct business transaction between the seller and buyer is possible on the network, curtailing the transaction cost [32]. Moreover, e-commerce based on information communication network infrastructure is different from traditional business in terms of product types and business transactions. It is expected that the world EC market will grow rapidly. Research agencies predict a 70-100% mean yearly growth. Therefore, it is predicted to continuously increase the portion of total sales based on e-commerce in a firm. On the basis of these, we analyze major issues in the economic aspect and then reflect them in the growth stage model of EC.

The previous EC models provide limited frameworks regarding some elements of EC. This article attempts to provide an EC growth stage model for predicting the shaping process of EC.

3.1 The Development of the Framework for the EC Analysis

This study extracts major variables to adequately explain the phenomenon of EC better than previous research EC models. We attempt to divide the various EC issues into four aspects: 1) the social aspect [18; 21], 2) the economic aspect [28; 18; 36], 3) the political aspect [18; 36], and 4) the technical aspect [39; 21; 36]. The detailed explanation of each aspect follows.

3.1.3 Political Aspect

To successively promote EC, regulations and legislation should be established. After the government establishes a general policy, actions, standards and plans for facilitating EC, they need to drive forward to a pan-government policy in line with the industry policy, the active support, and the institutions considered on government dimension. Without this preparation of policy, the continuous diffusion of EC will not happen. Therefore, the policy level and the time predicted for policy establishment are important elements for the determination of EC growth. On the other hand, e-business on the Internet is performed through different procedures from those of the off-line business [16]. Thus, it is necessary to establish new laws for the electronic signature to recognize electronic business and transaction [11]. Settling the core of the disputes and the electronic registry should be reached by the agreement. The intellectual ownership on the Internet, patent rights, trademark rights and conveyance are to be entered into in domestic and foreign agreements.

3.1.4 Technical Aspect

To facilitate e-commerce, it is necessary to develop the essential factors and subside EC technologies. EC uses various forms of information such as data, voice, and pictures between the contracting parties in a business on the basis of ICT. Because EC is in a developing state, there are many tasks to be solved technically and socially. These problems and tasks will be gradually settled. However, to make EC active, the technical issues like the network infrastructure, the security for safe deals and the electronic payment system must be seriously considered [20]. That is, the technical infrastructure should be prepared to facilitate the shaping process of EC [39]. A safe network must exist to make EC possible and then communication functions reorganized. In addition, the technical aspects need to be established the security and the standard of information sharing, the platform of software and hardware, the building of databases and the

electronic payment system to exchange products and services.

These are the major issues in the four aspects of EC in terms of society, economy, policy, technology. On the

basis of this review, we attempt to arrange the detailed variables to be analyzed in the four aspects of EC (see Table 2).

Table 2. Analysis Category of EC Growth Stage

Analysis Domain		Explanation
Aspects	Analysis Variable	
Social Aspect	Social Trust	the degree of reliance of social members accepting e-business through network [19].
	E-business Awareness	the degree of awareness of social members about the various trade through e-business [19].
	Risk degree	the degree of risk in the various trades through e-business [8].
Economic Aspect	Product	the type of products in e-business [19].
	Transaction Cost	the cost of products in e-business [19; 8].
	Gross Sales	the relative importance of sales in e-business [6].
Political Aspect	Laws & Institutions	the laws and regulations in online business [11].
	Policy & Publicity	Policy and public information for the diffusion of the e-business [22].
Technical Aspect	Technological Infrastructure	the degree of development and application in the e-business technology [30; 8].
	Standardization	the degree of Standardization for information sharing and electronics with e-business [10]
	Security	the degree of the advance of security systems in performing e-business [10]

3.2 Development of EC Growth Stage Model

We attempt to provide a growth stage model for EC on the basis of Nolan's growth stage theory and industry life cycle model. We divide EC growth into four stages: initiation, growth, maturation, and transition; we then

analyze major issues on EC according to a social aspect, a economic aspect, a political aspect and a technical aspect. The EC growth stage model applied in this study can be seen in Figure 3. We then analyse the characteristics of each step on the basis of the EC analyse category defined in Table 2.

<Figure 3> EC Growth Stage

3.2.1 Initiation Stage

In the initiation stage, enterprises try to propose the product and service to customers and buyers through e-commerce. The acknowledgment degree of social members and the reliability of EC are low, but the danger degree is high.

In addition, the demand of the product is small, but the amount of sales is increasing. The products for this stage focus generally on special products such as the books, flowers, S/Ws and CDs with low prices and simple processes for selling and buying. The number of EC users are few. That is why not only the transaction cost is somewhat high, but also the sale price of EC is low. This high transaction cost in the initiation stage will play as a factor to delay the diffusion of EC.

The institution and laws concerning EC in the initiation stage are not arranged systematically, and a preparation is made to make them legal. The policy plans of EC are mainly acted out by governments. The

education and public information for EC diffusion usually made by experts become more popular among the public. The essential technology of the technical infrastructure is developed in this stage, and unstandardized EC technologies compete with each other. They will have keen competition that leads toward standardization. The security technology is somewhat vulnerable to external infringement and hackers, because in this stage the basic technology and network infrastructure is still developing.

3.2.2 Growth Stage

In the growth stage, the competitions among many enterprises are more accelerated due to the innovation of ICT and EC diffusion. Therefore, product sales and services are diffused step by step among customers and in the company. In proportion to the understanding of social

members and the social trust for EC, the danger degree become weak.

In this stage, it is necessary to affirm the EC support system using information technology as fast as possible. This will obtain a relative advantage in the customer market by occupying the electronic market before other companies can.

In the initiation stage, the companies open their homepages, and send their information through electronic catalogs to introduce their products and service to customers. However, in the growth stage the total product selling on the Internet will be expanded and the amount of sales is increasingly enlarged. Though EC diffused, the existing intermediaries will disappear and new type of middleman will have an advent. That is, if the customer spends more time searching for a product on information, the electronic intermediary will be needed to execute it in cyber space. Through this, the transaction cost per unit will be lower and lower.

EC institution and law of the growth stage become systemic and strengthen the background for facilitation of EC use, settlement, and diffusion. EC policy and public information led by the government in the initiation stage are transferred into public organizations and companies at the growth stage. The public information and education of EC are expanded for the general users of EC.

EC technology in the growth stage become more standardized as the unstandardized technology drops out. As the technology standardizes, the technology diffusion speeds up. With this, the security technology is improved for identification and certification, approach control, alteration prevention, and auditing. In particular, the certification agency is affirmed, the form of certification is set, and the standard protocol for digital signatures is established in the growth stage.

3.2.3 Maturity Stage

Social trust and customer acknowledgement of EC become mature in this stage. As the degree of danger on the EC lowers, the market share and the revenue of the EC gradually increase.

At this point, the customers will know well the characteristics of each internet business each, and various types of internet business models will appear. As the various types of products become standardized by the high market share products, the differentiation is reduced. In addition, with the technology diffusion, imitations are easily made. That is why the EC market is being aggravated and overwhelmed with competitors.

Therefore with a mature EC market, a strategy is needed to adjust the competitive advantage from differentiation to cost. Intangible digital products such as music, software, movies, research information, and VODs are going to be transferable on a massive scale. However, with users increased through EC, the transaction costs per unit become low, the degree of the sale price of EC will be high in the total sale price.

In the previous stage, the laws for EC encouragement and EC usability were confusing due to the scattered and

systematically unmanaged legal issue. However, in the mature stage, the law will be unified. The users' acknowledgments of EC diffusion play an important role. Therefore, the education and publicity for users is to be made.

Moreover, in this mature stage, the technology base of EC will be completely standardized and then spread extensively. One of the most important technologies in EC is security. This will be completed and standardized in relation to the telecommunication security, shopping mall certification, security technology of customer data and so on.

3.2.4 Transition Stage

The transition stage is the transformation period to facilitate EC growth, re-establishing new strategies, products and ICT facing limitation in the previous growth stage. That is, the technology and knowledge accumulated during the EC growth stage get newly arranged, applied and then a new strategy of information communication technology will be provided.

Furthermore, the various business domains of EC are reviewed, arranged and unified. EC systems run loosely in the past will be newly evaluated and redeveloped according to the new information strategy. The EC laws revised by separate countries will have been unified into a law of international EC.

New technological advances to challenge technological are needed. In technology research, when standard technology is compared with research ambition for the technology, if research ambition is lower than the technology standard, it will be categorized as a technology-push. On the other hand, if higher, it will be categorized as the demand-pull [24; 9; 35].

Until now, EC research is inclined to the technology-push. However, in the transition stage, with new theory and research ambition diffused, the paradigm of technology research [23] will be changed into the demand-pull. The companies that do not grope for technical advances in the transition stage will be combed out in competition with other companies that are entered in the e-commerce market with advanced technology.

4. Conclusion

EC is regarded as a new type of business system in which a product and service are transferred to clients on the basis of the information communication technology. The rapid diffusion of Internet use and the active efforts for making networks rapid, the endeavor of the company and the financial institution for the support of EC and the advanced technology for payment system have made EC a new paradigm of the global digital economy in the 21 century. However, among the research until now, there has been no research presenting an EC growth stage model for the phenomenon of EC diffusion process, and the prediction of the further direction of EC growth.

In this paper, on the basis of the stage theory suggested by many researchers, we present an EC growth stage model. We divided EC growth into four stages: initiation, growth, maturity, and transition, and then classified major issues of EC into four categories: social, economical,

political, and technical aspects. With this, we identified the major characteristics according to EC growth stage. The characteristics of EC growth stage discussed in this study are outlined in Table 3.

Table 3. Characteristics of EC Growth Stage

Analysis Domain		Electronic commerce Growth Stage			
Aspects	Analysis Variables	Initiation	Growth	Maturity	Transition
Social Aspect	Social Trust	Low	Medium	High	Very High
	Awareness of E-business	Low	Medium	High	Very High
	Risk Degree	High	Medium	Low	Very Low
Economic Aspect	Product Type	Special	General	Digital	-
	Trade Cost	High	Medium	Low	Very Low
	Gross Sales	Low	Medium	High	Very High
Political Aspect	Laws and Institutions	Preparation	Individual EC Law	Unification of Domestic EC Low	Unification International EC Low
	Policy and Publicity	Nationally Oriented	Enterprise Oriented	Consumer	General
Technical Aspect	Network Infrastructure	Development	Standardization	Application	New Paradigm
	Standardization	Low	Medium	High	Very High
	Risk Degree	Low	Medium	High	Very High

The EC growth stage model suggested in this research will provide individuals and organizations with a useful conceptual framework for understanding the process of EC. However, in further study, the actual application of the EC growth stage model presented in this paper should be applied in practical e-commerce circumstances.

Abstract

This paper attempts to address a detailed understanding of the diffusion of WBSS, introducing a classification model of WBSS, analyzing the cases of four categories of WBSS, and providing a characteristics of the four types of WBSS. A model of four types of Web-based shopping systems is suggested: (1) general-direct-sales; (2) general-intermediary-sales; (3) specialized-direct-sales and (4) specialized-intermediary-sales. On the basis of these four categories of WBSS, the paper analyses the distinguishing characteristics of WBSS, which has implications for both theory and practice. We hope that this research will mark the starting point in on-going research towards many unresolved issues on Web-based shopping systems.

Key words: Web-Based Shopping Systems, Classification Model of WBSS, Characteristic Analysis.

1. Introduction

Internet technology has evolved into a dynamic source of information as well as an extraordinary business tool that is able to reach any user [6, 14]. Internet technology also allows organizations to overcome many of the physical constraints that often prevent them from doing business [21]. Therefore, time and space, the two age old limitations of human beings, can be overcome more easily than ever today [16]. There is a growing desire to understand

electronic commerce and to utilize new technology within the Internet business [6, 10, 12, 14].

However, many organizations lack a clear understanding of how to make effective use of Internet technology as a means of new business supporting global electronic commerce [4, 15, 26]. Organizations need to plan effectively before they venture into Internet business [6, 10, 19, 20]. The aim of this paper is to answer the above questions and to provide a theoretical background of further WBSS diffusion study. In order to do so, we introduce the concept of WBSS and analyze the characteristics of each type of WBSS identified, focusing a review of cases that are utilizing WBSS. Finally, we provide the major characteristics of the four types of WBSS.

2. Web-Based Shopping Systems

Web-Based Shopping Systems (WBSS) can be described as Internet-based shopping systems for selling and buying products, information, and services [2]. According to Porter [19], "the organizations that will be most successful will be those that use Internet technology to make traditional activities better and those that find and implement new combinations of virtual and physical activities that were not previously possible." Though there will be several ways to do this on the Internet, WBSS can succeed in this regard due to its particular characteristics, which we will discuss in more

detail below. There are various types of configuration of WBSS, such as those adopted by Amazon.com, eBay.com, Del.com, Tesco.com and so on. Figure 1 provides a multi-tier

architecture for WBSS, one which is adopted for the purposes of this research.

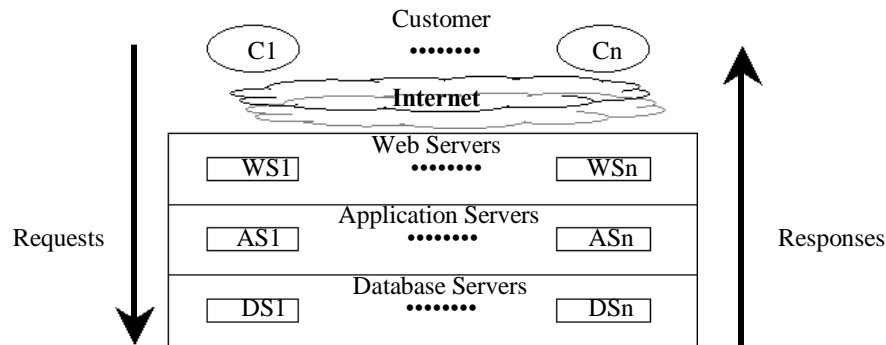

Figure 1. Multi-tier Architecture of Web-Based Shopping Systems [2]

As can be seen in Figure 1, WBSS consist of Web servers, application servers, and database servers [2]. First, Web servers support Web-based shopping between seller and buyer, merchant and customer, and manufacturer and supplier. Web servers fill the role of middleman between the back-end systems and front-end clients [12]. Second, application servers support information retrieval, personalization, transactional other management, security management, and payment management. They include shopping agents or search engine, security system, certificate system, customer relationship management (CRM) system, and payment system [2, 12]. For example, Amazon.com developed not only its Web site but also incorporates Web-based shopping applications for order processing, invoicing, payment, shipment, inventory management and procurement. Finally, database servers manage all data related Web-based shopping between WBSS and customer. For instance, eBay.com is utilizing Web and database connectivity systems to carry out its successful business process of creating a feedback and rating system for all buyers and sellers on its auction site. To sum up, Web servers, payment system in application servers and database servers are indispensable to WBSS. We might conclude that the application of WBSS promises to be a driving force for

electronic commerce by allowing organizations to create global electronic markets, increase efficiency, and lower transaction costs through digital commerce with customers and businesses around the world.

3. A Classification Model of WBSS

We can consider WBSS as a new business enabler with the potential to change the ground rules by which businesses interact with their clients [2, 12]. Carrying out global business on WBSS is becoming more important to many organizations. The purpose of this sections is to develop a classification model of WBSS, and suggest its characteristics to provide a detailed view of WBSS.

3.1 Development of a Classification Model of WBSS

According to Peppers and Rogers [18], “the core issue confronting business is how to achieve sales and which products to sell.” On the basis of this definition, in terms of a global business medium, it would appear helpful to classify various types of WBSS applications, therefore, by product type and sales type.

Firstly, the sales type of WBSS is examined. For instance, Amazon.com sells multiple products such as books, CDs,

and software as well as is directly responsible for the products sold on its WBSS (www.amazon.com), while Fastparts.com sells electronic parts, and is indirectly responsible for sales products in the role of intermediary (www.fastparts.com). On the basis of this observation, the sales types of WBSS are classified into two types: direct sales type and indirect sales type. As a real marketing channel, WBSS support two-way sales types between the seller and the customer. One is a direct-sales type, which is directly responsible for a guarantee of quality and delivery for the sales products [1, 18]. The other type related to indirect sales, and is indirectly responsible for a guarantee of quality and delivery for sales products [18]. That is, the indirect sales type relays business transactions between the manufacturer, merchant, distributor and consumer [25].

Another distinguishing factor of WBSS is the type of product being sold via this medium. In order to gain a meaningful insight for classifying the different product types sold WBSS, this study explore the products sold by some well-known dot-com companies. For example, Del.com and Amazon.com are selling products directly to global customers without any intermediaries. However, the product types are different from each other, i.e., Dell.com is selling only a single product such as a computer (www.dell.com), whilst there are multiple products such as books, CDs and software sold by Amazon.com (www.amazon.com). Based on this observation, the product types sold on WBSS are divided into two groups: single product type and multiple product type, as outlined in Table 1.

Table 1. Product Type of Web-Based Shopping Systems

Type	Definition	Examples
Single Product	• Single industry product	• Software, CD, Book etc.
	• Unified group image product	• Baby clothes, Sports equipment
Multiple Product	• More than two industrial products and products that are not unified into a group	• Department store products

Firstly, the single product type includes the product of a single industry such as a book, a CD, software, a flower, etc., as well as unified groups of products such as sports equipment, baby clothes and cars. Secondly, the multiple product type includes more than two industrial products, for example department store products, as well as products that are not part of a group of products.

On the basis of the product and the sales type of WBSS, a classification model of WBSS can be developed (see Figure 2). In the model, the horizontal axis displays the product type of WBSS, while the vertical axis displays the sales type of WBSS. This research thereby proposes a model which classifies Web-based shopping systems into the following four types: 1) General-Direct-Sales (GDS); 2)

General-Intermediary-Sales (GIS); 3) Specialized-Direct-Sales (SDS); and 4) Specialized-Intermediary-Sales (SIS). The general-direct-sales type means that this product type is multiple, and product sales are direct. The general-intermediary-sales type is the WBSS type selling multiple products indirectly. The specialized direct-sales type sells single products directly. The specialized-intermediary-sales type focuses on single products and indirect sales. However, not all WBSS conform to these four types: hybrids are possible for example. Nonetheless, this model serves primarily as a basic framework of WBSS for analytical purposes. In the next section, four cases are introduced in order to demonstrate the characteristics of each type of WBSS in more detail.

Classification Model of WBSS		Sales Type of WBSS	
Product Type	Single	Direct sales	Indirect sales
	Multiple	GDS	GIS
		SDS	SIS

Figure 2. A Classification Model of Web-Based Shopping Systems

3.2 Case Analysis of the Four Categories

This section aims to expand our view of WBSS and to explore the four categories of WBSS previously identified. In order to do this, we address four dot-com cases, derived from Web-sites, and then attempt to analyze each category. The dot-coms were selected because they are well-known dot-coms in each type (e.g., Hansolcs.com, Dell.com and Fastparts.com), and by searching Web-sites it seems to be well-matched with a GIS type (ShopNow.com).

3.2.1 General-Direct-Sales (GDS)

Hansol CSN is a cyber department store, which does not have any physical shop and sells several kinds of products that are identical to those of an actual department store. Therefore, the product prices in this category are cheap because goods can be sold directly to the customer without a salesperson, and intermediaries such as suppliers can be cut out. In doing so, Hansol CSN can reduce the transaction costs of selling products on WBSS (source: www.hansolcs.co.kr).

In addition, Hansol CSN provides one-to-one marketing, based on customer management databases that store customer information to analyze their characters, needs and preferences. Moreover, CSN carries out differentiation strategies such as one hundred percent exchange/refund, quick delivery, membership management and a variety of other services. One hundred percent exchange/refund is a customer satisfaction system that exchanges or refunds a purchase when a customer is not satisfied. Furthermore, it is claimed that this cyber department reduces traffic

congestion and avoids parking difficulties, because it does not have physical stores or car parks, so that customers are directly able to access product information and order from home (source: www.hansolcs.co.kr).

3.2.2 General-Intermediary-Sales (GIS)

ShopNow.com is a leading electronic commerce marketing company that helps businesses participate in Web-based shopping business. Based on its full suite of e-commerce solutions, ShopNow.com claims that it helps customers and merchants safely and easily buy and sell merchandise online. The ShopNow.com WBSS provides millions of products and services from more than 40,000 merchants. Customers can rapidly and efficiently search the variety of products by comparative shopping functions on ShopNow.com WBSS (source: www.stores.shopnow.com).

ShopNow.com not only supports technology and outsourcing services to retailers, manufacturers and other businesses, but also launches and manages the Web-based shopping systems on their behalf. Shoppers can purchase desired products and services from merchants located around the world. The major strategic option of ShopNow.com focuses on the global community. Hence, an International Business Division was recently established to expand ShopNow.com into Western Europe and Asia. From North America, this is led by individual divisions, each with a good knowledge of the international marketplace. By pursuing strategic alliances and partnerships in other regions of the world, ShopNow.com is hoping to accelerate its goal of becoming a pre-eminent Internet business service

provider worldwide (source: www.stores.shopnow.com).

3.3.3 Specialized-Direct-Sales (SDS)

Dell.com is one of the best examples of the specialized direct sales type of WBSS. Dell.com sells computer equipment directly to its customer on the WBSS. Dell.com currently sells more than \$14 million in PC products over WBSS each day. Its Web-based shopping business has over 25 million visits per quarter. By the year 2003, the company expects to handle half of all its business, ranging from customer inquiries to orders and follow up services, through the SDS type of WBSS (source: www.dell.com).

The chairman of Dell.com has claimed that Web-based shopping business as a new business model would facilitate a dramatic drop in costs and destroy old competitive advantages. The advantages of the Dell.com model are claimed to include near-zero inventory, less risk of obsolescence, more state-of-the-art products and a favorable cash flow [11, 18]. Since March 1999, Dell.com and Amazon.com have agreed to offer linked cyber shops and provide customized contents for their respective customers. Dell.com and Amazon.com can therefore offer mutual customer services, competitive prices, and ease of navigation (source: www.dell.com; www.amazon.com).

3.3.4 Specialized-Intermediary-Sales (SIS)

Fastparts.com trades in electronic components and equipment. Fastparts.com is an e-commerce systems provider that enables electronic manufacturers to deliver trading exchange, auction and shopping venues. The company provides an Internet based trading exchange and marketplace for the electronics manufacturing and assembly industry, as the leading business-to-business provider (source: www.fastparts.com).

Fastparts.com WBSS has sold \$140 billion in electronic parts and hundreds of millions of dollars in manufacturing

equipment. Fastparts.com serves as a 'spot market' where OEMs, contract manufacturers, distributors, and part makers buy and sell electronic parts at market-driven prices, providing franchised supply service. In addition, FastParts.com periodically offers various inventories to sell its members' products on Internet auction. Auctions are pre-announced to all members, and bidding is generally open for two or three days. Though anyone can use the FastParts.com shopping architecture to access information on parts, price and availability, the actual bidding, buying or selling of parts requires membership. There is no charge to become a member. All members must agree to abide and be bound by the FastParts.com operating rules and protocols (source: www.fastparts.com).

4. Characteristics Analysis of The Four Categories

We can analyze the distinguishing characteristics of the four categories of WBSS as follows. Firstly, the relationship between seller and WBSS is examined. For example, some sellers are themselves owners of the WBSS, whilst others are a lessee or brokerage within the WBSS [5, 14]. The second focuses on the number of sellers [24, 25]. The third considers product type [11, 18], and the fourth, the responsibility of guarantee for the product sold [25, 18]. Based on these analyses of each type of WBSS, a suitable firm that is well-matched with the four types of WBSS is suggested [11, 25]. Next, we illustrate the strength of the four types of WBSS [14]. An attempt is then made to analyze the strategy type of each WBSS, in accordance with the strategic options suggested by Wiseman [27]. These are: differentiation, cost, innovation, growth and alliance. Differentiation is defined as making a distinction between product and service in comparison to a competitor's. Cost is a competitive advantage that is achieved through an increase in competitors' costs, or a decrease in one's own

cost. Innovation is the act that renovates the product or the service. Growth is achieved through product variety, the expansion of marketing areas, and the increase in the number of business transactions. Alliance gains competitive advantage through firms joining together, inter-organizational agreements, and joint investment. Finally, we consider critical success factors to continuously maintain the competitive advantage of the four types of WBSS. Critical success factors (CSF) are defined as “the limited number of areas in which results, if they are satisfactory, will ensure successful competitive performance for the organization” [22]. According to the eight analysis domains defined above, detailed characteristics of four types of WBSS are investigated.

4.1 General-Direct-Sales (GDS)

The general-direct-sales type is applicable to direct sales and multiple products. This type uses the WBSS to sell many products that are identical to those of an actual department store. As can be seen in the Hansol CSN case, this type is itself an owner of the WBSS as well as the only seller, selling several kinds of products to multiple buyers in the world. The GDS type is therefore directly responsible for the guarantee of the product sold. As seen in the Hansol CSN case, these types of WBSS are in keen competition with each other. Therefore, a differentiation strategy will be well-matched with this type, with a new to gaining a competitive advantage through differentiation of service or product, in comparison to other competitor WBSS.

The strength of the GDS type is that it provides a cyber warehouse which needs less initial investment expense and staff requirement, in comparison to actual department stores. Therefore, the GDS type can not only make high profits due to a reduction in maintenance and other costs, but it can also solve traffic and parking problems, because customers do not need to leave home to go shopping.

The CSF of this type of WBSS are achieved by utilizing customer information and by having a creative design of WBSS [3]. Firstly, the application of consumer information increases customer satisfaction, which itself facilitates a successful competitive advantage of this type. This is because utilizing customer information can reduce a customer's search time, through a quick response of product and service based on the customer database accumulated by Web-based shopping [24]. Secondly, customers indicate that they prefer new and attractive features of WBSS, which create a feeling of shopping at a real department store. Thus, this type of WBSS needs a creative design based on the latest information communication technology (ICT); such as virtual reality, multimedia, being three dimensional and intelligent agents [24]. For example, multimedia and virtual reality types of architecture are able to present the customer with an interesting experience, somewhat similar to shopping at real department stores.

4.2 General-Intermediary-Sales (GIS)

The general-intermediary type of WBSS is suitable for indirect sales and multiple products. This type includes many shops such as book stores, computer shops, gift shops, wine stores, sports stores, and so on. This type of WBSS sells customers various kinds of products via several different cyber shops. In the case of ShopNow.com, there are many sellers dealing in several types of products for a variety of customers in the global electronic market. These sellers are lessees within the GIS. Thus, the GIS itself has an indirect responsibility for products sold, because individual sellers within the GIS are directly responsible for the products.

This type of WBSS provides a strategic opportunity to small- and medium-sized enterprises, which are faced with a shortage of funds, human resources and technical

expertise in comparison to larger companies. This is because this type of WBSS allows relatively easy and low-cost entry of small- and medium-sized enterprises into Web-based shopping business areas. Namely, those small- and medium-sized companies that have never carried out traditional online business can undertake Internet business thereby extending their marketing territory [24].

The strength of the GIS type of WBSS is that it provides various cyber malls that customers can choose according to their needs and preferences. This kind of selective buying can serve as a major attraction to customers, as compared to other types of WBSS. However, it is important for shops within GIS to maintain a high quality of products and services, because this can influence customer satisfaction, which in turn affects the successful diffusion of GIS.

Other types of WBSS cannot establish the variety of shops, nor provide the range of products that the GIS type can, due to limited capability such as systems management, operating costs and human resources. Therefore, GIS has a competitive advantage over other types of WBSS, and has a greater capacity for growth, through its ability to provide a diversity of products, a high quality service, and many kinds of shops. Thus, the most suitable strategy for the GIS would appear to be a growth strategy.

As seen in the ShopNow.com case, there are many shops and varieties of products within the GIS type. When customers visit this type of WBSS to make a purchase, they can have difficulty in finding the product best suited to their preference. Therefore, by providing a comparative shopping function based on intelligent search engines [23, 24], the GIS type of WBSS can support the customer in finding the best priced or highest quality products without spending considerable time searching for several cyber stores. Thus, the CSF of this type of WBSS is its effective comparative shopping function, which in turn will increase its advantage.

4.3 Specialized-Direct-Sales (SDS)

The specialized-direct-sales type is a specialized WBSS dealing with direct sales and single products. As can be seen in the case of Dell.com, the seller is identical to the owner of the SDS system. Thus, the seller is a single seller as well as an owner of the SDS type of WBSS. As a result, the SDS itself bears direct responsibility for the product sold.

This type of WBSS provides opportunities for global marketing to manufacturing companies and smaller shops, which have limited capital and business resources. For example, manufacturing companies can sell products directly to the customer without any intermediary. Also, this WBSS type will help smaller shops to become 'Giants of marketing', competing with giant corporations, because physical size is not an important factor in determining market strength.

The strength of the SDS type lies in its ability to provide a specialized cyber shop. Organizations that have limited resources can efficiently focus their capabilities in selling a specialized single product. The initial stage of Dell.com is a major example of this type of application. The SDS type needs to concentrate on a cost strategy, as in the case of Dell.com, since it is necessary to maintain low prices for specialized products, in comparison to other types of WBSS, which sells various kinds of products. Through the lowered cost of selling products, these kinds of WBSS will have a competitive advantage against general types of WBSS.

A CSF for the SDS type of WBSS is specialization. The focus is on one top priority out of service, cost, quality or speed related to the Web-based shopping business, in order to have a competitive advantage with other WBSS. In addition, people are under considerable time constraints in this day and age. If customers discover that this type of WBSS makes it easier to purchase the hard-to-find-products they prefer [8], customer satisfaction is likely to increase.

This is a major advantage of this type of WBSS.

4.4 Specialized-Intermediary-Sales (SIS)

This type of WBSS sells single products indirectly. This type of WBSS can be thought of as a basic level of a virtual organization that links people, assets and ideas to create and distribute products and service [13, 9]. This is because buyers and sellers can negotiate and trade products, services and information in real-time, based on a specialized-intermediary-sales shopping architecture. As can be seen in the case of Fastparts.com, there are many sellers, selling a single product, within SIS. These sellers take on the role of broker. Thus, the SIS type itself has an indirect responsibility for the product sold, because individual sellers within the SIS type of WBSS are directly responsible for the product guarantee.

The SIS architecture can offer a significant opportunity for auction market, in particular, and acts as an intermediary between seller and buyer. Therefore, the SIS type needs to be kept up-to-date to provide the most recent data on products and services, because companies may want to access the latest information related to their market. The strength of the SIS type of WBSS is that it plays the role of cyber agent, able to support business-to-business electronic commerce. Its role as cyber agent between businesses is a basic form of virtual organization, because the key attribute of a virtual organization is strategic alliances or partnering [9].

As can be seen in the Fastparts.com example, the successful diffusion of this type of WBSS will depend on alliances and tight co-ordination with various WBSS. Therefore, an alliance strategy is well matched with this type of WBSS in order to gain a competitive advantage, because firms can negotiate directly with each other and trade products and services with other types of WBSS.

The CSF at play here is risk management. For example,

this WBSS type mediates business transactions between businesses, so that the SIS type requires strong risk management against electronic fraud or theft that can occur in business-to-business transactions [17]. If the SDS type reduces the risk associated with Web-based shopping, customers will trust this architecture to provide a safe and secure service. Such trust can lead to a strong competitive advantage for the SDS type in comparison to other architectures.

5. Conclusion

In these relatively early days of electronic commerce, WBSS are offering organizations new opportunities to undertake Web-based shopping around the world. However, in spite of this, many WBSS are disappearing from the Internet business world, whilst other organizations such as eBay.com, Amazon.com, and Tesco.com, are growing in global electronic markets, providing a new business model. Successfully utilizing and upgrading WBSS to survive in the e-business world is still far from easy, apparently. Hence the need for research of the kind described here.

WBSS are diffusing rapidly across national boundaries. A growing number of companies are taking advantage of WBSS by selling products, services and information, ranging from groceries to department stores, from SMEs to large firms, and from young organizations to established organizations. WBSS not only increase the ability of organizations to trade with customers, but also offer firms a new opportunity to reach millions of global clients worldwide. In addition, WBSS have the potential to radically change the way businesses interact with their customers. The traditional roles of manufacturers, distributors and suppliers are blurring as a result of WBSS. Within the Web-based shopping environment, customers should be the ultimate winners, because they can quickly compare products and prices from a global range of seller

faster and more easily than ever before, putting them in a better bargaining position.

Given this as background, this research has attempted to develop a classification model of WBSS and to analyze the characteristics of four types of WBSS. In building this model, we have classified WBSS into the following four types: 1) general-direct-sales (GDS); 2) general-intermediary-sales (GIS); 3) specialized-direct-sales (SDS);

and 4) specialized-intermediary-sales (SIS). The classification model provides what is hoped to be a useful theoretical background for further studies of WBSS.

We have analyzed the major characteristics of the four types of WBSS utilizing appropriate examples from practice. As a result of this analysis, specific characteristics are synthesized in Table 2.

Table 2. Characteristics of the Four Types of WBSS

Analysis Domain	Types of WBSS			
	GDS	GIS	SDS	SIS
Seller Character	• Owner	• Lessee	• Host	• Brokerage
Seller Number	• Single	• Multiple	• Single	• Multiple
Product Type	• Multiple	• Multiple	• Single	• Single
Guarantee of Product Sold	• Direct	• Indirect	• Direct	• Indirect
Suitable Firm	• Department store	• Small-medium Enterprise	• Shop • Manufacture	• Auction
Strength	• Cyber Warehouse	• Cyber Malls	• Cyber Shop	• Cyber Agent
Strategy Type	• Differentiation	• Growth	• Cost	• Alliance
CSF	• Dynamic information • Creative development of WBSS	• Diversification • Support of comparative shopping	• Specialization • Easy buying of hard-to-find product	• Connection • Risk Management

As shown in Table 2, the four kinds of WBSS have different characteristics, with each having their own strengths and weaknesses as an enabler of new business. As such, the development of new business processes, strategic planning, and system architectures should be necessary for success. The characteristics of the four categories of WBSS provide insight for researchers investigating new research subjects related to Web-based shopping and Internet business, and potentially helpful guidelines for practitioners seeking ways to gain sustainable advantages over their competitors from e-business.

However, since this research is an exploratory study on WBSS, the number of cases analyzed to explain each type is limited. Therefore, it may be fruitful for further research to analyze more cases to test the utility of the proposed

model, in particular focusing on certain types of WBSS architecture. In addition, there are like to be some examples that do not fit the four types of WBSS identified. For example, Amazon.com is well known as a specialized book selling dot-com company. However, Amazon.com is actually selling other products such as CDs, software and so on. Thus, it is necessary to be cautious in applying the model.

It is hoped that this groundwork, and the subsequent results generated by this paper, can provide both theoretical and practical contributions. From the theoretical perspective, this study proposes a model of WBSS classification and characteristics of four types of WBSS. It can therefore be utilized in research related to Web-based shopping and electronic commerce by providing theoretical basis for

further study. From the practical perspective, since organizations around world are interested in the Internet business, there is hope that this study will pave potentially guidelines for organizations looking for appropriate ways of undertaking Web-based shopping business.

An Integrative Framework for Examining Customer Loyalty in Online Environments

Alvin Y.C. Yeo

alvin_yeoyc@yahoo.com

Abstract

Organisations are increasingly turning to the Internet to complement their traditional brick-and-mortar businesses. In our research, we are concerned with the current challenges of customer loyalty, or rather the lack of, in online environments. This paper discusses an approach which examines the relationship between customer e-loyalty and key antecedents like trust, customer satisfaction, perceived risk and corporate image.

Insights from this study will assist marketing managers in prioritising resources on training programs, communication and promotion initiatives. This will lead to improved segmentation techniques, more targeted marketing-mix and positioning strategies and finally, better e-customer relationship management.

1. Introduction

According to market research firm Jupiter Research [27], online retail revenue is forecasted to reach \$105 billion by 2007, accounting for 5 percent of all U.S. retail spending. More significantly, the Internet medium will influence 34 percent of all U.S. retail spending by 2007. This rapid growth of e-retailing reflects the compelling advantages that it offers over conventional brick-and-mortar stores, including greater flexibility, enhanced market outreach, lower cost structures, faster transactions, broader product lines, greater convenience, and customization [64] [70].

Indeed, some recent studies reported that there might be systematic differences in customer attitudes and behaviour for products and services chosen online versus offline. For example, price sensitivity may actually be lower online than offline (e.g. [14] [41]). Perhaps this is because consumers are easily able to compare and contrast competing products and services with minimal expenditure of personal time or effort. According to Kuttner [40], "The Internet is a nearly perfect market because information is instantaneous and buyers can compare the offerings of sellers worldwide. The result is fierce price competition and vanishing brand loyalty."

Reicheld [57] asserts that the fundamental task of businesses today should be managing customer loyalty. After all, there is much agreement that building customer loyalty is a key factor in winning market share [35] and developing a sustainable competitive advantage [38]. The presence of numerous web sites means that e-retailers have a tenuous hold at best on a large number of "eyeballs" [64]. It thus does not come as a surprise that there is mounting interest to understand the determinants of customer loyalty in online environments. This would allow appropriate strategies to be implemented in order to reap the benefits of a loyal customer base.

To this end, a primary objective of this paper is to identify those managerially actionable factors that impact e-loyalty through a proposed integrative framework. This article is structured as follows. We first briefly discuss the concept of customer e-loyalty. We then introduce four focal constructs, which could potentially influence customer e-loyalty, namely trust, customer satisfaction, perceived risk and corporate image. We conclude by noting the managerial implications and limitations of this study.

2. Customer e-Loyalty

In research conducted in the 1960s and 1970s, customer loyalty was interpreted as a form of customer behavior (i.e. repeat purchasing) directed toward a particular brand over time (e.g. [68]). This is not surprising as most research originated from the field of packaged consumer goods [34]. Day [12], in particular, criticizes behavioral conceptualizations and argues that loyalty has an attitudinal component.

Attitude, which measures the degree of a consumer's disposition, was hence suggested to supplement the behavioural approach [1]. More recently, Dick and Basu [16] argued that loyalty is affected by the relative strength of the relationship between attitude and behaviour. Oliver [50] augmented this school of thought by arguing that consumers could become 'loyal' at each attitudinal phase. Specifically, consumers may become loyal in a cognitive sense first, then later in an affective sense, still later in a conative manner and, finally, in a behavioural manner, which has been described as "action inertia".

The cognitive form of service loyalty has been described to be of “shallow nature” [51] where customers “have not ceased attending to alternatives, but maintain their awareness of alternatives without “constant and frenetic testing” [21]. In addition, given that the future behaviour of customers is generally of more interest to marketers than current attitudes and/or behaviour, it is natural that the most frequently researched component of loyalty in the past decade is future intentions or conative loyalty [22] [71].

However, it is not well understood how accurately intention predicts actual purchase behavior [3] [43]. The operationalisation of future loyalty as a choice profitability for the next purchasing incidence would be subject to numerous situational factors as well, which cannot be easily monitored [73]. Hence, it is useful to conceptualise “customer e-loyalty” herein as retained preference [53] and as willingness to recommend the e-retailer to other people [31] [13].

3. Suggested Antecedents

3.1 Customer Satisfaction

Satisfaction has been identified as the driver of loyalty by some researchers [49] [52] [6] [8] [22] [3] [16] [50] and as non-significant by others [24] [36]. Reichheld [56] [57] is the flag bearer for the latter movement and suggests that loyalty, not satisfaction, should be the primary focus of a firm’s marketing activities. Perhaps the varying relationship found between satisfaction and service loyalty is due to an incomplete portrayal of loyalty in these studies [28] which by itself, is a complex phenomenon that warrants a multifaceted conceptualization [16]. Given the unequivocal debate on the satisfaction-loyalty (and its sub-components) linkage (e.g. [43] [28] [60]), the strength of that link should be tested:

H_{1a}: The greater the customer satisfaction, the greater is the customer e-loyalty.

Meanwhile, rather than driving the relationship, trust has also been argued to be reflective of the level of customer satisfaction [24]. Although trust is usually understood as a future-oriented attitude, i.e. as a state of mind that goes beyond past experience, one can hardly deny that a certain amount of positive experience with a person or organization will at least support the development of trust towards this person or organization [23] [25] [32]. We hypothesise that:

H_{1b}: The greater the customer satisfaction, the greater is the trust.

3.2 Trust

Just like customer satisfaction, trust is one of the most widely examined and confirmed constructs in relationship marketing and more recently, electronic commerce research (e.g. [37] [10] [24] [32] [45] [46]). Despite attempts to understand the construct better, it remains elusive. For example, even though studies have generally found positive effects of trust on loyalty [24] [25] [47] [69], some studies refute the effects [17] [23] [26] [46].

In this paper, we argue that the intangibility (customers have difficulty evaluating both goods and services on the web before they have been purchased and delivered) and heterogeneousness (the lack of standards, particularly for services, makes it difficult to judge quality in advance of purchase) of electronic commerce “positions trust as perhaps the single most powerful relationship marketing tool available to the e-retailer” [7]. This is mainly attributed to its ability to diminish the perceived risk and vulnerability in a relationship that leads to a higher commitment to the relationship [23]. This, in turn, reduces transaction costs, as there is less necessity to establish expensive control mechanisms.

Specifically, trust is shown to have a positive influence on relationship outcomes in electronic commerce [33]. For example, the likelihood of Internet product purchase is influenced by the amount of consumer trust regarding the delivery of goods and use of personal information [33]. Other research also shows that the fairness of a company’s website with respect to information privacy is a significant factor in building trust and in ensuring the continuation of the relationship with the e-retailer [11]. In consonance with the general school of thought (e.g. [47]), we propose that trust is an essential antecedent of loyalty:

H₂: The greater the customer trust, the greater is the customer e-loyalty.

3.3 Perceived Risk

The perceived risk construct was introduced to marketing in the 1960s by Bauer and his associates at Harvard Business School [5] [9]. It is defined by Dowling and Staelin [19] as a consumer’s perceptions of the uncertainty and adverse consequences of engaging in an activity. Consumer behavior is motivated to reduce risk [5] [67]. When consumers intend to buy a product or a service, they often hesitate to make the final decision because they can’t be sure that all of their buying goals will be accomplished with the purchase [59].

Donthu and Garcia [18] found that Internet shoppers are more less risk averse than Internet nonshoppers. According to SRI International, about 70 percent of Internet users have the risk-taker personality type. Miyazaki and Fernandez [44] further proposed that the

rate of purchasing products online is negatively related to the perceived risk of conducting online purchase. They also suggested that higher levels of Internet experience could lead to lower risk perceptions regarding online shopping and fewer specific concerns regarding system security and online retailer fraud.

The variability and the non-standardized nature of the online offerings could lead to uncertainty about cost and product performance [48] and make it difficult for a consumer to evaluate alternatives before purchase [29]. The heightened uncertainty resulting from the lack of knowledge and information implies higher perceived risk, which affects customers' decision whether or not to make that online purchase [62]. However, it is also apparent that the amount of risk a buyer perceives depends on the characteristics of the buyer and the type of product or service being considered [30] [62].

In tandem with previous studies (e.g. [65] [66]), perceived risk is viewed as the subjective expectation of a loss or sacrifice. We thus hypothesise that:

H_{3a}: The greater the perceived risk, the less is the customer satisfaction.

H_{3b}: The greater the perceived risk, the less is the customer loyalty.

3.4 Corporate Image

Many conceptualisations of image have been advanced in the past [20] [39] but generally, image has been treated as a “gestalt”, reflecting a customer's overall

impression [72] [15] or as an “idiosyncratic cognitive configuration” [42]. Importantly, a growing number of companies have tried to position themselves through the communication channel [4] with the objective of building strong corporate images in order to create relative attractiveness. The importance of corporate image is heightened in the online world because customers, are more often than not, inundated by the variety of the offerings on the Internet. An obvious choice would be to go for a name they trust, select a company they have heard of, one with a reputation for service, quality and reliability.

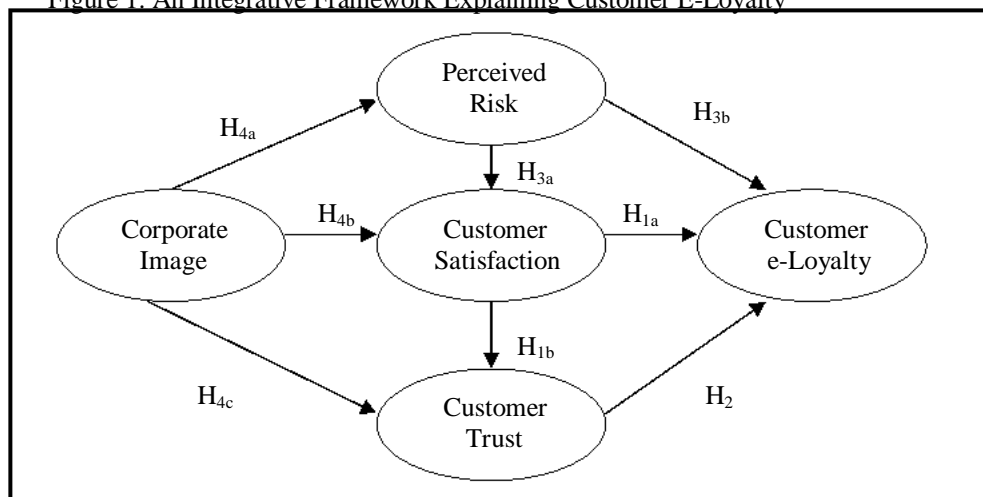

Corporate image could be treated as an outcome from accumulated attitude derived from experience and/or direct or indirect market communication [4]. As a consequence for the relationship level, it is not apparent whether corporate image should be seen as independent from perceived quality and customer satisfaction (as proposed by [4]) or as dependent (as proposed by [61]). Corporate image is defined in this study as the customer's emotional stereotypes associated with the e-commerce service provider. Given that perceived quality, trust and customer satisfaction are emotionally and holistically anchored [2], we thus hypothesize that:

H_{4a}: The better the corporate image, the lower is the perceived risk.

H_{4b}: The better the corporate image, the greater is the customer satisfaction.

H_{4c}: The better the corporate image, the greater is the customer trust.

Figure 1: An Integrative Framework Explaining Customer E-Loyalty

4. Managerial Implications & Conclusions

The antecedents of customer loyalty in the traditional brick-and-mortar marketplace have been studied in detail [63]. However, to the best of our knowledge, there have been no studies evaluating the roles of corporate image, trust, perceived risk, customer satisfaction and loyalty in online environments within a

single study. This study thus hopes to make a contribution towards this critical knowledge gap. Based on our model, more comprehensive and richer models of e-loyalty could be developed and tested.

As noted by Peterson [54], electronic markets will lead to intense price competition resulting in lower profit margins. Customer loyalty has been mooted as the only

source of sustainable competitive advantage for firms [57]. From a managerial perspective, an analysis on the underlying dimensions of elusive and difficult to operationalise constructs (e.g. corporate image) could provide insights into their relationships with loyalty, allowing marketing managers to justify expenditures on training programs and communication and promotion initiatives that contribute to higher levels of customer loyalty. Further, for compelling value propositions and effective marketing-mix strategies to be crafted, the effects of focal constructs like customer trust have been included. Such an understanding will allow companies to adapt operational variables (e.g. communication message) to increase consumers' receptiveness towards their online offerings. Finally, the study could be used to build indices to supplement measures of financial performance and market share. This, in turn, allows for the competitive benchmarking of e-marketing strategies.

There are some limitations of this research that should be considered when interpreting its findings. Our model does not take into account individual-level variables that also may have an impact. Such variables could be out of the control of the e-retailer (such as customer inertia) and other variables that are jointly determined by individual-and-business factors (such as reposed trust and satisfaction) which may also impact e-loyalty [58]. Also, the suitability of the Internet for e-retailing depends to a large extent on the characteristics of the products and services being marketed [55]. This study does not control for such differences across product & service categories. Researchers can develop richer models that capture and address these limitations.

Contextual Criteria to Select a Framework for Enterprise Architecture

Abstract

Enterprise Architecture is considered to be an efficient tool to overcome on managerial problems, especially those which come from information technology environment of the enterprise. One of the steps must to be taken to have an Enterprise Architecture is to select an appropriate Framework. Frameworks are the most important components in any Enterprise Architecture. Those are essentially needed to create an integrated Enterprise Architecture. There are many frameworks proposed for specific use in certain enterprises. However there are some more general frameworks which are applied in different situations. These general frameworks are FEAF, TEAF and C4ISR. In this paper some criteria to select a framework are introduced. These criteria are based on the context for Enterprise, Architecture and Framework. Although all of the examples here, include only these three frameworks, the provided criteria are applicable on other frameworks in the area of Enterprise Architecture.

Keywords

Framework, Selection Criteria, Enterprise Architecture, Zachman.

1. Introduction

Many of the concepts in the area of Enterprise Architecture could be found in other areas such as civilization or informatics, so it seems no further explanation is needed. Unfortunately this is not true in this area and almost all of the concepts have to be redefined. This need comes from lack of unique definitions for some of them or this fact that most of these concepts have migrated from a domain to a new completely different domain. For instance *Architecture* that is a well-known keyword for most of us, has a distinct meaning in this new area.

What is an Enterprise?

There are many definitions for the term *enterprise* which could be categorized in two broad classes. The first class includes those who see an enterprise from the viewpoint of its information systems. Mary Johnson and Larry Whitman of the University of Texas Automation & Robotics Institute, define an enterprise as a *complex system of cultural, process and*

technology components engineered to accomplish organizational goals [1].

The second class includes those who define an enterprise from an organizational viewpoint. In *TEAF* documents, an enterprise is described as *an organization supporting a defined business scope and mission. An enterprise is comprised of interdependent resources (people, organizations, and technology). These resources must coordinate their functions and share information in support of a common mission (or set of related missions)* [2].

We may categorize the views in defining an enterprise into *Systematic View* and *Organizational View*. Although the second one is in more interest in the enterprise architecture area but both views could be seen equally important. This is true specially when we notice that an architecture is the bridge connecting them to each other :

Figure 1 : Architecture maps organization into information systems.

What is an Architecture?

Originally architecture comes from civilization. It is used in the area of informatics today in some different ways but the way we deal with is *enterprise architecture*.

Zachman offers enterprise architecture to be *the set of primitive, descriptive, artifacts that constitute the knowledge infrastructure of the enterprise* [3]. However this is a general definition could be applied on many areas, there are more specific definitions such as one which presented by *CIO*¹. *EA*² is *a strategic information asset base that defines the business, information necessary to operate the business, technologies necessary to support the business operations, and transitional processes for implementing new technologies in response to the changing needs of the business.*

¹ Chief Information Officers Council in the United States

² Enterprise Architecture (will be used this point forward)

Ultimately an architecture effort will result in an IT environment for the enterprise or conforms its current IT environment to a new one. Therefore, any enterprise architecture may have up to three time-phased views [5]:

- *Baseline or Current Architecture* – Describes the current state of the environment (Often called “As-Is”).
- *Target Architecture* – Describes the future state of the environment (Often called “To-Be”).
- *Transition Architecture* – Includes: Business Improvement Efforts, Technology Migration Strategies, Project Development Initiatives and Deployment Plans which transform the enterprise architecture from its current state to a target state.

What is a Framework?

Framework is considered to play the most important role in enterprise architecture. For any architecture project it is vital to select a framework. It guarantees final products to be interoperable and supporting for business needs.

Generally speaking a framework is a comprehensive, logical structure for descriptive representations (i.e., models) of any complex objects [4]. Specifically EA framework is simply a logical structure for classifying and organizing the descriptive representations of an enterprise that are significant to the management of the enterprise as well as to the development of the enterprise's systems [6]. Frameworks steer architecture, organize architecture products and promote interoperability within the products during an EA project.

Generally, when we speak of frameworks in the area of EA, we mean Zachman framework, which is the fundamental framework in this area. It is first introduced by Zachman (1987) and then extended and formalized by Sowa & Zachman (1992).

Zachman framework is a table, consisting of six rows and six columns. There are two different ideas for rows and columns (Zachman, 1987):

1. Rows represent different perspectives of the different participants in building enterprise architecture.
2. Columns are different ways in which we describe the same product for different purposes.

There is a cell, at the cross point of each row and each column, which contains a unique model.

Figure 3 depicts Zachman framework, as it is known today. (Model names are ignored for the sake of brevity):

Scope					
Business					
System					
Technology					
Detailed Specifications					
Functional					
Enterpris					

Figure 3 : Zachman Framweork

2. EA Frameworks

One of the steps must to be taken in any enterprise architecture effort would be selecting a framework. Using a framework will ensure uniformity and standardaization when migrating and integrating information systems [9].

There are many frameworks introduced in order to build an enterprise architecture, from which those that are candidates in doing federal architectures are selected here to describe about and use as samples.

Most federal organizations (in the US) have standardized on the following three frameworks [9]:

Federal Enterprise Architecture Framework (FEAF) [4]: The Clinger-Cohen Act of 1996 mandated that Federal Agencies develop and maintain an enterprise IT architecture. The FEAF was established in 1999 by the Chief Information Officers (CIO) in response to this mandate. The purpose of the FEAF is to facilitate shared development of common processes and information among Federal Agencies and other government agencies [10].

In designing the Framework, the CIO Council identified eight components vital for developing and maintaining the Federal Enterprise Architecture, then drilled down to a further granularity of detail. These components are [10]:

- **Architecture Drivers** are external stimuli that cause the Federal Enterprise Architecture to change.

- **Strategic Direction** ensures that changes are consistent with the overall Federal direction.
- **Current Architecture** is the current state of the enterprise.
- **Target Architecture** is the target state for the enterprise within the context of the strategic direction.
- **Transitional Processes** are those processes that apply the changes from the current architecture to the target architecture, in compliance with architecture standards (such as various decision making or governance procedures, budgeting, engineering change control, etc).
- **Architectural Segments** are subsets or a smaller enterprises within the total Federal Enterprise.
- **Architectural Models** provide the documentation and the basis for managing and implementing changes in the Federal Enterprise.
- **Standards** (some of which may be made mandatory), voluntary guidelines, and best practices, all of which focus on promoting interoperability.

The FEAF consists of four levels, the first level providing a high level description of the above components, and the next three levels describing these components in increasing details [10].

More details will be gained via breaking the components into two layers : *Business* and *Design* at level II, then dividing *Design* layer into three sub-layers : *Data*, *Application* and *Technology*.

The idea of breaking components in details in a way such that mentioned above mainly comes from EAP methodology introduced by *Spewak (1992)*.

The fourth level also provides a logical structure for classifying and organizing the artifacts. This logical structure is actually a tailored version of the Zachman Framework [10] consisting its first three columns and five rows.

Treasury Enterprise Architecture Framework (TEAF) [2]: TEAF is an EA framework for the department of treasury and its agencies. It is aligned with the FEAF [11].

At the heart of the TEAF is the TEAF Matrix which provides a customized

version of Zachman table [11]. This matrix is a 4 by 4 matrix shown in figure 5 :

Planner Perspective				
Owner Perspective				
Designer Perspective				
Builder Perspective				

Figure 4 : The TEAF Matrix

Both FEAF and TEAF adapt NIST¹ model. It has been advised to be a basic model for information architecture consisting of five layers. However both of them customize this model for their specific purposes. Layers in NIST (Firstly introduced as sub-architectures in DOE² methodology) are [12]:

- **Business:** Organizations, Customers, Business Functions, Standards, Policies and Procedures.
- **Information:** Information Flow, Internal, External, Content, Format and Presentation.
- **Applications:** Automated Data Processing, Manual Systems, Procedures and Logical Data Structure
- **Data:** Physical DB Design, DB and File Structures and Data Dictionaries
- **Technology:** Computers, Facilities, Communications Network and Security Infrastructure.

Command, Control, Communications, Computers, Intelligence, Surveillance and Reconnaissance (C4ISR) Framework [13]: In December 1997, the DoD³ published its C4ISR Architecture Framework. This framework applies to all branches of the armed services and includes the numerous major and subordinate commands, field organizations, and task forces within each service [9].

The framework has four main parts: definitions of three standard views; products; references; and high-level

¹ National Institute for Standards and Technologies

² Department Of Energy

³ Department Of Defence

guidance in how to use the framework to describe an architecture [15].

“View” plays a role as “Layer” in the NIST model or as “Perspective” in the Zachman framework. These three architectural views are :

- **Operational Architecture View** describes the tasks and activities, the *operational nodes* and the information flows between nodes that are required to accomplish or support an operation.
- **Systems Architecture View** translates the required degree of interoperability into a set of system capabilities needed, identifies current systems that are used in support of the operational requirements and facilitates comparison of current/postulated system implementations with the needed capabilities.
- **Technical Architecture View** articulates the criteria that govern the implementation of required system capabilities [9, 15].

These three views have explicit linkages between themselves in order to maintain consistency and integration of the architecture [9, 15].

C4ISR has this advantage that provides some *Universal Reference Resources*, which serve as sources for guidelines, and attributes that must be consulted while building architecture products [13].

Also its other advantage is a *Six-Step Architecture Process*. This is described briefly in the framework document as the fundamental steps to build architecture in accordance with the Framework [13].

3. Framework Selection

Selecting a framework must be a step in building enterprise architecture. This is specially true for those enterprises which have no architecture before. Some enterprises may have frameworks selected before. It is important to note that although having already a framework, architects must evaluate the current framework in order to understand its ability to response to the drivers forcing the enterprise to be changed.

In [9] some framework selection criteria are mentioned for federal agencies. These are:

- **Area of Policy**
 - Regularity and legislative direction.

- Agency policy.
- Compatibility needed with another Agency or joint policy

- **Enterprise**

- Context for the enterprise: e.g., subordinate to a larger enterprise, closely related to another enterprise.
- Experience with a particular framework.
- Mandates and drivers: e.g., emphasis on business versus infrastructure or operational versus technical issues

- **EA Products**

- Priorities, intended uses and desired level of detail: e.g., large-scale modernization versus stable IT environment.
- Resource and schedule constraints on modeling efforts.
- Availability of existing architecture products.

Among these criteria, the context for the enterprise is in our interest here. Also we focus on the context for architecture and show that both have some counterparts in the context for framework.

We provide four classification schemes here, first two of which are about *the Context for the Enterprise* and two last ones are about *the Context for the Architecture*.

Organizational vs. Operational: Of course each organization, have many operations to do. When we talk about operations here we don’t mean any activities an organization performs. Operations are distinct from other activities in two following ways:

1. Typically an operation is not a simple office or customer related service. It is as critical as there will be no more need to the organization if it doesn’t perform the operation.
2. An operation usually invokes many more resources than other activities. The resources might include human, machines, time, fund and etc.

Examples of operations are: Military Operations, Fire Fighting Operations, Crisis Management, Software Production Process, a Soccer Match and so on.

Regarding this definition there are two broad categories for enterprises: *Organizational Enterprise* vs. *Operational Enterprise*. Also we may name them *Structural Enterprise* vs. *Behavioral*

Enterprise respectively. Note that these two types of enterprises are often mixtured in a unique organizational unit.

In order to provide better understanding of this point, refer again to our samples of an operation and consider folowing descriptions:

- A military operation (Operational Enterprise) is done by a defense related deapartment (Organizational Enterprise).
- A software production process is done by a software engineering company.
- A fire fighting operation is done by the fire guard.

In the same way we would see that frameworks themselves could be seen as having more operational or organizational emphasis. It means that some frameworks form an architecture which shows the enterprise as an organization whereas others establish an architecture that depicts the enterprise as an operation.

Having enterprises categorized in this way, we could name frameworks as the same way. So we have *Structural (Organizational) Framework* and *Behavioral(Operational) Framework*.

The best sample of an operational framework is C4ISR. It focuses on the operational nodes and elements at the top level of its architecture and so is well organized to build architecture for an operation.

On the other hand, we have FEAF & TEAF, both accepting NIST structure as their reference architecture pattern. As we have shown before it begins with the *Organization* as its top level. These are structural frameworks.

To finalize examples, now we offer following proposals in order to build architecture:

- To build architecture for the organizations such as Department of Defense, select FEAF, and to build architecture for its military operations, select C4ISR.
- To build architecture for a software engineering company, select TEAF, and to build architecture for its projects development process, select C4ISR.

As a result we could say that if the enterprise you want to build architecture

for, is an operational one, you may choose an operational framework such as C4ISR. But what to do, in the case of organizational ones?

Nested vs. Flat: Every organization has many subunits in its structure. Some of these subunits might be seen as enterprises themselves. For example in a government there are some ministries (or departments) that are enterprises themselves such as Department of Defense or Ministry of Education. We name such enterprises as *Nested Enterprise* and we mean it includes some other enterprises.

For an enterprise to be considered as a nested one, just having other enterprises included is not enough, but also these sub-enterprises must be devised to be engaged with architecture. If sub-enterprises have not been considered in the architecture or have been seen as a simple black box with some input/output lines, we could not suppose the main enterprise as a nested one.

If any of two conditions mentioned above are not present then the enterprise may be called a *Flat Enterprise*.

Similar to the enterprises, frameworks may be *nested* or *flat*. Two of three frameworks suggested by CIO for federal organizations are good examples for these two types of frameworks: FEAF & TEAF.

FEAF is considered to be a *Nested Framework* for its *Architectural Segments* component. As it has been shown before those are sub-organizations or sub-divisions of the major business in the federal organization. These segments are considered to be other enterprises within the federal enterprise [4].

Although we could ignore segments in FEAF for a flat enterprise, there is a more appropriate framework for flat enterprises: It's TEAF. TEAF is well-matched with FEAF, but it has no architectural segments included. So we might consider the TEAF as a *Flat Framework*.

We may use C4ISR for building architecture in a flat enterprise, however, note that a flat enterprise seems to be an organizational enterprise more than an operational one.

Level of Details: When planning for architecture projects, we might decide about architectural products, for example which of them are required? And in which level of details? So architectures (after planned) are not as the same to each other in the level of details for final products.

Furthermore frameworks are not equally focused on their products either. In some frameworks such as C4ISR, there are many descriptions on how to create products? Steps to be taken? What are included in each product? There are even attributes for each product fully described. Such a framework is suitable for implementing a final IT environment. We call any framework like this a *Low-Level Framework*.

To get more familiar with this concept let us verify our three accepted frameworks in this manner. As it is said before the C4ISR is a low-level one. Not only there are a lot of descriptions about its products documented officially, but also there are many researches and work done on tools and methodologies for building architecture using C4ISR framework. TEAF could also be seen as a low-level framework but not as low-level as C4ISR. It defines attributes for its products but it has no step-by-step method to achieve them.

On the other hand we have FEAF as a high-level framework, that is not engaged with the details of products and how to produce them.

If your goal is to provide a real working IT environment you may prefer C4ISR to TEAF or FEAF even if the subject enterprise be an organizational one. In other words you as the architect should have the art of ranking these factors against each other.

States of the Architecture: This could affect the architecture effectively. Remember three states which were mentioned before for any architecture. However for an architecture it is not obligatory to have exactly those three states. It may only concern with the current (or target) state of the IT environment.

In such a way, it is not true that all of the frameworks support the three possible states of the architecture. For example C4ISR only deals with one state (current or

target). Although it has some products to keep some notes on the future technologies or activities, but obviously these are not a complete set of architectural products.

On the other side both FEAF and TEAF support the three states for any architecture as mentioned before. This is specially true for FEAF that supports any of these three states with a certain component.

So if the project is planned to check the current state and provide a migration plan to achieve an offered future state you must select each of the FEAF or TEAF.

4. Conclusion

Having classified framework selection criteria, we have reached to some properties, an enterprise or an architecture may have. As an architect you may choose the framework which its properties match with the one for the enterprise and the architecture in the best way.

As we said before in some situations we may have two or more properties occurred simultaneously, while they seem to be contradicting each other. As it was mentioned earlier, the role of the architect is very important in such cases.

However a notable point to focus is that these situations may occur rarely. This is due to the most important part of our taxonomy that describes an enterprise to be structural or behavioral.

An organization often comprises other organizations but operations included in an operation are smaller than to be seen as an enterprise. So an operational enterprise may not be seen as a nested one.

Furthermore, we are more interested in details for operations than organizations. This is because operational enterprises are often *more mission critical* than organizational enterprises. Any mistake in these enterprises could result in *immediately unpredictable crashes*.

These doesn't mean structural enterprises are not mission critical. It means their failures could be recovered more easily. While for operational ones these failures could not be recovered at all. As a consequence most of the times, low-level architectures is needed for operational enterprises not for organizational

enterprises. Table 1 summarizes all the criteria discussed in this paper:

	Enterprise				Architecture			
FEAF	√			√		√		√
TEAF	√		√		√			√
C4ISR		√	√		√		√	

So far we suggested a taxonomy of enterprises in this paper. For an enterprise, to be fitted in this taxonomy easily, we need to define an enterprise in a new manner:

An enterprise is any collection of sub-units, inter-connected to each other through the flow of information.

This seems to be a very simple definition, but it could be applied on both types of the enterprises discussed earlier as well. We may expect an enterprise to be necessarily a giant object but if we accept architectures apply on enterprises then we may notice to Zachman, Inmon and Geiger who believe that an architecture is used to describe an object [7]. Also as it was said by Zachman and Sowa (1992) the logic and rules of the framework can be used for structuring the description of any complex object.

Future Work

Many problems exist in this area, need to be solved yet. Following this work, we will consider on other framework selection criteria, trying to represent a full taxonomy of all the criteria.

Also we think about more contextual aspects of enterprises, architectures and frameworks as the selection criteria. Some of these aspects are:

- Conceptual vs. Technical
- Homogeneous vs. Heterogenous
- Dynamic vs. Static
- Single Dimension vs. Two Dimension

Abstract

The purpose of this work is to show that the use of real options can contribute to a better evaluation of companies devoted to Electronic Commerce – Business-to-Business. For such, usual company-evaluation techniques are presented and the advantages and disadvantages of each one are discussed, with emphasis to the real-option technique. Additionally, the similarity between asset investment and call options is shown, and internal and external real options existing in a Business-to-Business company are identified. Finally, this work describes how to evaluate a company acting in Business-to-Business by employing the concepts of real-option theory.

1. Introduction

In recent years, the development of Internet-bound technology has yielded the extraordinary growth of Electronic Commerce among companies, called Business-to-Business (B2B), leading to the constitution of several electronic marketplaces. Transactions among companies have become faster and safer and have had their costs reduced, attracting a larger number of purchasers and suppliers into this new business environment.

Despite many successful stories of B2B companies created in the past few years, their growth has been facing difficulties due to technical, organizational, economical and legal challenges. Such uncertainty scenario has led to a significant loss in the value of such companies.

The new economy has revolutionized traditional evaluation theories. While in the old economy evaluation models were based on tangible assets, such as factories, machinery and finished products in stock, in the new economy intangible assets, such as intellectual capital or clients, have also started to be computed as company values.

The evaluation of Internet companies has been greatly affected by the uncertainty of markets. The impossibility to foresee how companies will perform in the future makes the evaluation of these companies using traditional methods inadequate because these methods do not consider managerial flexibility. A new trend in evaluation methods concentrates in the exploration of uncertainty, approaching businesses or investments as real options.

This work presents a proposal for evaluating B2B Internet companies that takes into consideration the existing uncertainties in the Internet B2B environment by applying the real-options theory.

First, we present the traditional methods for evaluating Internet companies. Then, we emphasize the positive and negative aspects of each method. Next, we present a typical configuration of the environment where B2B companies operate and the existing relationship dynamics between a given company and all other companies with which it interacts. Based on this configuration, we show the existing internal and external options that add value to that company.

2. Usual Evaluation Methods for Uncertainty Environments

The mostly used methods for evaluating companies in uncertainty environments are (Trigeorgis, 1996):

- Discounted Cash Flow
- Sensitivity Analysis
- Simulation
- Decision-Tree Analysis
- Real Options

2.1. Discounted Cash Flow

In the absence of managerial flexibility, the discounted cash flow is the best method to calculate the value of a company (Trigeorgis, 1996).

The discounted cash flow analysis – DCF – is the tool mostly used by academics and by analysts in order to evaluate investments, especially because it is a method easy to understand. However, DCF does not deal in a convenient way with strategic factors emerged from future uncertainty and the flexibility companies makes use of to respond to situations different from the ones expected (Teisberg, 1995).

A dynamic version for DCF was created by McKinsey (Desmet et al., 2000) in order to deal with future uncertainty. This version, instead of assuming a unique future cash flow deriving from a set of predetermined decisions, takes into account that the analyst initially assumes a set of future uncertainties and contingent decisions, translating them into alternative scenarios. These scenarios can be expressed together in a decision tree. Then the probability of each scenario is evaluated.

These probabilities are obtained from the analysis of similar projects or by means of macroeconomic analysis.

Both methods, static and dynamic DCF, use a unique discount rate adjusted to the perceived risk. The evaluation of the discount rate is usually based on data from projects with a similar risk – or, ideally, with identical risk. However, the use of only one discount rate has some problems. The relative risk of an enterprise can vary for each different scenario, or even for different project stages. As an example, we can observe in some exporting companies that some of their costs can have different risks if compared with revenue risks because they can be exposed to currency risks when their raw material derives from the domestic market. Therefore, it is advisable to use more than one discount rate in the analysis of this kind of project (Luerhman, 1998, p. 60).

One of the best examples of the dynamic version of DCF was created by McKinsey in order to evaluate Amazon.com (Desmet et al., 2000). In this example, McKinsey has combined the classic DCF method, microeconomic analysis and probability-weighted scenarios.

2.2. Sensitivity Analysis

The net present value of a project is a function of the forecasts of some variables: the project's life, salvage values, product prices, production costs, size and growth of the market and others.

Sensitivity analysis is the process of investigating these forecasts in order to identify the key variables and determine the impact of each of these primary variables on the net present value of the project. The sensitivity analysis is made by varying the value of the primary variable selected, holding other variables unchanged. (Trigeorgis, 1996, pg 52.)

The sensitivity analysis is important to identify the variable that contributes the most to the investment's risk. A variable can have a high variance compared with other variables (higher risk) but make an insignificant contribution to the project's risk and, thus, we can consider that investment decisions are independent from a very accurate precision in its estimate. On the other hand, if a variable has a low risk, it can demand a better estimate of its value. Therefore, if we commit errors in its estimate they can generate significant impact on the project's value. The relevance of each variable will indicate the necessity or not to spend more time or money in it to attain information in order to contribute to the reduction of the uncertainty of the project as a whole.

The sensitivity analysis also has some limitations. It considers the effects on the net present value at a time ignoring the possibility of interdependencies between variables, that is, the effects of the variation of a variable on other variables. In this case, the result might be underestimated, not corresponding to the results that would occur in practice. Another limitation is that a variable can present a dependency in time that is an error in the estimate of one year, which can spread to the following years causing great impact on the net present value.

When variables are interdependent, it is necessary to examine the project's net present value according to alternative scenarios with the simultaneous variation of a limited number of variables as a function of their interdependence.

2.3. Simulation

The simulation technique is used in the attempt to imitate managerial decisions in the real world. In order to obtain the desired results, a mathematical model is developed holding equations that represent the operations accomplished by the system being analyzed. This model must capture the most significant characteristics of the project as it evolves in time and encounters random events. The Monte Carlo method is the traditional method used in simulation. It includes the following steps:

- The project is modeled by means of a set of mathematical equations and identities contemplating the more significant primary variables;
- Probability distributions are specified for each of the above variables in a subjective way or from past empirical data;
- A random sample is then drawn from the probability distribution for each variable, allowing the calculation of the net cash flow for each period;
- The process is repeated until the average and standard deviation of the net present value can be obtained.

Although this procedure can handle sophisticated models, it has some limitations: (Trigeorgis, 1996, pg. 55):

- It is difficult to estimate the probability distribution for each significant variable.
- Even if the probabilities were determined, it is difficult to capture and shape all the interdependencies among the variables of the model.
- If the result of the simulation is a risk profile of net present value, the meaning of an outcome probability distribution of the NPV is questionable, since it is not clear what discount rate should be used.
- The management cannot easily translate the risk profile into clear decisions for action.
- Using the variability of project outcome as a measure of risk instead of the systematic risk, which would be the most appropriate risk for the company's shareholders, is dangerous.
- In some situations, the management can assume that a group of projects is viable when analyzed as a group, even when some of them are individually unacceptable.

2.4. Decision-Tree Analysis

Decision-tree analysis is a methodology that attempts to account for uncertainty and the possibility of subsequent decisions by the management. It helps the management to structure the decision problem by means of mapping all the dependent alternative courses of action. This methodology is especially applicable to analyze complex decisions of sequential investments when the uncertainty is decided in different points in time.

The decision-tree analysis is a good methodology for analyzing sequential investment decisions when uncertainty is resolved at diverse points in time. It forces the management to recognize the interdependencies between the immediate decision and subsequent ones.

Although this method is sufficiently flexible, allowing the representation of the managerial flexibility found in practice, it has practical limitations. For example, decision-tree analysis can quickly become very complex if the number of paths through the tree increases too much motivated by the number of decisions. Another problem is the difficulty to determine the appropriate discount rate.

2.5. Real Options

Options are contracts that give their holder the right, but not the obligation, to buy (call option) or to sell (put option) an asset at a predetermined price (exercise price) on or before a specified date (expiration or maturity date). For a call option, when the exercise price is above the market price of the asset, the option is said *out-of-the-money*. Conversely, if the market price of the asset is above the exercise price, the option is said *in-the-money*.

An option is called American option if it allows its owner to exert the option before the maturity date. It is called European option if it can be exercised only at the maturity date.

We can find different models to estimate a price for an option with sufficient precision. The mostly known models are the binomial model developed by Cox, Ross and Rubinstein (1979), and the Black-Scholes model (1973).

The evaluation of an option is based on the following premises (Weston, Copeland, 1992, p. 446):

- Frictionless capital markets (for actions, headings and options). This means: a) they do not have transaction costs or taxes; b) there are no restrictions on short sales; c) all shares of all securities are infinitely divisible; and d) borrowing and lending are unrestricted.
- Asset prices obey stationary stochastic processes along time.
- Risk-free rate is constant along time.
- Underlying assets pay no dividends.

Most of these premises can be relaxed without changing the basics of the option pricing model.

2.5.1. Binomial Model

The binomial option pricing model is a discrete model along time. This model starts by reducing the possible

option price modifications for the following period to two: price can move up or down from its current level. This simplification is acceptable if the period of time is very short, so that a great number of small movements is accumulated along the option's life (Brealey, Myers 1992). Thus, for a one-period model, the investor assumes that the price of the action – S – at the end of the period can have one of two values: uS with probability q or dS with probability $1 - q$. Let C be the current value of a purchase option; C_u and C_d the value of the call option at the end of the period if the option price is equal to uS and dS , respectively. In the one-period model, the option expires at the end of the period, and then the option's value in maturity date equals $C_u = \max(0, uS - X)$, X being the option's exercise price, with probability q and $C_d = \max(0, dS - X)$ with probability $1 - q$.

This procedure can be easily extended to multiple periods. If the time to the option's expiration, τ , is subdivided in n equal subintervals, each of length $h = \tau / n$, and the same valuation process is repeated starting at the expiration date and working backwards recursively, the general multiplicative binomial option-pricing price for n periods will be:

$$C = \sum_{j=0}^n \frac{n!}{j!(n-j)!} p^j (1-p)^{n-j} \max(u^j d^{n-j} S - X, 0) \frac{1}{(1+r)^n}$$

The first part, $\{ n! / [j!(n-j)!] \} p^j (1-p)^{n-j}$, is the binomial distribution formula giving the probability that the stock will take j upward jumps in n steps, each with probability p . The last part, $\max(u^j d^{n-j} S - X, 0)$, gives the value of the call option at expiration conditioned to the stock following j ups, each by $u\%$, and $n-j$ downs each by $d\%$ within n periods. The summation of all possible option values at expiration multiplied by the respective probability of occurrence ($j = 0, \dots, n$), gives the expected terminal option value, which is then discounted at the riskless rate over the n periods (Trigeorgis, 1996, p. 85).

2.5.2. Black-Scholes Model

In 1973, Black and Scholes presented a rigorous method to value stock options based on the premise of risk-free arbitrage. The term *risk-free arbitrage* means that investments which have the same risk/return rate must be equally priced. If it is possible to determine the payments of a risky investment and then to construct a portfolio with other investments that offers exactly the same payments, then the price of the two assets must be equal. If the prices are not equal, then the occurrence of arbitrage is possible, that is, purchasing an asset by a lower price and selling the same asset for a higher price.

The Black-Scholes model formula is:

$$C = S N(d_1) - X e^{-rfT} N(d_2),$$

where

$$d_1 = \frac{\ln(S/X) + rfT}{\frac{s \sqrt{T}}{2}} + \frac{1}{2} \frac{s \sqrt{T}}{2}$$

$$d_2 = d_1 - s \sqrt{T}$$

$N(d_1)$ and $N(d_2)$, respectively, are the cumulative standard normal distribution function of a unit's normal variable d_1 and d_2 ; S is the price of the asset; X is the exercise price; T is time to maturity; σ^2 is the return volatility of the asset; r_f is the risk-free rate; and e is the base of natural logarithms, constant = 2,71828...

The Black-Scholes model was developed over of some hypotheses that introduce some limitations to its use. The Black-Scholes model assumes (Copeland and Antikarov, 2001, p. 106):

- The option alone may be exercised only at maturity (European option).
- There is only one source of uncertainty.
- The option is contingent on a single underlying risky asset.
- The underlying asset pays no dividends.
- The current market price and the stochastic process followed by the underlying assets are known (observable).
- The return variance on the underlying assets is constant through time.
- The exercise price is known and constant.

The payment of dividends reduces stock price. Consequently, call options will become less valuable and, conversely, put options more valuable as dividend payments increase. Damodaran (Damodaran, 1997, p. 735) presents an adjustment for dividends when valuing short-term options and another for long-term options. He also suggests some other adjustments that allow calculating the value of an option for an early exercise.

For short-term options, that is, within a short time before expiration (less than one year):

Adjusted stock price = Current asset value - Present value of the expected dividends or

$$S' = S - S \frac{\text{Div}_t}{(1+r)^t}$$

$$C = S' N(d_1) - X e^{-rt} N(d_2)$$

where:

$$d_1 = \frac{\ln(S'/X) + rfT}{s \sqrt{T}} + \frac{1}{2} s \sqrt{T}$$

$$d_2 = d_1 - s \sqrt{T}$$

For the long-term period, assuming that the dividend yield (dividend yield = y = share/current asset value) is expected to remain constant during the option's life, the Black-Scholes model can be expressed as:

$$C = S e^{-yt} N(d_1) - X e^{-rt} N(d_2)$$

where:

$$d_1 = \frac{\ln(S/X) + (rf-y)T}{s \sqrt{T}} + \frac{1}{2} s \sqrt{T}$$

$$d_2 = d_1 - s \sqrt{T}$$

The adjustments in the Black-Scholes formula have two effects: a) the asset value is discounted back to the present at the dividend yield to take into account the expected drop in value from dividend payment; and b) the

interest rate is offset by the dividend yield to reflect the lower carrying cost from holding the stock.

2.5.3. Mapping a Project onto an Option

An investment opportunity is similar to a call option because the company has the right, but not the obligation, to acquire the asset as, for example, a new business. So, if it is possible to determine options that are similar to investment opportunities, the values of these options can be taken as reference for the value of these investments. Given the characteristics of an investment, it is very difficult to obtain a similar option. Thus, the only trustworthy way of getting the desired option is by means of the construction of an option. In order to obtain such option, it is necessary to establish a correspondence between the characteristics of the investment opportunity and the variables that determine the value of a call option (Luehrman, 1998, p. 52). Figure 1 shows the mapping of an investment opportunity onto a call option.

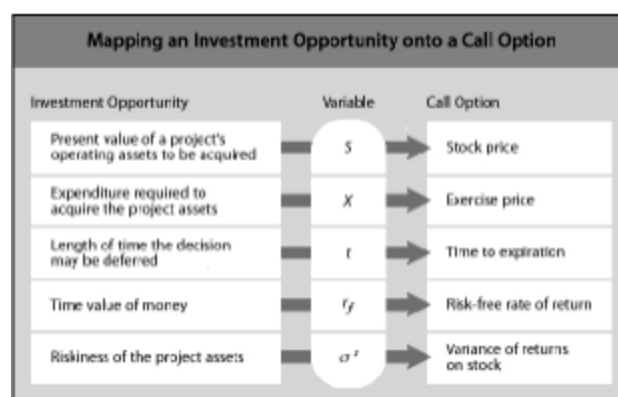

Figure 1: Mapping an investment opportunity onto a call option

Source: Investment Opportunities Real Options: Getting Started on the Numbers, Luehrman, T. A., Harvard Business Review, July-August, 1998

The net present value of an investment opportunity is the difference between its net present value S and how much it costs, $NPV = S - X$. When the NPV is positive the investment adds value to the business. Conversely, if it is negative, the company does not invest in this new opportunity, that is, $NPV = 0$. In terms of real options, this result can be expressed as being the value of the call option = $S - X$.

In the traditional methods of asset evaluation, managerial flexibility is not taken into account. Managerial flexibility is similar to a deferral option and adds value to the investment opportunity. By means of deferment the company postpones the outlay relative to the investment and, by applying this amount, it earns the value of the money in time and creates the possibility to do the investment later in case the asset value goes up. If the last alternative occurs the company can exercise the option. If, in contrast, the asset value decreases, it can either abandon the business or wait to see if its value goes up in time, avoiding loss of money with the investment.

Brealey and Myers (1992, p. 579) developed a methodology that simplifies the effort of valuing a call option using the Black-Scholes model. This methodology follows four steps:

1st step: a) let σ^2 be the variance of returns per unit of time in our project; b) multiply variance per period by the number of periods t to get cumulative variance $s^2 t$; c) take the square root of cumulative variance to change units, expressing the metric as standard deviation rather than variance. Luehrman (1998, p. 54) called this result *cumulative volatility* ($s \sqrt{t}$).

2nd step: calculate the ratio asset value to the present value of the option's exercise price. Assuming that the option's exercise occurs in t periods, the current value of the exercise price is equal to $PV(X) = X \div (1 + rf)^t$ and the desired quotient: $S \div PV(X)$.

3rd step: the option's value in function of the value of the exercise can be obtained by entering the values obtained in steps 1 and 2, above, in table 6 – *Call Option Values, percent of share prices* – presented in the appendix of the book *Principles of Enterprise Finances* (Brealey, Myers, 1992).

The value of a European put option value (kept until its expiration date) can be calculated using the following equality:

Value of put option + price of the asset = value of the call option + present value of the exercise price (X).

Using the Black-Scholes model's formula, it is possible to verify the impact of the variation of each variable on the value of a call option. Table 1 shows the impact for each variable:

Table 1: Impact of the Variation of a Variable onto the Value of a Call Option and a Put Option

Increasing	Option Value	
	Call	Put
Asset Price	↑	↓
Exercise price	↓	↑
Time to Expiration	↑	↑
Risk-free rate of return	↑	↑
Variance of Returns on Asset	↑	↓
Dividends	↓	↑

2.5.5. Relationship Between the Binomial and the Black-Scholes Methods

The results produced by binomial method approaches to the ones of Black-Scholes model when the time interval between a period and the following one is very short as the number of branches in binomial tree becomes large (Weston and Copeland, 1992, p. 454).

Figure 2 shows the evolution of an option value using the binomial model and the Black-Scholes Model. The input data in this example are: asset present value - \$100; exercise price - \$250; time to expiration - 7 years; risk-free rate of return - 10%; standard returns on asset - 40,55% and a changeable number of steps.

In the calculation of the option values we used the following tools: a) for the binomial method: *Peter*

Hoadley's Options Strategy Analysis Tools: Binomial Tree Option Calculator (<http://www.hoadley.net/options/binomialtree.aspx?tree=B>); b) for the Black-Scholes method: *Numa Option Calculator* (<http://www.numa.com/derivs/ref/calculat/option/calc-opa.htm>).

In the construction of the graph we used a maximum of 150 steps. This number is due to limitations imposed by the calculators used. We used Microsoft Excel to adjust a logarithmic curve to points obtained from the calculators.

Figure 2: Relationship Between Binomial and Black-Scholes Method

2.5.6. Types of Real Options

There are eight common categories of real options (Trigeorgis, 1996, p. 2):

1. Option to defer – enables the management to defer investment for a project or one of its stages. This option can be expressed as an American call option on the gross present value of the completed project's expected operating cash flows with an exercise price equal to the required outlay.

2. Option to expand – enables the management to increase operation capacity if market conditions turn out more favorable. This option can be expressed as a call option to acquire an additional part of the base-scale project, paying an additional expansion cost as exercise price.

3. Option to contract – enables the management to operate below capacity or even reduce the scale of operations thereby saving part of the planned investment outlay. This option can be expressed as a put option where the asset price is represented by the percentage of the basic project equivalent to the reduction, being the exercise price equal to the potential saving.

4. Option to shut down and restart operations – enables the management to shut down installations if cash revenues are not sufficient to cover variable operating costs. If prices rise sufficiently, operations can be restarted. This option can be expressed as a call option to acquire that year's cash revenue and the exercise price equal to the variable cost of operating.

5. Option to abandon – enables the management to abandon the project permanently in exchange for its salvage value. This option is similar to an American put

option on the project's current value with an exercise price equal to the salvage or a best value alternative, such as selling the project to another company.

6. Option to switch – enables the management to switch from one way of operation to another, such as adopting a flexible process that allows for different technologies. It can be represented by a portfolio of options that consists of both call and put options.

7. Growth option – sets the path of future opportunities of strategic importance for the company. It can be represented by composed options where each new business opportunity is a contingent option to the previous exercise of other options.

8. Multiple interacting options – involve a collection of various options. Upward-potential-enhancing and downward-protection options are present in combination. They can be represented by composed options.

3. A Generic Model for B2b Companies

Figure 3 presents the “B2B Global Model”, a generic model proposed for the B2B environment. Components of this model can be virtual companies (pure-play dot-com), mixed companies (bricks and clicks) or, in some cases, traditional companies (bricks and mortar).

In operational terms, the B2B Company presented in the generic model offers suppliers and consumers a virtual place where they can perform transactions in an easy and safe way. The technological solutions and tools offered by the B2B Company reduce the total costs and make the transactions between suppliers and consumers more efficient. The B2B Company offers several kinds of services such as: collaborative planning, forecasting and replenishment, catalogue of products and the implementation of supply chains.

The representation of the B2B Company makes explicit the sectors in charge of Technology, Marketing, Law and Payment because of their importance to the company and its relationship with the external elements interacting with it. Such sectors have a strong integration among one another. For example: the Technological area provides support to Marketing by means of CRM tools; the Legal area provides support to the Payment area by modeling the agreements made among the diverse elements that compose the Company's internal and external environment.

To carry their transactions in the B2B environment, the companies need external support from other companies, especially those related to the areas of technology, marketing, law and payment. These companies are represented in the model by the name of e-Technology, e-Marketing, e-Law and e-Payment, respectively. Other companies that do not belong to these groups are called e-Others. These companies can be virtual companies, traditional companies or mixed companies (bricks and clicks).

Governmental institutions, market-specific entities, unions and other regulation and control institutions with which companies in the B2B environment relate are also represented in our model by e-Laws.

There are several particular cases of B2B models which are subsets of the generic model presented here, such as: (a) purchases made to Suppliers effected by a single Buyer, such as Wal Mart Stores (www.walmartstores.com); (b) sales performed by a single Supplier, such as Ford do Brasil (www.ford.com.br), which sells parts to their distributors exclusively through the Internet; or (c) company that are service providers, such as an ASP provider.

Below, the nomenclature referring to the components in the model, as presented in Figure 3, is described:

- **Co_k** – B2B Company k – k^{th} electronic-commerce solution provider, connecting Suppliers and Consumers in a virtual environment and providing Client services.
- **Su_i** – Supplier i – i^{th} goods and/or service provider.
- **Co (k , Su_i)** – relationship between the k^{th} B2B Company and the i^{th} Supplier. The same Supplier can appear in the model associated to other companies.
- **Cs_i** – Consumer i – i^{th} goods and/or service consumer.
- **Co (k , Cs_i)** – relationship between the k^{th} B2B Company and the i^{th} Consumer. The same Consumer can appear in the model associated to other companies.
- **Cl_i** – Client i – i^{th} client.
- **Co (k , Cl_i)** – relationship between the k^{th} B2B Company and the i^{th} client. The same Client can appear associated to other companies.
- **Te_j** – e-Technology j – j^{th} technology-solution provider.
- **Te (j , Co (k , Cl_i))** – support provided by the j^{th} technology-solution provider to the i^{th} client in its relationship with the k^{th} B2B Company. The same Client can be supported by the same technology-solution provider in its relationship with other companies.
- **Ma_j** – e-Marketing j – j^{th} marketing-solution provider.
- **Ma (j , Co (k , Cl_i))** – support provided by the j^{th} marketing-solution provider to the i^{th} client in its relationship with the k^{th} B2B Company.
- **La_j** – e-Law j – j^{th} legal-solution provider or regulatory agent.
- **La (j , Co (k , Cl_i))** – support provided by the j^{th} legal-solution provider or control made by the regulatory agent on the i^{th} client in its relationship with the k^{th} B2B Company.
- **Pa_j** – e-Payment j – j^{th} financial institution.

- $Pa(j, Co(k, Cl_i))$ – relationship between the j^{th} financial institution and the i^{th} client in its relationship with the k^{th} B2B Company.
- Ot_j – e-Other j – j^{th} provider of other services. An example of a company in this class could be a recruiting company of specialized personnel.
- $Ot(j, Co(k, Cl_i))$ – support provided by the j^{th} provider of other solutions to the i^{th} client in its relationship with the k^{th} B2B Company.
- $Pr(Co_i, Co_j)$ – e-Partnership – joint efforts between the i^{th} B2B Company and the j^{th} B2B Company sharing functions and expertise in order to provide their Clients excellence in technology and services.
- $SC(Co(k, Su_i), Co(k, Cl_j))$ – Supply Chain – supply chain connecting Supplier i to Consumer j in its relationship intermediated by B2B Company k .

4. Evaluating B2b Companies

The value of a B2B Company is equal to its value without managerial flexibility added by the value of its internal and external real options. The value of the company without managerial flexibility can be obtained using the traditional net present value.

Internal options are those inherent to managerial flexibility that only affect the company. Below there are some examples of internal real options:

- Option to expand – possibility of a B2B Company to expand its transactions with suppliers and consumers in case it has extra capacity or, conversely, to invest if it is economically feasible.
- Option to defer – alternative to postpone a new internal project or one of the stages of a project of the company.
- Option to contract – possibility to reduce its performance in the market, if one of its segments is not profitable.
- Option to shut down and restart operations – alternative to cancel one or more activities of the company for a certain period of time until the conditions of the market become more attractive to the company.
- Option to abandon – alternative to abandon the project permanently or permanently close the activities of the company.
- Option to shift – possibility to change the kind of activities in the market.

External options are those related to other companies, that is, suppliers, consumers, clients, solution providers, partnerships, Governmental institutions, unions and others, such as:

- Option to switch – alternative to change the technology used affecting the relationship with other companies.

- Option to expand – the partnership with an international law office can assure the extension of legal support to the Company in new geographic regions, minimizing costs and speeding up the presence of the company in new regions.
- Option to contract – the reduction of profits of certain segment of a company can force it to lock up its activities with a certain group of companies, harming them in some way. The existence of an option to contract will give the right to the company to lock up these activities without suffering any legal constraint.

We could mention many other examples of real options, but the ones presented clearly demonstrate the value of these options and how they affect the value of a company.

Using the components of the “B2B Global Model” in figure 3, we can identify the existing real options and calculate their respective values. Representing by NPV the net present value, ROV the real option value, Co_k the evaluated company and by *Modified NPV* the total value of the Company_k, then the total value of Company_k can be expressed by:

$$\begin{aligned} \text{Modified NPV}(Co_j) = & \text{NPV}(Co_j) + (\text{NPV without} \\ & \text{managerial flexibility}) \\ & \Sigma \text{ internal ROV} + (\text{Total value} \\ & \text{of internal real options}) \\ & \Sigma \text{ external ROV} \quad (\text{Total value} \\ & \text{of external real options}) \end{aligned}$$

where

$$\begin{aligned} \Sigma \text{ external ROV} = & \Sigma \text{ ROV}(Co(j, Su_i)) + \\ & i = 1..n \quad (\text{Total value of} \\ & \text{supplier options}) \\ & \Sigma \text{ ROV}(Co(j, Cs_i)) + \\ & i = 1..m \quad (\text{Total value of} \\ & \text{consumer options}) \\ & \Sigma \text{ ROV}(Co(j, Cl_i)) + \\ & i = 1..p \quad (\text{Total value of} \\ & \text{client options}) \\ & \Sigma \text{ ROV}(Co(j, Te_i)) + \\ & i = 1..o \quad (\text{Total value of} \\ & \text{technology provider option}) \\ & \Sigma \Sigma \text{ ROV}(Te(k, Co(j, Su_i))) + \\ & i = 1..n \quad k = 1..r \\ & \Sigma \Sigma \text{ ROV}(Te(k, Co(j, Cs_i))) + \\ & i = 1..m \quad k = 1..r \\ & \Sigma \Sigma \text{ ROV}(Te(k, Co(j, Cl_i))) + \\ & i = 1..p \quad k = 1..r \\ & \Sigma \text{ ROV}(Co(j, Ma_i)) + \\ & i = 1..q \quad (\text{Total value of} \\ & \text{marketing provider options}) \\ & \Sigma \Sigma \text{ ROV}(Ma(k, Co(j, Su_i))) + \\ & i = 1..n \quad k = 1..q \\ & \Sigma \Sigma \text{ ROV}(Ma(k, Co(j, Cs_i))) + \\ & i = 1..m \quad k = 1..q \\ & \Sigma \Sigma \text{ ROV}(Ma(k, Co(j, Cl_i))) + \\ & i = 1..p \quad k = 1..q \end{aligned}$$

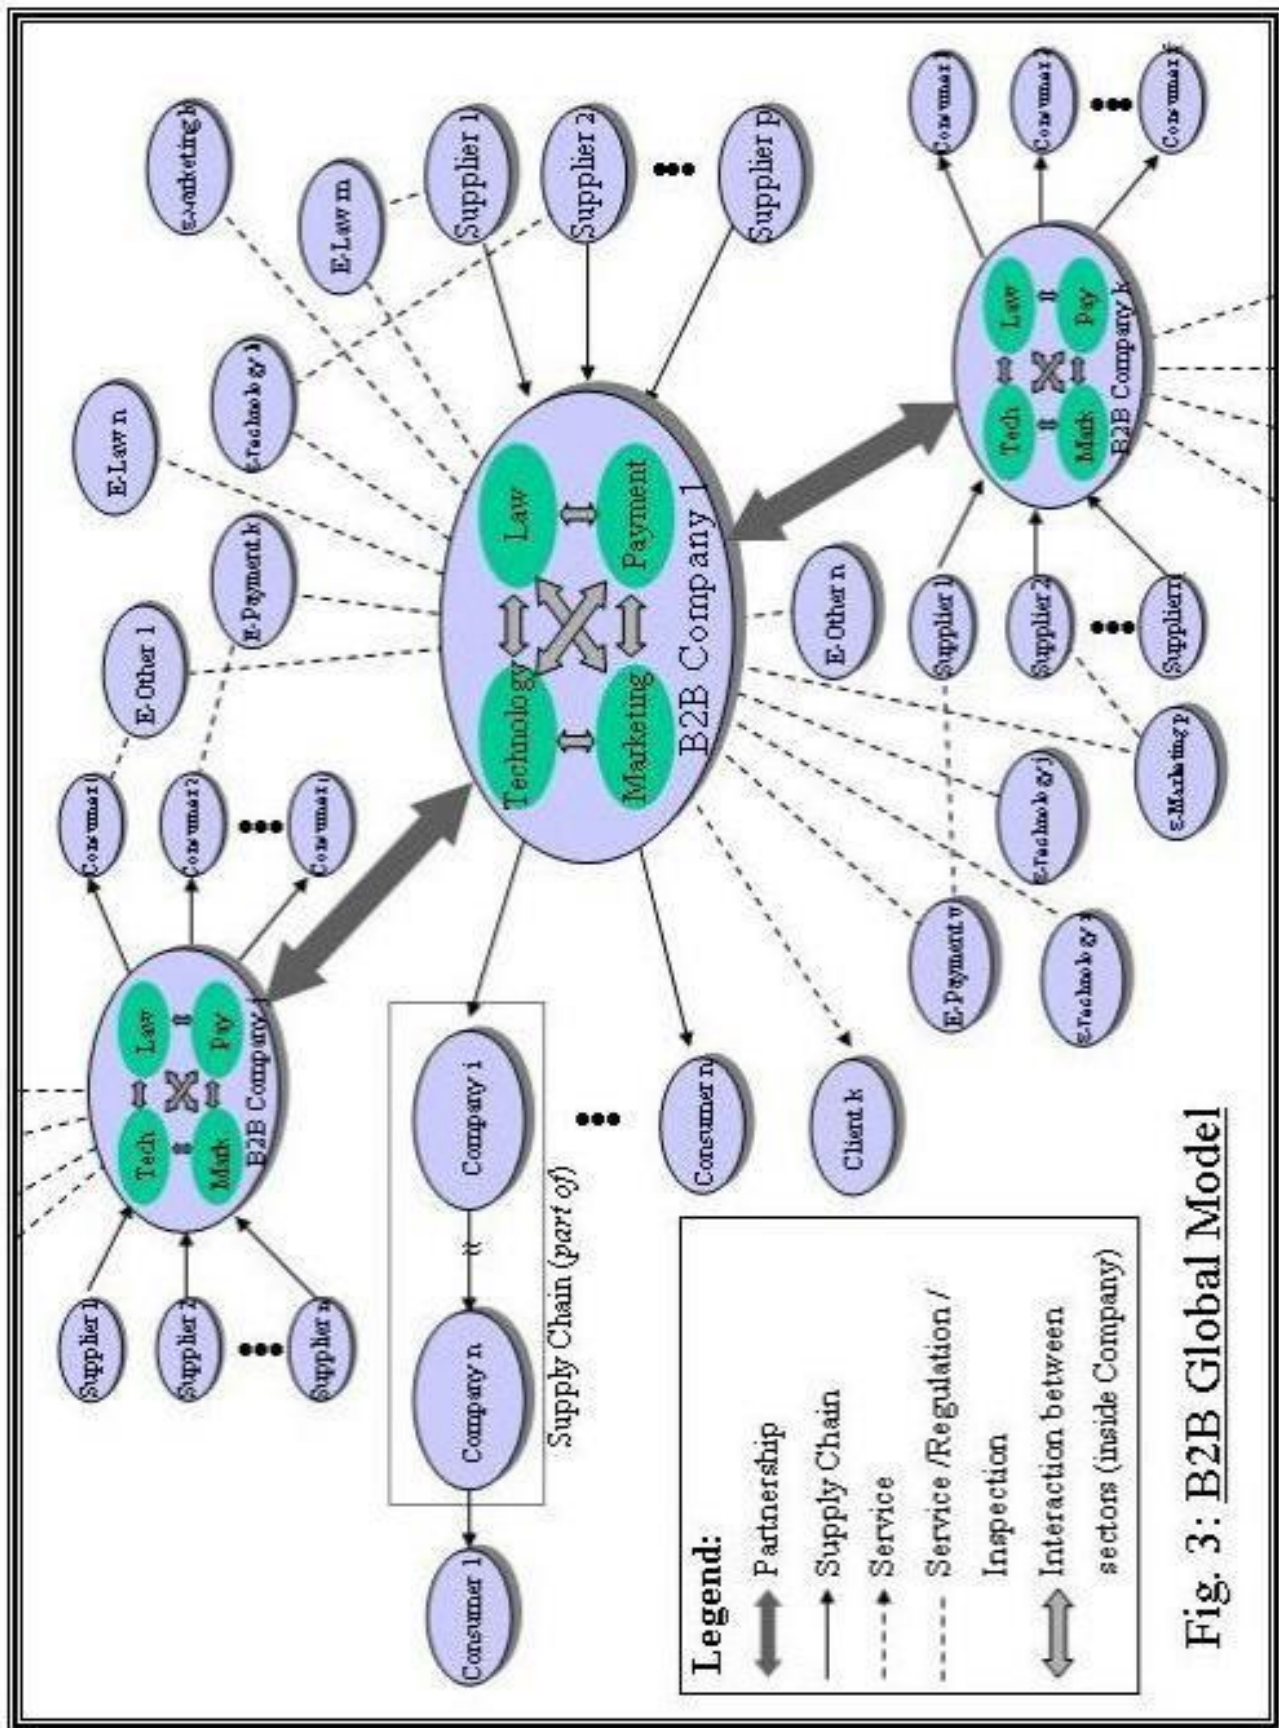

Fig. 3: B2B Global Model

$$\begin{aligned}
& \sum_{i=1..q} ROV (Co (j, La_i)) + \\
& \quad \text{(Total value of} \\
& \quad \text{law provider options)} \\
& \sum \sum_{i=1..n \ k=1..q} ROV (La (k, Co (j, Su_i))) + \\
& \sum \sum_{i=1..m \ k=1..q} ROV (La (k, Co (j, Cs_i))) + \\
& \sum \sum_{i=1..p \ k=1..q} ROV (La (k, Co (j, Cl_i))) + \\
& \sum_{i=1..r} ROV (Co (j, Pa_i)) + \\
& \quad \text{(Total value of} \\
& \quad \text{payment provider options)} \\
& \sum \sum_{i=1..n \ k=1..r} ROV (Pa (k, Co (j, Su_i))) + \\
& \sum \sum_{i=1..m \ k=1..r} ROV (Pa (k, Co (j, Cs_i))) + \\
& \sum \sum_{i=1..p \ k=1..r} ROV (Pa (k, Co (j, Cl_i))) + \\
& \sum_{i=1..s} ROV (Co (j, Ot_i)) + \\
& \quad \text{(Total value of} \\
& \quad \text{other provider options)} \\
& \sum \sum_{i=1..n \ k=1..s} ROV (Ot (k, Co (j, Su_i))) + \\
& \sum \sum_{i=1..m \ k=1..s} ROV (Ot (k, Co (j, Cs_i))) + \\
& \sum \sum_{i=1..p \ k=1..s} ROV (Ot (k, Co (j, Cl_i))) + \\
& \sum_{i=1..t} ROV (Pr (Co_i, Co_j)) + \\
& \quad \text{(Total value of} \\
& \quad \text{partner options)} \\
& \sum \sum_{i=1..m \ k=1..n} ROV (Sc (Co (j, Cs_i), Co \\
& \quad (j, Su_i))) \\
& \quad \text{(Total value of} \\
& \quad \text{existing options in supply chain)}
\end{aligned}$$

The list of real options presented above is theoretical, because it would be very expensive and it would take too much time to identify and obtain all the values of these options. In practice, we need to select the more valuable real options and work with those that are feasible to be exercised. Furthermore, interactions among real options present in combination generally make their individual values non-additive. The nature of such interactions and the conditions under which they may be small or large, as well negative or positive, may not be trivial.

5. Conclusion

This work has brought new contributions to the evaluation of Business-to-Business companies. Initially, we have examined techniques presented in the literature: discounted cash flow, sensitivity analysis, simulation, decision-tree analysis and options, discussing each one's advantages and disadvantages. We have concluded that, with the exception of real options, none of them contemplates managerial flexibility.

The use of the "Global B2B Model" in the evaluation of B2B companies is an advance because it allows the identification of the types of companies that operate in this environment: suppliers, consumers, customers and others related to the areas of Technology, Marketing, Law and Payment. This identification allows us to take into account all companies with which the company being evaluated relates to.

The identification of these companies and their characteristics allows us to collect all existing internal and external options for the company being evaluated. We have shown that the calculation of the value of any one of these options is possible by establishing a correspondence between its characteristics and those of a call option or a put option and, in some cases, of a portfolio of call and put options. The methodology presented for the calculation of each option was based on the work by Luehrman (1998).

Finally, we have concluded that the calculation of the company's value can be done taking into account the net present value (without flexibility) of the company plus the total value of the internal and external real options of the company being evaluated. It is important to emphasize that in practice, due to the existence of a great number of direct relationships and partnerships with other companies, it is necessary to verify which options are more representative for the calculation of the company's value in virtue of the effort, cost and time consumed in the calculation of each option value.

Investigating the Influence of Learner Diversity on the E-learning Acceptance

Yao-kuei Lee

Abstract

University students' demographics have been changing in the past two decades. Students diversity becomes an important factor in evaluating e-learning acceptance. Using a previously validated e-learning acceptance model, the paper investigated the construct means differences among various academic departments and between nontraditional continuing education and traditional higher education students, and tested the differences in model relationships between nontraditional and traditional student groups. Inferential statistics (t tests, ANOVA) and multiple-group Structural Equation Modeling (SEM) using LISREL were performed for the data analysis. The results revealed that different needs of various learner groups for e-learning, rather than academic discipline or gender, seem to drive the differences in intention to use IT for distance education and for supplementary learning. In addition, two relationships in the path model varied between nontraditional and traditional students groups. System functionality predicted intention to use e-learning as a supplementary learning tool for traditional students, but not for nontraditional students. Perceived usefulness predicted intention to use e-learning as a supplementary learning tool more strongly for nontraditional students than for traditional students. The implications for management and practices are discussed.

1. Introduction

E-learning has become an important teaching and learning tool worldwide [1] [17]. Most noticeably, it has been used or promoted in the following four areas: corporate training, universities, government, and K-12 education.

An e-learning system is an integrated system as opposed to stand-alone, single-function systems. Recently, more advanced e-learning systems, such as WebCT (<http://www.webct.com>) and Cyber University of NSYSU (<http://cu.nsysu.edu.tw>) have been developed. These systems are specifically designed for teaching and learning purposes and can be used to integrate course development tools, course material (audio, video, and text), e-mail, live chat sessions, online discussions, forums, and the World Wide Web. With this kind of system, instructional delivery and communication between instructors and students can be conducted either synchronously or asynchronously.

In the past two decades, demographics of university students have been changing in the U. S. and Taiwan [12] [6]. The two noticeable changes are: (1) the increase of female students and (2) the increase of older, working students. In the adoption of innovation (in this case, e-learning), the factors predicting e-learning adoption may vary across demographic groups. To better address e-learning adoption problem for different demographic groups, it is necessary to study the effects of these two changing factors on the e-learning adoption. For example, gender has been reported to have influence on the adoption of e-learning [5]. Appropriate actions can then be planned separately for either female or male group to improve the acceptance. The influence of another changing factor, students diversity, therefore is worth investigating. For example, older working students have a tendency to be enrolled as nontraditional continuing education students. Comparing with traditional higher education students, these nontraditional students generally have different living schedules and needs and, therefore, may vary in their intentions to use an e-learning system. The purpose of this study then is to investigate how learner (student) diversity will influence the acceptance of an e-learning system. In particular, the following research questions guided the study:

1. Do learners of different academic departments have similar perceptions and use intentions regarding e-learning acceptance?
2. Do non-traditional and traditional learners have similar perceptions and use intentions regarding e-learning?
3. Do the relationships between learners' behavioral intentions to use an e-learning system and determinant factors differ for non-traditional and traditional learners?

2. Literature Review

2.1 Research Model

Lee and Pituch [9] proposed and empirically supported an e-learning acceptance model as shown in Figure 1. The model is derived from the Technology Acceptance Model [10] and Diffusion of Innovation (DOI) perspective [14]. This model uses behavioral intention as a surrogate for IT acceptance of novice learners. The acceptance criteria were categorized into behavioral intentions to use the e-learning system as a supplementary learning tool (IU1) and as a distance education method (IU2). Lee and Pituch

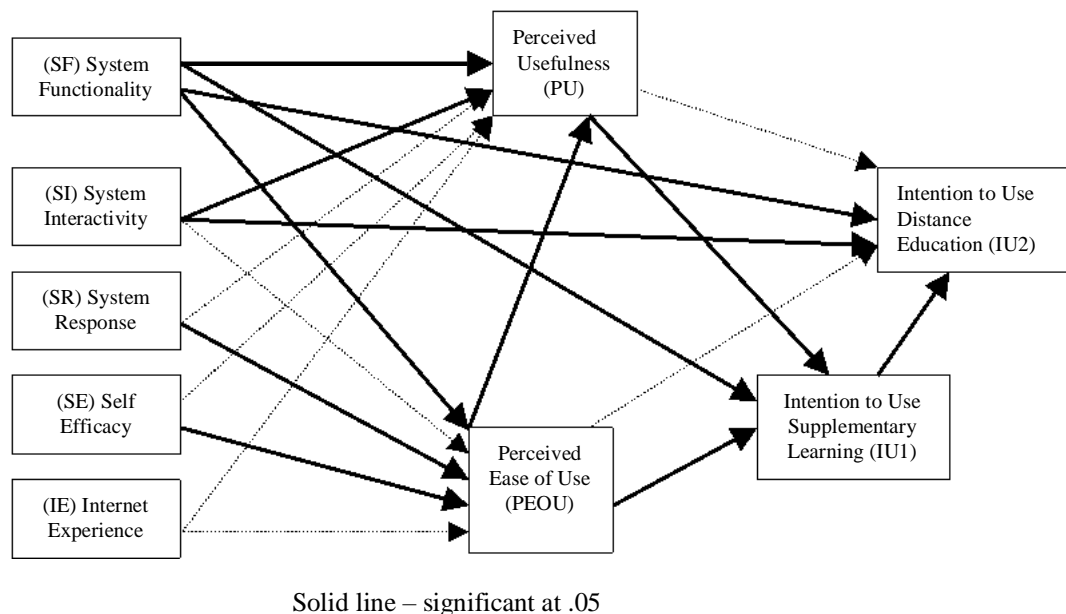

Figure 1. E-learning acceptance model (Lee & Pituch [9])

found that factors related to IT acceptance included perceived usefulness (PU), perceived ease of use (PEOU), system characteristics (functionality, interactivity, and response), and learner characteristics. The system characteristics are defined as follows. System functionality (SF) is a learner's opinion or perception of system functions related to learning and relative advantage as to time and place in learning. System interactivity (SI) is a learner's opinion or perception of the e-learning system's ability in enabling interactions between teacher and students, and among students themselves. System response (SR) is the degree to which a learner perceives whether the system response is fast/slow, consistent, and reasonable in requesting a system service [2]. For the learner characteristics, self-efficacy (SE), based on [4], is defined as one's self-confidence in his or her ability to perform certain learning tasks using an e-learning system. Internet experience (IE) is the extent to which a prospective learner uses the Internet [15].

2.2 The Influence of Learner Diversity

Human needs and behavior are related. Maslow's theory of the need hierarchy is the single most influential theory of human motivation. The theory indicates that there are five basic needs: physiological, safety, social, esteem, and self-actualization. These five needs are related to each other and are being arranged in a hierarchy of prepotency. The theory postulates that behavior is motivated biologically, culturally, and situationally to satisfy those needs.

Human needs influence their adoption behavior. Rogers [14] stated that compatibility of an innovation is an important determinant for adoption and compatibility is "the degree to which an innovation is compatible with the existing values, past experiences, and needs" (p. 224).

Various demographic groups have different values, experiences, and needs, therefore, may affect IT adoption. For example, gender, as one of the demographics, was reported to have influence on IT adoption [6] [19] and, in particular, on e-learning adoption [10].

The diversity of learner investigated in this study includes two demographic factors: academic departments and educational divisions. For example, nontraditional students are those who most likely have full-time employment, attend school in the evening, and have a family. Technology advancement has enabled this group of learners to continue their education in ways that seemed impossible before [11] [18]. That is, they have needs to use e-learning technology to achieve their educational goals. An old proverb has stated, "Necessity is the mother of invention." Similarly, different needs between nontraditional and traditional students may influence their perceptions of the e-learning system and intentions to use such system.

The e-learning acceptance model (as shown in Figure 1) has been validated by prior research. It provides a sound framework for further research to identify if the construct means differed among students in various academic departments, and between nontraditional and traditional student groups. The relationships in the model is also examined to determine if they vary for nontraditional and traditional student groups.

3. Methodology

For this study, data collected from an earlier research [9] were grouped by academic departments and educational divisions. In brief, participants in the study consisted of postsecondary students enrolled in computer classes at a college in Taiwan. Students were given a 40-minute live

demonstration of an e-learning system¹ and 30-minute to individually practice with it. A total of 259 surveys were collected from participants in the demonstration and practice. The response rate is 80.7% based on a total of 321 class members. Respondents were all in degreed programs, had ages ranging from 18 to 32 with an average of 22, and were relatively balanced between educational divisions (traditional higher education students 55.2%, non-traditional continuing education students 44.8%). The students were from several academic departments (MIS 76, Pharmacy 69, Healthcare Administration 81, others 33). The “others” category includes students from Nursing and Industrial Hygiene departments. The survey instrument was the same as the earlier study [9]. For Research Questions 1 and 2, inferential statistics such as one-way ANOVA and t tests were used to determine which factor means differed significantly among different academic departments or between educational divisions. For Research Questions 2, multi-group Structural Equation Modeling (SEM) approaches [3] [8] [16] using LISREL 8.50 were performed to determine the moderating effects of educational divisions on the research model. A measurement invariance across groups [7] is tested first. Then the differences in path coefficients between two groups are tested and identified [8].

4. Findings and Discussion

As shown in Table 1, with regard to students’ intention to use e-learning for supplementary learning (IU1) and that for distance education (IU2), there are no significant differences among students in different academic departments ($F = 0.91, 1.16; p = 0.436, 0.324$ separately), using a 0.05 significant level. But there are significant differences in factor means of perceived ease of use ($F = 3.08, p = 0.03$), system functionality ($F = 3.0, p = 0.03$), and self-efficacy ($F = 2.88; p = 0.04$) among different departments. Furthermore, Tukey’s post hoc analysis indicated that MIS students have a significantly higher perception of system functionalities than Pharmacy students, and “other” department’s students have a significantly higher self-efficacy than Healthcare Administration students. Students in the “other” category were from Industrial Hygiene and Nursing departments and were taking the computer course as an elective. Generally, they should have interests and self confidence in IT. Therefore it is not unusual for this group of students to have a significantly higher self-efficacy than average students in Healthcare Administration. Using a significance level of 0.10, there are significant differences in Internet experience among different departments’ students. As to the usefulness, system interactivity, and system response, there are no significant differences among different departments.

In the comparison between nontraditional and traditional students as shown in Table 2, nontraditional

students have significantly higher perception of usefulness ($t = 2.30, p = 0.02$) and intention to use for distance education ($t = 2.33, p = 0.02$). Using a significance level of 0.10, nontraditional students have significantly higher perception of system functionality and intention to use for supplementary learning.

Table 1. Differences in factor means based on academic departments

Factors	Academic Departments				ANOVA	
	MIS	Pharmacy	Healthcare	Other	F	Prob.
PU	5.06	4.86	4.83	5.02	0.93	.43
PEOU	5.25	4.90	4.86	5.33	3.08	.03**
IU1	5.24	5.07	4.97	5.24	0.91	.44
IU2	5.39	5.04	5.13	5.27	1.16	.32
SF	5.91	5.43	5.69	5.82	3.00	.03**
SI	4.94	4.87	4.75	5.00	0.58	.63
SR	4.73	4.78	4.89	4.76	0.39	.76
SE	4.84	4.72	4.44	5.06	2.88	.04**
IE	5.32	5.10	4.83	5.32	2.35	.07*

Note. * $p < .10$. ** $p < .05$.

Table 2. Differences in factor means between nontraditional and traditional students groups

Factors	Non-traditional		Traditional		<i>t</i> value	Prob.
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>		
PU	5.08	0.93	4.80	1.00	2.30	.02**
PEOU	5.16	1.06	4.95	1.12	1.55	.12
IU1	5.26	1.10	5.00	1.14	1.87	.06*
IU2	5.39	1.10	5.04	1.28	2.33	.02**
SF	5.84	1.02	5.60	0.97	1.92	.06*
SI	4.97	1.09	4.79	1.13	1.26	.21
SR	4.91	1.00	4.71	0.99	1.58	.12
SE	4.66	1.21	4.75	1.10	0.59	.56
IE	5.05	1.40	5.15	1.18	0.61	.54

Note. * $p < .10$. ** $p < .05$.

An examination of the mean differences for the constructs between the nontraditional and traditional students through the path model ($SE \rightarrow PEOU \rightarrow PU \rightarrow IU1 \rightarrow IU2$) indicates that the difference is small for self-efficacy and generally increases on the path to IU2 as shown in Figure 2. The p value for the t -test of these difference decreases from .559 to .02. These results show that the educational division differences are in the latter part of the path model. Comparing with the gender study [10], the differences occurred at the opposing end of the path model.

The findings suggest that, although there is no difference in learners’ confidence in using the e-learning technology, nontraditional students have higher beliefs of technology usefulness and higher intentions to use such technology for distance education than do the traditional learners. One possible explanation for these findings is that they may be driven by actual needs. Generally,

¹ The e-learning system used is the Cyber University at National Sun Yat-sen University (Taiwan). It provides Internet users with a guest account.

Figure 2. Trend of the differences in factor means between nontraditional and traditional groups

nontraditional students work full-time during the day, attend classes at night, and struggle with the responsibilities of work, family, and school. The e-learning technology provides a relative advantage in learning over a face-to-face class as to time and place independence and many-to-many communication. Using this technology as a distance education method would be more compatible with their living schedule and needs. Therefore, nontraditional learners perceive the technology more useful and have higher intention to use the technology as a distance education method. This is consistent with the compatibility characteristics of the innovation adoption theory [14]. Based on the same rationale, different academic departments' students may not have varying needs, therefore, their intentions to use the technology for either supplementary learning or distance education are indifferent. The same rationale can be applied to explain the indifference in the intentions to use between male and female students [10].

A multi-sample SEM was performed to compare the structural equation model over nontraditional and traditional students groups. The purpose of this analysis was to understand whether educational division had a moderating effect on the research model. Prior to testing the differences in model path estimates between non-traditional and traditional students, measurement models were tested for each group separately. Table 3 shows that the measurement models for both non-traditional and traditional students had adequate model fit. In addition, the difference in fit between a baseline model that allowed all factor loadings to vary across the two groups and a factor loading invariance model that constrained the factor loadings to be the same for these groups provides support for the more restrictive model. As presented in Table 3, the difference in the fit of these models is not statistically significant, $\chi^2_{\text{difference}} (41, N = 259) = 49.69, p > .05$. In addition, since the overall fit indicators provide support for the invariant factor loading model, this measurement model was used to test the difference in the relationships among constructs for the non-traditional and traditional learners.

Following the establishment of a common measurement model, multi-sample SEMs across

educational divisions were performed. The first model tested path invariance by constraining all structural paths, reflecting the relationships among constructs, to be the same across both academic divisions. The model indicated an acceptable model fit, $\chi^2/df = 1.39$, CFI = .962, NNFI = .956. However, the modification indices indicated that the chi-square would decrease 7.636 if the path from SF to IU1 were estimated separately for both groups. A second model was specified accordingly and tested. The fit of this model was acceptable, $\chi^2/df = 1.37$, CFI = .963, NNFI = .957, and this model was more consistent with the data than the initial model, $\chi^2_{\text{difference}} (1, N = 259) = 7.96, p < .05$. For this second model, the modification indices indicated that the chi-square would decrease 6.895 if the path from PU to IU1 were estimated separately for each group. This third model was specified and tested. The model fit was acceptable, $\chi^2/df = 1.37$, CFI = .964, NNFI = .958, and this third model had better overall fit than the second model, $\chi^2_{\text{difference}} (1, N = 259) = 3.84, p = .05$. Finally, the modification indices for this third model were all small and did not suggest any further refinements to the model.

The moderating effects of educational division on the relationships in the path model are presented in Table 4. The direct effects found to be the same across educational divisions are shown in the common metric column. The values shown in the nontraditional and traditional columns are the standardized path coefficients estimated separately for each group. In particular, system functionality predicted intention to use IT for supplementary learning for traditional students (0.504, significant) but not for nontraditional students (0.110, insignificant). Perceived usefulness predicted intention to use for supplementary learning more strongly for nontraditional students (0.511, significant) than for traditional students (0.287, significant). The multi-sample SEM path model for educational divisions is illustrated in Figure 3. One possible explanation is that the reason for having the intention to use the technology for supplementary learning might be different for nontraditional and traditional learners. Nontraditional learners generally have a higher tendency to miss some face-to-face classes due to family or work reasons. Thus, they may be more apt to rely on the technology to make up instruction time at home. The time and place flexibility in learning provided by system functionality, the many-to-many communication provided by system interactivity, all supported by a consistent and fast system response would enable them to do that. Therefore, belief of technology usefulness which is impacted by system functionality, system interactivity, and system response would have more influence in intention to use for supplementary learning for nontraditional than for traditional learners. But for traditional learners, most of them are full-time students, have a lower tendency to miss classes, and have more time to meet with instructors and other students. Therefore, system interactivity and system response are not as important. Instead, system functionality has more influence in their intention to use e-learning for supplementary learning.

5. Conclusions

Theoretically, this study further identifies some of the differences in the factor means of the e-learning acceptance model among students in different academic departments (MIS, Pharmacy, Healthcare Administration, and other), and between nontraditional and traditional student groups. An initial conclusion can be drawn from this research together with prior study [10] that different needs of various learner groups, rather than academic discipline or gender, seem to drive the differences in intention to use IT for distance education and for supplementary learning. Therefore, in practice, faculty members or educational administrators should promote or implement e-learning for student groups such as nontraditional students who have greater needs for the technology and are more likely to have higher intentions to use it.

In addition, two relationships in the path model varied for nontraditional and traditional student groups. Enhancing the usefulness of an e-learning system may substantially increase the likelihood that non-traditional

students, especially, may use the system for supplementary learning purposes. That is, the overall system functionalities, interactivity, response, and ease of use need to be improved. In order to enhance traditional learners' intention to use the technology as a supplementary learning tool, improvements in system functionality would produce the most significant results. The implication is that faculty members or educational administrators can take different actions for various learner groups to improve their intention to use for supplementary learning purpose.

Abstract

In order to cope with the coming of future digital television broadcasting, terrestrial broadcast companies have started to upgrade their program transmission relay devices from analog to digital. Although well-defined specifications can be referenced from all manufactures, with all the intricate factors such as functionalities, features, pricing, operation cost, and after service, it becomes a heavy burden as far as how to choose the most appropriate equipment in the procurement of digital microwave relay system. The goal of this report is to set up all kinds of evaluation items utilizing hierarchical structure model, and to choose the most appropriate digital microwave equipment using fuzzy assessment method.

1. Introduction

The digital microwave relay system plays an important role in the future digital television broadcasting system and can be used for more than ten years. Therefore, the chosen microwave machine needs not only to meet the standards of product specifications and features but also to consider the future expansion capability such as most up to date functionalities, adequate spare parts, inexpensive long-term operation cost, and business opportunities.

This study presents a real case for evaluation. The north-south bound microwave

relay system in the west of Taiwan has 8 stations and 7 sections; total up to 14 sections back and forth (Refer to Fig. 1). Average

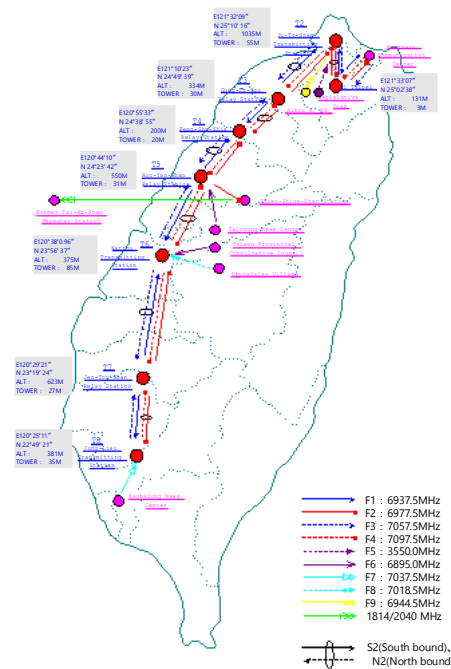

Fig.1 Western digital microwave relay system map

distance between each section is about 30 kilometers and above. In order to meet the system reliabilities and basic function requirements, project specifications are published in advance for vendor's reference. Three machines from two manufactures are selected for consideration, to comply with the basic requirements. Therefore, other criteria need to be used on top of the basic requirements and specifications in the assessment process.

2. Theory Exploration

2.1 Fundamental Requirements of Digital

Microwave Relay System

Digital microwave transmission channel in this project requires one route for DS3 (44.736Mbps—program transmission) and one route DS1 (1.544Mbps —enterprise intranet), system reliability is set for 99.975 % and above (with disconnection rate 21.6 second per day).

2.2 Factors contribute to System Reliability

System reliability involves microwave machine transmission power, receiving threshold, FEC (forward error correction) function, hot stand-by architecture and adoption of space diversity, etc. (Please refer to Table 1). Although the three machines from the two manufactures do achieve more than 99.975 % system reliability, they retain the leading position in some areas of the system architecture. Especially when all figures are derived from theoretical computation rather than reality, this increases difficulty during the assessment.

System gain, which is one of the system reliability elements, includes transmission power (dBm) and receiving threshold (dB). Therefore, the higher the transmission power and the lower receiving threshold are, the larger the system gain will be. (Please refer to Table 1) System reliability is also relatively increased. Among other items; factors such as FEC function can increase system gain 2 ~ 2.5dB and hot stand-by function increases overall system reliability 50 % should not be neglected. In additional, machine with lower transmission power tends to have less long-term operation cost. Cost saving can be used to acquire additional receiving antenna to increase the system reliability through space diversity

technology. The resulting effect is far better than increasing output power.

Table 1 General function comparison

Brand	A	B	C
Model	MDR-XXXX	DVR-XXXX	C-XXXX
Frequency Band(GHz)	6.425~7.125	6.875~7.125	U6
Modulation(QAM)	16	64	32
FEC	N/A	Single-Lee	Reed-Solomon
Capacity	DS3+DS1	DS3+DS1	DS3+4XDS1
System Reliability	99.9841	99.977	99.99
Frequency Stability	0.001%	0.001%	0.0003%
TX BW (MHz)	15	10	14
TX Power (dBm)	30,33	29,31	29
T/I Ratio Cochannel 32dB(dB@10 ⁻⁶ BER)	27(dB@10 ⁻³ BER)	30(dB@10 ⁻³ BER)	30(dB@10 ⁻⁶ BER)
T/I Ratio Adjacent channel 3dB(dB@10 ⁻⁶ BER)	-4(dB@10 ⁻³ BER)	-8(dB@10 ⁻³ BER)	-22(dB@10 ⁻⁶ BER)
Dispersive Fade Margin (dB@10 ⁻⁶ BER)	57(dB@10 ⁻³ BER)	59(dB@10 ⁻³ BER)	60(dB@10 ⁻⁶ BER) 61(dB@10 ⁻³ BER)
RX Threshold (dBm)	-78.5	-76	-76
Network Management	Non-SNM P Architecture	Non-SNM P Architecture	Starview/SNMP
Hot Stand-By	SouthBound-Yes, NorthBound-No	SouthBound-Yes, NorthBound-No	SouthBound-Yes, NorthBound-Yes
Prices	NT \$: 29192256	NT \$: 34565321	NT \$: 30001290

2.3 Wave Usage Charge

Wave usage charge calculation formula published by Ministry of Transportation and Communication in 1990 is as follow:

Formula: $(BW \div 1\text{MHz}) \times (W \div 1\text{Watt}) \times 14000 \times 0.4$
Identical bandwidth, Power 2W, 1W are used for comparison.

$$2W: (15\text{MHz} \div 1\text{MHz}) \times (2W \div 1W) \times 14000 \times 0.4 \\ = 168000 \text{ dollars/year.}$$

$$1W: (15\text{MHz} \div 1\text{MHz}) \times (1W \div 1W) \times 14000 \times 0.4 \\ = 84000 \text{ dollars/year.}$$

Price difference for the 14 sections of the

entire system is 1176000 dollars per year. Annual saving of 1.17 million would be adequate for the purchase of two receiving antennas (RFS UXA12-65A one unit costs 665176 dollars). Using space diversity technology can increase system reliability.

2.4 Transmission Channel Capacity

Capacity of DS3 and DS1, even though all three machines fulfill the basic requirements, one of the machines has one route for DS3 plus 4 routes for DS1. As the commercial value of DS1 channel declines with the opening of the three major fixed-network communication companies, the utilization of the enterprise intranet and the enhancement of efficiency cannot be quantified by dollar figures. This item is, therefore, included as one of the important elements.

3. Fuzzy Assessment Model

3.1 Hierarchical Structure Model

Due to the wide range of areas covered by selection criteria, there are a lot of items need to be considered. A hierarchical structure model as shown in Fig. 2 is used in order to take into equal consideration of all areas to build an assessment architecture model.

3.2 Grade of Evaluation and Grade of Importance of the Evaluated Items

Different items are evaluated in the selection process. Each item has its own grade of evaluation and grade of importance as shown in Table 2 [1]. Each grade of evaluation and grade of importance is further divided into 11 linguistic variables.

Great deal of uncertainty and fuzzy occur when using linguistic variables in many circumstances.

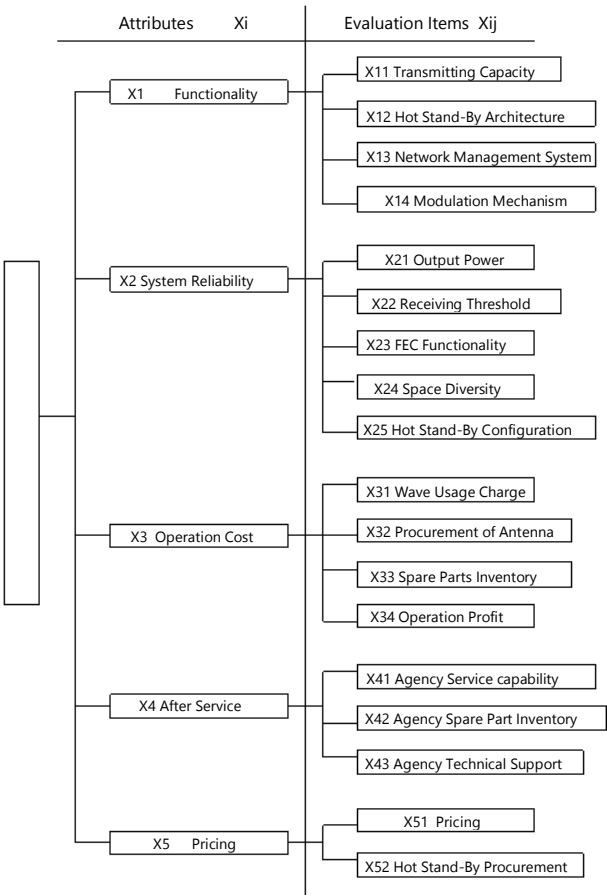

Fig. 2 A hierarchical structure model

Therefore, ambiguous linguistic variables are represented by triangular fuzzy numbers as shown in Table 3 [1].

3.3 Evaluating the Aggregative Rate Method

Let w_i represent the weight of the attribute X_i , and w_{ik} denote the weight of the item X_{ik} as shown in Fig. 1, $g(a_{ij}, b_j)$ represent the value [1] which is derived by the defuzzified method after multiplying the grade of evaluation (a_{ij}) and grade of importance (b_j) .

In referencing the Lee et al. [2] algorithm, calculation steps are as follows:

Step 1. Let

$$R2(k) = \frac{\sum_{j=1}^{n(k)} W_{kj} * g(r_{kj}, i_{kj})}{\sum_{j=1}^{n(k)} W_{kj}}$$

$$= \sum_{j=1}^{n(k)} W_{kj} * g(r_{kj}, i_{kj}) \quad (1)$$

for $k=1, 2, \dots, 5$, where $n(k)$ is the number of evaluation items for attribute X_k , then we have $n(1)=4, n(2)=5, n(3)=4, n(4)=3, n(5)=2$; $g(r_{kj}, i_{kj})$ is the rate of pair (k, j) for each evaluation item X_{kj} ; W_{kj} is the weight of the item X_{kj} .

Step 2. The final rate of aggregative evaluation is by the centroid method as follows:

$$\text{Let } R1 = \frac{\sum_{k=1}^5 W_k * R2(k)}{\sum_{k=1}^5 W_k}$$

$$= \sum_{k=1}^5 W_k * R2(k) \quad (2)$$

Then, the value of R1 is the rate of aggregative evaluation.

3.4 Data Example

Assume there are 3 sets of actual data representing selected machines A, B and C. Other company may assign different weight values to each attribute and evaluation item according to actual demand. Fixed Weight Value and Grade of Importance are used in the selection process. The values do not affect by different machine model. Evaluation Rate and Grade of Importance of each item are shown in Table 4.

Final evaluation result can be obtained after calculation through above mentioned fuzzy assessment algorithm. As shown in Table 5, the

result after sorting is $B > A$.

Table 2 Linguistic variables of grade of Evaluation and grade of importance [1]

11 Evaluation Rate Sequence	11 Grade of Importance Sequence
1: 11th Grade	1: Extremely Unimportant
2: 10th Grade	2: Especially Unimportant
3: 9th Grade	3: Very Unimportant
4: 8th Grade	4: Unimportant
5: 7th Grade	5: Somewhat Unimportant
6: 6th Grade	6: Ordinary
7: 5th Grade	7: Somewhat Important
8: 4th Grade	8: Important
9: 3rd Grade	9: Very Important
10: 2nd Grade	10: Especially Important
11: 1st Grade	11: Extremely Important

Table 3 Fuzzy numbers of grade of valuation and grade of importance [1]

Grade of evaluation	Fuzzy Numbers	Grade of Importance	Fuzzy Numbers
1	(0.0,0.0,0.1)	1	(0.0,0.0,0.1)
2	(0.0,0.1,0.2)	2	(0.0,0.1,0.2)
3	(0.1,0.2,0.3)	3	(0.1,0.2,0.3)
4	(0.2,0.3,0.4)	4	(0.2,0.3,0.4)

6	(0.4,0.5,0.6)	6	(0.4,0.5,0.6)
7	(0.5,0.6,0.7)	7	(0.5,0.6,0.7)
8	(0.6,0.7,0.8)	8	(0.6,0.7,0.8)
9	(0.7,0.8,0.9)	9	(0.7,0.8,0.9)
10	(0.8,0.9,1.0)	10	(0.8,0.9,1.0)
11	(0.9,1.0,1.0)	11	(0.9,1.0,1.0)

4. Conclusion

This study attempts to assess the most appropriate digital microwave system from the perspective of fuzzy theory. Weight values, evaluation items and grade of importance, which can be adjusted according to real situations in order to fulfill company's requirements.

The Effects on Workers in the Privatization Process in Taiwan

A case study: An empirical Analysis of privatizing SOEs

Jung-chin Chen

International Graduate School of Management
University of South Australia
cyc168@ms6.hinet.net

Abstract

This research aims at empirical analysis the effects on workers in the privatization process from a broad range of perspectives including employees, managers and representatives of labor union. Also of interest is the relationship between these variables and six measures of the effects on workers in the privatization process, such as gender, age, salary, level of education, level of position and years of experience.

The results had rejected our hypothesis (H1) of independence. It has noted that part of variables significant a relationship were observed on six measures of the effects of workers with these variables: gender, age, level of education, level of position, years of experience and salary.

Finally, the research suggests that the government, when implementing privatization policy, should consult the useful measures of industrialized countries and consider the effects on workers. Six useful strategies should be developed to enhance communication with workers and publicity, so as to adjust the resistance mentality of working for the implementation of the privatization policy.

1.1 Motivation

As the state-owned enterprises (SOEs) in Taiwan now face the great impacts and organizational change (OC) brought by privatization, liberalization and globalization, this time can be considered wartime. Following privatization of SOEs, management style and working environment have been changed rapidly. The change of the working environment has made a noTable impact on the working conditions and job security of the employees. Clearly, privatization policy has many social and economic impacts. Thus, even though privatization of SOEs has become the major trend of development for many countries in the world, promotion of privatization can easily incur strong resistance from workers. During this period of transition, the author has found leadership crises exist within the enterprise. The relationship between leadership style and worker commitment has examined by Blau (1985). A consideration leadership style was found to have a greater influence than a concern for structure leadership style (or task-oriented style) on commitment. Also, Williams and Hazer (1986) included consideration leadership style as one of their antecedents to commitment.[1][2]

It is necessary to develop an effective measure and to establish new leadership style between organization and workers through communication so as to transform

resistance into assistance. The research aims at exploring the effects on workers in the privatization and to provide leaders with useful leadership strategies as reference.

1.2 Objective

The main aim of this study is to investigate the effects on workers in the privatization process. Also of interest is the relationship of these variables with workers commitment on six factors, such as gender, age, salary, level of education, level of position and years of experience.

Hypothesis 1 (H1)

There is statistically significant no difference in the these variables with six measures of the effects on workers such as gender, age, salary, level of education, level of position and years of experience.

2. Research Methodology

2.1 Sampling Plan

The sampling included workers, managers and representatives of labor union of a large scale SOEs selected in Taiwan (omit).

Questionnaires will be mailed or emailed to workers, managers and representatives of labor union of the sampled SOEs. The sampling characters of questionnaires survey were shown in Table 1.

A Chi-square goodness of fit test on sampling and population was carried out to test gender, age and level of position as shown in Table 2. For the item of gender, the respondent of statistics ($\chi^2=2.428 < 3.841$, at the 0.05 level of significance) was accepted. For the item of age, the respondent of statistics ($\chi^2=12.472 < 15.507$, at the 0.05 level of significance) was accepted. For the item of level of position, the respondent of statistics ($\chi^2=12.472 < 15.507$, at the 0.05 level of significance) was accepted.

Table 1 Sampling Characters

Item	Variety	Sample(N)	Sample(%)
Gender	Male	792	91.7
	Female	73	8.3
Age	25 below	4	0.5
	25-34	123	13.9
	35-44	328	37.5
	45-55	305	34.7
	55 above	117	13.4
Level of education	Junior school	45	5.2
	Senior school	278	31.7
	Polytechnic Diploma	356	40.6
	University	160	18.3

	Post graduate above	37	4.2
Level of position	Top manager	11	1.3
	Mid manager	27	4.2
	Grass-roots cadre	115	13.1
	Worker	713	81.4
Years of experience	5 below	54	6.2
	5-15	132	15.3
	15-20	244	27.9
	20 above	446	50.9
Salary (per month)	NT\$30000 Below	3	0.3
	NT\$30000-50000	194	22.1
	NT\$50000-70000	589	67.2
	NT\$70000-90000	64	7.3
	NT\$90000 Above	26	3.0

Table 2 Chi-square goodness of fit test on Sampling

Item	Variety	Sample(%)	P(%)	Chi-square test
Gender	Male	91.7	89.3	Statistics ($\chi^2=2.428$) is lower than the value (3.841) at the (0.05) level of significance.
	Female	8.3	10.7	
Age	25 below	0.5	1.2	Statistics ($\chi^2=12.472$) is lower than the value (15.507) at the (0.05) level of significance.
	25-34	13.9	15.2	
	35-44	37.5	39.2	
	45-55	34.7	31.8	
	55 above	13.4	112.6	
Level of position	Top manager	1.3	1.3	Statistics ($\chi^2=7.644$) is lower than the value (7.815) at the (0.05) level of significance.
	Mid manager	4.2	3.4	
	Grass-roots cadre	13.1	12.7	
	Worker	81.4	82.4	

2.2 Data-gathering instruments

A survey questionnaire was developed to measure the responses for the six constructs of the effects on workers. Some of six constructs were refined by deleting a few items from the original list of items. Thus, using a rigorous statistical scale validation technique, the survey instrument, consisting of the refined six constructs shown in Table 3 (Chen, 2002, 2003), was developed.[3][4]

One instrument used in this study was a 25-item questionnaire adapted from Chen (2002, 2003). The questionnaire consisted of 25 items on 5-point Likert scale. On each of the 25 items workers were asked to indicate from 1 (strongly disagree) to 5 (strongly agree).[3][4]

2.3 Respond

Questionnaires were mailed or e-mailed to workers and managers of the sampled SOEs with a request to forward these to workers and manager in the department of the sampled SOEs. The survey will be conducted in three waves, spaced six weeks apart. Of the total 1450 questionnaires mailed or e-mailed, the author will expect about 865 completed and usable questionnaires were returned, yielding a 59.6 per cent response rate.

3. Data Analysis and Finding

3.1 Foreword

In this section, for each of the six measures, a Chi-squared test was carried to test the workers commitment and classification. It is interesting to examine the factors on workers in privatisation which it is felt have contributed significantly to workers and SOEs. A brief analysis of the six measures follows.

3.2 The analysis of the effects of workers on Six Factors

Chi-square test on safeguard of workers' rights and interests

With respect to Chi-square test on safeguard of workers' rights and interests represented by the items shown in Table 5. Through the analysis of Chi-square test, results showed that only the variable of years in experience in the personal condition had obvious variation at the (0.008) level of significance. The larger proportion significant, there were workers of the lower level of position stressed the importance of safeguard of workers' rights and interests.

Chi-square test on compensation of potential loss

With respect to Chi-square test on compensation of potential loss represented by the items shown in Table 7. Through the analysis of Chi-square test, results showed that 3 variables: age, years in experience and salary of per month in the personal condition had obvious variation. The item of age showed workers (55 above) having the highest commitment and workers (25 below) having the lowest commitment. The item of years of experience, at the (0.007) level of significance, indicated workers' agreement with the years of experience increasing however increasing. The item of salary of per month, at the (0.001) level of significance, indicated workers' agreement with salary increasing however increasing.

Chi-square test on education and communication

With respect to Chi-square test on education and communication represented by the items shown in Table 9. Through the analysis of Chi-square test, results showed which 4 variables: age, level of position, level of education and salary of per month in the personal condition had obvious variation. The item of level of education indicated that almost 70 per cent workers agree to factor 3, but only 60 per cent workers (post graduate above) agree to factor 3. The item of age showed workers' commitment with age decreasing however increasing. The item of level of position indicated workers' commitment with position decreasing however increasing. The item of salary of per month indicated workers' commitment with salary increasing however decreasing.

Chi-square test on leadership trusts and employee

consultation

With respect to Chi-square test on leadership trusts and employee consultation represented by the items shown in Table 11. Through the analysis of Chi-square test, results showed that 2 variables: level of education and years in experience in the personal condition had obvious variation. The item of level of education indicated that workers' disagreed to education increasing however increasing; over 70 per cent workers (post graduate above) disagree to factor 4. The item of level of position indicated mid manager having higher disagree and worker having lower disagree.

Chi-square test on participation of employees and the labor union

With respect to Chi-square test on participation of employees and the labor union represented by the items shown in Table 13. Through the analysis of Chi-square test, results showed that 3 variables: age, level of position and salary of per month in the personal condition had obvious variation. The item of age showed workers (45-55) having the lowest agreement and workers (25 below and 55 above) having the highest agree. The item of level of position indicated workers' agreement with position increasing however increasing. The item of salary of per month indicated workers' agreement with salary increasing

Chi-square test on encourage the employees to learn and to cultivate a second specialty

With respect to Chi-square test on encourage the employees to learn and to cultivate a second specialty represented by the items shown in Table 14. Through the analysis of Chi-square test, results showed which 4 variables: age, level of position, level of education and salary of per month in the personal condition had obvious variation. The item of level of education indicated that workers (senior school) is the higher agreement than workers (junior school) on factor 6. The item of age showed workers (25 below) are the lower agreement. The item of level of position indicated workers' commitment with position increasing however increasing. The item of salary of per month indicated workers' commitment with salary increasing however increasing.

4. Discussions and Suggestions

4.1 Discussions

The effects on workers in the privatization process, the analysis of six factors is presented from Table 3 to Table 15. The relationship of these variables with workers commitment on six measures, such as gender, age, salary, level of education, level of position and years of experience are shown in Table 5, 7, 9, 11, 13 and 15. Years of experience in the personal condition have a significant relationship on safeguard of workers' rights (see Table 5). Age, years in experience and salary of per month in the personal condition had obvious variation on compensation of

potential loss (see Table 7). Age, level of position, level of education and salary of per month in the personal condition had obvious variation on education and communication (see Table 9). Level of education and years in experience in the personal condition had obvious variation on leadership trusts and employee consultation (see Table 11). Age, level of position and salary of per month in the personal condition had obvious variation on participation of employees and the labor union represented (see Table 13). Age, level of position, level of education and salary of per month in the personal condition have a significant relationship on encourage the employees to learn and to cultivate a second specialty (see Table 15).

The results had rejected our hypothesis (H1). It has noted that part of variables significant difference were observed on six measures of the effects of workers in these variables: gender, age, level of education, level of position, years of experience and salary of per month.

4.2 Suggestions

The research has found various issues and impacts on workers in SOEs selected. Moreover, the research has worked out six effective measures for the government and decision-makers of the company to help them conduct successful communication with the staff, transform resistance into assistance and promote the policy of privatization.

During the process of privatization, workers' rights and interests staff ought to be taken into account and full communication should be ensured to reduce resistance. In the past, it is relatively easy to deal with substantial reforms of technology while analysis is needed to understand the reasons why workers reject reform.

Following lack of communication during the process of privatization, which leads to lack of consensus and resistance from workers. The labor union and workers are also against the company in the privatization process. Future decision-makers should prevent the labor union from political zing the issue of privatization, which will be delayed the promotion of privatization.

Focusing On The High-End Or Low-End? Local Attacking With Network Externalities

Abstract

Network externalities can encourage adoption when a network is growing in size. Network externalities, however, can also encourage abandoning when a network is getting small. Therefore, the challenger's action focusing on persuading a part of the market can eventually affect the whole market when network externalities are at work.

This paper discusses two local attacking strategies, namely, "focusing on the high-end" and "focusing on the low-end", and compares their effects. The conclusions show that the former strategy generally exhibits stronger eventual effects than the latter. Although direct effects are local, the eventual effects could be global when network externalities are strong and/or consumers have small differences in their reservation prices.

Based on our results, the incumbent should set a price keeping all installed users away from being stranded. If any installed user gives up the incumbent's technology, he or she may be the fuse to trigger the chain reaction. Thus, a better approach is to "make the fuse wet". To the challenger, local attacking strategies work better when network externalities are strong and/or reservation prices of installed users are nearly the same.

Keyword: Network Externalities, Attacking Strategies, Targeting

1. Introduction

Network externalities is the phenomenon that adopters' utility increases with the number of equivalent adopters [5] [6] [7] [14] [20]. Network externalities have proven themselves as a hot topic in the fields of economics and management. Moreover, it manifests undoubted relevance in information economies. Telephone, email [3] and computer operation systems are the most representative products characterized by network externalities. It also exhibits the property of increasing return [2] [18], and various inefficiencies [8] [11] therefore shaping a new business model in information economies.

Applicable are conventional and classic strategic thinking: building alliance, taking first-mover advantages, and managing consumers' expectation [19]. However, various counter-intuitive but insightful strategies are proposed and analyzed in the context of network externalities. For instance, allowing piracy in software markets [9], planned obsolescence [13], introducing

"clones" [10], predatory pricing under some conditions [4], and providing an adapter [1]. Analyzing the characteristics and influences of network externalities can help managers apply economic principles to improve on their decisions such as product line design, pricing strategies, property rights and taking advantage of lock-in effect [18].

We follow the research [21] that explained why challenger firm can win over incumbent firm in industries characterized by network externalities. Theoretically, network externalities stand on the incumbent's side and create enormous switching costs for installed users, or namely, the installed base. Based on the work [12], challengers have little chance to successfully penetrate into industries characterized by network externalities. However, it is interesting to note that in the history of industry this theoretical inference is not followed. The phenomenon that challengers win over incumbents takes place again and again. [21] successfully explained the phenomenon existed in growing markets. By contrast, attacking strategies in this paper can explain the same phenomenon even when markets do not grow in sizes.

One of the competitive strategies is seeking for sponsorship. Sponsorship can help one of the oligopolists to offer a lower price than marginal cost and thus gain competitive edge against the rival [15].

Another frequently cited research [17] showed that firms might race excessively and incompatibly in research and development. The government can take on the "force licensing" policy to slow down this race to improve social welfare. Our paper, on the other hand, proposes that the challenger firm can use local attacking strategies without interventions of governments.

Before we introduce this paper's purpose, we first come to the precise definition of "local attacking strategies". Marketing activities can be utilized to target the whole market or to target at a specific segment. Marketing activities, such as advertising or promotional campaign, utilized to target the whole market can be very expensive and lost of focus. On the other hand, marketing activities can be utilized to target at a specific segment. We name these marketing activities "local attacking strategies" because they do not attempt to persuade the whole market, by contrast, a particular part of the market. We will show that focusing on a rather small segment can affect the choice of the whole market in the context of network externalities.

Briefly, the purpose of this paper is to illustrate that attacking strategies by the challenger can destruct the

incumbent's installed base. In this paper, the effects of two local attacking strategies are analyzed and compared. One strategy is "focusing on the high-end" and the other is "focusing on the low-end". This paper will show that local attacking strategies not only have local direct effect, but also have global eventual effect on the number of the incumbent's installed users.

The attempt of this paper is new in the fields of industrial organization and management science. Firstly, this paper shows that network externality can amplify the effect of a challenger's attacking strategies. Although the direct effect of attacking strategies is local, the strategic effect amplified by network externality could be enormous.

Explaining the similar phenomenon, this paper attempts to extend [21] to explain the challenger's victory even without a growing market. The increasing return property of network externality is well known but, however, network externality also makes a network more vulnerable when a network is under attack.

This paper is organized as follows. The current section describes this paper's purpose, importance and status in the literature. The next section describes the model. The third section solves the problem and discusses the results. Finally, the conclusion is drawn.

2. Model

The model consists of one incumbent firm, one challenger firm and a number (M) of users. The incumbent possesses a technology and set a price for usage right in a specific time period, for instance a year. Every user in the market is assumed to have paid for the technology in the previous time period but needs to decide whether to pay the incumbent again for the coming year's usage. That is, the incumbent firm occupies the market in the beginning of the model.

This paper does not analyze the dynamic and competitive issues between the incumbent and the challenger. The focus is put on the one-shot effect of the challenger's attacking strategies and network externality between technology adopters. The analysis is limited to the scope in which the challenger takes one strategy and the incumbent is not ready to notice or react to the challenger's attack. Thus, the game theoretical view is not applied on the interactions of the incumbent and the challenger, but applied on the interactions between technology adopters.

Since the challenger is new in the market, he/she may concentrate his/her marketing resources to attract some (locally), but not all (globally), of the consumers in the market. Intuitively, "focusing on the high-end" and "focusing on the low-end" are two candidate strategies. The only decision to be made in this model is challenger's strategy.

Let us first elaborate these strategies. The term "high-end" refers to consumers, who may have higher income or wealth, possessing higher reservation prices. By contrast, the other term "low-end" refers to consumers possessing lower reservation prices. Moreover, "focusing

on the high-end" strategy is concentrating marketing resources to target consumers with higher reservation prices. On the other hand, "focusing on the low-end" strategy is concentrating marketing resources to target consumers with lower reservation prices for the incumbent's technology.

It is hard to judge which of these two strategies is better. The former, "focusing on the high-end", may lead the challenger to seize a higher-margin segment as a niche. On the other hand, "focusing on the low-end" may help the challenger expand its market share in a higher speed.

To reflect the direct effects of these two strategies, we model the former strategy, "focusing on the high-end", in a way that a challenger moves the consumer with the highest reservation price out of the incumbent's installed base. Similarly, we model the latter strategy, "focusing on the low-end", in a way that a challenger moves the consumer with the lowest reservation price out of the incumbent's installed base. The consumer, who is "targeted" by a challenger, "uninstall" the incumbent's system and stops using the incumbent's technology, and consequently leave no value to other consumers and the incumbent.

The incumbent charges a price at the end of the model to every consumer who decides to renew the contract with the incumbent. One must notice that in this paper the incumbent is assumed to set a price maximizing his/her short-term profit without considering the competition. Thus, the incumbent's price is fixed when consumer reservation prices and the strength of network externality are given. In other words, the incumbent does not expect the emergence of the challenger. Accordingly, this paper does not attempt to provide any equilibrium but the optimal move (the optimal local attacking strategy) for the challenger.

To clearly identify every consumer and his or her reservation price, we next sort and give subscript "i" to consumers by their reservation prices. Moreover, consumer Q 's reservation price is called P . Accordingly, The consumer with the lowest reservation price, P_1 , is called G_1 in this paper and correspondingly the consumer with the highest reservation price, P_M , is indexed as G_M .

Consumers decide in a sequence of C_1, C_2, \dots, C_M . Therefore, we set that there are M periods and M consumers. In the first period, the consumer (C_1 or C_M) who is targeted by the challenger refuses to pay the incumbent again. In the following $M - 1$ periods, consumers decide in a sequence (C_2, C_3, \dots, C_M or C_1, C_2, \dots, C_{M-1}) and just one consumer decides in each period, respectively. The sequence may reflect the reality well because the consumer with a lower reservation price is more sensitive to market change such as the challenger's strategic actions. On the contrary, the consumer with a higher reservation price is more satisfied with the incumbent's system thus less willing to search for alternatives.

The distribution of consumers' reservation prices indeed matters. We assume that distribution follows a

linear pattern of $P_i = a + b + r(n - 1)$, where “n” represents the number of consumers who still are installed users of the incumbent’s technology. That is, P_1 equals $a + b + r(n - 1)$ and P_M equals $a + b + r(n - 1)$. The parameter “a” thus represents the reservation price difference between consumers. On the other hand, the parameter “r” therefore represents the strength of network externality.

The linear pattern of reservation prices of consumers is a approximation of uniform distribution setting [14]. On the other hand, the linearity of network utility on the number of adopters is following the model of [21] and similar to the setting [16].

The incumbent’s price, P , also plays an important role in the effectiveness of a challenger’s attacking strategies. Intuitively, a higher price without losing any consumer can generate the maximal short-term profit. How much can the incumbent charge? In order to retain all of consumers in the system, the price cannot exceed the lowest reservation price P_1 with $n = M$. Moreover, any price beneath P_1 , statically, does not attract more consumers but only directly reduce the profit. To focus on the effect of a challenger’s attacking strategies, the price set by the incumbent is modeled to be $P = a + b + r(n - 1)$. The price set by the incumbent is modeled as a constant in this paper. The only decision is made by the challenger to choose one of the two attacking strategies.

The model operates as follows. The incumbent sets a price equal to $P = a + b + r(n - 1)$, equivalently $a + b + r(M - 1)$. Next, the challenger decides to target at C_M , the consumer with the highest reservation price, or C_1 , the consumer with the lowest reservation price. These two approaches are named “focusing on the high-end” and “focusing on the low-end”, respectively. In the mean time, the consumer targeted by a challenger does not pay the incumbent again. Finally, the remaining consumers decide whether to renew the contract with the incumbent and pay the price in a sequence specified above. The number of consumers who do not pay the incumbent again measures the effectiveness of attacking strategies.

For easy reference, we list notations used throughout this paper in the following.

C_i : the consumer with the i^{th} low reservation price

P_i : the reservation price of C_i consumer

a : the reservation price difference between consumers C_k and C_{k+1} , where k is an integer between 1 and $M - 1$

r : the strength of two-way network externality between any pair of consumers

n : the number of consumers who still use the incumbent’s technology in the current period

M : the total number of consumers in the market

P : the price set by the incumbent which is equal to P_1 with $n = M$, that is, $P = a + b + r(n - 1)$

3. Analysis

Now we start to analyze the first targeting strategy: “focusing on the high-end”. A challenger concentrates his or her marketing resources to target the consumer with the highest reservation price. The effects of such attacking strategy are shown as Figure 1.

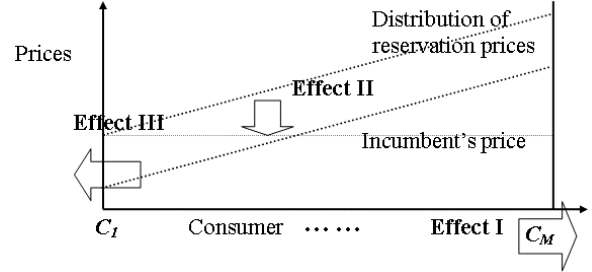

Figure 1: Effects of “focusing on the high-end” strategy

Firstly, the targeted consumer does not pay for the incumbent’s technology (Effect I), that is the direct effect. Since consumers’ reservation prices are constructed upon other consumers’ equivalent adoptions, the reservation prices of remaining consumers all drop an amount of r (Effect II). Consequently, the reservation prices of some consumers may fall beneath the incumbent’s price and refuse to pay it (Effect III). Moreover, some other consumers abandon the incumbent’s technology and the reservation prices drop more. Those effects (Effects II and III) form a self-reinforcing loop, which is triggered by the “focusing on the high-end” strategy (Effect I). Although only one consumer is affected initially by the challenger’s strategy, more than one consumer is eventually affected. The argument is proved more rigorously in the following.

Proposition 1 :

When the challenger uses the “focusing on the high-end” strategy and $\frac{a}{r} \geq 2$, eventually 2 consumers will not pay for the incumbent’s technology.

Proof:

When consumer C_M is targeted and does not pay the incumbent again, all consumers’ reservation prices drop an amount of r . Consumer C_1 ’s reservation price now becomes $a + b + (M - 2)r$, which is below the price, $a + b + (M - 1)r$, set by the incumbent. Consumer C_1 refuses to pay the incumbent again. Next, consumer C_2 ’s reservation price thereafter becomes $2a + b + (M - 3)r$, which is above the price, $a + b + (M - 1)r$, set by the incumbent when $\frac{a}{r} \geq 2$. Consumer C_2 pays the price and stays as an installed user and the stop-point of the chain reaction of abandoning. The consumers ($C_3 \sim C_{M-1}$) with a higher reservation price than C_2 deservedly pay the

price for the incumbent's technology. Only G_I and G_M are affected by the challenger's strategy. Proposition 1 is proved.

Under another condition, $\frac{k}{k-1} \leq \frac{a}{r} < \frac{k-1}{k-2}$, the effect of "focusing on the high-end" strategy would be stronger.

Proposition 2 :

When the challenger uses the "focusing on the high-end" strategy and $\frac{k}{k-1} \leq \frac{a}{r} < \frac{k-1}{k-2}$, eventually k consumers will not pay for the incumbent's technology, where k is a positive integer between 3 and $M-1$.

Proposition 3 :

When the challenger uses the "focusing on the high-end" strategy and $\frac{a}{r} < \frac{M-1}{M-2}$, eventually all (M of) consumers will not pay for the incumbent's technology.

Proposition 4 :

When the challenger uses the "focusing on the high-end" strategy and $\frac{a}{r} < 1$, eventually all (M of) consumers will not pay for the incumbent's technology.

When the four propositions are proved, we observe that the incumbent's installed base is more "fragile" when reservation price difference between consumers (a) is smaller and/or network externality (r) is stronger. The more "fragile" the incumbent's installed base is, the higher the incentive for the challenger to launch an attacking action.

To the incumbent, what are the ways to make the installed base more "solid"? The reservation price difference between consumers (a) is a characteristic of the market and may be hard to change. On the other hand, network externality (r) can be strengthened by technical functions facilitating consumers' interactions or providing convenience to interact with friends by the incumbent's technology.

Intuitively, the incumbent shall enhance consumers' value (r) from interactions. The installed base, however, becomes more fragile when network externality (r) gets stronger. Therefore, the incremental value from interactions is double-edged to the incumbent. Its advantage is that it helps the incumbent to achieve higher performance in terms of consumer satisfaction or profits. On the other side, it makes the incumbent's installed base more vulnerable. The double edge traps the incumbent into a dilemma whether to add consumer's value from interactions.

To the challenger, the values of " a " and " r " can help to estimate the effect of "focusing on the high-end"

strategy. When " a " is relatively small and " r " is relatively large, the "focusing on the high-end" strategy can be expected to have a larger effect on the incumbent's installed base.

For instance, players in online games interact frequently and closely, that represents a stronger network externality, namely larger " r ". Players in online game industry mainly consist of students. They can be considered to have similar reservation prices. A challenger may concentrate his or her marketing resources to offer attractive deals such as free usage or cash rebate. According to the propositions above, the challenger uses the "focusing on the high-end" strategy and the remaining players lose contact to players who refuse to pay the incumbent again and lose value from communication with them. Some of remaining players may feel dissatisfied and do not repurchase the incumbent's service. As more players switch their choice, the remaining players will tend to switch also. Those may form a self-reinforcing loop and make the "focusing on the high-end" strategy very powerful to destruct the incumbent's installed base.

Now let us analyze the second targeting strategy: "focusing on the low-end". A challenger concentrates his or her marketing resources to attract the consumer with the lowest reservation price. The effect of such attacking strategy is shown as Figure 2.

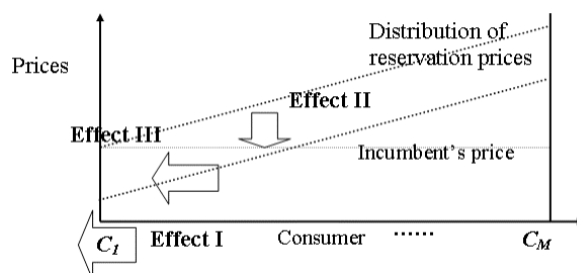

Figure 2: Effects of "focusing on the low-end" strategy

First, the targeted consumer (C_1) refuse to pay the incumbent again (Effect I), that is the direct effect. Other remaining consumers' reservation prices drop an amount of " r " (Effect II). Consequently, the reservation prices of some consumers may fall beneath the incumbent's price and refuse to pay it (Effect III). Accordingly, more consumers leave and the reservation prices drop more. Those (Effects II and III) form a self-reinforcing loop, which is triggered by the "focusing on the low-end" strategy (Effect I). Although only one consumer is affected, more than one consumers will eventually be affected. The argument is proved more rigorously in the following.

Proposition 5 :

When the challenger uses the “focusing on the low-end” strategy and $\frac{a}{r} \geq 1$, eventually only 1 consumer will not pay for the incumbent’s technology.

Proposition 6 :

When the challenger uses the “focusing on the low-end” and $\frac{a}{r} < 1$, eventually all (M of) consumers will not pay for the incumbent’s technology.

Similar to propositions 1 to 4, propositions 5 and 6 also indicate that the incumbent’s installed base is more “fragile” when reservation difference between consumers (a) is smaller or network externality (r) is stronger. The incumbent faces the same dilemma whether to facilitate consumers’ interactions and add some value to consumers via more convenient communication.

One may notice that the incumbent in this model set a price that makes one consumer (C_1) on the threshold of paying for the incumbent’s technology or not. The pricing rationale is most profitable in the short run or without competitors. The single on-the-threshold consumer, however, can be a fuse triggering the chain reaction of abandoning due to network externality. One intelligent way is to lower the price to take all consumers away from the threshold point, that is, “make the fuse wet”. Once the incumbent adopts such defensive strategy, the challenger may face difficulties to trigger the chain reaction by local attacking strategies.

Again we turn back to the challenger. The values of “ a ” and “ r ” can help to estimate the effect of “focusing on the low-end” strategy. When “ a ” is relatively small and “ r ” is relatively large, the “focusing on the low-end” strategy can be expected to have a larger effect on the incumbent’s installed base.

For instance, word processing software (such as MS Word) may be one of the markets consisting of diversifying consumers. Students, professionals and administrators may have different reservation prices. In the model, the difference of consumer reservation prices may be large. On the other hand, network externality may be low to medium, that is, the value of “ r ” may be small. Based on propositions 5 and 6, we have the theoretical result that the challenger’s “focusing on the low-end” strategy only has a limited effect.

When two local attacking strategies are analyzed, we are on the position to compare their effects.

Proposition 7 :

The “focusing on the high-end” strategy is more effective than the “focusing on the low-end” strategy when $\frac{a}{r} \geq 1$.

Proposition 8 :

The “focusing on the high-end” and “focusing on the low-end” strategies are the same effective when $\frac{a}{r} < 1$.

To be clear, proposition 1 to 8 are summarized in Table 1.

Table 1: Comparison of two local attacking strategies

Number of consumers switch Scenario	Strategy	Focusing on the high-end	Focusing on the low-end
$2 \leq \frac{a}{N_j}$		2	1
$\frac{k}{k-1} \leq \frac{a}{N_j} < \frac{k-1}{k-2}$		$k (3 \leq k \leq M-1)$	1
$1 \leq \frac{a}{N_j} < \frac{M-1}{M-2}$		M	1
$\frac{a}{N_j} < 1$		M	M

According to Table 1, we find that “focusing on the high-end” strategy is superior to the “focusing on the low-end” strategy in some cases however only the same effective in other cases. To sum up, “focusing on the high-end” strategy weakly dominates “focusing on the low-end” strategy in the context of network externality.

4. Conclusion

This paper analyzes the effects of two local attacking strategies by a challenger. The “focusing on the high-end” strategy is found superior to “focusing on the low-end” strategy in some industry scenarios.

Two local attacking strategies are shown to have larger eventual effects than the direct effects in the context of network externality. That is, local attacking strategies although only have limited direct effects but can trigger the chain reaction, which results in larger eventual effects.

By analysis of this paper, a challenger can estimate the effect of his or her local attacking strategies. When consumers have same similar reservation prices, the chain reaction is easier to be triggered and local attacking strategies have significant effects. On the contrary, local attacking strategies only have limited or local effects when consumers are very distinct in their reservation prices. The reason is that chain reaction is harder to be triggered.

In addition to consumers’ heterogeneity in reservation price, the strength of network externality should be considered when estimating effects of local attacking strategies. Strong network externality represents larger value via communication between the consumers. The power to strengthen and facilitate chain reaction is stronger when network externality is stronger. Accordingly, effects of local attacking strategies arise with network externality.

On the contrary, weak network externality hardly pushes the chain reaction to go on. Therefore, the effects of local attacking strategies become weaker in the context

of weaker network externality.

From the incumbent's point of view, it is unwise to take over as much as consumers' surplus in the industries characterized by network externality. One consumer, who is stranded or stand on the threshold of abandoning or not, can be the fuse to trigger a scale of chain reaction. A better approach is to adequately lower the price to leave more surplus to consumers, that can be regarded as "make the fuse wet" approach. Although that approach reduces the short-run profit, it can effectively retain the installed base stable and subsequently the seat of incumbent.

The strategic implication to the challenger is to find the "fuse", the consumer(s) who are least satisfied with the incumbent's current offering. "To light the fuse" can effectively take advantage of network externality. The better fuse is the high-end consumer(s) because of stronger eventual effects theoretically guaranteed by network externality. Practical targeting strategies are offering "rebate when old exchanged for new" or "special deal", or concentrating advertising and channel efforts to target at the better fuse.

Future researches extending or improving this paper can: (1) analyze the value of the timeliness of incumbent to stop the chain reaction, (2) provide defensive strategies and analyze their effects, (3) form a sequential attacking-defending game for an incumbent and challenger, and (4) consider the cost factors and subsequently provide a decision support model.

In addition, network externality between consumers may not always be anonymous, but local with identities. That is, a research may extend this paper by considering local network externality and find differences in results. Another natural extension of this paper is to consider different distributions of consumers' reservation prices. The form of distribution can indeed affect the effects of attacking strategies.

Abstract

Researchers all over have discussed and debated the contents of service quality. Multi-dimensionality of the service quality construct has been proposed. Further, researchers have attempted to prioritize the service quality dimensions. Authors have, as a part of a larger research initiative have made an attempt to analyze the prioritization among different service dimensions across different services types based on nature of service act and target of service act. Authors have concluded that a generalization of priority across all service types is not admissible. They also suggest different weights for different service quality dimensions depending upon the service types.

1. Introduction

In the 'age of customer', delivering quality service is considered an essential for success and survival [12], [18], [22] and [28]. What constitutes service quality has attracted the attention of researchers all over the world. The debate continues.

Johnston [14] suggests that one of the pressing issues before services research concerns the identification of the determinants of service quality. This should be a central concern for service management academics and practitioners, as the identification of the determinants of service quality is necessary in order to be able to specify, measure, control, and improve customer perceived service quality.

Early studies during 1980s focused on determining what service quality meant to customers and developing strategies to meet customer expectations [18]. The early pioneers of services marketing in Europe, especially the Nordic School, argued that service quality consists of two or three underlying dimensions. Lehtinen and Lehtinen [16] referred to physical and interactive quality while Christian Gronroos [13] identified a technical dimension, a

functional dimension and the firm's image as a third dimension. In later years, Parasuraman, Zeithaml and Berry [18] published empirical evidence from five service industries that suggested that five dimensions more appropriately capture the perceived service quality construct. Building on the pioneering work of the Nordic School of services management and particularly Christian Gronroos, they established service quality as the core of services marketing. Their landmark article in 1985 conceptualized service quality as a gap between consumers' expectations and perceptions [18] inspired many other researchers to examine the services quality construct within a marketing premise [2]. However, their contribution has not gone unchallenged. Much of this interest has centered on the controversy generated by their Service Quality Gaps Model [18], and particularly the SERVQUAL instrument developed to measure service quality [19]. Many researchers who have used the SERVQUAL instrument have been critical of its paradigmatic foundation, its convergent and discriminant validity, the use of difference scores and the use of negatively phrased items [5], [1], [21] and [4].

Variations from unidimensionality [11] to two, three, four, six and eight factor structures have been reported [1], [3], [5], [10], and [25]. Spreng and Singh [26] have hinted at the possible combination of some of the five dimensions due to high inter-correlations. Johnston and Silvestro [15] went on to add the customer's perspective to the 12 service quality characteristics. This led to the identification of an additional five service quality determinants: attentiveness/ helpfulness, care, commitment, functionality, integrity; it also led to a refining of some of the other definitions.

A number of other authors have also postulated their own determinants of service quality, though in some cases they appear to

have been based on Berry et al.'s [2] well-publicized work.

Lately even the developers of the instrument have produced evidence confirming the doubts expressed about the five-dimensional configuration. Thus, despite the 'many' studies which have analysed the dimensions measured by SERVQUAL, 'there is no clear consensus on the number of dimensions and their interrelationships'. This uncertainty hampers our understanding of service quality and casts doubts over the use of the SERVQUAL instrument in future research. It also shows that a considerable amount of research still needs to be done concerning the dimensionality of perceived service quality in general and SERVQUAL in particular, as called for by its developers [20].

Chowdhary and Prakash [9] have suggested a two factors' theory -that a more detailed approach is required wherein each factor needs to be considered independently and not as an aggregate dimension. They report evidence to support two-factor theory for services that was discarded by earlier researchers. They argue to differentiate between the factors and the outcome of performance along these factors. The study describes the two factors as 'vantage factors' and 'qualifying factors'. Marketers need to be selective in that certain factors behave as vantage factors while others as qualifying factors. The two are different in nature and require a differential treatment.

2. Relative importance of dimensions

Parasuraman et al. [19] have observed that their instrument (SERVQUAL) can be used to evaluate the relative importance of the dimensions of quality in influencing customers' overall perceptions of a service. The relative weight that customers seem to give to each quality dimension can be determined. One of the important result that has been reported in the early studies of relative importance is that customers are quite consistent in both their imputed and their direct rankings of the importance of the service quality attributes. In this key study, reliability was demonstrated to be the most important dimension and empathy (a composite of understanding and access) the least important across a seemingly wide array of service types. Zeithaml et al. [28] also report, using a variation of SERVQUAL that tangibles proves to be consistently unimportant. A pertinent question here is that whether such a generalization is possible. Chowdhary [8] suggest that generalizations are difficult to make

because of variation in the basic nature of services (labor or capital intensity) and that the type of industry affect the design of service. It was seen that *empathy* and *responsiveness* were found to be more important for labor intensive industry while *tangibles* and *reliability* affected the assessment of quality dimensions in case of capital intensive services. This was also confirmed by the results from a similar study done for 'Management Education' where the single most important dimension was the knowledge of the teacher (assurance).

Services USP (unique selling proposition) can be woven around different criteria (tangibility, customization, labor intensity, etc.). This criterion in turn could be the KPD (key performance dimension). Different user groups can see each type of service in turn as performing on a number of factors across different dimensions. From among these factors, some are the *key factors* and are relatively more important for the consumer. A number of these KFs could be simultaneously important for these user groups, though the relative importance of these dimensions may vary from one user group to another. There may also be a general shift in consumer preference for a dimension for example from 'medical-care' through 'patient-care' to 'hospital-care', in case of the consumers of healthcare. Their importance may also vary from one consumer to another.

3. Service types

Service classifications have been offered since early 1980s. Different authors have suggested different taxonomies based on different criterions. Of these four are noteworthy- Chase [6], Chase and Tansik [7], Schmenner [24], Wemmerlov [27] and Lovelock [17]. Chase segments by the extent of customer contact in the delivery of the **service**. Schmenner classifies **services** using two dimensions, with the degrees of interaction (generalized from "contact") and customization on one axis and the degree of labour intensity on the other. Wemmerlov [27] more recently proposed a classification scheme where the variables of differentiation are the degree of routinization of the process, the "object" of the **service** process, and customer contact. His operationalization of contact differs from both Chase and Schmenner in that he redefines it to be "direct", "indirect" or "no" contact with the customer, rather than simply as "high" or "low". Lovelock [17] has suggested categorizing services into four distinctive categories based on what a service

organisation is actually processing and how does it perform that task. A service organisation may be servicing individual customers or alternatively it may be servicing their possessions. Further the servicing may be physical as in case of hair cutting or a travel by train. Alternatively, the servicing may be intangible as in case of education, entertainment or consultancy. He therefore suggests a 2X2 classification of service processes.

Table 1: Population for Study			
		Who or what is the recipient of the service?	
		People	Possessions
		People Processing <ul style="list-style-type: none"> Hospitals and nursing homes Hotels Beauty saloons Fitness Centers 	Possession Processing <ul style="list-style-type: none"> Freight transportation Repair shops Retail outlets Laundry and dry cleaning
		Mental Stimuli Processing <ul style="list-style-type: none"> Telephone companies Management consulting MBA Education Cable operators 	Information Processing <ul style="list-style-type: none"> Accounting firms Banks Insurance Legal services

4. Research issue

The above cited literature review has discussed the service dimension and the tools to evaluate service quality. Yet it is insufficient in establishing any generic relative importance of service dimensions. Researcher believes that such a generalization may not be possible across all service types. This study seeks to make out whether some generalization is possible within service types and does that vary with classification variables. For the purpose of investigation, researcher has used Lovelock's classification.

The pertinent research question was whether the different categories of service processes show a pattern vis-à-vis the importance of different determinants of service quality (the five dimensions suggested by Parasuraman, et al.). The objective was to identify the relative importance of service quality dimensions for different service processes. For each category, four different services were identified. Thus in all sixteen services were identified. Respondents were asked to free list what they felt was important and added value to their consumption

of a particular service type. A survey of 356 respondents returned a 989 free-list items shown in table 2.

In the next phase of analysis, the free list items were classified using the five dimensions of Parasuraman et al. It was observed the price with reference to cost, fees, charges, discounts, etc. figured repeatedly and so it was categorized separately as the sixth dimension and was called 'fees'. For a list for any particular service type, we could now generate the relative importance matrix using tally marks. These were then converted into percentile scores. Thus, we could get a score for each dimension for each service type. Similarly, the score were calculated for each service process category.

5. Discussion

First, the six service quality dimensions corresponding to each of the service types were ranked based on the mean scores for the subset of four services comprising each group.

If any the ranks of service dimensions across each service type were similar, some kind of generalization of relative importance of dimensions was possible. It was decided to test the following hypothesis.

H₀: $\rho_s = 0$

Null Hypothesis: There is no rank correlation in the population; that is, different types of services have dimensions (tangibility, reliability, responsiveness, assurance, empathy, and fees) having different priorities (ranks).

H₀: $\rho_s \neq 0$

Alternative Hypothesis: There is population rank correlation; that is, irrespective of the service types, dimensions have similar priorities (ranks).

Table 2a: Spearman's rank correlation (r_s) test				
People Processing	1.00	-0.03	-0.47	-0.31
Possession Processing		1.00	0.56	0.26
Mental Stimuli Processing			1.00	0.53
Information Processing				1.00

For small values of n ($n=6$), we use Spearman's rank correlation test tables that give values for combined areas in both tails.

Table 2b: Spearman's rank correlation test tables					
N	0.02	0.10	0.05	0.02	0.01
6	0.600	0.771	0.829	0.886	0.943

Thus, null hypothesis was accepted at all the abovementioned levels of significance. It can therefore be concluded that for different service types, consumers rate service quality dimensions differently. This supports Rosen and Karwan's study [23] that the proposition that one can generically order the quality dimensions (in terms of relative importance as suggested by Parasuraman, et al [20]) for any firm is appealing, but is not likely to be supportable. The reasons for this are intuitive from a strategic operations perspective and are observable when conducting the tests for 'relative importance' across a truly broad sample of service types.

Subsequently, two-step cluster analysis procedure was deployed to reveal natural grouping (or clusters) within a data set for each service quality dimension that would otherwise not be apparent. Similarity between clusters was computed on the basis of log-likelihood method. The likelihood measure places a probability distribution on the variables. Continuous variables (tangibility, reliability, responsiveness, assurance, empathy and fees) were assumed to be normally distributed, while categorical variable (service type) are assumed multinomial.

Further, all variables are assumed to be independent. Empirical internal testing indicates that the procedure is fairly robust to violations of both the assumption of independence and the distributional assumptions. One important observation is that two-way cluster analysis in almost all cases (5 out of 6, barring reliability) resulted in 2 X 2 distributions of service types.

Once the clusters were obtained, based on Euclidean measure of distance test of differences between cluster means for small sample sizes was applied to ensure if the difference in cluster-means is significant or not at $\alpha = 0.05$.

Tangibility is clearly an important issue with services that require a more visible action that is people-processing (A) and possession-processing (B) services. Perhaps tangible cues buttress tangible actions for these cases. Customers need more tangibility to identify with services where value is created in their physical presence on the service process. Since the presence of customer is not a concern in case of services with an intangible action, customers of mental-stimuli (C) and information processing (D) have rated tangibles as low on expectations. Still it must be noted that need for tangibility is higher as we move from services targeted at possessions to services those are targeted at people (39.64 (A) > 19.758 (B); 8.34 (C) > 6.19 (D)). Tangibility, therefore, is more important an issue for universities and cinema halls than for insurance companies and accounting firms. Thus tangibility is most important for people processing services followed by possession processing, mental-stimuli processing and information processing services in that order.

Respondents from the services selected for the study rated reliability as the most important service dimension. As in most cases of services, only a post purchase evaluation is possible, customers expect service processes to be reliable to match their expectations. In case of this dimension two-step cluster analysis resulted into two clusters with people processing services as one cluster and the other three being included in the second cluster. Respondents for cluster one, are relatively less concerned about reliability perhaps because tangibility serves as a surrogate for it. All the others in cluster two rate it as quite important (Mean = 34.22 , s.d. = 7.12). Further, as we move towards services that are targeted at possessions of customers, whereby the presence of customer on the process is not necessary and the services are carried out largely in back-offices, there is a greater need for reliability of service process. More reliability is expected as

services include intangible actions. Thus, reliability is very important for information processing services (ATM-deposit, or ability of your lawyer) followed by possession processing, mental-stimuli processing and least important in case of people processing services.

Cluster analysis clubbed people-processing and information-processing as one cluster; and possession-processing and mental-stimuli-processing as the second cluster, for “assurance” dimension. Test of difference between means of two clusters was administered to ascertain if there was a significant difference in the means of two clusters. Analysis suggested null hypothesis to be accepted, that is there was no significant difference in the means. Subsequently, two clusters ((A, C) and (B, D)) based on distance of mean values of four service-types were formed and the test for differences was applied. A t-value of 2.38 (> 2.145 the critical value) was obtained and the alternate hypothesis was accepted. The difference in means was significant at $\alpha = 0.05$ for one tailed test.

Assurance, the knowledge and courtesy of employees and their ability to convey trust and confidence (competence, courtesy, credibility, security) was important for services targeted at the individual customers necessitating considerable contact between the employees and customers ((A=22.33) and (C=28.42)). Further, as the nature of service act grows more intangible the need for greater assurance was felt (C (28.42) $>$ A (22.33) and D (19.36) $>$ B (17.43)) to reinforce the confidence of customer. Thus customers of mental-stimuli-processing services (C) that require meaningful customer contact and are largely intangible (MBA teaching, management consulting, etc.), expect greater assurance from service providers. Subsequently, the importance of assurance decreases in the order: people-processing, information processing and last the possession processing.

Test of difference of means based on both, the two-step cluster analysis and distance, for responsiveness, suggested accepting null hypothesis. That is no grouping of service types was available that results into significant difference to suggest that responsiveness was more important in any one of service types or groups. In fact, responsiveness was uniformly considered as less important service dimension by respondents of all service types. In these times of transition, ours is still a deficit market economy. The customers are less expectants and waiting time is often not a big consideration. The

customer therefore accepts less spontaneity and slothfulness in service delivery. This may change as markets mature over time and customers need to be lured and pampered.

Two-step cluster analysis identified people-processing (A= 16.71) and information-processing (D= 23.19) services as one cluster (Mean = 19.95, s.d. = 6.5) where empathy is considered important. In people-processing services the presence of customer is substantial that requires service providers to make an extra effort to understand his/ her needs and make the stay pleasant. At the other extreme is a largely intangible service (information processing) to be carried out in back-office away from the customer. The customer’s concern is higher-that service be explained to him/ her, and he/she may be understood well before the provider sets out to create the service. A tangible (visible) service is more certain. Further, if it is targeted at a customer’s possession the trepidation is less. A video repair service engineer may be less empathic than a lawyer who must appreciate a customer’s concern and viewpoint. Similarly, an hotelier must be more conscious of a customer’s preferences as he/ she stays with him. Thus, empathy is least with possession-processing services (B=8.43). Mental-stimuli-processing (C= 11.67) occupies an intermediate position.

In absence of risk of personal well being (people-processing) or the risk of information processing the other services are generally available in standardized modes in near perfect markets (cable operators, telephone companies, retail outlets, dry cleaning etc.) The choice of provider therefore gets associated with the monetary cost of obtaining the service. Prices for information-processing services are very competitive (bank rates or insurance premium) and therefore the prices of these have a limited affect on purchase decision making (A= 9.06). On the other hand, the concern for well-being of self is paramount in case of people-processing services and so the cost of contentment takes a low priority (D= 5.4).

6. Deduction

Though certain trends are visible, yet the researcher would like to draw attention to some of the precincts of this study. In most cases, the notions of most of the concepts vary. Different respondents had different connotation of the same word. Say- safety/ security; reliability, credibility and assurance; location, accessibility; etc. were often used interchangeably. Ranking of dimensions also depended on the current state of

the competition in a particular industry and varied from industry to industry within a service type. While markets have matured for some industries, they are not very competitive for others. Some for example the cable operators, telephony and insurance till recently, have monopolistic tendencies.

Given the state of competition and market within the different service industries, following can be concluded:

- Tangibility is more important for services with more tangible actions. Further, the importance reduces as one shifts from services targeted at people to service targeted at possessions.
- Need for reliability is more for services with intangible nature of service act. Services targeted at possessions of the customers will also require more reliability.
- Services targeted at the individual of the customer requires more assurance than those targeted at the possessions. Further more assurance will be needed for services with intangible act.
- Responsiveness did not allow for any kind of clustering. Customers ranked it last on priority across different service types. Perhaps they are less expectant for this service dimension.
- Information-processing and people-processing services require more empathy as compared to other two types.
- Prices were considered relatively more important by consumers of possession-processing and mental-stimuli processing services.

**Business-to-business relational bonding over the internet:
some evidence from Australian service industry**

Australia

Track: Customer Relationship Management

Extended Abstract

Internet marketing and relationship marketing are becoming prevalent in Australian firms. The advent of the internet has created numerous opportunities for marketing professionals to enhance current marketing practices, including relationship marketing. However, the investigation of marketing relationships in an internet environment is scant. Further, there appears to be no investigation of this phenomenon within the context of Australian service industries. Given these gaps in the literature, the research problem investigated in this research is: How does B2B internet use affect inter-firm relationships in service industries?

Thus this paper addresses the problem: How does B2B internet use affect inter-firm relationships in Australia service industries? Essentially, I argue that internet use does not hinder exchange relationships and effective internet use may enhance exchange relationships in the long run, with the internet directly affecting communication in an exchange relationship. Therefore this research constructs a comprehensive theoretical model that summarise the relationship facilitating aspects of the internet in a B2B context. The literature does not investigate this research problem in any depth. However, a framework about internet-facilitated marketing relationship in the extant literature was integrated and synthesised with literature about internet marketing and relationship marketing to arrive at two research issues:

RI 1: How are the relational bonds in an inter-firm relationship influenced by internet use?

RI 2: How do these relational bonds interact in an internet environment?

To investigate these three research issues, a combination of qualitative and quantitative two-stage methodological approach was used. The first stage was eleven convergent interviews to build on the extant literature and to further confirm and refine the theoretical framework. In the second stage, a survey methodology was used to test the model about internet-facilitated inter-firm relationships in Australian business internet banking users. Data was analysed and the hypotheses specified in the main model were tested using structural equation modelling techniques. Thus this research involved both theory building and theory testing.

The findings of this research have implications for the two research issues. The results for the first research issue showed that the internet has little negative impact on relational bonding in the B2B context. That is, technology-mediated transactions in financial services may not be detrimental to established relationships because trade efficiencies are more of a concern for

businesses rather than the social aspects. Moreover, the impact of internet use on relational bonds of trust and dependence is moderated by the length of B2B internet use. The findings for the second research issue were that most interrelationships between structural and social bonds in an internet environment are in line with the generic literature. In addition, the findings of this research highlight some important issues in relationship marketing research. That is, inter-relationships of the relational constructs depend on the context in which the relationship exists.

The main contribution of this theory building research is the development and confirmation of a final theoretical framework about internet-facilitated inter-firm relationships. This research has both theoretical and practical implications in the area of internet marketing and relationship marketing. The framework was built from theory and empirical research to represent this process and provides a foundation for further research.

Abstract*

Collaborative filtering uses information about customers' preferences to make personal product recommendations and is achieving widespread success in e-Commerce. However, the traditional collaborative filtering algorithms do not response accurately to customers' needs. The quality of the recommendation needs to be improved in order to support personalized service to each customer. In this paper, we present novel method to improve the accuracy of the collaborative filtering algorithm. We borrow vector space model from information retrieval theory and use it to effectively discriminate the preference weights on the items for each customer. The proposed method achieves more accurate recommendations for customers who purchase similar types of products repeatedly. Our experimental evaluation on the well-known MovieLens data set shows that our method does result in a better accuracy.

1. Introduction

The explosive growth of the world-wide-web and emergence of e-Commerce has led to the development of automatic item recommendation systems. A recommendation system is based on a personalized information filtering technology, and is used to predict whether a particular user will like a particular item. Personalization service of a good quality to customer will control the success and failure of customer relationship management and e-Commerce as a whole. Many research efforts have given birth to various algorithms for such personalization services. The most representative among them is collaborative filtering. In recent years, many researches for the performance enhance of collaborative filtering have been proposed. As results, various recommendation algorithms have been proposed.

Among them, a user based recommendation system works as follows. For each user, it uses historical information to identify a neighborhood of people that in

the past have exhibited similar behavior and then analyze the neighborhood to identify new pieces of information that will be liked by the user. Despite its success, GroupLens, and other similar collaborative-filtering based recommendation systems suffer from major problems [1][2][3][4].

Collaborative Filtering treats customers with different buying patterns identically. For example, customers who purchase many products evenly and others who purchase only a few products repeatedly, obviously have different buying patterns and these patterns may be used as valuable information for recommendation systems. In our work, we propose a preprocessing method in which we take into account those buying patterns and turn them into weight calculation to derive and differentiate users from one another. We show, through experiments, that our preprocessing method indeed works better than conventional collaborative-filtering based recommendation systems.

Section 2 introduces related work about collaborative filtering. In section 3, we explain our proposed method. In section 4, we evaluate our approach on the well-known MovieLens dataset. The paper ends with a conclusion.

2. RELATED WORK

Tapestry[5] is one of the earliest implementations of collaborative filtering based recommender systems. This system relied on the explicit opinions of people from a close-knit community, such as an office workgroup. However, the case which the user does not put the comment to treat on the document is difficult be achieved for the accuracy recommendation. Later, several ratings-based automated recommender systems were developed. The GroupLens research system[1][2][6] uses a nearest-neighbor approach to find a subset of all users that have the most similar preference history as the active user. When this neighborhood is found, the similarity between the active user and a neighbor determines how much the neighbor influences the prediction for the active user. If the similarity is high, the neighbors have high influence on the final prediction. Thus, the final prediction is a weighted combination of the neighbor preferences. The above two way directly use the preference about the item of the customer. According to this reason, it's drawback that they don't recommend accuracy.

Our work, which uses the vector space model, a class of method to assign weights to each data object, is able to solve these problems.

3. Preprocessing Method

The traditional collaborative filtering algorithms directly use the preference about the item of the customer for recommend item to customer. But in this paper we associate weight showing the preference on item of each customer.

We use the vector space model[7][8] as follows. Let C be an $m \times n$ customer-item matrix containing historical purchasing information of m customers on n items. In this matrix, C_{ij} is one if the i th customer has purchased the j th item.

3.1. Vector Space Model

The following matrix $C(m \times n)$ is used to express to the preference about the item n of the customer m .

$$C = \begin{bmatrix} C_{11} & C_{12} & \dots & C_{1(n-1)} & C_{1n} \\ C_{21} & C_{22} & \dots & C_{2(n-1)} & C_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ C_{m1} & C_{m2} & \dots & C_{m(n-1)} & C_{mn} \end{bmatrix}$$

- m : Customer
- n : item
- C_{ij} : The preference about the item j of the customer i

Element C_{ij} of matrix C is the preference of the customer i to item j . $\max[C_{i1}, C_{i2}, \dots, C_{ij}, \dots, C_{in}]$ expresses the largest preference value among items of the customer i , and thus $cf_{i,j}$ of (1) is normalized preference value by the maximum.

$$cf_{i,j} = \frac{C_{i,j}}{\max[C_{i1}, C_{i2}, \dots, C_{ij}, \dots, C_{in}]} \quad (1)$$

(2) gives the customers who purchase many products evenly a low value, and gives the customers who purchase a specific product many times a high value. In (2), N represents total number of items and n_i represents the distinct number of items purchase by the customer i .

$$icf_i = \log \frac{N}{n_i} \quad (2)$$

The weight calculation of the matrix $C(m \times n)$ is done as shown in (3).

$$w_{ij} = cf_{i,j} \times icf_i \quad (3)$$

3.2. User Similarity Computation

This general formulation of collaborative filtering first appeared in the published literature in the context of the GroupLens project. The basic idea in similarity computation between set of items rated by both customers (C_1 and C_2).

There are a number of different ways to compute the

similarity between customers. Here we present two such methods. These are cosine-based similarity(4), correlation-based similarity(5).

$$sim(C_1, C_2) = \cos(\vec{C_1}, \vec{C_2}) = \frac{\vec{C_1} \cdot \vec{C_2}}{\|\vec{C_1}\| \|\vec{C_2}\|} \quad (4)$$

$$w(C_1, C_2) = \frac{\sum_{j \in I_{C_1 C_2}} (C_{1,j} - \bar{C_1})(C_{2,j} - \bar{C_2})}{\sqrt{\sum_{j \in I_{C_1 C_2}} (C_{1,j} - \bar{C_1})^2} \sqrt{\sum_{j \in I_{C_1 C_2}} (C_{2,j} - \bar{C_2})^2}} \quad (5)$$

$I_{C_1 C_2}$: set of items rated by both customers (C_1 and C_2)

3.3. Prediction Computation

The prediction $p_{1,j}$ is the prediction for customer G for item j

$$p_{c1,j} = \bar{C_1} + \frac{\sum_{i \in U_{cj}} w_{c1,i} \times (C_{i,j} - \bar{C_1})}{\sum_{i \in U_{cj}} |w_{c1,i}|} \quad (6)$$

U_{cj} : set of users who rated item j

3.3. Proposed Method

We use a vector space model for our preprocessing method. The following matrix is to add expression (3) with matrix $C(m \times n)$. It is used to computation the prediction $p_{1,j}$ of customer G on item j . ($C+W=CW$)

$$\begin{bmatrix} C_{11} & C_{12} & \dots & C_{1(n-1)} & C_{1n} \\ C_{21} & C_{22} & \dots & C_{2(n-1)} & C_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ C_{m1} & C_{m2} & \dots & C_{m(n-1)} & C_{mn} \end{bmatrix} + \begin{bmatrix} W_{11} & W_{12} & \dots & W_{1(n-1)} & W_{1n} \\ W_{21} & W_{22} & \dots & W_{2(n-1)} & W_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ W_{m1} & W_{m2} & \dots & W_{m(n-1)} & W_{mn} \end{bmatrix} = \begin{bmatrix} CW_{11} & CW_{12} & \dots & CW_{1(n-1)} & CW_{1n} \\ CW_{21} & CW_{22} & \dots & CW_{2(n-1)} & CW_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ CW_{m1} & CW_{m2} & \dots & CW_{m(n-1)} & CW_{mn} \end{bmatrix}$$

(7) is similarity measure of customer G and G

$$w(C_1, C_2) = \frac{\sum_{j \in I_{C_1 C_2}} (CW_{1,j} - \bar{CW_1})(CW_{2,j} - \bar{CW_2})}{\sqrt{\sum_{j \in I_{C_1 C_2}} (CW_{1,j} - \bar{CW_1})^2} \sqrt{\sum_{j \in I_{C_1 C_2}} (CW_{2,j} - \bar{CW_2})^2}} \quad (7)$$

(8) is the prediction $p_{1,j}$ is the prediction for customer C_1 for item j

$$p_{c1,j} = \bar{CW_1} + \frac{\sum_{i \in U_{cj}} CW_{c1,i} \times (CW_{i,j} - \bar{CW_i})}{\sum_{i \in U_{cj}} |CW_{c1,i}|} \quad (8)$$

4. Experimental Evaluation

4.1 MovieLens Database

We use the MovieLens dataset[9]. The database contains ratings from 6,040 users on 3,900 movies. User ratings are recorded on a numeric five-point scale. We divide the data set into a training set and test set in the ratio of 8:2. We use MAE(Mean Absolute Error) to evaluate the precision of the forecasting.

$$|\bar{E}| = \frac{\sum_{i=1}^N |e_i|}{N} \quad (7)$$

4.2 Experimental Result

We implemented two different similarity algorithms pure cosine, correlations and tested them on our data sets. For each similarity algorithms, we implemented the algorithm to compute the neighborhood and used weighted sum to generate the prediction. We ran these experiments on our training data and used test set to compute Mean Absolute Error(MAE).

Figure 1 Impact of the similarity computation measure on user-based collaborative filtering algorithm. (No preprocessing data)

Figure 1 shows the experimental results with no preprocessing dataset. Figure 2 shows the experimental result with preprocessing dataset. It can be observed from the results that correlation computation for preprocessing method has advantage, as the MAE is significantly lower in this case. Hence, we select the adjusted preprocessing method for the rest of our experiments. Figure 3 shows experimental result that MAE of customers who purchased only a few categories of products repeatedly is lower than customers who purchased many different types of products evenly. Many customers in e-Commerce environment have tendencies to repeatedly purchase similar group of products over and over again.

5. Conclusion

Recommender systems provide powerful new technology for extracting additional value for a business. These systems benefit users by enabling them to find items they like. Conversely, they help the business by generating more sales. Recommender systems are rapidly becoming an indispensable tool in e-Commerce and need for innovative technologies are overwhelming especially,

for improvement of accuracy of recommender systems.

Figure 2 Impact of the similarity computation measure on user-based collaborative filtering algorithm (preprocessing data)

Figure 3 Sensitivity of the genres size on user-based collaborative filtering algorithm

In this paper we presented and experimentally evaluated a new preprocessing method for a user-based recommendation system. Experimental result showed that our weight calculation method provides more accurate recommendation than those provided by traditional user-based collaborative filtering techniques.

Future Strategies for a Click-and-Mortar Bank: A Case Study of the Nordea Group

Michael Holm Larsen
Department of Informatics
Copenhagen Business School
Denmark
mhl.inf@cbs.dk

Niels Bjørn-Andersen
Department of Informatics
Copenhagen Business School
Denmark
nba.inf@cbs.dk

Abstract

The case study describes one of the most ambitious and successful attempts of creating a Nordic based large international financial service company, capable of spearheading the transition to the digital economy. Nordea is in the midst of various transformation processes across the organisation due to several years of multiple cross boarder mergers and acquisitions, new composition of the group executive management, increasing thrives towards automation of business processes to reduce costs, and different innovations involving a change of the roles of value network partners.

The focus of the study is on the future e-business challenges to the Nordea Group internally, in its collaboration with network partners, in its utilization of the largest number of on-line customers of any bank (3,1 million in 2002), and the implications for the value proposition of the Nordea Group customers.

1. Introduction

A networked world entails entirely new ways for the financial sector to generate and protect customer value. This is a case study of the largest financial services group, Nordea, in the region of the Baltic Sea with approximately EUR 251 billion in total assets. The case focuses on the changing role of business partners and the customer value proposition of the Nordea Group.

Nordea (short for Nordic Ideas) has a very large customer base containing 9,7 million private customers, 1 million corporate customers and 500 large corporate customers. The distribution network of Nordea is the most comprehensive in the region entailing 1,245 bank branch offices in 22 countries, and 40.000 employees.

2. The History – An Ongoing Process of Mergers and Acquisitions

A brief historic outline of the Nordea Group reveals an ongoing process of mergers and acquisitions. The Nordea Group was established in March 2000. The merger of the two groups MeritaNordbanken and Unidanmark (parent company of Unibank) resulted in the creation of the Nordea Group, which in 2002 was the leading financial services group in the Nordic and Baltic region. The group is listed on the stock exchange in Copenhagen, Helsinki and Stockholm, and had a market capitalisation of EUR

15.6bn at that time.

The MeritaNordbanken-Unidanmark merger and the acquisition of Norwegian Christiania Bank og Kreditkasse was expected by top-management to create annual synergies of EUR 360m when fully realised by the end of 2003. To ensure the further improved efficiency of the Group, a second wave of integration process had been initiated. This second wave was expected to create annual synergies of the same magnitude when fully realised by the end of 2004.

An overview of the many M&A's is shown in the following figure.

Ten Years of Nordea's History

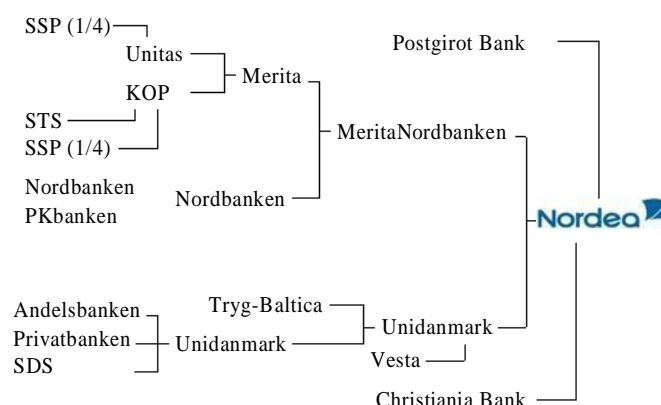

Figure 1: Ten Years of Nordea's history.

3. The Market and Strategic Focus

The Nordic countries (Denmark, Finland, Norway and Sweden) are the home market of Nordea. The three Baltic states of Estonia, Latvia, and Lithuania as well as Poland are seen as emerging markets for Nordea. The proportion of Nordea's loan portfolio provided to customers in the Nordic countries at the end of 2001 was 88% of the total loan portfolio.

Nordea has significant positions in Nordic banking markets, i.e. 40 per cent market share in Finland, 25 per cent in Denmark, 20 per cent in Sweden and 15 per cent in Norway. Also, in the Nordic insurance market Nordea has significant positions. In life insurance the figures are: Finland 35%, Denmark 10%, Norway 9% and Sweden 6%. Furthermore, Nordea is a leading asset manager in the Nordic financial market with EUR 100 billion (including

private banking) under management.

Nordea also operates on an international basis. The Group has a network of international branches and representative offices to support its Nordic and international customers.

Nordea wants to be the preferred partner of Nordic and international medium-sized companies, large corporate customers and institutional customers in this region. Outside the Nordic and Baltic Sea region, Nordea operates to support core customers and competencies through its own units or partners. Nordea is also a leading international shipping bank. Nordic and selected European asset management products and services are offered to international institutional customers, and private banking products are offered to high net worth individuals in selected European countries.

The strategic direction of Nordea is market leadership and growth, which are closely linked. Nordea has a clear strategy for growth. Nordea will work to further deepen the customer relationship and increase customer loyalty and thereby business volumes with existing home market customers. In the Baltic Sea region, Nordea will grow through increasing market shares achieved by organic growth as well as acquisitions. Being a universal bank and bancassurer, Nordea offers a broad range of financial solutions and advisory services, focusing on opportunities for cross-selling and up-selling. The role of branch offices is changing into focused service, advisory centres and sales offices along with the intensified use of the Internet, call centres and mobile banking. Nordea is and aims to remain a world e-leader in e-based financial solutions.

4. New Composition of Group Executive Management and the Organisation in Nordea

Following the appointment in summer of 2002 of Lars G Nordström as new Group CEO, the composition of and the responsibilities within Nordea's Group Executive Management was changed from 1 October 2002.

A new organisational unit, Group Processing and Technology, was established with the responsibility of central production and processing as well as coordination of Group-wide integration projects. According to the news release, "The new unit will speed up consolidation and integration and free up resources in business areas, thus enabling an even stronger customer and business focus". The new unit will consist of Group IT, Electronic Banking, Global Operations Services and Production & Productivity. The focus on Group Processing and Technology chaired by the deputy group CEO underlines that information technology continuously maintained its key role as the most important business enabler.

The new Group Executive Management team announced a plan to speed up and complete the transformation of Nordea into a fully integrated Nordic financial services group. "We will act as a team and each of us will take on Group responsibility for implementation of our Nordic strategy. We will concentrate on our strengths, compete and continuously improve

performance to create value for shareholders and customers", says Lars G Nordström, Group CEO of Nordea.

Nordea operates in three business areas: Retail Banking, Corporate & Institutional Banking, and Asset Management & Life. Each business area is responsible for financial results, customer relations, distribution, products and business development and support. In 2001 the revenue split between the different business areas was approximately: Retail Banking 71%, CIB 21%, Asset Management 4.1%, Life 1.3% and General Insurance 6.4%.

Nordea has three vital support functions, i.e.

- *Group Processing and Technology* includes Group IT, Electronic Banking, Global Operations Services and Production and Productivity.
- *Group Corporate Centre* includes Group Credit and Risk Control, Group Treasury, Group Planning and Control, Group Finance, Investor Relations and Group Corporate Development.
- *Group Staffs* includes Group Support and Procurement, Group Human Resources, Group Identity and Communications, Group Legal and Group Compliance.

The organisational chart of the Nordea Group is shown in figure 2.

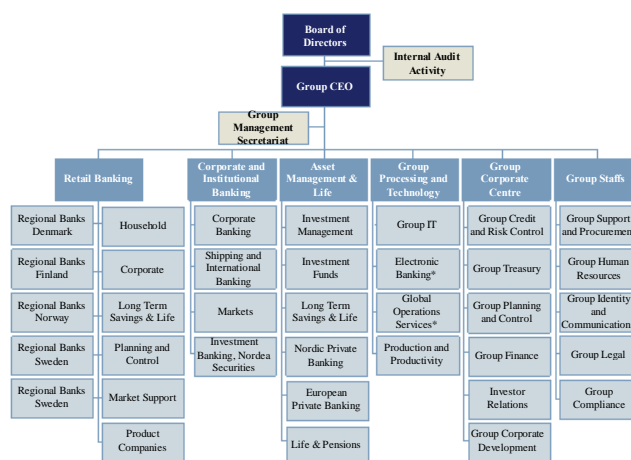

Figure 2: The organisational chart of the Nordea Group.

4.1 The Nordea Group Mission and Vision

The **mission** of the Nordea group is: "Making it possible. By providing a broad set of seamless and easily accessible financial solutions and competitive advisory services, Nordea helps customers where we operate to reach their objectives".

The **vision** of the Nordea group is: "We will be valued as the leading financial services group in the Nordic and Baltic financial markets with a substantial growth potential. We will be number one or number two or show superior profitable growth in every market and product

area in which we choose to compete. We will have the leading multi-channel distribution with a top world ranking in e-based financial solutions.”

4.2 The Nordea Group Values and Performance

The **values** of Nordea are:

- “We create value. We thoroughly understand our customers and anticipate their financial needs and we always try to generate added value for each customer. We learn from our colleagues and share Nordic ideas.
- We are innovative. We explore our competencies and try out new ideas to improve existing services, create new solutions or meet new needs. We embrace new technology and are committed to excel through continuous improvement.
- We are empowering. We respect our customers and proactively offer financial solutions and services making their lives and business activities easier. We make decisions close to our customers and exercise leadership through clear guidelines, objectives and follow-up and transparent information.
- In our operations, we are committed to a Nordic heritage of freedom, equal opportunities, care for the environment and good citizenship including ethics, honesty and sincerity.

The Nordea Group considers **performance** as:

- “We will create value for our shareholders measured by total shareholder return in the top five of our peer group of European listed financial services companies.
- We will enhance value through concentration on core business, stable and broadly based growth of revenue, operational excellence and an optimal use of capital combined with balanced risk-taking.
- We will rank among the best financial services companies in measurements of customer satisfaction and brand loyalty.
- We will attract, develop and retain highly motivated, competent and empowered employees. Measurements of Nordea employee expertise and motivation are to show continuous high levels of employee satisfaction.
- We are committed to always improve but never claim to be perfect.”

5. Financial Status and Changes in Market Capitalisation

On August 22, 2002, Nordea released their Interim Report for the Second Quarter 2002 concluding: “Stable development in our core earnings and a satisfactory credit quality form a strong basis for our business. The divestment of the General Insurance activities will further increase our earnings stability. While maintaining a sharp

focus on cost control we are investing in future growth and increased efficiency”, says Thorleif Krarup, (the former Group CEO of Nordea). Furthermore, the interim report explained:

“Operating profit before investment earnings is EUR 409m, and unchanged compared to first quarter. Total income is EUR 1,513m, which is up 1% on first quarter, supported by growth in loans and deposits, net interest income is up 2%, and strong commission income is up 4%. Total expenses are EUR 1,065m, and are up 3% on first quarter, reflecting investments in the second wave of integration. Satisfactory credit quality is maintained. Loan losses are down to EUR 56m (EUR 63m) corresponding to 0.16% of loans, annualised. Operating profit is EUR 315m.

Weak equity markets resulting in investment earnings of EUR -50m. The financial buffers in Life operations were satisfactory. Pension fund allocation is EUR 152m, which reduced pre-tax profit correspondingly. Integration and focus on core areas were stressed. Sale of General Insurance was concluded by the end of September 2002. Finally, the second wave programme consolidated into 15 main projects”.

Figure 3 presents the share performance and the value creation in Nordea compared with Nordic peers until week 39 of 2002.

	Absolute performance since YE 2001, %	Absolute performance last 12 months, %	Absolute performance 5 days, %	Total shareholder return ⁽¹⁾ since YE 2001, %	Total shareholder return ⁽¹⁾ last 12 months, %	Market capitalisation, EUR million

Note: Last closing prices as of September 26, 2002

(1) Total shareholder return is defined as growth in the value of a shareholding over a specified period, assuming that dividends are reinvested to purchase additional units of equity at the closing price applicable on the ex-dividend date.

(2) BEBANKS Index = The Bloomberg Europe Banks and Financial Services Index is a capitalisation-weighted index of all companies involved in the bank and financial sector of the Bloomberg Europe 500 Index. The index contains of today 73 shares. The index was developed with a base of 100 as of December 31, 1996.

Figure 3: Share performance and the value creation in Nordea compared with Nordic peers.

In his comments on the financial performance, Nordea Group CEO Lars G Nordström says in an interview with the Danish paper Jyllands-Posten: “Not only must Nordea employees run faster and face tough cost-cutting measures, they must also learn to hate to lose to their competitors”, “Our asset management must be better than that of Den Norske Bank, and our payment service must be better than Danske Bank's”. And he went on, “As a branch manager in Nordea I must hate that you as a branch manager in Danske Bank is better than me!”.

6. The IT Situation of Nordea

Nordea increases efficiency and integration through consolidation of IT production. The current IT operations in all four Nordic countries will be merged into a common IT platform to support increased productivity and higher cost efficiency. Consolidation of IT production is a major initiative in the ongoing second wave of integration

programme. The aim of the programme is to simplify, unify, speed up and re-engineer internal processes and to consolidate and share group infrastructure across borders and business areas in order to benefit from the scale of Nordea.

The IT production comprised some 1050 employees and had a cost base in 2002 of around EUR 330m mid 2002. According to the plan this would have to be consolidated and incorporated with contractual obligations for delivery, quality etc to the customers in the business areas and group functions. However, due to the many mergers, and a very business oriented IT-strategy, the architecture was extraordinary complex. Nordea had any type of software and operating system found in any bank in the Nordic region. It was believed that a policy of reducing the number of technological platforms each of which was to be consolidated into one single location, standardised network and desktops would have a significant impact on the Group's future cost development.

The committed cost saving potential is approximately 20 per cent of the future overall production costs without executing the planned consolidation process. The effect will be gradually increasing with full-year sustainable effect after 4 years estimated at EUR 70m. The largest cost reductions emerge from centralised and standardised hardware and software and reduced costs for licences. Expected investments of EUR 60m will be accounted for in 2002-2004 resulting in a positive cash flow from 2004, among other things resulting in downsizing by around 250 employees over the period

The in-house solution was expected to create large cost savings while maintaining control and future flexibility. This has been chosen after thorough analyses of several possible solutions including outsourcing.

7. e-Business Achievements

Nordea pursues a Multi-Channel strategy, where customers can combine their use of channels and select the most convenient channel at any given moment. With high accessibility, integration and efficient business processes in all channels, Nordea wants to ensure the highest customer satisfaction and services that meet customer's expectations. Knowledge about the customers is seen as the focal point for the development of integrated e-solutions. Accordingly, Nordea aims to develop similar system for customers and employees in order to provide consistent customer experiences and support the Multi-Channel strategy.

Customer satisfaction and retention will be further improved with the integration of e-solutions throughout all business processes of Nordea. Increased internal and external use of electronic channels/e-solutions/internet technologies shall further improve the supporting of the relationship between Nordea customers and employees.

Nordea offers a variety of eBusiness solutions to their B2C as well as their B2B customers. Some of the most important examples are presented below:

E-payment and Solo Market. Net customers can make secure online purchases using e-payment. In 2002 Nordea had over 1,800 e-payment agreements with vendors who accept e-payment and more than 600 are represented at the electronic marketplace Solo Market, accessible from the national web site in Denmark, Finland, Norway and Sweden. Online buyers thus have convenient access to a wide range of goods and services - including customers using WAP and GPRS phones.

For e-commerce vendors, net customers are an ideal target group, sufficiently large in number, with modern attitudes and purchasing power, familiar with online operations. By accepting e-payments, vendors eliminate invoicing and credit risks. This is particularly important with a large number of small transactions.

Furthermore, via Solo Market, vendors get access to buyers in market places in Denmark, Finland, Norway and Sweden. Nordea's local home pages (www.nordea.dk, www.nordea.fi, www.nordea.no and www.nordea.se) have become important portals, as online customer typically visits the e-banking services 4 to 5 times on average a month via these portals.

E-invoice. E-invoice is a kind of semi-direct debit - an e-invoice sent to the customer's or buyer's computer rather than printed on paper. A company that uses online invoicing saves on postage costs and can provide better service in an interactive online customer relationship. A customer using e-invoice can receive an invoice directly to his computer, and approve payment without having to retype the details. Via this online invoice, the customer can also link to the online service of the vendor in order to obtain more information. The main emphasis has been put on consumer invoicing. B-2-B invoicing is going to be the next step.

E-identification and E-signature. Many enterprises and public sector institutions need to be able to identify their online customers/clients. As early as 1992 the insurance companies in Finland began to use bank delivered e-identification. In dealing with authorities, this service can be used for example to send information to the corporate register maintained by the National Board of Patents and Registration of Trademarks. Net customers can also sign agreements with third parties using their electronic IDs as a signature. There is also significant potential for an electronic signature of contracts.

E-salary. E-salary is a service designed to enable employees to browse through their monthly salary data electronically via e-Banking services. Thus, the sending of a pay slip on paper will no longer be necessary. A substantial benefit is also that the pay slip details are saved in files thereby providing the user access to earlier salary data.

CoinClick (www.coinclick.dk) is a micro-payment system allowing service providers to charge for small amounts in a very easy, secure way. It was developed and launched in August 2002 by the two largest banks in Denmark, i.e. Danske Bank and Nordea, in corporation with the association of regional banks, the electronic payment processing company PBS, and the largest Danish

telecom operator TDC (Tele Denmark Communication). Among them these organisations have 1,5 million Internet bank customers and 1,9 million users of mobile services.

CoinClick is an Internet account - a type of 'web wallet' - for the payment of small sums ranging from approximately 8 cents to 8 Euro. Users can establish an account on Coin Click's home page or via their net bank. By using CoinClick customers can easily pay for digital services (music files, invoices, financial advice and sports news, etc. using Internet and mobile phones.

CoinClick offers two types of accounts: Payment in advance and payment in arrears. While the former is free, payment in arrears accounts cost only one DKK per month for the buyer. For vendors, fees depends on sales volume, but will typically be around 10%.

Identrus™ LLC and SWIFT on TrustAct. Identrus is a provider of global e-commerce trust systems that delivers validation and warranty protection for B2B eCommerce.

SWIFT (www.swift.com) and Identrus™ LLC (www.identrus.com) have entered into an alliance to offer a joint solution to facilitate business-to-business (B2B) trusted communication and give financial institutions. Based on Identrus' identity trust services and Swift's messaging capability, financial institutions all over the world can help their corporate customers identify trading partners, trust their communications implicitly and protect themselves in the event of a dispute.

Swift's internet-based messaging service, TrustAct, enables banks to provide secure delivery and receipt of messages that businesses exchange on the Internet. In addition, TrustAct keeps a log of business-to-corporate business messages and provides full non-repudiation. This non-repudiable evidence, together with the Identrus system non-repudiation of digital signatures, is essential for audit trails or dispute resolution.

In June 2002, Nordea agreed with the e-market place for the forest industry, PapiNet (www.papinet.org), to use TrustAct. Hereby, Nordea integrates banking into e-business flows of the global forest industry. PapiNet was initiated by the forest industry to facilitate standards of communication and commerce.

PapiNet is the global initiative to develop, maintain and promote the implementation of global electronic transaction standards for the paper industry. The purpose is to facilitate the flow of information and facilitate computer-to-computer communications among all parties engaged in the buying, selling, and distribution of forest, paper and wood products. The set of standards is referred to as the PapiNet standard. The standards include common terminology and standard business documents (e.g. purchase orders, shipping notices, and invoices).

Nordea and PapiNet have modelled a solution to integrate security and banking services into the business-process messaging of the global paper industry. The joint solution provides cost reduction potential for PapiNet members due to integrated financial and business-process messaging, simplified dispute resolution and global Internet-initiated payments provided by the

banks of their choice. The solution builds on Identrus PKI security and Swift's TrustAct messaging infrastructure. It covers the entire value chain from order to settlement.

The various e-business initiatives are a proven success as illustrated in the following numbers:

- 3.100.000 e-customers of the 9,7 million private customers
- 110 million Internet log-on per year
- 125 million Internet payments per year
- 5+ million calls per month - and 85% of the calls stay in the IVR

Also, the numbers show that Nordea is well ahead in the transformation from a traditional bank to a click-and-mortar bank.

8. The Role of Banks in Mobile Payment Systems

Mobey Forum is a global, financial industry-driven forum with over 30 members. Mobey Forum's mission is to encourage the use of mobile technology in financial services. Nordea is one of the founders of Mobey Forum. The common denominator for all Mobey Forum members is their commitment to accelerating the take-off of user-friendly mobile financial services by promoting open, non-proprietary technology standards for services like payment, remote banking and brokerage.

Nordea believes that mobile net-terminals will play an increasing role because it is personal and trusted. Everyone will have one, it is always near and it is always on. It will eventually be connected to the Internet - all the time. It can be a card reader for one-hand operated e-bank-logons and card payments. Blue tooth and similar technology make it ideal for machine-to-machine interaction.

There is divergence of opinions on Telco's future interest in, and ability to provide efficient payment services in competition with banks. Never the less, it is an increasing threat for banks that value network partners as Telco's previously only providing all types of communication access, etc. now are engaging in providing payment solutions to customers - a threat that is not only prevailing on the B2C market, but also on the B2B market.

Payment methods related to mobile phones can broadly be classified into two categories: e-money (pre-paid cards as well as network-based electronic money) and "conventional" electronic payment systems (e.g. bank accounts transfers) through wireless access, where new electronic access to otherwise conventional payment mechanisms is provided. Payments by mobile phone further contribute to blurring the distinctions between the participants in payment systems (banks, non-bank financial institutions, telephone companies, internet access providers), cf. Arbussá (2000).

To conclude, although nowadays banks continue to be at the centre of the retail payments system in Europe, the role of financial intermediaries in the provision of

payments systems is changing. Since electronic payment technologies require large fixed investments and often networks that exhibit significant economies of scale, we are witnessing a process of alliances among firms that intervene in payment systems. These alliances are not confined to banks or other financial institutions, but include technology vendors and telecom operators as major participants.

9. Redefining the Value Proposition?

The head of E-banking in Denmark Jens Galatius was looking through his office window at the water in Copenhagen Harbour and the skyline of Copenhagen city on the other side of the water.

“It is clear that the overall strategy of moving the banking business from traditional cash and asset management to a net-centric click-and-mortar financial institution was going to increase the need for new e-business systems. But it is not quite clear what would be the most urgent agenda”.

Furthermore, he was wondering how Nordea better could leverage upon its large customer base in the Nordic and Baltic countries. But the water reflecting the skyline did not provide an answer.

Moreover, he considered the future role of banks in the relationship with customers and partners. He started sketching a “diamond” (see the figure below) in order to better focus on the individual relationships between the actors. The worrying scenario was that telecom companies could be providers of network services as well as transaction payment services. This clearly represented a challenge that banks in general and The Nordea Group in particular should be aware of.

Figure 4: Nordea's relationships with customers and partners.

As other players were likely to enter the competitive arena, a re-examination of the value proposition might be relevant. The race is set on keeping and moving products (and customer segments) from business partners as Telco's in a profitable way. Hence, a question that needs to be addressed from the Nordea Group is: “What kind of

services will be demanded from the customers - and to what extent may Nordea have the possibility of being the preferred business partner?”

More considerations went through the mind of the e-banking director and he started listing different challenges, focus areas and initiatives. The list contained the following (non-prioritised) items:

1. Further develop multi channel distribution - online, offline and interfaces. Attractiveness and difficulties.
2. Increased emphasis on business process automation, like straight through processing (STP) between the ERP-system and the customers.
3. What would customer orientation entail in the future?.
4. Data mining for increased customer intimacy.
5. Increased digitalisation of customer service introducing more self-service and making it more attractive.
6. Integration of systems with those of corporate customers - such as development and deployment of Identrus and TrustAct to other industries than the forest industry
7. Establish collaboration with key corporate customers on R&D
8. How can Nordea create an enhanced value proposition to its corporate customers from being present in all Nordic and Baltic countries?
9. ...

You are a consultant trying to facilitate the Nordea Group pursuing their goals – what do you recommend – and why?

10. Discussion

In this section, the questions for the students are presented. Also, possible models applicable for analysis of the case are presented. Finally, some reflections upon the first teaching experiences are presented.

10.1 Questions to the Nordea Case

The list of questions to be addressed is:

- [Q1] How would you assess the e-business status of Nordea compared to other banks, in the B2B area as well as in the B2C area?
- [Q2] To what extent does the financial situation and market capitalisation of Nordea compared to Nordic peers constitute a “burning platform”?
- [Q3] What do you regards as the major value proposition of Solo Market?
- [Q4] How would you assess the key strategic options of the Nordea Group?
- [Q5] (Please refer to the list in the last section of the case for a list of possible strategic initiatives. Which of these do you find most appropriate? Would you

suggest others? Formulate a vision for the chosen ones, and argue why).

- [Q6] Nordea holds the largest customer base among the Nordic Banks, but the market shares is not the same in the different countries.. When developing new e-services, Nordea wants to exploit the large customer base and the fact, that the bank covers all the Nordic and Baltic countries. What advice could you provide the top management?

The questions are aimed at students studying for a Masters of Science in business administration related to information technology and/or e-business. Moreover, the questions should be appropriate irrespectively of whether the students are in the beginning of a MBA-program or in the end of a strategy course.

10.2 Models Applicable for Analysis

The case study invites to discuss an array of challenges at the financial institution Nordea. Several strategy-related models may be applied to the analysis of the case study, e.g. Hax & Wilde (1999), Hamel (2000), Hackbarth & Kettinger (2000) and Porter (2001).

The attractiveness of the industry may be analysed based on Hackbarth & Kettinger (2000) and Porter (2001) highlighting the e-business imperative of the industry analysis, and in particular stressing the e-banking bargaining power of multi channels, offline and online, and end users (B2B as well as B2C).

Hamel (2000) framework for business concept innovation building upon the resource-based view and the core competences tradition, is especially relevant in evaluating the development and deployment opportunities of Identrus and TrustAct in other industries than the forest industry, emphasising customer interfaces and the value network.

The Delta model proposed by Hax & Wilde (1999) provides several possibilities for analysis including product strategy, data mining for increased customer intimacy, collaboration with key corporate customers on R&D, and "System Lock-In" through partnership and standardised relations with selected actors in the business value network.

10.3 Reflections from First Test-Run

The Nordea teaching case has successfully been used at an introductory seminar of the 18 month part-time EMBA Global e-Management www.gem.cbs.dk offered at Copenhagen Business School. The learning goals were partly to introduce the students to strategic analysis and decision-making in a complex business world, partly to emphasise e-business challenges and solutions in a particular industry. The students had two hours to analyse the case in groups after having read it. Further, they had to present the answers to the questions before the e-banking director of Nordea Denmark at their domicile. After the presentation, the questions and answers were discussed facilitated by the e-strategy professor and program

director. Although the students had only just started at the MBA-program, their analysis pin-pointed the key-strategic issues.

National Open University
Yudah University
Taiwan
Oliver_lin@tp.edu.tw

Abstract

USA small and medium firms facing a more competitive environment in the Internet era have no choice but to rely more on IT to improve the quality of their products and management practices. IT seems already to play a crucial role in the development of new opportunities including E-Business. The growth in IT investment indicates an increased awareness of the importance of adopting new technologies to remain competitive and take new challenges.

The main research hypotheses stipulate that the investment in IT will have a direct impact on firm's performance that certain organizational and personal factors will interact to affect the overall performance. This study cited Regress, Factor Analysis, Discriminant Validity Analysis, Skewed, Path Coefficients and Varimax Rotation to test hypothesis.

The results of this study, besides testing the instrument for assessing IS variables in the context of a developing economy, lend support to prior research findings. User satisfaction with IS had a significant impact on performance. The direct impact of IT investment on performance was not detected. This study found an indirect effect of investment in IT on performance. Many other IS variables did affect performance.

1. Introduction

E-Business is expected to experience fast growth over the next several years. Forrester Research, Inc. of Cambridge, Mass., forecasts that revenues generated by e-Business will be as much as \$6.9 trillion by 2003. By 2002, e-tailing, a category of e-Business that involves the purchasing of consumer goods and services online, will be a \$41 billion business, compared to a forecasted \$12 billion in revenues at the end of 2000, according to Jupiter Communications, Inc., a New York market research firm [1]. A study done by the University of Texas revealed sales revenue over the Internet in 1998 was more than \$300 billion and employed more than 1.2 million workers [2]. These figures are increasing rapidly. Figures from Forrester, Gartner, IDC, Jupiter and others all predict that worldwide business-to-business (B2B) e-Business will exceed \$13 trillion by the year 2003 [3].

The expanding literature on electronic commerce is primarily focused on business-to-consumer (B2C) e-Business, although business-to-business (B2B) e-Business has a larger potential impact on the economy

[4,5]. Predictions for worldwide e-Business exceed \$3 trillion in 2003 with growth rates exceeding 100% per year. GartherGoup estimates that worldwide B2B e-Business will surpass \$7.29 trillion in 2004, close to 7% of the forecasted total global sales transactions [6]. Vennat (2000) says, "The beauty of e-commerce is that a business does not have to be big to win big. Information technology allows companies of all sizes to improve productivity and extend their reach to a broad customer base; innovation is the name of the game". It is crucial to study the efficiency and effectiveness of investing in Information Technology (IT), specially focusing on e-Business in selected industries.

1.1 Theoretical Foundation

To examine the contribution of IT to output, it is helpful to work within the well-defined framework of the theory of economic production. This theory postulates that the output of a firm is related to its inputs (one of which will be IT) via a production function and predicts that each input should make a positive contribution to output. Also, the marginal cost of each input should, on balance, be offset with production of at least equal benefit.

1.2 Definition of Terms

1.2.1 E-Business

Numerous definitions have emerged since the introduction of e-Business. Experts define e-Business as the integration of business processes; enterprise applications, relationships and organizational structure to create a high-performance business model, capable of delivering differentiated business value [7,8,9,10]. The implementation of e-Business applications includes the reengineering of business processes and the use of the Internet technology to disseminate information electronically [8]. Wigand [11] views e-Business as the seamless application of Internet technology alone the entire value chain of business processes, enabling the accomplishment of business goals.

1.2.2 Small Business

The U.S. Small Business Administration (SBA) guidelines use annual sales volume and/or number of employee, depending on the industry, for classifying businesses as to size. Under the SBA guidelines, a small business could have fewer than 100 to as many as 1500 employees, or annual sales from \$2.5 to \$17 million, depending on the industry [12]. The standard most often cited by the SBA's Office of Advocacy for the public at large is fewer than 100 employee [12]. Weinstein [13] used \$10 million as the sales breakpoint for small business. In some studies, a small or medium size firm in

the manufacturing or service sector is defined as having between 20 and 100 employees [14,15]. The definition was based on Miller and Toulouse (1990) where companies with fewer than 100 employees were included in their study. Jones [16] combined employee and sales limits to define a small business as one with annual sales of no more than \$10 million and fewer than 100 employees. That is the definition used in this study.

2. Research Questions

Several researchers [17,18,19,20], some of whom did not explicitly address the "Productivity Paradox", reported that investment in IT did not produce expected gains in productivity. However, several other researchers [21,22,23,24,25,26,27,28,29,30,31] have noted the existence of a relationship between IT investment and an increase in productivity. Thus, the author has conflicting findings. Clearly, the business value of computers is an

area where many unanswered questions and ambiguous results exist. It is hoped that this study will be a small step towards remedying this situation by attempting to answer two questions. The first question will address the "Productivity Paradox". The second question will attempt to identify areas of IT investment that are associated with corporate productivity.

3. Results and Analysis

Approach of this paper could be qualified as an effectiveness-oriented approach [32] since this study concerned with issues of information content quality, IT support, use of systems, and impact on user and organizational performance. The rubber industry composition of the SMEs, which were included as potential respondents, is provided in the following table. Table 1 also shows the industry composition of the responding and the non-responding factions in the survey.

Table 1: Industry composition of sample population and respondent population

Industry/Rubber	Number in Sample	%	Number of Respondents	%	Number of Non-Respondents	%
Local	231	66.9	126	61.7	105	74.5
Export	114	33.1	77	38.3	37	25.5
Totals	345	100.0	204	100.0	141	100.0

A t-test was run to determine whether there was a statistically difference between the respondent population with in each group. For each case the hypotheses can be stated as:

$$H_0: u_1 = u_2$$

$$H_1: u_1 \neq u_2$$

The test run is a two-tailed t-test, which tests the null hypothesis that there is no difference in the mean scores of the two groups. Controlling the type I error at $\alpha = 0.05$, with $n_1 + n_2 - 2$ degrees of freedom, the critical t for both groups (with more than 120 member each) is 1.96. The corresponding decision rules are:

$$\text{If } t < |1.96|, \text{ conclude } H_0$$

$$\text{If } t > |1.96|, \text{ conclude } H_1$$

The respondent population is statistically not different from the non-respondent population on the characteristic used to select companies within the rubber industry. Not surprising since this study had a response rate of more than 50%. Based on the results of these tests, it seems unlikely that the study conclusions project any significant bias due to non-response.

3.1 The Rubber Industry: Descriptive Statistics

Based on the rate of return recorded by the surveyed companies the performance of the company statistics from 1997 to 2001 are shown in the Table 2.

The investment in IT in 2001 was increased to new levels. The average investment was approximately USD\$52,640 with a maximum reaching USD\$100,000.

More statistics will be shown as the author studied each individual variable in the context of its relations with other study variables.

3.2 Assessment of the Measurement Model

To assess company performance, the author used two measures: the first, perceptual, based on the assessment of company's performance in comparison to its competitors as perceived by the respondent. The second, financial-oriented, was based on the rate of return over a five-year period. In order to generate one measure the author loaded the variables into one factor as reported in table 4. Based on previous research [33] only measures with loadings higher than .70 were included in the final measure. This is considered to be high loading since the item explains almost 50% of the variance in a particular measure.

To the question: compared to your closest competitor how do you evaluate the performance of your company? The answers in Table 4 show that the respondents had a skewed perception in compared to their closest competitors.

The majority of respondents (94%) perceived their company performance as the same or higher than that of their closest competitor. This perception couldn't be supported by the measure of performance based on the financial information provided by the same respondents.

3.3 Investment in IT Relative to E-Business

Investment in IT for 2001 ranged from USD\$3,000 to USD\$540,000. The majority of investment was made for the acquisition of inexpensive components to maintain or improve existing systems. On the other hand, 25% of the surveyed companies invested more than USD\$23,000 each in IS. This is a significant amount and indicates that the management expects an improvement in the business functions of the company.

Table 2: Average firm performance (financial statement in USD\$1000)

	N	Minimum	Maximum	Mean	Std. Deviation
Financial Information (Performance 1997)	78	3.00	550.00	50.1231	145.30674
Financial Information (Performance 1998)	90	.14	650.00	51.4960	160.94306
Financial Information (Performance 1999)	96	1.10	590.00	45.5375	141.43396
Financial Information (Performance 2000)	96	2.30	580.00	45.8931	138.79276
Financial Information (Performance 2001)	96	2.60	540.00	43.1188	129.15950
Valid N (listwise)	78				

Table 3 summarizes investment in IT for 1997-2001.

Table 3: Average firm IT investment relative to e-business (USD\$1000)

	N	Minimum	Maximum	Mean	Std. Deviation
Investment in Computer Technology (Cut Operating Costs)	132	0	80	24.86	20.392
Investment in Computer Technology (Increase Sales or Market Share)	132	0	75	22.50	20.005
Investment in Computer Technology (Do Other Functions)	132	10	100	52.64	25.700
Valid N (listwise)	132				

Table 4: Perceived performance (compared with competitors in robber industry)

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid 3	12	5.9	6.9	6.9
4	24	11.8	13.8	20.7
5	60	29.4	34.5	55.2
6	42	20.6	24.1	79.3
7(Superior)	36	17.6	20.7	100.0
Total	174	85.3	100.0	
Missing System	30	14.7		
Total	204	100.0		

3.3.1 IT Use by Business Function

Table 5 reports that administrative use of IT is most common with more than 60% of moderate or extensive use of computers to generate reports, manage data, and control activities. The electronic communications, mainly e-mail, was used with 76% of the companies reporting an extensive use of this communication tool while e-Business was used with only 20%.

3.4 Correlation Between IT Investment and Performance Relative to E-Business

There is not a strong correlation between the independent study variables, which indicates that they measure different attributes. All correlations indicated are significant at $p = 0.1$.

3.5 Hypothesis Testing

The statistical analysis, as indicated above, followed a two-step procedure. The path coefficients for the model were calculated. Second, path coefficients that were not

statistically significant were removed where theoretically justified. Because coefficients change when a variable is deleted from an equation, it was sometimes necessary to repeat the second step in order to delete new coefficients that had become non-significant. Following Pedhazur [34], this second step was performed until an optimal model was obtained. In other words, a model in which no path coefficients could be deleted without significantly losing to the data. The procedure was applied first to the whole sample, then to each of the sub-samples. The final models along with direct, indirect and total effects coefficients are presented in the following figures and tables.

Hypothesis 1: Investment in IT has a significant and positive impact on:

H_{0-1a} -- user satisfaction

H_{0-1b} -- perceived ease of use

H_{0-1c} -- perceived usefulness

Total effect of Information Technology Investment on:

Table 5: Use by function

Task	Almost Never		Moderate		Almost Always	
	Count	%	Count	%	Count	%
1. Report Production	24	12	60	29	120	59
2. Letters & Memos	31	15	89	44	84	41
3. Data Mgmt	12	6	31	15	161	79
4. Decision Making	78	38	78	38	48	24
5. Trend Analysis	90	44	37	18	77	38
6. Planning/Forecasting	69	34	49	24	86	42
7. Problem Solving	79	39	60	29	65	32
8. Budgeting	76	37	54	27	74	36
9. Activities Control	65	32	42	21	97	47

ISupport			0.3004	0.3035	1							
ESupport	0.455	0.2221	-	-	-0.3944	1						
ITraining	0.163		0.2481	0.3659	0.4005	-0.1128	1					
ETraining	0.298	0.2747	0.3005	0.2601	0.1515	0.3401	0.1522	1				
Satisfaction	0.251		0.3637	0.4131	0.2059	0.1767	0.1931	0.2462	1			
Attitude	0.191		0.1542	0.2057	0.1440	0.2145	0.1969	0.4083	0.2233	1		
IT Investment	-0.33	-0.098			0.3296	-0.400				-0.2803	1	
Performance	0.327		0.2352		-0.2607	0.2084	-0.2233		0.3295	0.1675	-0.1776	1

Table 7: Effect of information technology investment on satisfaction, ease of use and usefulness

	Total effect = Direct effect + Indirect effect			T	P
User Satisfaction	2.05074998	2.002637	0.048112975	2.219	0.0568
Ease of Use	0.454284	0.454284	-	1.455	0.1726
Usefulness	0.081744	0.081744	-	0.178	0.8948

Table 7 presents the results for the Path Analysis of the effect of IT Investment. The data support the first proposition, that is the investment in IT has a significant and positive impact on user satisfaction ($t = 2.22$, $p = .06$). The data also support the second proposition that investment in IT will positively affect perceived ease of use. However data do not support the third proposition which implies that the perceived usefulness will increase with the increase of IT investment. When the data are analyzed using the whole sample there is a negative relationship between investment in IT and the perceived ease of use. However, a more detailed analysis produced

some additional and interesting results. Indeed, when the author looked at the overall relationship between the IT investment and the perceived ease of use the author found that there was a slightly positive relationship though not significant.

Hypothesis 2: Training has a significant and positive impact on:

H_{0-2a} -- users satisfaction

H_{0-2b} -- perceived ease of use

H_{0-2c} -- perceived usefulness

Total effect of Training on:

Table 8: Total effect of training

	Total effect = Direct effect + Indirect effect			T	P
User Satisfaction	0.99506758	0.819548	0.175519583	4.952	0.000
Ease of Use	1.033253	1.033253	-	5.554	0.000
Usefulness	1.13409516	1.038476	0.095619158	5.475	0.000

The data provide support for Hypothesis 2, which stated that training will affect positively and significantly user satisfaction, perceived ease of use and usefulness. In fact, a direct positive and significant effect of training was found in the three variables. There was, however, no significant indirect effect of training on the perceived ease of use.

Hypothesis 3: User satisfaction, Perceived ease of use, and Perceived usefulness will have a significant and positive impact on:

a- IT utilization

b- Organizational usage

H_{0-3a-a} -- User satisfaction will have a direct positive impact on IT utilization.

H_{0-3a-b} -- User satisfaction will have a direct positive impact on organizational usage of IT.

Total effect on Utilization of:

Table 9: Total effect on utilization

	Total effect = Direct effect + Indirect effect			T	P
User Satisfaction	-0.349955	-0.349955	0	5.875	0.0000
Ease of Use	0.28600735	0.19454	0.091467352	3.003	0.0231
Usefulness	0.44549908	0.361929	0.083570079	5.905	0.0000

The data do not support the first proposition, which stated that users satisfaction will impact positively the utilization of computers. However, it showed that ease of use and usefulness, as hypothesized, will impact positively and significantly the utilization of IS. Moreover, positive indirect effects were also detected in the case of ease of use and usefulness.

H_{0-3b-a} -- Perceived ease of use will have a direct positive impact on IT utilization.

H_{0-3b-b} -- Perceived ease of use will have a direct positive impact on organizational usage of IT.

H_{0-3c-a} -- Perceived usefulness will have a direct positive impact on IT utilization.

H_{0-3c-b} -- Perceived usefulness will have a direct positive impact on organizational usage of IT.

Total effect on Usage of:

Table 10: Total effect on usage

	Total effect = Direct effect + Indirect effect			T	P
User Satisfaction	0.251258	0.251258	-	3.621	0.0204
Ease of Use	0.25042154	0.180112	0.070309538	2.451	0.0358
Usefulness	0.14951917	-0.119122	0.049602827	-2.141	0.0000

The level of IT usage was significantly related to user satisfaction and the perceived ease of use that provides partial support for hypothesis 3. However, usefulness did have the positive impact expected on usage. It rather had a 'mild' negative impact at -0.1495. Therefore indicating

that perceived usefulness doesn't play the expected role found in previous studies.

Hypothesis 4: IS support will have a significant and positive impact on IT Utilization

Total effect of IS Support on:

Table 11: Total effect of IS support

	Total effect = Direct effect + Indirect effect			T	P
IT Utilization	0.12507037	0.160289	-0.205359373	2.273	0.0451

Data do not provide support for Hypothesis 4. On the contrary, it shows a negative impact of support on IT utilization (t = 2.27, p = .05). The degree of influence is not important but is significant.

Hypothesis 5: Users attitude will have a significant impact on organizational usage.

Total effect of Users Attitudes on:

Table 12: Total effect of users attitudes

	Total effect = Direct effect + Indirect effect			T	P
Organizational Usage of IT	0.189115	0.189115	-	2.749	0.0268

Data provide support for the proposition that user attitudes have a positive impact on IT usage.

Hypothesis 6: IT utilization will have a significant and positive impact on performance.

Total effect of IT Utilization on:

Table 13: Total effect of IT utilization

	Total effect = Direct effect + Indirect effect			T	P
Performance	0.13015271	-	0.130152706	2.614	0.0238

IT utilization did not have a significant direct effect on performance. But, the author could not reject the hypothesis that there is a significant and positive impact of IT utilization on performance since there is an indirect and positive impact of utilization on overall performance. Thus, the author could safely confirm that the data support Hypothesis 6.

Hypothesis 7: Usage will have a significant and positive impact on performance.

Results in Table 14 support total effect of organizational usage on performance.

Data support the proposition linking usage to performance. The results in Table 29 provide additional support, where User Satisfaction was linked to usage that, in fact, could indicate a relationship between satisfaction and performance. The relationship confirmed in the overall model.

Hypothesis 8: Performance is positively correlated with the degree of investment in IT.

Total effect of Information Technology Investment on:

Table 14: Total effect of organizational usage

	Total effect = Direct effect + Indirect effect			T	P
Performance	0.983211	-		3.185	0.0217

Table 15: Total effect of information technology investment

	Total effect = Direct effect + Indirect effect			T	P
Performance	0.02446	-	0.02446	2.771	0.0245

Data do not provide a strong support for the hypothesis. There is a weak relationship that wasn't significant between the investment in IT and the performance.

3.6 Overall Model

Table 16 summaries the results reported above for the relationship of independent variables to performance.

Table 16: Total effect on performance relative to e-business

	Total effect = Direct effect + Indirect effect			T	P
Investment in IT	0.02446	-	0.02446	-	-
Training	0.16610886	-0.250544	0.164435142	-3.741	0.0201
Experience	0.16958303	0.201633	-0.03204997	3.178	0.0218
Support	0.30099592	-0.30418	0.08318408	-4.489	0
Ease of Use	0.36050275	0.227269	0.133233752	3.163	0.0219
Usefulness	0.06342629	-	0.06342629	-	-
Satisfaction	0.37255624	0.285189	0.087367239	3.947	0.0001
Attitudes	0.28629	0.28629	-	3.939	0.0001
IT Utilization	0.13015271	-	0.130152706	-	-
Organizational Usage	0.39377	0.39377	-	5.811	0

4. Limitations and Assumptions

A limitation involves the external validity. While the respondent companies surveyed were adequate in number and presumably representative of the population of interest, generalizability is limited to only SMEs in the rubber industry. Since the population sampled was SMEs in the rubber sector, very limited conclusions can be made about SMEs in general.

The findings of the study, thus, apply only to SMEs in the rubber sector. To improve the quality of the data collected where possible measurements should be taken from users as the computers are introduced and then take additional measures as they use the computers more extensively.

5. Findings of the Study

5.1 IT Investment

Investment in IT in the rubber industry is limited both in absolute and relative terms. The average investment over a period of five year was USD\$52,640. The trend seems to be an increased investment, however, it cannot be statistically confirmed. A strong relationship was found between the investment in IT and the perceived usefulness. The direct effect, at 0.192787 ($p < 0.005$), indicates that users perception is affected by the investments made in a particular year. This could in turn have an effect on performance through and increased use of IS. In fact, the author found that there is a significant relationship between the perceived usefulness and IT utilization, which corroborates prior findings. Furthermore, the negative relationship, found between the investment in IT and the ease of use, could be explained by the fact that users are resisting change. Thus, perceiving that the new systems will be more complicated and add to their daily tasks a new task: learning how to use the new tools. Another explanation could originate from accounting reporting rules where, due to investment, the overall results of the company, especially on the year of investment, could be affected negatively. This in turn will affect the attitudes of the users toward the source of the sub-performance e.g. the investments made in IT.

The author cannot compare the investment made in other industries, but the author could affirm that even within the rubber industry there were many differences between companies. There should be guidelines of the minimum investment made in IT as a proportion of the revenue if this sector is to become more competitive. On the other hand, the investment in IT is more restricted than expected. No major investments in a production related IT were reported.

5.2 Organizational Performance

A measure such as ROA, the ratio of profit to total assets, may be limited in several instances. Large investments in technology may have a negative impact in a particular year. Knowing the year in which the investment was made is crucial. If profits do improve measurably, changes are not expected to be detected until the system is fully operational, which presumably occurs in the period following the implementation of the system.

Support, contrary to what the author hypothesized, had a negative impact on performance. This could be explained by the fact that companies performing poorly would push strongly the introduction or the use of IT as a way to improve their performance. This additional effort would be perceived by the users as an indicator of poor performance rather than a tool to improve performance.

5.3 Perceptual Variables

The findings indicate that the perceived ease of use is a key variable linking the exogenous variable such as IT investment and computer usage. The importance of the perceived ease of use is further illustrated by its direct effect on the perceived usefulness that in turn affects satisfaction, which has a direct effect on system usage. Moreover, the direct positive effect that training has on the perceived ease of use suggests that training enhances a user's self-efficacy and help un-thwart the use of computers. This encompasses the importance of training and suggests that those programs should emphasize individual's self-confidence and perception regarding an information system. Experience in using computers has a positive impact on system utilization indication that it is important that users gain experience, through training for example, to be inclined to use more adequately the IT available. Nonetheless, experience didn't affect the perceived ease of use, which could be interpreted that experience, with a direct effect on the perceived

usefulness, does not affect the perception of how easy it is to use IT.

The total effect of the perceived ease of use is greater than that of perceived usefulness on usage. This supports the findings of Igbaria et al., [33] that were inconsistent with prior research. This may indicate that users in SMEs are inclined to accept IT based on the ease of use rather than the usefulness. These findings corroborate the fact that the perceived ease of use has a direct impact on computer usage that was greater than that of the perceived usefulness. A plausible interpretation of these results is that users are ready to face some difficulties to get the information they need. But if the difficulties they have to face are high, or perceived so for that matter, they will seek other sources to meet their information needs regardless of the perceived usefulness of the system. This emphasizes the importance of perceived ease of use in developing new systems for SMEs.

Following Igbaria et al. [33], the author suggest that a possible explanation for the importance of the perceived ease of use is the lack of experience on the part of the users. Our survey indicates no significant relationship between experience and ease of use. Furthermore, experience had a negative direct impact on usage. Suggest that usage of the system decreases with experience though utilization was positively affected. This could be explained by the fact that users become more efficient, know exactly what information they need and how to get it without spending much time using the system. The effect of the perceived ease of use is that early in the use of the system, especially in a SME environment, its effect becomes non-significant after a prolonged exposure [33].

Consistent with most prior research [33], a positive relationship was found between support and perceived ease of use. This could be explained by the fact that users in a developed environment are more inclined to accept the technological innovation and introduction. The fact

that management supports, or provides the support for, the use of IT makes that technology to become perceived as easy to use.

DeLone (1988) found that the availability of technical support, mainly for training purposes, did not result in greater IS success in a small firm context. Since most of the companies in the present study didn't have internal support for their information systems, it may be the external support did not meet their specific needs. This indicates the importance of having and developing an adequate information systems support for SMEs. It remains that, consistent with our hypothesis 4 support of the IS function has a positive and direct effect on computer utilization.

5.4 Time Lag between IT Investment and Performance Relative to E-Business

In general, the findings of this research, if limited to being a cross-sectional, demonstrate a lack of direct relationship between the investment in information technology and company performance. It was found however a positive relationship, though statistically weak, that indicates the possibility of a causal relationship. As Weill [31] suggested, the author performed an analysis of the expected relationship using a time lag of 1 year to 5 years. Following Weill [31] regression analyses were performed.

$$RP_n = b + b_1X_n + b_2X_{n-1} + \dots + b_6X_{n-5}$$

Where RP_n = Rate of return for year n ; b_j = regression coefficients; X = investment in IT (predictor variable).

The results are indicated in the following table:

Table 17: Results of regression analyses for rate of return

Dependent	Independent Variables						R^2	P
	IT Invt 01	IT Invt 00	IT Invt 99	IT Invt 98	IT Invt 97	IT Invt 96		
RR01	0.00403					-0.0017	0.21	0
RR00		-0.00081					0.05	0.006
RR99			0.00373				0.03	0.0023
RR98								

*Non-significant coefficients were not indicated.

The five possible outcomes were tested as well as interaction between different year investments. The results of the five regression analyses are presented in Table 17. The standardized b , R^2 , and p value were reported. All interaction terms were not significant, which could indicate or be explained by the absence of a coherent IT strategy with in the sampled SMEs. Moreover, the results of the regressions were not satisfactory. Limited effects were found as resulting from IT investment. In the sample firms, most of the significant coefficients indicated a negative relationship between the investment in IT and the performance measured by the rate of return.. The time lag for detecting any effects

didn't show any significant changes in the results. Actually, most results indicated that the effects were perceived the same year the investments were made. The effects faded away or were non-significant in the subsequent year.

Investment in IT, or any combination of it thereof, did not appear to have any significant direct influence on the performance. To understand the reason for the negative correlation between investment in IT and performance one can infer that respondents' high awareness of financial performance hampers their assessment of the effects of IT investment. This high level of emphasis on

financial performance may affect the perception of the benefits that result from investing in IT and the use of IS.

6. Recommendations

6.1 Recommendations to Managers

The research model has a number of implications for the managers in the rubber industry. The results confirmed that computer usage has a significant impact on company performance relative to e-Business. This suggests that practical steps should be taken to increase the use of the IT to both make those investments profitable and increase the efficiency in the data processing. Training was found to have an important impact on both the perceived ease of use and usefulness suggesting that users should have access to adequate if not extensive training before being introduced to new systems. Researchers can help define training programs aimed at increasing the awareness of the importance of the IS in general and the particular software introduced. Ease of use has a direct effect on usage, as well an indirect effect via usefulness and satisfaction. This suggests that efforts to improve the perceived ease of use should be deployed through training and familiarization sessions.

A possible strategy could involve the creation of an IT training center for all the rubber industry under the auspices of their federation. This will allow for the sector to have its own center that will respond to the needs of the member companies. This center could be created with the cooperation of the vendors and suppliers of the technology used in the industry. Training, through attitudes, will have a positive impact on performance.

Finally, investment in IT had a significant influence on perceived usefulness. This was the only significant link through which IT investment positively influenced the company performance. This suggests that efforts to improve perceived usefulness have a strong impact on firm performance in SMEs. This could be achieved through extensive training which could be used to influence the perceived usefulness by increasing the possible uses of IT and the ease with which the IT will be used [33].

The fact that the investment in IT has a negative impact suggests that either the respondents were reporting the year where such investment occurred, which could have put some strains on the finances of the company, or that the investment in IT implied the introduction of new procedures yet to prove their efficiency.

6.2 Towards an Understanding of IT Investment Relative to E-Business

Investing in IT is seen more and more as a necessity to keep the organization afloat and competitive. What are the implications of such investment? One should caution that those implications resulting from the study findings could not apply to all organizations across the industrial spectrum. Thus, the author would outline the following implications:

- Investment in IT should be considered in enhancing efficiency and usefulness.
- To improve organizational performance, IT investment should include training for users of the IS.
- When evaluating the impact of IT investment on organizational performance, performance measures such as return on investment, sales by total assets, and return on sales, should be considered. Subjective measures of performance such as comparisons to competition performance should be limited.
- Measures, such as IT budget as percentage of revenue, percentage of IT spent on training, should be considered as measures of IT investment.

Previous studies have commented on the relationship between IT investment and organizational performance, but none, to our knowledge, has provided evaluation of this relationship.

7. Conclusion

This study represents a careful and systematic effort to examine the impact of IT investment and other technology related variables on company performance relative to e-Business. It incorporates a number of features including behavioral variables and behavioral intention variables, and a relatively large sample size, which lends significant strength to the study.

The research model was built based on an extensive review of relevant literature. The study is among the few that addressed the issue of use of IT in the context of small business. It extended the existing research by including the company performance in the model. The author did not limit the study to the technology acceptance or the success of the use of IS but the author went beyond to explore the effects of the IT investment on performance.

In conclusion, the main contribution of this study was to highlight the complexity of the IT investment question and hopefully reveal the shortcomings of many of the far reaching statements found in the decision-makers circles. A second implication is that new insights may be found by approaching the question of returns to IT expenditure from another perspective. This may help us understand what factors influence firm benefits from IT expenditure. SMEs appear to use IT mainly to increase efficiency rather than for strategic development in e-Business.

Distribution Network Design and Customer Service

Abstract

In distribution network design, it is implicit that transportation costs, travel distances, and transit times are tightly correlated. Therefore, one can argue that models directing at minimizing travel distances not only minimizes transportation costs, but also minimizes transit times. The center of gravity, and its various extensions, is an example of such a model. Quantitative analyses such as mathematical programming and stochastic models, the transportation costs are often the only factors of interest.

A universal metric for customer service is the customer's lead time – the time it takes to get the right quantity of the right product to the right place. If the right quantity of the right product is available, then the lead-time is the time it takes to take the goods to the right place. For example, when inventory is available, the time to get the product from the warehouse to the customer consists of the time to process the order plus the time it takes to transport it to the customer. These times do not vary much. Moreover, customers generally are aware of and accustomed to them.

If the required quantity of a product is not available, the lead-time is based on two components - inventory availability and product acquisition time. Product acquisition time is the time to get the product back in stock. This is the time to process and ship the product from some other location such as another warehouse, a manufacturing plant or a supplier.

In this paper, we examine the impact of distribution network design on customer's lead time. We conclude that the number of shipping locations may have some effect on customer's lead time. However, the effect of outbound transportation on lead-time can be small relative to product acquisition time. Acquisition time is the time to get the product back in stock. Production-inventory management determines this component of the lead-time, not distribution management.

1. Introduction

It is said that about every five years, large business organizations undertake a distribution network design project to determine if their facilities are properly positioned and located. Changes to the distribution system, e.g., opening/closing warehouses/plants involve major capital expenditure. Invariably, the analyses center

on the cost of doing business, rather than how distribution network design affects customer service.

1.1 Decision Variables

Distribution system design is a complex combinatorial problem. The complexity arises from the fact that there are so many interdependent decision variables.

Oftentimes, one or more decision variables set the constraints for other decision variable. For example, plant production capacities warehouse capacities are constraints that must be satisfied in deciding on which shipping location should service which customers, or how each plant's output should be allocated among distribution points for each product. The decision variables include:

1.11 Distribution facility planning.

Distribution facilities include depots, warehouses, consolidation centers, logistic platforms, and distribution centers. Design issues include location (distance between a distribution center and a market area served by it), handling capacities (throughput at each distribution center), storage capacities, processing and storage costs, and utilization costs.

1.12 Production facility planning.

Production facilities are the plants for fabrication, transformation, and assembly. Deciding what and how much to produce at each plant depends on location, production and storage capacities, costs (production and storage costs), and utilization level.

1.13 Sourcing strategy.

In distribution system design, selecting the supplier(s) for each purchased item usually depends on location, price, quality, and availability.

1.14 Distribution channels design –

Which shipping location should service which customers? How should each plant's output be allocated among distribution points for each product?

1.15 Selection of Transportation modes, routes and rates.

For long-haul movements, business organizations usually outsource the transportation of goods to a third party logistics provider. However, many businesses opt to maintain its own fleet for local pickup and delivery. Decisions on mode of transportation (by air, land, or sea), capacity (e.g., how many trucks in the fleet), route, shipment quantities and frequencies (e.g., to split or not to split shipments), schedule, etc., have impact on cost, availability, service quality and reliability (delivery time, variability/punctuality, reputation, etc.).

1.16 Production-Inventory decisions

Major decisions in distribution system design include what and how much to produce at each plant; which inventory control system to implement, etc.

The complexity increases with the number of decision variables.

1.2 Objectives

The goal of supply chain management is to fulfill customers' need for the 4 R's – to get the right quality of product in the right quantity at the right time to the right place. In distribution system design, deciding how best to fulfill the customers' need for the 4 R's depend on location, forecasted demand of each customer for each product, delivery time windows and frequencies, etc.

What is the 'best' way to fulfill the customers' need for the 4 R's? To know what is 'best,' one must first understand the objectives of distribution network design, from the vantage point of the business organization making the decision.

First, we must assume that we know what the 4 R's are, i.e., we know what quantities of which product our customers need, and we know when and where our customers want them. (Of course, we can not simply assume that we know what the 4 R's are. But this is beyond the scope of this paper.) Then, design objectives can be summed up by two words: service and cost.

What is customer service? A universal metric for customer service is the customer's lead time – the time it takes to get the right quantity of the right product to the right place. A way to operationalize this conceptual measure of customer service is to look at what constitutes customer's lead time.

2. The Cost Objective

Decisions on distribution system design are customarily based on forecasted demand (for each product at each customer zone), dimensions and weights of the goods flowing through the network, handling requirements (Fragile and/or perishable versus durable and/or robust), packaging, and costs (production, inventory, etc.).

In modeling, it is implicit that transportation costs, travel distances, and transit times are tightly correlated. Therefore, one can argue that models directing at minimizing travel distances not only minimizes transportation costs, but also minimizes transit times. The center of gravity, and its various extensions, is an example of such a model. Quantitative analyses such as mathematical programming and stochastic models, the transportation costs are often the only location factor of interest.

Network design affects the cost of doing business, and the flow of goods and services. The faster the flow of goods and service in one direction, the lower the inventory, and the quicker funds (\$\$\$) flow back in the reverse direction.

Decisions are either demand-pulled, supply-pushed, or more frequently, both demand-pulled and supply pushed. By demand-pulled, we mean market-related factors such as the profile of customers, the profile of the competition, the need for room for expansion, etc.

Supply-pushed location factors are based on the cost of doing business. The cost of doing business includes the cost of acquiring and operating plants, distribution centers, warehouses, transportation facilities, communications equipment, data processing means, etc. Inbound and outbound transportation costs depend on the number, and the location of various components of the distribution network.

Figure 1, based on an illustration in [3] shows the relationship between various cost categories and the number of shipping location.

Inbound transportation cost increases with the number of shipping locations because there are more locations to receive shipments from the suppliers.

Outbound transportation cost, however, decreases with the number of shipping locations because with more shipping locations to serve the customers, each shipping location serves its nearest customers.

Figure 1. Cost vs. Number of Shipping Locations

More shipping locations means more inventory because each location has to maintain an adequate level of inventory. The operating cost (labeled DC's) also increases with the number of shipping locations.

Let:

N = number of shipping locations.

C_{Inbound} = Inbound transportation cost
 $= a_1 + b_{11} N + b_{12} N^2$

C_{DC} = Distribution-center operating cost
 $= a_2 + b_{21} N + b_{22} N^2$

$C_{\text{Inventory}}$ = Inventory-holding cost
 $= a_3 + b_{31} N + b_{32} N^2$

C_{Outbound} = Outbound transportation cost
 $= a_4 + b_{41} /N + b_{42} /N^2$

Let $\alpha = a_1 + a_2 + a_3 + a_4$, $\beta_1 = b_{11} + b_{21} + b_{31}$, $\beta_2 = b_{12} + b_{22} + b_{32}$, $\beta_3 = b_{41}$, $\beta_4 = b_{42}$, then the total cost =

$$C = \alpha + \beta_1 N + \beta_2 N^2 + \beta_3 /N + \beta_4 /N^2 \quad (1)$$

For example,

$$\begin{array}{llll} a_1 = 35.00 & a_2 = 33.00 & a_3 = 17.00 & a_4 = 10.00 \\ b_{11} = 10.00 & b_{21} = 2.00 & b_{31} = 5.00 & b_{41} = 80.00 \\ b_{12} = -0.75 & b_{22} = 0.00 & b_{32} = -0.50 & b_{42} = -12.50 \end{array}$$

Then

$$\begin{array}{ll} \alpha = 95.00 \\ \beta_1 = 17.00 & \beta_3 = 80.00 \\ \beta_2 = -1.25 & \beta_4 = -12.50 \end{array}$$

Solving the unconstrained integer programming problem in (1) yields the optimal solution of $N = 3$.

3. The Time Objective

The customer's lead time is a source of competitive advantage, and is a constraint that must be satisfied. This constraint may be stated in terms of "service level." In inventory theory, the "service level" is probability (likelihood) of meeting a customer's required lead time. For example, a "service level" of 99% means that 99% of the time, the right quality of product in the right quantity is delivered to the right place at the right time.

3.1 If item is available in inventory

If the right quantity of the right product is available, then the lead-time is the time it takes to take the goods to the right place. Outbound transportation lead time decreases with the number of shipping locations because with more shipping locations to serve the customers, each shipping location serves its nearest customers.

Figure 2. Outbound Lead-Time vs. No. of Shipping Locations

When inventory is available, the time to get the product from the warehouse to the customer is almost always fixed. It consists of the time to process the order plus the time it takes to transport it to the customer.

Figure 2 shows the relationship between outbound lead-time and the number of shipping location. With one shipping location, the lead-time is about 1 week. With two shipping locations, the lead-times drops to approximately 4.5 days, and with three shipping locations, the lead-times drops to about 3.5 days, etc. With 5 or more shipping locations, the lead-time is about 2 days.

Evidently, when inventory is available, lead-times normally do not vary much. More importantly, customers generally are aware of and accustomed to them.

3.2 If item is not available

Now, if the required quantity of a product is not available, then the lead-time is based on two components: inventory availability and product acquisition time. Indeed, the acquisition time is only relevant when the inventory is unavailable.

Acquisition time is the time to get the product back in stock. This is the time to process and ship the product from some other location such as another warehouse, a manufacturing plant or a supplier.

Suppose a warehouse processes all the orders for which it has inventory in t_1 days and the outbound transportation lead-time $t_2 = a + b_1/N + b_2/N^2$, where N is the number of shipping locations. If inventory is available, the customer's lead time = $t_1 + t_2$ days.

Let p = probability that the item is available. If the item is not available from inventory, the average time to acquire out-of-stock product is t_3 days.

The expected customer's lead time = $t_1 + t_2$ days + $(1-p) * t_3 = (t_1 + t_2 + t_3) - pt_3$ days. For example, suppose $t_1 = 1$, $t_2 = 1.0 + 7.5/N - 1.25/N^2$, and $t_3 = 10$. Figures 3a and 3b show the lead-time as a function of N and p .

Figure 3a. Lead-time as a function of N

What determines the customer's lead-time? The customer's lead-time depends on the transit time (t_2 is about 3.5 days for $N=3$, the minimum cost solution found in Section 2.), the order processing time (one day), the probability that inventory is available, and the acquisition time (10 days).

Notice that in Figure 3b, the lead-time curve is a steep linear function of p . On the other hand, beyond $N=3$ (in our example), the lead-time curve shown in Figure 3a is rather flat with respect to the number of shipping locations N .

Figure 3b. Lead-time as a function of p

4. Number of shipping locations

Now, which of the components of lead-time is dependent on the number of shipping locations? Clearly, the number of shipping locations impacts only one of these elements: the outbound transit time to the customer. This transit time generally depends on the distance from the warehouse to the customer. In most supply chains the average distance decreases as shipping locations are added to the network.

Suppose the product is available 90% of the time. For $N=3$ (the minimum cost solution in Section 2.), t_2 is about 3.5 days. The expected customer's lead time = $(1 + 3.5 + 10) \cdot 90\% \cdot 10 = 5\frac{1}{2}$ days. Outbound transportation impacts 3.5 days of the customer lead time. That's 65% of the total!

Think about the capability of the network to decrease

transit times by adding more shipping locations. However, as seen in Figure 3a, the lead-time curve is rather flat with respect to the number of shipping locations N . In a 3-shipping location network, for example, the transit time is reduced by about half a day by adding a 4th shipping location. Adding a 5th shipping location further reduces the transit time by about 1/3 of a day, etc.

Figure 3b tells us a very different story. At $N=3$, and $p = 90\%$, we see that the total lead time is about $5\frac{1}{2}$ days. The linear curves in Figure 3b tell us that every 10% drop in probability that the item is available, will add a day to the customers' expected lead-time. For example, if p drops to 80%, the expected lead-time is about 6 $\frac{1}{2}$ days, if $p = 70\%$, the expected lead-time is about 7 $\frac{1}{2}$ days, etc.

Figures 3a and 3b assume that, when the item is not available from inventory, the average time to acquire out-of-stock product is 10 days. If the item has to be sourced from abroad, the acquisition time may take 3 weeks. This case is illustrated in Figures 4a and 4b below:

Figure 4a. Lead-time as a function of N ($t_3 = 21$)

Figure 4b. Lead-time as a function of p ($t_3 = 21$)

Figure 4a shows the lead-time to be flat, with respect to the no. of shipping locations. Facility location may have some effect on customer's lead time. However, the effect of outbound transportation on lead-time can be small relative to product acquisition time (see Figure 4a). Acquisition time is the time to get the product back in stock. Production-inventory management determines this component of the lead-time, not distribution management.

The goal of supply chain management is to fulfill customers' need for the 4 R's – to get the right quality of product in the right quantity at the right time to the right place. The next section presents some real world examples illustrating the consequences of (a) not having the right quantity, (b) not having the right product, and (c) not knowing where the right quantities of the right products are. In each case, the failure was nothing short of spectacular.

5. Product, Quantity, Time, Place

5.1 Not having the right quantity

During the Internet boom of the late 1990's, networking gear (routers, switches) was hard to get. Desperate customers resorted to placing duplicate orders with multiple equipment vendors.

Each vendor, like Cisco, forecast robust growth and, to "lock in supplies", solicited long-term bids from multiple contract manufacturers. Each contract manufacturer wanted to lock in its supplies and started negotiation for long-term deliveries from chipmakers.

For the few chipmakers in the world, it all added up to an extraordinary surge in demand for their products. They promptly raised their prices or rationed their output, which frightened buyers so much they decided to hedge by placing still more orders, which re-enforced the vicious cycle.

However, customers intended to acquire only a fraction of this stupendous production – from whoever delivers first among their many orders. The whole pyramid, bloated with phantom demand, eventually imploded – the bubble burst. In 2001, Cisco was forced to write down \$2.2 billion worth of obsolete inventory, victim of a pernicious pathology in its supply chain [4].

5.2 Not having the right product

Nike went live in June 2000, with its much-ballyhooed demand forecasting application, acquired from i2 for \$400 million.

Nine months later, the inaccurate forecasts produced by the new systems had led Nike to write-off \$90 million in inventory of unsellable shoes, on top of an estimate of \$100 million in lost sales, due to shortage of sneakers in high demand [5].

5.3 Not knowing where the right quantities of the right products are

In August, 1999, Hershey announced that its IT teams had just completed its R/3 implementation — a \$112 million project which includes ERP from SAP, CRM from Siebel, and supply chain software from Manugistics.

A month later, Kenneth L. Wolfe, then CEO and

Chairman of Hershey Foods, told Wall Street analysts that the company was having problems with their new SAP implementation, and that the problems were going to keep Hershey from delivering \$100 million worth of Kisses and Jolly Ranchers for Halloween that year [2].

That year, order management and fulfillment processes broke down, causing the company to fail to meet many retailers' orders. The immediate impact was about \$150 million in lost sales for the year. Hershey's stock price fell more than 8 percent on that day.

Who is to blame for Hershey's dilemma in 1999? The new ERP system did not know where the right quantities of the right products are. According to Carr [1], Hershey had informal mechanisms for dealing with the tremendous buildup of inventory to prepare for the holiday rush. Hershey had rented warehouse space on a temporary basis, and spare rooms within factory buildings to store inventory. Unfortunately, these locations hadn't been recorded as storage points in the SAP data model!

Before SAP fulfills a customer order, it first checks its records of available inventory, and in this case a significant amount of inventory was not where the official records said it was [1].

In short, Hershey might have the right product, at the right quantity, at the right place. Unfortunately, their new ERP system did not where the inventory was, and \$100 million worth of candies were not delivered to right place in time for the Halloween and Christmas holidays.

6. Summary

A universal metric for customer service is the customer's lead time – the time it takes to get the right quantity of the right product to the right place.

In this paper, we examine the impact of distribution network design on customer's lead time. We conclude that the number of shipping locations may have some effect on customer's lead time. However, the effect of outbound transportation on lead-time can be small relative to product acquisition time. Moreover, customers generally are aware of and accustomed to outbound lead-times.

Acquisition time is the time to get the product back in stock. Production-inventory management determines this component of the lead-time, not distribution management.

Thus, the objective of facility planning should be focused on minimizing cost, i.e., find a minimal-annual-cost configuration of the distribution network that satisfies product demands at specified customer service levels.

Examining the contribution of internal customer service to improved e-procurement performance: A Case Study investigation

Dr Simon Croom and Professor Robert Johnston,
Operations Management Group,
Warwick Business School,
University of Warwick,
Coventry
CV4 7AL
UK
simon.croom@wbs.ac.uk

Abstract

Much of the existing published research into the impact of electronic procurement has focused on the cost efficiency or implementation issues of its adoption. Issues relating to the significance of improved compliance on procurement performance were noted in our earlier paper [7], yet little if any research has so far set out to quantify the impact of electronic procurement on internal customers' perceptions of service quality. This paper provides an examination of the impact of e-procurement adoption on internal users' perceptions of service quality. Employing Johnston's [15] 15 service quality criteria, we compared users' perceptions of pre- and post-electronic procurement processes for two categories of supply: computer consumables and stationery. Using an online survey (appendix 1) a pilot study was conducted in a single organisation that has employed 'supply-side' electronic procurement for 18 months. We found that users expressed 'delight' in many aspects of the service provision relating to the design characteristics of the e-procurement system, but dissatisfaction with issues concerning the actual system delivery (particularly related to IT infrastructure and networks).

This paper only provides early results from the pilot study, so further conclusions from our research must be deferred until a more significant sample of responses have been analysed.

1. Introduction

Over the last 20 years a significant body of literature has developed on service quality and customer satisfaction. It is generally accepted that customer satisfaction has a significant impact on customer retention and loyalty (see for example [2], [18], [25]) on customer attraction (see for example [25]), staff satisfaction (see for example [13], [26]) and therefore on an organisation's financial performance (see for example [23], [10]).

Most service research however has been predominantly concerned with business to consumer (B2C) services; in particular retail services and banking. Few papers deal with business to business (B2B) or internal service issues. Indeed a analysis of 15 back issues of the *Journal of Service Research* and the *International Journal of Service Industry Management* reveals that over 80 per cent of recent papers are concerned with B2C services (see figure 1).

Furthermore, despite the recent rise in web based delivery channels and the rise in interest in e-business it is surprising that few research papers have so far been published in this area. Recent publications such as [32], [20], [28], [31] and [34], for example, have all been concerned with, in the main B2C service and, exclusively, external customers.

Data from research organisations such as Forrester Research and Gartner, has demonstrated that the greatest potential from e-business will be in B2B and internal services. It is interesting to note that research in the manufacturing area has been predominantly focused on internal activities (see for example [1], [9], and [12]).

Although the notion of internal service is not new (see for example [5], [11], [17]), there are few papers on e-service applied to internal services (notably [30], [3], [29] and [6]).

The purpose of this paper, which results from an ongoing research project into e-business, is to build on an earlier paper concerned with the application of e-service in internal services and continue to try to add some knowledge to this important but largely neglected area. We focus in this paper on an investigation of internal

customers' perceptions of the impact on service quality of e-procurement.

2. The Impact of E-Service on Internal Customer Satisfaction

The purchasing and supply (procurement) activity of organisations is an important internal service found in all organisations, public, private, governmental and charities and can be responsible for a large amount of spending on, for example materials components, facilities, subcontract capacity, IT equipment and supplies, consumables, stationery, travel and insurance. Indeed most organisations spend at least one third of their turnover/income on the purchase of goods and services ([33]; [16]).

Procurement is traditionally an internal service provided by a dedicated team of professionals. The function is usually responsible for the identification of (internal) customer's needs, translation of those needs into specifications, management of the delivery of goods and services and an assessment of the (internal) customer's satisfaction with those goods and services. The other elements of the process involve communication with suppliers –

sourcing, requests for tenders, price negotiation, ordering receipt and invoicing.

Electronic procurement systems in essence mirror the procurement process through the provision of two distinct, but connected, infrastructures - internal processing (via, for example, corporate intranet) and external communication with the supply base (via, for example, Internet-based platforms) [8]. The critical difference is that such systems allow individual employees to order goods and services directly from their own PCs through the web. Requests and orders are channeled through various forms of 'hub' or database which acts as an online catalogue of specifications, prices and often, authorisation rules. Such systems allow individual employees to search for items, check availability, place and track orders and initiate payment on delivery.

In our earlier paper we investigated the impact of changing internal services into e-services, concentrating on the evolution of procurement processes to e-procurement. Whilst there are numerous e-procurement system platforms in use, our study took a broad definition of e-procurement as "the use of internet protocol systems to support both the internal and external stages of the traditional purchasing process". Our initial study was exploratory in nature, consisting of a study across 97 organisations investigating the impact of the change from traditional procurement functions

to electronic procurement (e-procurement) on internal service quality.

Based on surveys, telephone interviews and site visits and observations of IT and Purchasing executives and manager, as well as managers in a number of user departments across a total of 97 organisations we reached three main conclusions, that e-procurement led to significant reductions in costs, an improvement in reliability of the procurement processes and an improvement in internal customer satisfaction.

In terms of internal customer satisfaction in particular, respondents reported that the replacement of bureaucratic requisition and approval process with rapid IT-based systems enhanced customers' perceptions of service availability, speed, responsiveness, flexibility in particular. Customers also expressed satisfaction over their greater ability to exercise more control over their budgets. The increased levels of satisfaction were reported despite the fact that e-procurement systems usually required much greater personal intervention by the users themselves.

We concluded our initial paper with a proposed causal map of the relationships between the quality of internal service delivery, staff satisfaction, the level of compliance and the consequent results from e-procurement use. Figure 1 below shows this posited causal relationship.

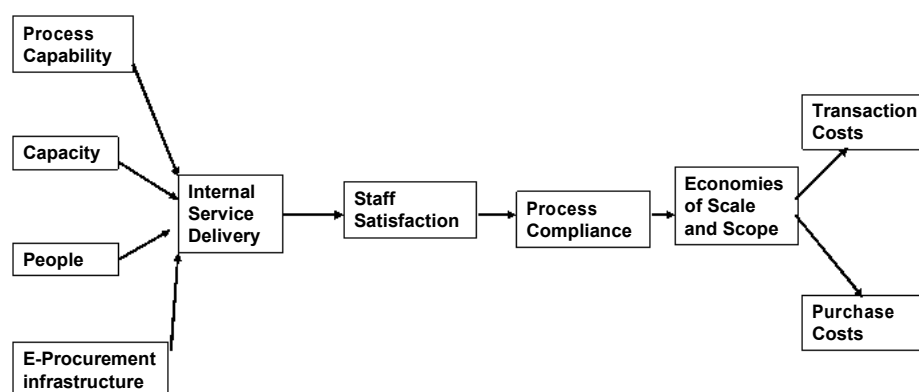

Figure 1: A Causal Relationship between Internal Customer Satisfaction, E-Procurement Compliance and Procurement Costs [7].

Whilst our earlier exploratory research [7] gave an indication that internal service quality was considered by managers in the providing functions (I.T. and Purchasing) to be a significant factor in supporting the performance benefits e-procurement performance, we had little evidence of internal end users' perceptions. In particular, since our study only included managers of user/internal customer departments rather than the operatives who regularly placed orders using the e-procurement system, we recognized that

opportunities to adopt a 'gap model' approach could offer further insights into the internal service dynamics associated with electronic procurement deployment. Utilising Slack et al's [27] interpretation of the Parasuraman et al's ServQual model, we amended the model to focus on *internal* customer service by highlighting the comparison internal users makes between different processes for placing orders and the potential for 'communications' to include policy statements and directives, figure 2 below.

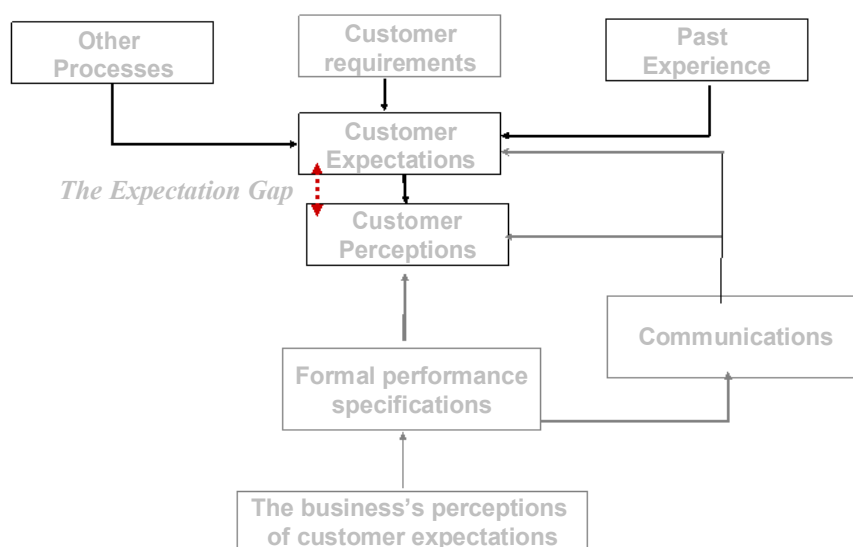

Figure 2: Modified Internal Service Quality Gap Model
(Adapted from Slack, Chambers & Johnston, 2001)

As our previous paper noted [7] much of the existing literature on e-procurement has concentrated on issues relating to the *implementation* of e-procurement – benefits, costs, returns and rollout strategies. Little research to date exists relating to the *operation* of e-procurement systems. In our previous paper we examined the *implementation* issues surrounding the impact of internal service on process compliance (and consequently on process performance). In this paper we concentrate on an *operational* issue by examining the 'expectation gap' of internal customers (encompassing administrators, administrative assistants, secretaries, finance department staff and technical staff) who carried out the day to day ordering of supplies using an electronic procurement system. Our focus is to identify the characteristics and scale

of the impact of e-procurement on internal service quality.

3. Method

The initial contention motivating this study is that enhanced internal service quality leads to greater compliance with an organization's desired procurement procedures. We thus set out to investigate internal users perceptions of the performance of e-procurement in a single case organization (Company A) for two categories of supply, stationery and computer consumables, since these are now solely purchased using e-procurement. Company A introduced e-procurement approximately 12 months before the date of this study, so respondents had recent experience of non-

electronic procurement. The process for both categories of supply is described as 'supply-side' e-procurement, that is, the catalogue and ordering process is hosted on the supplier's servers. Most users surveyed also had responsibility for other categories of supply that were not available via the e-procurement system. Thus we contest that comparison between 'e' and 'non-e' procurement is valid given the users experiences of both scenarios.

In line with our earlier research [7] we again used Johnston's [15] 15 service quality criteria to investigate internal service relationships. A questionnaire was developed (Appendix 1) in which respondents were invited to contrast their perceptions of the performance of the e-procurement system with their previous (non-electronic) method of procurement. Data collection was via on-line delivery of the survey instrument to all active users of the organization's e-procurement *intranet*. Results were transmitted to us directly via email for each respondent, all responses were anonymous. The raw data was entered onto an Excel spreadsheet to facilitate data manipulation and analysis.

As with previous research into service quality (see for example [13], [22], [19]) we used a Likert scale to assess customers' perceptions of their experiences. We chose a 9-point semantic scale (as used in the second

generation SERVQUAL instrument [21], with 1 meaning completely unacceptable and 9 meaning always exceeds my requirements (see appendix 1). We plotted a simple difference score between the e-procurement and previous system. Three potential outcomes naturally exist – 'delighted' (i.e. the e-procurement process is perceived to offer greater service quality), 'satisfied' (i.e. there is no perceived difference between the previous system and current e-procurement process) and 'dissatisfied' (i.e. the previous process offered a greater perceived level of service quality). In evaluating the results from our survey we adopted Johnston's [14] notion of the 'zone of tolerance' to delineate between the three outcomes.

At the time of writing we had completed our pilot investigation of 12 primary users. The survey is ongoing and we therefore anticipate presenting analysis of a larger sample during the conference.

4. Findings

We found that each of the three outcomes was evidenced across the service quality criteria. Figure 3 provides a bar chart summarizing the sum of differences between the e-procurement system and the previous (non-electronic) system, identifying the three 'zones' of delighted, satisfied and dissatisfied perceptions relating to the e-procurement system.

Figure 3 Service Criteria Sum of Differences

From figure 3 we see that the advent of e-procurement adoption had impacted on users perceptions of service quality in the following manner:

‘Delighted’

The e-procurement system was found to ‘delight’ users in five specific criteria of e-service delivery: responsiveness, reliability, integrity, compliance, and security.

‘Satisfied’

Seven criteria showed little if any difference between the old and e-procurement processes. Users were found to be ‘satisfied’ in the characteristics of: attentiveness, care, friendliness, courtesy, communication, commitment and access.

‘Dissatisfied’

The e-procurement system was found to have led to dissatisfaction in users in two criteria of e-service quality: availability and flexibility.

5. Discussion

This paper set out to explore the impact of electronic procurement on end users perceptions of internal e-service quality. Little if any prior research has examined this aspect of e-service and we thus based this preliminary study on an analysis of the gap between pre and post-e-procurement *operation* on Johnston’s 15 service quality criteria. We concluded by setting out three categories of criteria according to the impact on users’ perceptions of the change to e-procurement operation: Delight, Satisfaction and Dissatisfaction.

The advent of e-procurement had improved perceptions of internal customer service quality to ‘delight’ users in the attributes directly related to the fundamental process capability of the system. Responsiveness, reliability, integrity, compliance and security may all be considered to reflect the design of the procurement process. The e-procurement system is perceived to be quick, easy to use, accurate and confidential.

Users were ‘satisfied’ with seven criteria reflecting high contact aspects of the procurement process. Where interaction with a

provider (including purchasing officer, supplier or system administrator) is necessary, there appears to be little discernable difference between the e-procurement system and previous process. In essence the high contact service criteria are ‘system neutral’.

Users were ‘dissatisfied’ in two respects. Firstly, due to problems associated with server downtime and system reliability, the e-procurement system was perceived to be more likely to be unavailable to users than the previous system. This concern with the e-procurement infrastructure, particularly network downtime, is compounded by the lack of flexibility – the e-procurement system provides ‘only one way’ to order items.

Once a user has gained access to the system, the e-procurement process offers a significant improvement in their perceptions of service quality related to the design aspects of the process. Service quality in the high contact elements of the e-procurement process do not appear to offer any significant advantage or disadvantage over the previous non-e procurement process. However, users find the performance of the network and communications infrastructure to be significant dissatisfiers.

6. Summary

This study has indicated that e-procurement influences internal customers’ perceptions of the service quality they receive. However, this study so far is limited by the fact that the study is merely a pilot study and further data collection is necessary before we can posit statistically significant conclusions. However, at this stage in the research our initial indications are that e-procurement enhances internal customer service satisfaction in those aspects of service quality directly related to the *design* of the system – the ‘functionality’ of the system as it is often described in practitioner literature. Internal customers expressed dissatisfaction in aspects of the *delivery* of the process, i.e. network and communications infrastructure reliability.

This research is ongoing and further data collection is anticipated to provide a far larger data sample base.

7. Appendix

Survey of Purchasing Processes at Company A

Stationery and Computer Consumables Supplies

Professor Robert Johnston and Dr Simon Croom of Warwick Business School are conducting a study into the nature and quality of the service offered by electronic and non-electronic purchasing processes for two categories of purchase – stationery and computer consumables. We wish to contrast the current process for buying stationery and computer consumables using the online system with how you used to purchase these two categories of supplies before the introduction of the online system.

The questionnaire contains 15 questions. Each is posed in the form of a statement about the processes and we would like you to use the 1 – 9 scale shown to reflect your opinion, based on your own experiences, of the current online process and the previous purchasing process you used **for stationery and computer consumables supplies only**.

In answering all of the questions please use the following 9 point scale, to rate each statement based on your experiences where:

- 1 = Completely unacceptable
- 2 = Very poor
- 3 = Poor
- 4 = Slightly below my requirements
- 5 = Meets my requirements
- 6 = Slightly exceeds my requirements
- 7 = Sometimes exceeds my requirements
- 8 = Often exceeds my requirements
- 9 = Always exceeds my requirements

Your participation in this study is greatly appreciated.

Question	The Current On-Line Procurement Process									Your Previous Ordering Process								
1. The helpfulness of any personal service provided by the process when it is needed.																		
2. The speed and punctuality of total purchasing process from order to delivery.																		
3. Your satisfaction with the care, concern and patience shown throughout the ordering process																		
4. The availability of the ordering process																		
5. The frequency with which the total purchasing process meets your required levels of performance																		
6. The respect and fairness with which you are treated																		
7. The extent to which you are made to feel welcome																		
8. The politeness with which you are treated																		
9. The frequency and quality of all communications you receive																		
10. The accuracy with which the total purchasing process is carried out																		
11. That the ordering process achieves what it is meant to achieve																		
12. The degree of commitment of all the staff involved in responding to you																		
13. The ease of completion of the ordering process																		
14. The flexibility of the ordering process in meeting different requirements																		

15. The level of confidentiality possible in the process

A Study of Effective Regulation Model in Privatizing the Public Enterprises

Steve CHEN

International Graduate School of Management
University of South Australia
Steve.chen@xshowbiz.com

Abstract

The privatization seems to be an important policy towards the solutions of public ownership faults. However, the privatizing a monopoly industry could not damage the consumers' interests inevitably. Thus, it is necessary to introduce the government regulation towards the privatized monopoly industry. The premises of the privatization combined with regulation model are: controlling the privatization of a monopoly industry shall increase the efficiency, improved service quality and lower the costs to consumers.

The method for this research is to review existing literature and study the regulations and the regulation in the developed nations comparing their variations and to find out the most efficient regulation models to design or amend for other nations. The objective of this study is to study the privatization experiences from the existing nations and convert to those nations may need for reference.

At the end, this paper also found that the effective regulation model may not only bring down the costs of the public services, but also improved the efficiency to a near market competition standard.

1. Introduction

This research paper looks at price capping theory and considers a case study, which explores incentives and relevant financial and technical points of price capping regulation. The paper will explore the optimal regulation framework which endorsed the price capping regulation framework (Laffont & Tirole, 1993); it will explore the Productivity Measurement with Adjustments for Variations in Capacity Utilization in price capping regulation theory and consider some conclusions and implications.

In 1994, research in the UK power industry found that privatization was not directly related to the improvement of productivity in the post-privatization era. (Burns and Weyman-Jones, 1994). Significantly, the research study on which these findings were based ended in 1993, before the introduction of price capping regulation and before the intensification of industry competition occurred. It missed the valuable opportunity to measure and compare productivity performance under

price capping reduction, versus market competition.

In contrast, recent studies from the electricity association of UK found: that privatization has almost doubled the productivity of the electricity industry. (Electricity Association, 1998, p.55). In the electricity industry, effective price regulation and more fierce market competition have resulted in a lowering of profit margins after peaking in 1989-90 and further resulted in an improvement of service quality. Household electricity costs have fallen at a rate of approximately 2.5% per annum after the privatization of the electricity industry. Commercial users experienced similar discounts and the prices are further negotiable subject to usage. The privatization of local electricity distributors has generally achieved higher profit margins and reduced the need to recruit employees.

The privatization of the gas corporations also achieved similar results. Once profit margins peaked in 1990~1991, prices have continued to fall, reflecting effective price regulation and intense competition in the gas industry. Actual prices for average households have fallen by 2.6% per annum. Commercial and industrial gas prices have also fallen at a rate of 5% per annum. At the same time, service quality has also improved significantly, including the discounted rate of gas pipes, improved safety records, and improved usage of gas pipes. While UK gas corporations have lowered their pipeline buildup and grown their services gradually, new entrants into the gas industry have expanded their business more aggressively to maintain the growth of the total service quantity supplied.

On the whole, consumers only increased their actual expenses in water and sewerage services, especially those consumers who were charged according to the sizes of their properties. However, water and sewerage price increases were supported by industry regulation offices (but the growth rate remained within a permissible range) because suppliers had to meet the European Union criteria and make new investments in infrastructure. Today, water quality and certain service items have greatly improved.

The struggle however, to meet these criteria is reflected by 25% of the sewerage industry which cannot meet the government requirement. The frequency of interrupted

water supply has grown and water pipe leakage has also become a public concern. This is especially problematic as water companies continue to enjoy high profit margins.

As such, the water supply regulator has instructed water companies to implement certain actions to lower the rate of water pipe leakage. The water supply regulator has raised the issues and its intention to tighten regulation and to lower the actual water prices in their next review in 1999-2000. While the regulator may intervene in the case of extraordinary price increases, the UK regulator remains committed to prices which reflect the real cost of supply.

From the perspective of employment, it is clear that total employment opportunities did not suffer from privatization. While privatization may lower employment opportunities in existing firms and organizations, new entrants still require new employees to compete with existing State-Owned-Enterprises (S.O.E.). In the telecommunication industry for example, British Telecom has conducted a few large scale redundancies over the years, but total employee numbers have actually increased. In addition, redundancies are frequently voluntarily and with generous severance packages.

The experience of privatization indicates that, effective regulation can increase productivity, lower prices, and improve quality producing greater economic benefit. Furthermore, the profit margin of privatized enterprises also tends to fall in the longer term. Newly privatized enterprises normally achieve higher surplus as a result of better costs control and less stringent governmental regulations in the initial stages of privatization. The main reason for softer regulations is that this will help gain support from investors in the privatization effort. Upon completion of the privatization, the regulator begins to tighten the conditions of price increases and provides incentives to introduce greater competition.

The Internal Rate of Return (IRR) is also an effective index which deems future profits as zero investment capital while converted into monetary terms. The IRR is being adopted as an instrument of comparison with the Return on Investment (ROI) or the profit margin. Thus, we can compare the ROI with capital costs in privatized enterprises which are regulated. Under competition, the normal ROI will tend to reflect or be close to capital costs. While capital costs are based on lending costs, the proprietor's weighted average is based on equity. In the UK, the capital costs of a privatized enterprise can be viewed as more valuable than government bonds, but in general enterprises it is considered less than the proprietor's equity.

The main reason for this is that while privatized enterprises remained dominant in the market, the regulator must ensure that they possess sufficient

financial capability. This lowers the risk of investing in privatized industries compared to other general enterprises, where capital costs or ROI are also lower. For example, the telecommunication regulation office set nominal capital costs between 8.4% - 13.4% for the telecommunication industry in the UK when actual capital costs are between 5.2%-8.8%. Generally it is true to say that the regulator sets the price capping based on actual capital costs to enable regulated enterprises to achieve 7% of actual ROI.

In some cases in the UK, for example with the British Gas Company and with British Telecom, investors do not receive the pro-normal ROI from investing in privatized enterprises until after an extended period. The reasons for privatized enterprises achieving pro-normal ROI include the government wishing to privatize enterprises successfully by underestimate the share price and the regulator getting involved with the regulation of pay increases.

2. Literature Review

Comparison between price capping regulation vs. rate of return regulation

Price capping regulation is closely related to inflation. Price capping is modified based on inflation and *the efficiency factor*. *The efficiency factor* is used to reflect the scale of productivity progress and in the UK, is symbolized as X. Price capping regulation is reviewed every 4-5 years. For instance, the price cap for British Telecom was initially set at RPI 3; then reduced to RPI 4.5 in 1989; adjusted to RPI 6.25 in 1991 and RPI 7.5 in 1993.

The objectives of price capping regulation are to amend or simplify the rate of return, which involved the "agreed rate of return" (Littlechild, 1989).

At the start of the privatization of British Telecom, services were 60% under the price capping regulation. Services have currently been lowered to 25%. This has illustrated the maturing of market competition.

Price capping, however, is under attack from many areas. This type of regulation has two major flaws. The first is the lack of motivation to lower the operation costs because increased costs can be transferred to consumers. The second is the ease of over-expanding investment because the profit is expressed as a rate of return on assets and new assets normally achieve a better rate of return (Averch and Johnson, 1962).

At the opposite end, high costs may not be passed on to its customers. Enterprises generate revenue when the cost-down rate is significant lower than efficiency factors. Thus, enterprises commonly improve performance regardless of operations or capital. However, costs and price may move in opposite directions after a period of time which may cause inefficient distribution of resources, (P?MC). Moreover, the public will question the effectiveness of

governmental regulations as high profits continue to be generated

For these reasons, the methods of calculation of price caps are reviewed every 4-5 years to maximize the results of the regulation. Governments have encouraged enterprises to raise prices within the set and acceptable range as happened in water companies. Government would also permit regulators to adjust the price capping calculation methods in unusual circumstances as in the case of British Telecom in 1991. Governments, however, refrain from intervening with prices once price capping calculations are formalized. Any inappropriate intervention in regulated enterprises would substantially affect internal performance.

Although one research study pointed out that price capping regulation is simpler than the rate of return regulation (Littlechild, 1988, P.56), price capping regulations have more complexity and are dispute in terms of manipulation. For instance, in the case of applying the rate of return regulation, there is much complex data involved such as enterprises assets, finance and forecasts of costs and revenue. For price capping regulation to work, complex enterprises and industry data are needed. However, price capping regulation requires almost as much data as the rate of return regulation. Currently, the regulation office requires more and more complex financial models to forecast the financial status of the regulated enterprise. An effective forecast model would require for instance, a nationwide forecast of demand; a model of costs and productivity relationships; future production costs (e.g. labor costs) and advanced price allocation efficiency in relation to fixed assets.

The objective of the modeling process is to establish a price regulation model. The price regulation model is aimed at assisting regulated enterprises achieve above normal return owing to industry uniqueness or monopoly unless the cost-down margin is lower than the efficiency factors. However, the normal rate of return is very difficult to calculate and requires precise capital costs. The calculation formula always raises disputes between the relevant parties. This also happens with the rate of return regulation law in the US. Apart from capital costs, the size of the asset radix and the methods of amortization are also controversial in both the UK and the US. While price capping regulation in the UK model aims to avoid the flaws in the US model, there remain many questions in the UK model.

The experience in the UK has shown that pricing variables are subject to the asset radix and the negotiated rate of return regardless of price capping regulation or the rate of return regulation. Since assets are sold at a discounted value during privatization, many concerns have been raised in areas such as purchasing costs, replacement costs and book values. For instance, the water company was sold at 90% of its actual

replacement value while the gas corporation was sold at 60% of its replacement value. In this case, it is crucial to evaluate the asset radix of the price capping regulation. Generally speaking, investors should not receive extraordinary profit from their investment amount which should include purchase costs. (Vass, 1997).

In proposing the X factors, the regulators compromised on the method of calculation. They decided on the cash flow model over the short term, which can allow a larger tolerance in net asset evaluation. The objective of the pricing formulae is to provide the regulated enterprises sufficient financial capability to fulfill the current and future public demand for investment.

In this model, the asset value is calculated based on its net book value or current value. The return to investors is over-valued during the privatization. However, if the asset value were calculated during the progress of privatization, for example when the purchase costs are, frequently under valued, more accurate values would result. Although, this may lower windfall gains from the price variation between the actual asset value and its purchase values, this would enable another variation between investors' rate of return and the return rate in the corporate accounting system. Thus, the practice accounts not support a model which went against accounting theory.

After many years of privatization, the regulation office finally took contingency actions to address the issues within privatization. For instance, with Transco (the former pipeline and storage department of the UK Gas Corporation), the monopoly and acquirer association included the asset purchase costs during the process of privatization as part of the index figures. The result of such action caused the windfall gain of investors to disappear and a price fall for its consumers. However when asset replacement is required, this means higher replacement values and service costs would rise dramatically (Fulwood, 1997; Newbery, 1997; Vass, 1997). This would enable a wealth distribution opportunity for customers although this calculation would also enable customers not to pay for actual costs. Asset evaluation became a good case study. Simpler regulation was insufficient as the situation turned complicated and controversial. Also, the UK regulator frequently intervened without following its review schedule when any consumers' disputes arose or new competitors entered the market. These actions caused many disputes and complaints between the regulator and the regulated enterprise. For instance, the telecommunication regulation office intervenes more times in British Telecom than when it was a State-Owned-Enterprise. The regulation office intervened in pricing, quality control, the rates equilibrium control and in consumer satisfaction matters (Souter, 1994:p.109). The CEO of British Telecom, Sir Valence, criticized the regulation environment in the UK

as hostile and unpredictable (Lapsley and Kilpatrick, 1997:p.81).

This also occurred in other industries. The relationships between the gas regulation office and its regulated enterprises were on the edge of rupture. The water regulation office intervened twice during the first five-year regulation period. The regulation office forced water enterprises to lower prices so as to share profits with its customers and even intervened in the bonus scheme of the enterprise. As a general rule in price capping regulation, bonus schemes of the regulated enterprises should not be an issue for the regulation office.

The regulator may amend the code of an unpredictable game. In this way the regulator and the regulated enterprises shall establish a stricter “regulation contract” or negotiate a clear code of conduct between two parties (European Policy Forum, 1996, Parker, 1997b). The price capping regulation since 1983 was designed by Professor Littlechild to minimize unnecessary and detailed governmental intervention. While it failed to minimize governmental interventions, it is highly efficient in encouraging corporate management to reduce internal inefficiency and lower service costs. The results of all types of governmental interventions in corporate strategies and economic behavior remain questionable but it is clear that negative effects have resulted.

Unexpected regulation intervention may lower the motivation for enterprises to improve efficiency because the improvement rate must exceed the X-factor to generate short term profits for shareholders. The major motivation for the regulator to pursue better efficiency is for short term profit and to be able to use this as an important index for corporate improvements in efficiency. However, regulated interventions aim to redistribute profits generated from this efficiency improvement to customers rather than shareholders. Regulated enterprises may lower efficiencies and waste resources to minimize profit and therefore avoid its prices being reviewed by the regulator. Similarly, there is a likelihood of wasted resources and lower efficiencies if the regulator intervenes in bonus distributions to shareholders.

The valuable experience of the UK regulation model that other nations can take on board is that price capping regulation is not simpler than rate of return regulation and does not use less information. In fact, both regulation models required the same amount of information. Furthermore, the regulator should amend regulations according to the review schedule and should not attempt to intervene to enhance operational efficiency. The regulator may intervene in regulated enterprises when there are pressures from governments, consumers and market competitors.

Regulators feel intervention is necessary to protect consumers from the high profiteering of regulated enterprises. Price capping regulation should introduce reforms to replace an annual bonus system or the profit sharing system (Burns, Turvey and Weyman—Jones, 1995). Profit sharing methods have caused a high level of concern in the UK and worldwide, as the design and costs incurred by the profit sharing system were disputed and not discussed revealing the intention of some enterprises to hide profits.

The profit sharing system is based on the price capping regulation but may be misunderstood and seen to be another system altogether. In fact, price capping regulation includes the profit sharing system. High profits are designed to show in following review periods, and do not reflect annual systems of profit sharing system.

We can prove the theory in the following case. Assume £1 per annum was generated from efficiency improvement. We assume an 8% conversion rate and that the cost-down would reflect in higher profits. If all things remained equal, the final benefits would be distributed as 32% to investors while 68% would be distributed to consumers.

The detail calculation per below:

$$\text{PV of } \pounds 1 \text{ for 5 years @ } 8\% / \text{PV of } \pounds 1 \text{ in perpetuity @ } 8\% = 3.99/12.49 = 31.95\%$$

The premise of this formula is that the net value of the efficiency improvement per £1 (assume 8%) would be returned to enterprise investors per five-year review period. After the five-year period, the net value of the efficiency improvement per £1 would be returned to consumers. Furthermore, the X-factor requires that 32% efficiency improvement benefits be distributed to enterprises investors while the rest of the 68% is distributed at a lower price to all consumers. The above 32/68 proportion is based on the assumption that the regulated enterprise shows improvement in the first year of the five-year period. If the improvement takes place after a few years, consumers enjoy greater benefits after the distribution. If the premise of the above calculation did not change till the fifth year, then the proportion between consumers and investors would be as high as 7/93. Therefore, price capping regulation is a profit sharing system where the timing of the benefit distribution is disputed. In price capping regulation, the consumers could be awarded their share of the profits ahead of the Investors.

3. The theory of incentive regulation

The theoretical foundation of incentive regulation in public utilities is the notion of optimal regulation. At present, there are two performance evaluation directions of the incentive regulation theory - the price capping regulation and the yardstick regulation. The Incentive regulation aims to induce regulated enterprises to improve efficiency, quality and the overall performance. The regulator adopts an intervention strategy to encourage the industry to embrace competition, to award those who uphold the regulation and punish those violating the regulation. Incentive regulation in public utilities adopts a framework of principle-agent relationships, where the regulator is the principle and regulated enterprises are the agents. Both parties tend to maximize its effective functions; where the regulators aim to maximize the social welfare function while regulated enterprises aim to maximize profits.

The economic incentives of price capping regulation have forced telecommunication network operators to increase or maintain service quality. According to one case study on telecommunication network operators, a substitution relationship was found between effectiveness and quality (Northworthy & MacDonald, 1994). The substitution relationship literally means consumers still pay the same prices even though service quality is down graded. Therefore the quality index should be incorporated as a contingency method for the calculation of total productivity. Thus, as service quality decreases, total productivity should fall accordingly. For instance, there are 18 states in USA which include 'service quality' as an item in its call rate evaluation. There are three states which include 'service quality' in price capping regulation schemes. Quality index data was collected from the open data of ARMIS (Automated Reporting Management Information System). However at present, there is not any reputable open data available in Taiwan.

Incentive regulations which aim to be successful in the telecommunication industry should include a thorough price index. A price index should incorporate significant indices and performance criteria such as the total turnover of the telecommunication services, customers groups, total demand, a telecommunication quality index, capital costs and a measure for efficiency. Performance measurement indices play a significant role in total productivity, marginal costs, quality and technical improvement (Northworthy and Tsai, 1999: p?). Performance indices enhance price capping regulations and the implementation of incentive regulation by maximizing the function of economic incentives.

4. The foreign regulation experience

This section explores the advantages and disadvantages of the public utilities privatization model in the UK. This model is now becoming the worldwide privatization template.

The most significant advantage has been to enable former state-owned enterprises (now privatized enterprise) to improve efficiency and to increase benefits for investors and consumers. In general, consumers benefit in two ways - from lower service costs and higher service quality, except in water and sewerage services. In the case of water and sewerage services, low levels of investment prior to privatization resulted in the need for the investment of large funds to improve service quality. These investment costs were transferred onto the consumers. Investors have benefited from privatization regulation laws, sometimes with extraordinary profits. These huge profits have frequently raised much public concern.

On the downside, price capping regulation law did not work as easily as formulated in 1983. Price capping regulation must incorporate operational costs, capital costs and demand growth into the calculation model. The regulated enterprises must also agree to the capital costs, and asset evaluation as per the requirement of the price capping regulation. Asset evaluation is an area of dispute because of the huge variance among the share price, net value and replacement value. This is commonly regarded as if the enterprise privatized at discounted values.

It seems that privatization under regulation achieves better performance, especially when a more appropriate system is still in the making. The regulator and the regulated enterprises should learn from the mistakes of regulation failures. A significant phenomenon was the reduction in high profitability at the early stage of privatization after tighter regulation was introduced and competition was intensified. Those nations interested in privatization and the privatization regulation may look to the UK experience.

In particular, the following points may be noted:

- (1) The direct intervention of government departments into privatized enterprises may not offer the best solution and incentive for efficient and effective regulation. In privatized monopoly enterprises, a regulation office with a detailed plan and review mechanism would offer more effective economic performance and improvement and would benefit both investors and consumers.
- (2) The positioning of the regulation as an opposing force between the regulator and the regulated enterprise is another point for consideration. While business aims to make profits for its investors, the regulator aims to minimize the profits from the regulated enterprises in order to benefit the consumers. This conflict can be seen to strengthen the relationship between the regulator and the regulated enterprise. The relationship is optimal at a certain level of opposition. Conversely, concerns are raised if both parties have close and steady relationships. This leaves room for unethical exchanges of information and even lobbying on the part of privatized enterprises to receive favorable treatment

and weakening the protection of consumers.

(3) Price capping regulation may not be easy to implement as it requires planning and as much information as the rate of return regulation. However, price capping regulation can lead to lower supply costs if spot regulation interventions were not allowed prior to the set review date. In the long term, the benefits resulting from lower costs would benefit consumers. The only problem is the presence of high profits in the short term, which would attract public criticism.

(4) Huge profits generated by regulated enterprises raise public concern and complaints are targeted at monopolized enterprises. Regulators are often pressured by the public to intervene in regulated enterprises that enjoy high profits. However such intervention lowers the efficiency motivation of the price capping regulation within the regulated enterprise. The difference between the price capping regulation and the rate of return regulation would diminish within the term of the review as the huge profits are removed.

(5) Regulation simulates or serves as a substitution for competition in the marketplace to enable the regulated enterprises to improve its performance. However unlike the true competition, man-made regulation cannot fully stimulate performance improvement and further raises some public concern. Thus, the regulator is likely to introduce more competition as long as this leads to improved economic performance. Prior to 1999, the telecommunication, gas and power generation industries remained State-Owned-Enterprises. The water supply industry remained monopolized even though the UK government tried to aggressively introduce competition into the industry (DOE, 1996; Robinson, 1997). Regulations should enable and encourage newcomers rather than acting as a hurdle into the industry.

(6) In the UK, the regulator must report to the related minister and the parliament regarding all regulatory actions. At the same time, the independent regulation must take place from the substance mode of the regulation rather than the formality mode. The work of the regulator lies in its expert opinion in its area of jurisdiction and the continuity of its policies rather than its reporting function. The work of the regulator should also be less concerned with social and political issues such as income redistribution. The balance between independence and public accountability could be threatened if the regulator is required to report its activities to the general public and if political interventions overwhelm its independence. In some nations, an over-centralized, single regulator is less acceptable than a regulator with open and democratic procedures. Furthermore, a committee-style or panel-type of regulation organization is replacing the existing single regulator model and public hearings and juridical examinations are added to enforce the regulations.

The UK experience has shown that effective regulation and privatization can energize a lethargic S.O.E., and can benefit consumers. It is important to note that the UK model is built on a specific political and economic system. Thus, the UK regulation model cannot simply be transferred to other political systems or nations but must be adapted and modified to the local environment.

The experience of price capping regulation in both the UK and the US

There are two methods of price capping regulation in both the UK and the US. The first is gain-sharing price capping regulation and the second is the sliding-scale price capping regulation. (Need more information on these 2 types of regulation. How does this relate to the next paragraph?)

In the telecommunication industry, network operators can benefit from the huge economic incentives brought about by regulation and can share these benefits with their customers. This can occur if price cap menus take into account the distribution mechanisms needed when setting the range of the X-factors. As the X-factors increase, the lower proportion of productivity profits is shared with customers. For instance, in 1995 in setting the federal price capping menus, the FCC (the Federal Communication Commission, of USA) raised its X-factors from 3.3% to 4.0%. In this case, if the telecommunication network operators chose the smallest X-factors, then they would have to distribute all the targeted productivity profits to their customers. If the network operators chose the largest X-factors, then they would not have to distribute any of the targeted productivity profits to their customers. Furthermore, if the network operators chose the median X-factors, then they would have to distribute the targeted productivity profits to their customers proportionally.

This scenario has led to five out of the seven Regional Bell Operating Companies (R.B.O.C.s) choosing the maximum X-factors while claiming that average productivity growth was not expected to exceed 3%. It is obvious that there are issues regarding asymmetrical data existing between the regulation office and the regulated enterprises. Telecommunication network operators tend to partially hide costing information in order to seek higher prices which then justify the higher X-factor target.

Therefore, in such cases, selective price cap menu regulation can more clearly reveal the cost structure information in regulated enterprises and would add to the amount of information held by the regulator. This type of regulation would resolve cases of asymmetrical data.

Price capping regulation and the X-factor has played a significant role in economic incentives. Apart from being an index for costing structure and operational

performance for telecommunication network operators, it is also an entry point for incentive regulation by the regulator.

In the US, the process of outlining and finalizing the regulation was open and consultative. The FCC organized many open conferences in order to gather information and opinions across the board. This led to the development of a strategy to support the telecommunication network operators. The FCC, however, decided on the final version of the price capping regulation.

The key points in the regulation included the calculation of X-factor, the amendment method of the X-factors, the sharing system and the linkage of X-factor, and regulation for external costs. Thus, the procedure was justified as conscientious but without being aggressive.

In the US, however, the FCC was empowered to legislate its own regulation which is not the case in other nations, such as Taiwan. If Taiwan adopted the same kind of regulation, for example, it would probably cost more to implement. The Department of General Telecommunication (DGT) may encounter costs from lengthy time delays as parties with vested interests attempt to intervene in the regulation by lodging relevant proposals to parliament for auditing. Unlike the UK experience, where the regulator negotiates the price capping formula with network operators directly and proposes all necessary indexes, such as the X-factor, the DGT in Taiwan does not possess the necessary power and may be further undermined by public skepticism.

5. The regulation experience in Taiwan

In general, the telecommunication industry has begun to experience liberalization due to breakthrough technologies, a booming service industry and government awareness of the need for global competitiveness. The US began its liberalization of the telecommunication industry from the 1980's, and this trend was followed by many other nations including the UK, Japan, Australia, New Zealand and members of the EU..

In Taiwan, the government has not been able to ignore global trends of liberalization and faces strong demands from local business and foreign Telco investors alike. This has enabled Taiwan to increase its competitiveness in a couple of ways. Firstly Taiwan has been able to transform itself into a regional transit center and secondly, it has been able to join the WTO and thus meet the demands of liberalization from local business and foreign investors.

In Taiwan, the telecommunication industry underwent a fundamental transformation based on two factors. The first factor was the speed of breakthrough technology

which dynamically transformed and made possible the liberalization of the domestic industry. The second factor was the liberalization and deregulation of the telecommunication industry worldwide. The liberalization of the telecommunication industry in Taiwan was based on fair competition enabling new market entrants to compete with the existing monopolized operator. This further increased competitiveness among the worldwide telecommunication industry.

Structural and legal reform began in Taiwan in January, 1996 when three telecommunication laws were legislated. The monopolized industry was privatized into Chung-Hwa Telecom, separating operational and administrative functions. In 1997, the telecommunication industry was further classified into two categories of business operations - the mobile networks and international direct dial business (IDD). The market continued to be liberalized.

By the end of 1997, the mobile network carriers had been liberalized. By 1999, the satellite carrier's network had been liberalized. By 2001, the telecommunication industry had liberalized all its services to all its licensed service carriers including the local exchange, long distance calls, international direct dials, broadband exchange and data exchange.

In May, 1997, the regulator of the telecommunication industry in Taiwan, the DGT, announced that it intended to replace the existing remuneration regulation rate with price capping regulation. The objectives of price capping regulation were to enable telecommunication network operators to have greater flexibility with pricing and profit while battling in the fierce competition environment under liberalization. In order to achieve the objectives, the price capping regulations included the incentive of costs reduction, and limited the previous monopolized advantages of Chung-Hwa Telecom in the market.

This research study looks at the process of legislating the price capping regulation which is economically oriented and based on economic and technical considerations. It further discusses the directions of governmental regulations and the process of formulating a more optimal regulation which is productive, rewarding and innovative.

According to the 26th Clause of the telecommunication (where is this from? Is it a charter, is it a piece of regulation? Please define): price capping regulation is only suited to the 1st type of telecommunication business and stands as the general code for the industry (Mao, 1998). At the moment, currently the Department of Transportation has amended this clause.

Price capping regulation was first presented by Littlechild in 1983 and then adopted to implement the

privatization of British Telecom in 1984. Price capping regulation was further adopted by the Federal Communication Commission (FCC) in the US during the early nineties. Currently, the theory of price capping regulation is widely adopted in telecommunication liberalization around the world, in countries including the USA, the UK, Canada and many European nations. The main reasons for the wide adoption of the theory are the incentive for economic efficiency and performance regulation. The most distinguishing characteristics of price capping regulation are that telecommunication network operators must achieve productivity goals set by regulations and that the rewards may be greater than under the previous remuneration rate regulation.

The idea of price capping theory with the X-factor of the price capping regulation was based on the goal of growing productivity. This concept also reflected if the telecommunication network operators had achieved the productivity goal, and then formulated the price within a maximum price range. If a telecom network operator achieved the productivity goal of the designated period, they were entitled to keep the super profit after deducting all operational costs and normal profit margins. The regulator would then reset the price capping maximum for the next period based on the performance of the previous period.

The productivity growth rate (the X-factor) is a significant factor in the study of price capping regulation which is used to set productivity growth targets for telecommunication network operators. Price capping formulae need to achieve effective economic efficiency incentives and performance regulation. From the point of view of consumers, higher productivity growth targets mean higher economic performance and higher economic returns could easily be achieved. In the longer term, price caps would be adjusted downwards by telecommunication network operators. The lower productivity growth target would cause a higher price capping goal. Thus, the network operators would achieve a higher rate of return and after-tax profit with costs-down operational policies and an improvement of service quality.

The incentive mechanism of price capping theory is derived from asymmetric data in an optimal regulation framework. Under price capping regulation, the regulator cannot easily predict the real costs of every type of telecommunication service and may not be able to accurately forecast cost savings due to managerial and technical improvements. However, the regulatory office may be able to design price capping formulae or various regulation contracts to induce telecommunication network operators to pursue maximum profit and cost reduction strategies. The regulation office may be able to design optimal price capping formulae or suitable regulation contracts which encourage telecommunication network operators to pursue profits, by selecting the best cost-down measures

which reflect actual costs.

When formulating the incentive mechanism of price capping regulation, the regulatory office must take into account two factors. The first factor is that network operators may reduce service quality to achieve cost-down results and the second factor is that network operators previously achieved profits from cross subsidization by operating both regulated and non-regulated telecom businesses.

For instance, in the U.S, local exchange carriers (L.E.C.s) operating in the local distance call market had to compete against inter-exchange carriers (I.X.C.), which were permitted to operate a local exchange service to compete with existing LECs. When there is cross subsidization, the long distance exchange and local exchange may not compete as fiercely as expected. Moreover, the improvement in the service quality of the LEC would be very limited if there were no real market competition.

6. Conclusion and its implications

This paper discusses the direction of governmental regulation in the area of price capping regulation and how to formulate optimal regulations prioritizing productivity, incentive investment and innovation. Laffont & Tirole (1993), endorsed optimal regulation as the goal of any price capping regulation framework. Price capping regulation and the method to induce more cost effective productivity and quality was further explored.

After the WTO classified the telecommunication industry as a global trading system and liberalization led to a maturing of the telecommunication industry, it was seen that price capping regulation would be better suited to a competitive market structure. Therefore this research is based on a new type of dynamic economic model with capital input. It has explored the incentives of price capping regulation and illustrated the measurement of total productivity in price capping regulation. It has looked at price capping regulation and sliding scale regulation from both economic and technical viewpoints during the process of liberalization in the telecommunication industry.

In the US, price capping regulation in 1991 and the Telecommunication Act of 1996 achieved several outcomes. Some phone users enjoyed the benefits of updated technology and there was competition among local exchange carriers. Furthermore proposed production growth goals were achieved despite fierce competition.

Many economic and finance regulation theories are based on asymmetric information. Incentive mechanisms of price capping regulation are based on telecommunication network operators having a sound

knowledge of costs and know-how in order to setup the incentive contract. Telecommunication network operators claim that price capping regulation has caused a drop in productivity, but in the case of the UK and the US, it has been shown that telecommunication enterprises can achieve high profitability from efficiency and increase benefits to customers. To ensure success of selective price capping regulation in the US, telecommunication network operators were allowed to choose preferred contracts in authorized business categories.

To enable the general public to benefit from increased productivity and quality, and lower prices from competition, price capping regulation formulae must incorporate a design of the optimal service index which includes measurement of service quality. While the substitution relationship between productivity and service quality has been proven in the US, in an emerging market, like Taiwan, the measurement of service quality methods and research methods must be linked to the index of price capping regulation.

Current accounting procedures do not offer the best information-gathering system for the telecommunication industry. Telecommunication network operators are frequently not called on to demonstrate the performance of the industry and pricing is not based on individual costs. In Taiwan, the DGT and Chung-Hwa Telecom came under public attack with complaints of unfairness, sloppy administrative procedures and lack of openness, when they tried to implement the call rate rationalization by addressing the telecommunication rate adjustment scheme. Public criticism also focused on the lack of detailed information for example in the case of the method for calculating the amortization of personnel costs. The difficulty was that the system did not distinguish between each type of business costs in the amortization of costs. In Taiwan, the accounting system for the telecommunication industry is based on the unified accounting procedures of the auditing department of the Executive Yuan, which is calculated based on departmental rather than on the rate of specific services or amortization.

It is clear that the research and control of the costing structure is very important. Thus it is crucial to establish a cost accounting system as a first priority. Telecommunication network operators must comply with the accounting procedures of the governmental auditing system and with corporate costs analysis and operating income accounting.

The findings of this paper indicate that regulation issues in the telecommunication industry are not simply domestic issues, but are a global phenomenon. In the future, the telecommunication industry will be faced with domestic and international competition. Therefore, consideration must be given to foreign competitors when formulating regulations. In this regard, the WTO has

played a significant role in the telecommunication industry by regulating competition and by acting as a major influence on the liberalization of the fundamental structure of telecommunication services and the direction of operations. As a result, Taiwan has adopted the new regulation model more quickly in order to improve operational performance by domestic telecommunication companies. In addition, the government is paying closer attention to the WTO conferences and decisions which help align the domestic telecommunication industry in Taiwan with international competition.

Abstract

We propose a mathematical programming methodology for identifying and examining regression rules extracted from layered feed-forward neural networks. The area depicted in the rule premise covers a convex polyhedron in the input space, and the adopted approximation function for the output value is a multivariate polynomial function of x , the outside stimulus input. The mathematical programming analysis, instead of a data analysis, is proposed for identifying the convex polyhedron associated with each rule. Moreover, the mathematical programming analysis is proposed for examining the extracted rules to explore features. An implementation test on bond pricing rule extraction lends support to the proposed methodology.

Keywords: Rule extraction, Neural Networks, Mathematical programming, Bond-pricing

1. Extracting Regression Rules from Neural Networks

Rumelhart and his colleagues in [3] proposed a learning algorithm, named the Back-Propagation learning algorithm, for training layered feed-forward neural networks. Since then, varieties of Artificial Neural Networks (ANN) have been widely used in many fields. However, in many applications, it is desirable to extract knowledge or rules from the trained ANN for the purpose of exhibiting a high degree of comprehensibility of ANN and gaining a better understanding of the problem domain. More precisely, it is desirable to have a solid way of extracting rules from a well-known ANN, like layered feed-forward neural networks, and then examining these extracted rules to gain more information about the problem domain.

In literature, there are some recent studies related to extracting rules from the trained ANN. For instance, [7], [8] and [10] extract rules from a trained ANN for classification problems; [6] and [5] from a trained ANN for regression problems. In their paper [5, p.1279], Saito and Nakano state "one future direction for knowledge-extraction technique is enabling to deal with neural networks of real-valued outputs." Thus, in this study we focus upon developing a solid way of extracting and analyzing regression rules that deal with the real-valued outputs.

From the literature, the rules extracted from the

trained ANN for regression problem most typically take the following syntax:

If (premise), then (action). (1)

The premise is a Boolean expression that must be evaluated as true for the rule to be applied. For example, a rule premise is $x \in \{x: 0.2 \leq x_1 + 2x_2 \leq 10.2\}$, where x is the outside input vector. The action clause consists of a statement or a series of statements, and is executed only when the premise is true. For example, a rule action is that the output value y is approximated by $g(x)$. The approximation function $g(x)$ can be a piece-wise linear function (cf. [6].) or a multivariate polynomial function whose power values could not be restricted to integers (cf. [5].). Specifically, the regression rules take the following syntax:

If ($x \in$ the i^{th} Area), then ($y' = g_i(x)$), (2)

where y' is the approximation of the output value y . The Area depicted in the premise covers a region in the input space. This type of rules is acceptable because of its similarity to the traditional statistical approach of parametric regression. The treatment of many topics using traditional statistical approach aims to strip away nonessential details and to reveal the fundamental assumptions and the structure of reasoning.

To identify the premise of a single rule, [6] and [5] focus on a way of data analysis on the training sample set or the generated sample set. The generated sample set contains data instances yielded from the trained ANN. With either training or generated sample set for extracting rules, the amount of data instances is finite, and the premise of a resulted rule covers merely discrete points, instead of an area. Impractically, to really catch the rules embedded in the trained ANN, the size of the data set should reach infinity. Besides, [6] and [5] have not provided a solid way of examining the extracted rules to gain useful information for the problem domain.

Here we propose the mathematical programming methodology for not only identifying regression rules extracted from layered feed-forward neural networks, but also examining the extracted rules to gain useful information. The Area depicted in the rule premise covers a convex polyhedron in the input space, and the adopted approximation function $g(x)$ is a multivariate polynomial function of x . The mathematical programming analysis, instead of a data analysis, is suggested for identifying the convex polyhedron associated with each rule. The mathematical programming analysis is also used to examine the extracted rules to explore features.

This paper is organized as follows. Section 2 gives details of the proposed method. Section 3 presents a study of applying the proposed method to the bond-pricing. Finally, Section 4 offers some conclusions and future work.

2. The Proposed Mathematical Programming methodology

Figure 1: The feed-forward neural network with one hidden layer and one output node.

Without losing the generality, we take the network shown in Figure 1 as an illustration of the proposed methodology. The network is a three-layer feed-forward neural network with one output node. In Figure 1, y denotes the output value of the neural network, and $x^t = (x_1, x_2, \dots, x_m)$ whereas x_i denotes the i -th outside stimulus input, with i from 1 to m , where m is the amount of stimulus input. ${}_2w_j^t = ({}_2w_{j1}, {}_2w_{j2}, \dots, {}_2w_{jm})$ stands for the weights between the j -th hidden node and the input layer, with j from 1 to p , where p is the amount of used hidden nodes, and ${}_3w^t = ({}_3w_1, {}_3w_2, \dots, {}_3w_p)$ stands for the weights between the output node and all hidden nodes. ${}_2q_j$ is the bias of the j -th hidden node and ${}_3q$ is the bias of the output node. The activation function

$\tanh(t) = \frac{e^t - e^{-t}}{e^t + e^{-t}}$ is used in all hidden nodes and the

linear activation function is used in the output node. That is, for the c -th input ${}_cx$, the activation value of the j -th hidden node ${}_ch_j$ and the output value ${}_cy$ are computed as in equations (3) and (4).

$${}_ch_j = \tanh\left(\sum_{i=1}^m {}_2w_{ji} {}_cx_i + {}_2q_j\right) \quad (3)$$

$${}_cy = \sum_{j=1}^p {}_3w_j {}_ch_j + {}_3q \quad (4)$$

To extract comprehensible multivariate polynomial rules from the layered feed-forward neural network with the $\tanh(t)$ activation function, an approximation of the

$\tanh(t)$ function is necessary. The following way of approximation is proposed. Assume that we are interested in the first and second ordered differential information. Then, the following function $g(t)$ is proposed to approximate $\tanh(t)$:

$$g(t) = \begin{cases} 1 & \text{if } t \geq k \\ b_1 t + b_2 t^2 & \text{if } 0 \leq t < k \\ b_1 t + b_2 t^2 & \text{if } -k \leq t < 0 \\ 0 & \text{if } t < -k \end{cases} \quad (5)$$

where $(b_1, b_2, k) = \arg(\min_{b_1, b_2, k} \int_{-k}^k (\tanh(t) - g(t))^2 dt)$, subject to $b_1 k + b_2 k^2 = 1$. $g(t)$ is continuous at boundaries of four polyhedrons ($t = k, t = 0, t = -k$), because $\lim_{t \rightarrow k^-} b_1 t + b_2 t^2 = 1, \lim_{t \rightarrow 0^+} b_1 t + b_2 t^2 = 0, \lim_{t \rightarrow 0^-} b_1 t - b_2 t^2 = 0$, and $\lim_{t \rightarrow -k^+} b_1 t - b_2 t^2 = -1$.

With the numerical analysis of Sequential Quadratic Programming (cf. [9].), we obtain $b_1 = 1.0020101308531$, $b_2 = -0.251006075157012$, $k = 1.99607103795966$, and

$$\min_{b_1, b_2, k} \int_{-k}^k (\tanh(t) - g(t))^2 dt = 0.00329781871956464.$$

$$g(t_j + {}_2q_j) = \begin{cases} 1 & \text{if } t_j \geq k - {}_2q_j \\ (b_1 {}_2q_j + b_2 {}_2q_j^2) & \text{if } 0 \leq t_j < k - {}_2q_j \\ (b_1 - 2b_2 {}_2q_j) t_j & \text{if } -k - {}_2q_j \leq t_j < 0 \\ b_2 t_j^2 & \text{if } t_j < -k - {}_2q_j \\ (b_1 {}_2q_j + b_2 {}_2q_j^2) & \text{if } t_j \geq k - {}_2q_j \\ (b_1 - 2b_2 {}_2q_j) t_j & \text{if } -k - {}_2q_j \leq t_j < 0 \\ b_2 t_j^2 & \text{if } t_j < -k - {}_2q_j \\ 0 & \text{if } t_j < -k - {}_2q_j \end{cases} \quad (6)$$

For the j -th hidden node, let ${}_2w_j^t x$. Thus $\tanh({}_2w_j^t x + {}_2q_j)$ can be approximated with $g(t + {}_2q_j)$, which is defined in equation (6). In other words, for the j -th hidden node, the activation value is approximated with a polynomial form of single variable t_j in each of four separate polyhedrons in the x space. For example, if $x = \{x: -{}_2q_j \leq {}_2w_j^t x \leq k - {}_2q_j\}$, then $\tanh({}_2w_j^t x + {}_2q_j)$ is approximated with $b_1 {}_2q_j + b_2 {}_2q_j^2 + (b_1 + 2b_2 {}_2q_j) t_j + b_2 t_j^2$. Thus, a comprehensible regression rule associated with a trained feed-forward neural network with p hidden nodes is like:

$$\text{If } x = \{x: -{}_2q_j \leq {}_2w_j^t x \leq k - {}_2q_j \text{ for all } j\}, \text{ then } y' = {}_3q + \sum_{j=1}^p {}_3w_j (b_1 {}_2q_j + b_2 {}_2q_j^2 + (b_1 + 2b_2 {}_2q_j) t_j + b_2 t_j^2).$$

To have a better representation of the area depicted in the rule premise, let us further introduce some notations. For the j -th hidden node, set i_j be 1 when the situation $k - {}_2q_j \leq t_j$ holds; 2 when $-{}_2q_j \leq t_j < k - {}_2q_j$ holds; 3 when $-k - {}_2q_j \leq t_j < -{}_2q_j$ holds; or 4 when $t_j < -k - {}_2q_j$ holds. Also,

$$\text{set } {}_2w_{j1} = {}_2w_j^t, {}_2w_{j2} = \begin{cases} {}_2w_j^t & \text{if } i_j = 1 \\ -{}_2w_j^t & \text{if } i_j = 2 \end{cases}, {}_2w_{j3} = \begin{cases} {}_2w_j^t & \text{if } i_j = 3 \\ -{}_2w_j^t & \text{if } i_j = 4 \end{cases}, {}_2w_{j4} = {}_2w_j^t, \\ {}_2u_{j1} = k - {}_2q_j, {}_2u_{j2} = (-{}_2q_j, {}_2q_j - k), {}_2u_{j3} = (-{}_2q_j - k, {}_2q_j), {}_2u_{j4} = k$$

$+ 2q_j, g_{j1}(t_j) \square 1, g_{j2}(t_j) \square \square_1 b_1 q_{j2} + b_{22} 2q_j + (b_1 + 2b_{22} 2q_j) t_j$
 $+ b_{22} t_j^2, g_{j3}(t_j) \square \square_1 b_1 q_{j3} - b_{22} 2q_j + (b_1 - 2b_{22} 2q_j) t_j - b_{22} t_j^2,$
and $g_{j4}(t_j) \square \square - 1$. Let $i \square (i_1, \dots, i_p)$ with $i_j \square \{1, 2, 3, 4\}$

for every $j, {}_1A_i \square \begin{bmatrix} w_{i1} \\ w_{i2} \\ M \\ w_{ip} \end{bmatrix}$, and ${}_1b_i \square (u_{i1}, u_{i2}, \dots, u_{ip})^t$.

Thus, for example, the premise $x \square \{x: -2q_j \leq {}_2w_j^t x \leq k - 2q_j \mid j = 1, 2, \dots, p\}$ can be expressed as $x \square \{x: {}_1A_i x \leq {}_1b_i \text{ with } i_j = 2 \text{ for every } j\}$.

In practice, the independent variables may have some constraints, and they are usually linear as shown in equation (7), where a_{ij} and ${}_2b_i$ are given constants. Let

$${}_2A \square \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1m} \\ a_{21} & a_{22} & \dots & a_{2m} \\ M & M & O & M \\ a_{n1} & a_{n2} & \dots & a_{nm} \end{bmatrix} \text{ and } {}_2b \square (b_1, b_2, \dots, b_n)^t.$$

Thus equation (7) can be expressed as ${}_2A x \leq {}_2b$.

$$a_{i1} x_1 + a_{i2} x_2 + \dots + a_{im} x_m \leq {}_2b_i, i = 1, 2, \dots, n \quad (7)$$

In sum, there are 4^p polyhedrons in the input space where the corresponding output value y is approximated with a multivariate polynomial function. The potential rule associated with the i -th polyhedron $\{x: A_i x \leq b_i\}$ in the input space is similar to the one shown in equation

$$(8), \text{ where } A_i \square \begin{bmatrix} {}_1A_i \\ {}_2A \end{bmatrix}, b_i \square \begin{bmatrix} {}_1b_i \\ {}_2b \end{bmatrix}.$$

$$\text{If } x \square \{x: A_i x \leq b_i\} \text{ then } y' = 3q + \sum_{j=1}^p {}_3w_j g_{ji}(t_j) \quad (8)$$

However, some of these 4^p potential rules are null. The Simplex algorithm (cf. [2].) can be applied to identify the null rules. If $\{x: A_i x \leq b_i\}$ is empty, the rule associated with the i -th polyhedron is null. $\{x: A_i x \leq b_i\}$ is a convex polyhedral set in the input space because $A_i x \leq b_i$ consists of linear inequality constraints. Furthermore, $\{x: A_i x \leq b_i\}$ is non-empty if the linear programming (LP) problem (9) has an optimal solution. In other words, if LP problem (9) has an optimal solution, then the rule associated with the i -th polyhedron $\{x: A_i x \leq b_i\}$ exists. Otherwise, that rule fails to exist. The process of extracting existing rules is summarized in Table 1.

$$\begin{aligned} &\text{Minimize: constant} \\ &\text{Subject to: } A_i x \leq b_i \end{aligned} \quad (9)$$

Table 1: The process of rule extraction.

- Step 1: Input all weights and biases of the trained feed-forward neural network to form ${}_1A_i$ and ${}_1b_i$.
- Step 2: Input the constraints associated with the independent variables to form ${}_2A$ and ${}_2b$.

Step 3: For each of the 4^p potential rules, says

$$\text{If } A_i x \leq b_i, \text{ then } y' = 3q + \sum_{j=1}^p {}_3w_j g_{ji}(t_j)$$

where $A_i \square \begin{bmatrix} {}_1A_i \\ {}_2A \end{bmatrix}$ and $b_i \square \begin{bmatrix} {}_1b_i \\ {}_2b \end{bmatrix}$, examine

whether the corresponding LP problem has an optimal solution. If the corresponding LP problem has an optimal solution, then the rule exists. Otherwise, that rule fails to exist.

$$\text{Minimize: } \frac{y}{x_k}$$

$$\text{Subject to: } A_i x \leq b_i \quad (10)$$

$$\text{Maximize: } \frac{y}{x_k}$$

$$\text{Subject to: } A_i x \leq b_i \quad (11)$$

Features embedded in the feed-forward neural network can be explored via further analyzing the existing rules. Take as an illustration the exploration of the relation between y' and the k -th independent variable x_k . The null hypothesis H_0 states there is no relation between y' and x_k while an alternative hypothesis H_1 argues $\frac{y'}{x_k} > 0$, and another alternative hypothesis H_2 is

that $\frac{y'}{x_k} < 0$. For the i -th polyhedron $\{x: A_i x \leq b_i\}$,

$\left. \frac{y'}{x_k} \right|_{x \square \{x: A_i x \leq b_i\}} > 0$ if the minimal solution to the optimization problem (10) is greater than zero, and $\left. \frac{y'}{x_k} \right|_{x \square \{x: A_i x \leq b_i\}} < 0$ if the maximal solution to the optimization problem (11) is less than zero. Because of the approximation stated in equation (5), $\frac{y}{x_k} =$

$$\sum_{j=1}^p {}_3w_j \frac{g_j(t_j)}{x_k} \text{ and}$$

$$\frac{g_j(t_j)}{x_k} = \begin{cases} 0 & \text{if } t_j \leq k - 2q_j \\ {}_2w_{jk}(b_1 - 2b_{22} 2q_j) & \text{if } {}_2q_j \leq t_j \leq k - 2q_j \\ {}_2w_{jk} b_{22} t_j & \text{if } k - 2q_j \leq t_j \leq {}_2q_j \\ {}_2w_{jk}(b_1 - 2b_{22} 2q_j) & \text{if } k \leq {}_2q_j \leq t_j \leq {}_2q_j \\ {}_2w_{jk} b_{22} t_j & \text{if } t_j \leq k - 2q_j \end{cases} \quad (12)$$

Thus, the optimization problems (10) and (11) are LP problems, and accordingly, they can be solved via the Simplex algorithm.

As for identifying features such as

$$\frac{y'^2}{x_k^2} \square 0 \text{ if } x_i \square x_j, \text{ the proposed method is as follows. For instance, let } \frac{y'^2}{x_k^2} \text{ be a negative constant at}$$

the [3,3,3,3]-th polyhedron. Thus “ $\frac{\partial^2 y'}{\partial x_k^2} > 0$ if $x_i < x_j$ ”

is not true at the [3,3,3,3]-th polyhedron, and “ $\frac{\partial^2 y'}{\partial x_k^2} < 0$

if $x > x^*$ ” is true at the [3,3,3,3]-th polyhedron if and only if the LP problem (13) has an optimal solution.

Minimize: constant

$$\text{Subject to: } A_{[3,3,3,3]} x^3 b_{[3,3,3,3]}, x_i > x_j \quad (13)$$

3. The Rule Extraction in the Bond-Pricing Application

This section adopts a case of bond-pricing to examine the proposed methodology. The domain knowledge with respect to the bond pricing model has been well established and thus serves to help investigating the learning process. In equation (14), bond price at time t , denoted by P_t , is governed by four factors: (1) r_t the market rate of interest at time t ; (2) F , the face value of the bond, which generally equals 100; (3) T_t term to maturity at time $t = 0$; and (4) C , periodic coupon payment, which equals $F r_c$.

$$P_t = \sum_{k=1}^{T_0} \frac{C}{(1+r_t)^{k \Delta t}} + \frac{F}{(1+r_t)^{T_0 \Delta t}} \quad (14)$$

By assuming one coupon payment per year (that is, coupon payments are made every 12 months), there are five well-known theorems with respect to bond prices which have been derived as follows: [3]

1. If a bond's market price increases, then its yield must decrease; conversely, if a bond's market price decreases, then its yield must increase. That is, $\frac{\partial P_t}{\partial r_t} < 0$.

2. If a bond's yield does not change over its life, then its discount or premium will decrease as its life gets shorter. That is, $\frac{\partial^2 P_t}{\partial T_t \partial r_t} < 0$, where $T_t = T_0 - t$ is the term to maturity at time t .

3. If a bond's yield does not change over its life, then the size of its discount or premium will decrease at an increasing rate as its life gets shorter. That is,

$$\frac{\partial^2 P_t}{\partial T_t^2} < 0 \quad \text{if } r_c < r_t$$

$$\frac{\partial^2 P_t}{\partial T_t^2} > 0 \quad \text{if } r_c > r_t$$

4. A decrease in a bond's yield will raise the bond's price by an amount which is greater in size than the corresponding fall in the bond's price, and the fall will occur if there is an equal-sized increase in the bond's yield. That is, $\frac{\partial^2 P_t}{\partial r_t^2} > 0$.

5. The amount change in a bond's price due to a change in its yield will be higher if its coupon rate is higher.

That is, $\frac{\partial^2 P_t}{\partial r_c \partial r_t} < 0$. (Note: This theorem does not

apply to bonds with a life of one year or to bonds that have no maturity date, known as consols, or perpetuities.)

We generate the training samples from a hypothetical period of 80 trading days, during which we derive r from a normal random number generator of $N(2\%, (0.1\%)^2)$. Then we use six hypothetical combinations of terms to maturity and contractual interest rate as depicted in Table 2, and generate the data with eighty measures of t , with $t = 1/80, 2/80, \dots, 80/80$ via equation (14). Thus we have 480 training samples with input variables T_t, r_c and r_t , and the desired output value of P_t , where $T_t = T_0 - t$ is the term to maturity at time t . The constraints of these input variables are listed in equation (15).

$$(1 \leq T_t \leq 4) \text{ AND } (0 \leq r_c \leq 0.030) \text{ AND } (0.016 \leq r_t \leq 0.023) \quad (15)$$

Table 2: Six hypothetical short-term bonds. Assume coupon payments are made annually.

Term to maturity (T_0)	Contractual interest rate (r_c)
2	0.0%
4	1.5%
2	3.0%
4	0.0%
2	1.5%
4	3.0%

We adopt the Back Propagation learning algorithm to train 100 feed-forward neural networks, each of which has 4 hidden nodes and different initial weights and biases. The final weights and biases of the feed-forward neural network with the minimum sum of square error are as follows: ${}_3q = 98.571$, ${}_2q_1 = -1.565$, ${}_2q_2 = 0.335$, ${}_2q_3 = -1.310$, ${}_2q_4 = -2.341$, ${}_3w^1 = (-5.531, -1.995, 4.625, -0.871)$, ${}_2w_1^1 = (0.393, -36.344, 15.955)$, ${}_2w_2^1 = (0.145, -40.733, -36.784)$, ${}_2w_3^1 = (0.409, 45.318, -62.477)$, and ${}_2w_4^1 = (0.027, 50.463, 100.840)$. We take this neural network as an illustration. Thus

$$t_1 = 0.393 T_t - 36.344 r_c + 15.955 r_t \quad (16)$$

$$t_2 = 0.145 T_t - 40.733 r_c - 36.784 r_t \quad (17)$$

$$t_3 = 0.409 T_t + 45.318 r_c - 62.477 r_t \quad (18)$$

$$t_4 = 0.027 T_t + 50.463 r_c + 100.840 r_t \quad (19)$$

$$\begin{aligned} g_{11}(t_1) &= 1.000 & \text{if } t_1 &\leq 3.561 \\ g_{12}(t_1) &= 2.183 - 1.788 t_1 + 0.251 t_1^2 & \text{if } 1.561 < t_1 < 3.561 \\ g_{13}(t_1) &= 0.953 - 0.216 t_1 + 0.251 t_1^2 & \text{if } 0.431 < t_1 < 1.561 \\ g_{14}(t_1) &= 1.000 & \text{if } t_1 > 0.431 \end{aligned} \quad (20)$$

$$\begin{aligned} g_{21}(t_2) &= 1.000 & \text{if } t_2 &\leq 1.661 \\ g_{22}(t_2) &= 0.307 - 0.834 t_2 + 0.251 t_2^2 & \text{if } -0.335 < t_2 < 1.661 \\ g_{23}(t_2) &= 0.363 - 1.170 t_2 + 0.251 t_2^2 & \text{if } 2.331 < t_2 < 0.335 \\ g_{24}(t_2) &= 1.000 & \text{if } t_2 > 2.331 \end{aligned} \quad (21)$$

$$\begin{aligned} g_{31}(t_3) &= 1.000 & \text{if } t_3 \leq 3.306 \\ g_{32}(t_3) &= 1.744 - 1.660t_3 + 0.25t_3^2 & \text{if } 1.310 \leq t_3 \leq 3.306 \\ g_{33}(t_3) &= 0.882 - 0.344t_3 + 0.25t_3^2 & \text{if } 0.686 \leq t_3 \leq 1.310 \\ g_{34}(t_3) &= 1.000 & \text{if } t_3 \leq 0.686 \end{aligned}$$

(22)

$$\begin{aligned} g_{41}(t_4) &= 1.000 & \text{if } t_4 \leq 4.337 \\ g_{42}(t_4) &= 3.721 - 2.177t_4 + 0.25t_4^2 & \text{if } 2.341 \leq t_4 \leq 4.337 \\ g_{43}(t_4) &= 0.970 - 0.173t_4 + 0.25t_4^2 & \text{if } 0.345 \leq t_4 \leq 2.341 \\ g_{44}(t_4) &= 1.000 & \text{if } t_4 \leq 0.345 \end{aligned}$$

(23)

$$\begin{aligned} y' &= 98.571 - 5.531 g_{1i_1}(t_1) - 1.995 g_{2i_2}(t_2) \\ &\quad + 4.625 g_{3i_3}(t_3) - 0.871 g_{4i_4}(t_4) \end{aligned} \quad (24)$$

Among the 256 (4^4) potential rules associated with this neural network, there are only eleven existing rules shown in Table 3. Namely, the other 245 potential rules are null. In Table 3, two polyhedrons are adjacent if they have adjacent values in one index and same values in the other indexes. Table 4 displays the amount of training samples contained in the corresponding polyhedron of each existing rule. Rules 3, 4, 5, 9, 10, and 11 provide the information of y in polyhedrons which contain no training samples.

In practice, we may be interested in features of first and second order differentiations of bond price; namely, the general principles about $\frac{y}{r_c}$, $\frac{y}{r_t}$, $\frac{y}{T_t}$, $\frac{y^2}{T_t r_c}$, $\frac{y^2}{r_c^2}$, $\frac{y^2}{r_t^2}$, $\frac{y^2}{T_t r_t}$, $\frac{y^2}{r_c r_t}$, $\frac{y^2}{T_t^2}$, $\frac{y^2}{r_c^2}$, and $\frac{y^2}{r_t^2}$.

$\frac{y^2}{T_t r_c}$, $\frac{y^2}{r_c r_t}$, $\frac{y^2}{T_t^2}$, $\frac{y^2}{r_c^2}$ and $\frac{y^2}{r_t^2}$. Then, from the eleven existing rules, we can examine the corresponding features embedded in the feed-forward neural network. Table 5 reports the result of such examination, indicating that $\frac{y}{r_c} > 0$ and $\frac{y}{r_t} < 0$ are true in all polyhedrons. Namely, the result lends support to the two rules. The rules of $\frac{y^2}{T_t r_c} > 0$, $\frac{y^2}{T_t r_t} < 0$, $\frac{y^2}{r_c^2} < 0$ and $\frac{y^2}{r_t^2} > 0$ are true in almost all polyhedrons.

The above learning process, nevertheless, is subject to a Type I error [1] for $\frac{y^2}{T_t r_c} > 0$. Specifically, $\frac{y^2}{T_t r_c} > 0$ is not unequivocal in the bond-pricing field. There are some relationships between T_t and r_c by intuition; for example, the price increases if T_t and r_c both increase and the price decreases if T_t and r_c both decrease. But we do not know exactly whether the price increases or decreases when T_t decrease while r_c increases, or vice versa. Thus $\frac{y^2}{T_t r_c} > 0$ is not an unequivocal characteristic in the bond-pricing field.

1. (The number of "Yes") / (The total number of "Yes" and "No") in one characteristic.
2. (The number of "Yes") / (The total number of "Yes" and "No") in one rule.
3. There is not a polyhedron that $r_c > r_t$ or $r_c < r_t$.

The corresponding features extracted from the trained neural network can be compared with the ones derived from the well-known bond pricing theorems. Such a comparison can help us gain out knowledge about the bond-pricing, and also investigate whether the learning is effective.

Table 6 shows the result of comparing features embedded in the neural networks with the ones derived from these well-known theorems. This table demonstrates that these rules have a mean of 100.00%

((100.00+100.00)/2) in satisfaction of both features $\frac{y}{r_c}$

> 0 and $\frac{y}{r_t} < 0$, and a mean of 72.24%

((90.91+81.82+66.67+40.00+81.82)/5) in satisfaction of

other four features. Moreover, each rule has an average satisfaction of 82.90 % on these six features. The results of the extracted rules are proved positive.

4. Conclusions and Future Work

In this study, we propose a mathematical programming methodology for extracting and examining regression rules from layered feed-forward neural networks. The mathematical programming analysis, instead of a data analysis, is proposed for identifying the premises of multivariate polynomial rules. Also, the mathematical programming analysis is claimed with the aim to explore features from the extracted rules. The proposed methodology can provide regression rules and features not only in the polyhedrons with data instances, but also in the polyhedrons without data instances.

Furthermore, the proposed method can be applied to any non-linear rules and features, as long as the adopted approximating function holds the proper nonlinear information. The approximating function $g(x)$ used in equation (5) here is designed as a piece-wise second order nonlinear function due to the assumption that we are interested in only the first and second order differential information. With respect to the bond-pricing application, features with the first and second ordered characteristics can be explored from extracted rules. Generally, $g(x)$ can be a piece-wise higher order nonlinear function, and the proposed method can be applied to the new $g(x)$.

In contrast with Setiono et al. [6], the approximating function used in equation (5) has a better total absolute error than the one associated with the approximating function proposed in Setiono et al. [6]. With the dataset used to extract rules approaches infinity, our total absolute error almost equals 0.124056, while theirs almost equals 0.142338 [6].

Issues worthy of future studies include the application of the proposed methodology to real world data, how to delete redundant constraints from the premise of a rule, and how to integrate extracted rules.

Abstract

Managing and estimating a good software is not an easy task. Because software estimation activities are concerned not only with time and effort scheduling, but also with specifying work activities, skill levels and scheduling of necessary resources. With duration, effort and other factors overlooked, poor reliability and functionality of software may occur. Furthermore, inaccurate estimation will lead to high pressure for the working team, and poor quality of final development. Hence, designing a right software metric is an important task. Due to these reasons, a software size model is being developed using a sample consisting of 122 student projects. This model takes several advantages: (1) there tends to be fewer counting problems than other software metrics, because this model is based upon simple counts; (2) the predicted software projects were calibrated to specific local environments rather than being based upon industry weights; (3) basic size components can be identified easily at the early stage of the development life cycle; (4) the model provides clues to project designers in planning and scheduling the development of new information systems.

1. Introduction

Software size models have become quite sophisticated since their introduction during the early 1970s. At that time, software development cost models were only based on a single parameter such as program size. These models were not accurate and reliable, as they were usually developed from a limited database, both in number of programs and a variety of applications. Furthermore, according to Boehm [2], these early models varied widely in their underlying assumptions and definitions of size, so the cost equations differed substantially.

Software size is a key factor to all software cost models, however, as late as the early 1980s, a few size estimation models were developed. Bozoki [4] developed a well-known expert judgment sizing model, a variant of which is now incorporated into the SEER family of models as SEER-SSM. PRICE Systems added a parametric sizing model. This model considers about twenty factors, including size calibration factor to estimate lines of code (LOC). Unfortunately, LOC is only restricted to using one particular language to estimate the software size.

Upon the introduction of Function Points Analysis by Albrecht [1], it is used to measure the functionality delivered by software and a measure about the functionality that the software delivers to the users [7] [13]. An extension of Albrecht method is known as Mark II

function points [13]. This model considers a system consisting of some logical transactions. Each transaction consists of inputs that are received, data stores that are referenced, updated and outputs that are generated. Based on the number of transactions in an information system, each transaction is individually sized and the total counts are obtained toward the overall information processing size for the whole system. In both of these two metrics, although significant effort has been devoted to strengthening the counting practices, but questions of subjectivity and measure interdependence remains. Function point method is a complex process that required a degree of training [11] [3]. While Mark II function point uses industry average weights as a measurement for construction. It is unclear how representative the systems contributing to the average are, and how stable the averages are over time. In addition, it is also unclear such weights are appropriate for new systems as well as system enhancements [12].

A similar approach, developed by Verner et al. [15], which is a bottom-up method in which the final counts of software are determined by summing up all individual components. The results of the method were very significant, but the sample data is restricted to only one system. This implies the model may not be generalized to other environments.

2. Research model

The objective of the study is to explore the possibility of developing a software metric using 4GL software projects. The model is simple and easy in estimating software size. It can be applicable to other software projects within the same environment as well. In the study, two sets of project specifications are examined. The first set is user specification, and the second set is program size in terms of executable statements (size).

2.1 User specification

The user specification is Data Flow Diagrams (DFDs) from which the software size components are extracted directly. This approach is totally different from those based on LOC and other software metrics, because the software size is predicted and estimated using simple counts (components) at the early stage of the development life cycle. Based on the details of DFDs, the software size components are extracted directly. Before studying the details of DFDs about the software projects, the context diagram is evaluated first. Walking through the context diagram, it shows how software projects are modeled and

interact with other modules/systems as a whole if any. However, context diagram is not detailed enough for representing the whole project's data movement, because it lays out only the sources/sinks and a single process with a generic name representing the entire software. There are no data stores and other components identified at this level. So DFDs are studied for understanding the entire software project level by level. By studying DFDs, project designers have better understanding about the data movement throughout a business process or an information system that the data undergoes.

From the first level of DFDs, it shows the main processing activities of the entire software project, such as processes are shown and data stores are added at this level. It is probably the most informative level compared to context diagram, because the context diagram gives project designers little information about what the software functions. Before proceeding with an explosion of next level of DFDs, project designers must be aware of the balance of the child diagram against the parent. To do so, they make sure both the 'data in' at the child level is identical with or adds up to the 'data in' at the parent level and that the 'data out' at the child level is identical with or adds up to the 'data out' at the parent level. The data pass between the processes on the child DFDs do not enter into this evaluation because they are internal to the process at the parent level.

After completing the level balancing, project designers explore each process on the balanced diagram into its own DFD. However, input and output requirements remain constant at that level but the data stores and sources are changed. If there are more details about each data process required, the next level explosion is continued by determining the next lower level's process until it cannot be subdivided, or it cannot be broken down to a point where the bubbles have a single input data flow and a single output data flow. This level is considered functionally primitive [6], because it cannot be further partitioned into subordinate components or the lowest levels have been reached [14] [6] [9] [8], so that the partitioning process is complete.

2.1.1 Calculation of software size components

When the entire software project is broken down into the functional primitives, we are in a better position to extract and count the size components. Before the components are counted toward the final size of a software project, it is essential to evaluate all DFDs carefully by determining their correctness. Because numerous errors, omissions, and inconsistencies can occur for several reasons, such as forgetting to include a data flow, making an arrowhead in the wrong direction, incorrect labeling

processes and/or data flow, or creating unbalanced decomposition in child diagrams etc. If the error checking procedure is complete, the process of identifying the size components can be started. The followings are the counting procedures for identifying the software size components.

(a) Input entity (in_enty)

The input entity refers to those input screens enter the boundary of an interface of a software project, or those are directly connected to different processes/modules by data flows. An input screen can be used for the creation of a new record, or can be used to change some existing data items from a database, or to delete an existing record. In the study, different functions of input screens are counted toward the size components. For those input screens that may not require any processing logic at all, such as a start menu or a query input screen. They are summed together to represent one input entity.

(b) Data flow(data_flow)

Data flows are those arrows flowing within each functional primitive. These arrows are those arrive at the processes/modules from input entities, or those enter from one process to another, or to data stores, or those leave from data stores to processes, and those depart from processes to output entities. Each occurrence of data flow within all functional primitives is counted toward the size.

(c) Process

Process is a transformation process for manipulating the incoming data and generating output according to the program statements given. The process component is important to each functional primitive, as it reflects the complexity of the module of the software. Thus, the higher the module complexity, the more interactions are required between input and output activities. In each functional primitive, the functions of the process are varied, such as updating the input data, verifying the existence of an entity (record) or preparing the outputs etc. All processes in each functional primitive are counted toward the size.

(d) Data_store

Data stores are the permanent or semi-permanent places for storing transaction data, they include the master files, transaction files, table files or any other semi-permanent files. The functions of the data stores are used either for looking up or updating purpose, depending on the

transaction processing required. If the data stores are used for looking up purpose, the counting of these data stores are summed together for representing only one data store. Since they are not required for transaction/data processing. However, if the files are used for updating purpose, such as changing the data items or deleting a record, then the data stores are counted individually. As they require different logic for transaction processing.

(e) Interaction

The number of interactions counted toward the software size including the data or control information passed between processes. The counting of interaction between two processes can be one way or two ways. In other words, in a functional primitive, a process acts as a calling process, while another one acts as a called process. In between, when a calling process only directs a called process to perform a specific job by passing either data or control information or both at the same time, one way of interaction is counted. Otherwise, when the called process finishes the execution, it is required to pass the processed information to the calling process, two ways of interactions are counted.

(f) Output entity (out_enty)

For each report/output screen that leaves from the boundary of a module/process after processing, it is counted once if different processing logic is required. On the other hand, if both output screen and printed report are the same length and having the same output data items, only one output entity is counted toward the final size. However, the following outputs are summed together as an output entity and counted toward the final size of the software project:

- i. A selection of menu screen: a displayed main menu offers several choices of selection are summed together, because they required no processing logic;
- ii. A starting output screen: like the initialization of conversational processing which leads the user to execute different jobs;
- iii. A query language output: a displayed message/output screen does not require any processing logic before it is retrieved.

After extracting the size components from all functional primitives, they all are added together and put into the equation for running multiple regression. The complete picture of the model using the size components identified above is presented in Figure 1.

2.2 Size

Size is the measure for expressing how large of the software is in terms of complexity. It is considered as a dependent variable. In this study, the size is referred to the total number of source statements run-on lines with a continuation indicator as a single statement. It excludes blank and comment lines of code, and other job control languages.

3. General data characteristics

All software projects in this study comprising the sample were built over a period of ten years by groups of senior students. Every software project was built to satisfy the real requirements of the external clients, normally most of the clients are from small medium enterprises. Before each project's work activity was carried out by a group of students, they were required to use a prototyping process for development, meeting with their clients on around three occasions over nine-week development period. This process is to ensure that the projects being developed would be satisfied and accepted by the clients. The projects addressed transaction processing, data retrieval and reporting, and file maintenance activities performed by the organizations. Under the software process employed, a software proposal outlining the functionality to be delivered was signed off by the client after one week. On system delivery, the client performed an acceptance test and system review. All projects satisfied the requirements of both the clients, as evidenced by the reviews, and the course administrators, as indicated by the marks awarded (although marks varied over the sample). A wide variety of software projects were constructed over the period. In total, more than seventy distinct working software projects were developed and reviewed.

Although the developers were students, they were in the final segment of their third or fourth year degree. Almost all of them completing their degrees went on to hold development positions with three months of the completion of the projects in the sample. More importantly, the software projects developed were functionality sound, providing an actual working solution to an actual client system. The students all had an equivalent amount of previous experience with the tools and the methodology used.

All software projects were implemented using the same tool, the Cogos 4GL Powerhouse. The software projects were all of the same generic class, such as transaction oriented data processing and retrieval applications. This commonality is advantageous in these factors that can be considered as constant in the system analysis, a condition not often encountered in software size research. When

they vary, factors such as these can clearly have an impact on software size. Given the potential contributors may be treated as constant, the degree of confidence adopted in regard to any size relationships supported by the data will consequently be greater.

Wdf is the coefficient of a data flow
 DF is the number of data flows
 Wds is the coefficient of a data store
 DS is the number of data stores
 Wo is the coefficient of an output entity
 O is the number of output entities

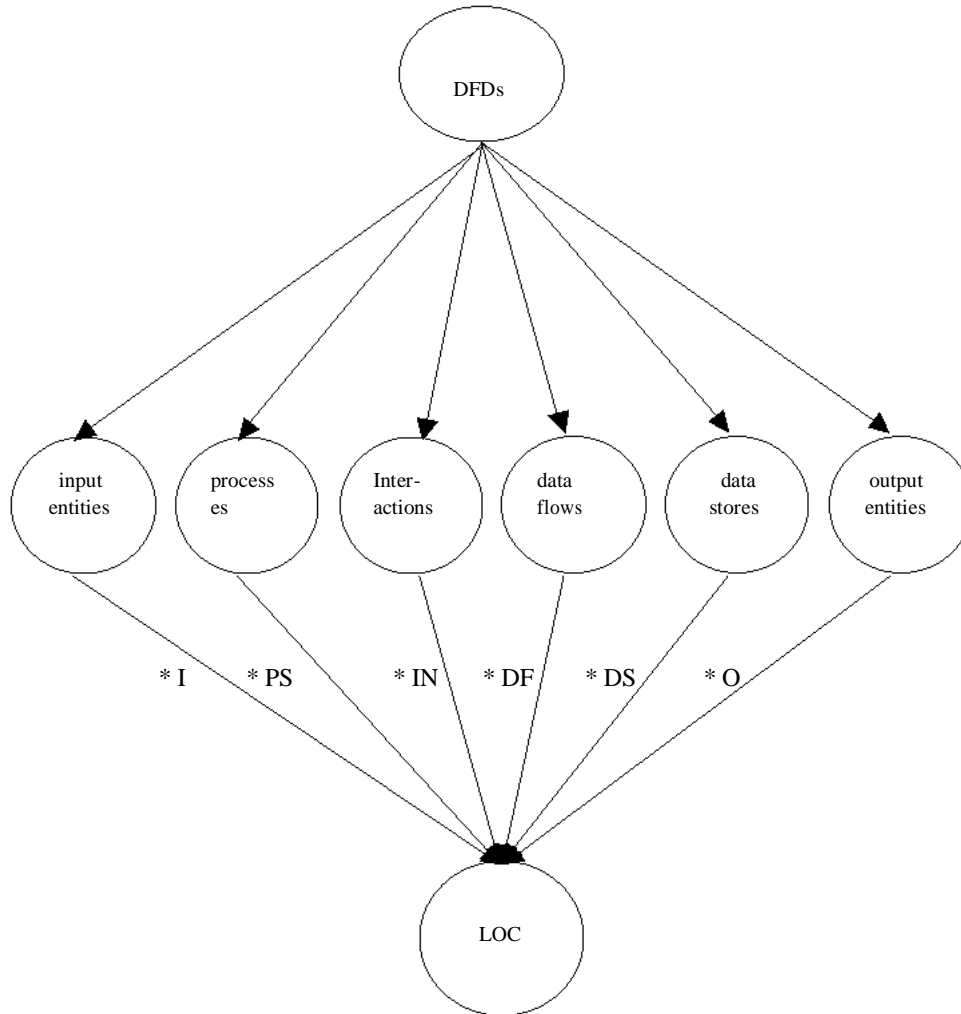

Figure 1- Size estimation using components of DFDs

$$LOC = Wi*I + Wps*PS + Win*IN + Wdf*DF + Wds*DS + Wo*O$$

Where:

- Wi is the coefficient of an input entity
- I is the number of input entities
- Wps is the coefficient of a process
- PS is the number of processes
- Win is the coefficient of an interaction
- IN is the number of interactions

4. Research methodology

The whole sample of 122 software projects is divided into two subsets of data randomly. The larger subset is called main sample consisting of two third of software projects. This subset is used for primary modeling analysis and prediction. The smaller subset called holdout sample

consisting of one third of software projects. This subset is used for validation of models developed previously using the main sample. In the study, a linear multiple regression analysis is applied for estimating and predicting the software size.

To evaluate the accuracy of regression model, the mean magnitude of relative error (MMRE) and the threshold oriented predicted measure are used. The accuracy of a project estimate is measured using the magnitude of relative error (MRE). The MRE is calculated for a project using the following formula:

$$MRE = 100 | (ACT - EST) / ACT |$$

where MRE is the magnitude of relative error, EST is the value of estimated size of a software project (in terms of LOC) and ACT is the value of actual size of a software project (in terms of LOC). Thus, the smaller the value of MRE, the better the prediction. But one important thing is that the positive and negative errors will not cancel each other out. So that the larger the value of MRE, the worse the prediction. Therefore, in an attempt to produce on average a good set of predictions, MMRE is calculated using the following formula:

$$MMRE = (1/n) \sum_i MRE_i$$

However, even the MMRE is small, there may be one or more predictions that can be very bad. So a second measure is used to examine the cumulative frequency of

MRE for a specific error level. We use the measure called PRED (p) or Prediction at Level p suggested by Conte et al. [5]. If k is the number of projects in a set of n projects whose $MRE \leq p$, the $PRED(p) = k/p$. Following the suggestion of Conte et al. [5], we report the PRED (.25) level for the estimation method. A value of $PRED(.25) \geq 0.75$ is considered desirable for size estimation.

5. Correlation analysis

Given the small degree of skewness and influential outliers are identified in some of the independent variables, the remedying steps are performed if necessary. It is essential to assess the independent variables whether they meet the basic assumptions, so as to identify any potentially useful (linear) relationships between dependent variable (size) and independent variables, as well as among independent variables themselves. After remedying the basic violations for some of independent variables, the stepwise multiple regression analysis is performed. The detailed results are presented in Table 1. Examination of the correlation matrix indicating there is a strong correlation results between dependent and independent variables. Since our focus is only to identify general patterns within the entire set of observations, the individual observations should not be omitted as they may strongly influence the regression results. Therefore, we need to identify them and access their impact if necessary.

Table 1 - Correlation coefficients

Variable	Size	In_enty	Out_enty	Interaction	Process	Data_flow	Data_store

Process	.735	.574	.415	.310	1.000	-	-
Data_flow	.498	.373	.527	.346	.407	1.000	-
Data_store	.738	.574	.500	.429	.481	.394	1.000

All are significant at 0.01

In Table 2, it indicates the model summary of selected variables before and after removing 11 influential observations. Examination of correlation matrix shows that there is not only close relationship between dependent and independent variables, but also improving both values of

adjusted R^2 and the standard error of the estimate. Therefore, we believe the influential observations identified previously have tremendous impact on final regression results. Thus, we accept the selected variables listed in the 'after' column for inclusion in the regression model.

Table 2 - Comparison of model summary of selected variables

Variable	Before			After		
	R ²	Adjusted R ²	Std. Error of the Estimate	R ²	Adjusted R ²	Std. Error of the Estimate
In_enty	.501	.494	213.59	.693	.689	200.43
Process	.757	.750	241.25	.794	.789	195.64
Data_store	.826	.819	230.18	.856	.851	187.73
Out_enty	.845	.836	200.95	.866	.859	170.01

From Table 1 and Table 2, the dependent variable is fully correlated to all independent variables. In other words, the independent variables have varying degree of effect on the dependent variable. Among the independent variables, IN_ENTY is mostly and highly correlated with SIZE. It is firstly considered for inclusion into the regression equation. According to the results presented in Table 2, the adjusted R² of IN_ENTY is 0.689 (which is about 69 %). By this value, it explains about 69% of effect of IN_ENTY to the SIZE. This is in the expected direction. Our concern is to estimate the size of software projects as early as possible using known variables. In system analysis stage of the development life cycle, in_enty is relatively easy to identify from each module/process using DFDs. More in_enty implies more time and effort are spent in designing and constructing the software. Therefore, IN_ENTY has a major effect to the size of software projects and it is in the expected direction.

The multiple R value has increased with the addition of the PROCESS variable by 7.2%. While the adjusted R² value has increased by 0.1. Indicating with the inclusion of this variable, it adds about 10% to the validity of SIZE which the software project has explained. This is true since the size of software projects can increase accordingly when more PROCESS is involved for processing. At the system analysis phase of the development life cycle, the number of PROCESS could be easily determined using DFDs. In a complete transaction, process is one of the components interacting with input and output. More PROCESS implies higher software complexity and complicated interactions between components of software projects. Therefore, the more the number of PROCESS involved for processing, the higher the complexity of the system interface.

The multiple R value is increased with the addition of DATA_STORE variable by 3.2%. While the adjusted R² has increased by 0.062, it implies with the inclusion of this variable, adding 6.2% to the validity of SIZE which the software has explained. The same result achieved was very

significant in a study conducted by Itakura et al. [10]. Its R² achieved was 0.8. In another study reported by June et al. [14], the R² achieved was 0.98 which is the highest correlation coefficient as compared to other independent variables under the same study.

In every module, the access to data store is necessary. The access to data store could be a simple query, addition, deletion or changing process. The influence of access to data store to size of software projects depends on what kind of function it performs. The influence of access to data store using a simple query would be less compare to the function of adding new records to the same data store. The simple query function does not require higher complex steps in operations, while addition function requires more interactions if more data stores are involved.

Finally, with the inclusion of OUT_ENTY, the multiple R value is increased by 0.3%. While the adjusted R² has increased 0.008, it implies that with the consideration of this variable. It adds 0.8% to the validity of SIZE which the software has explained. The explanatory power of this variable is small, it contributes less than 10% to the SIZE. Because producing the details of OUT_ENTY is fully depending on IN_ENTY, PROCESS and DATA_STORE. The output of the report is generated directly by retrieving from DATA_STORE, and the level of complexity required for producing a report relies on the design of process. Therefore, the portion of effect to size of software projects by OUT_ENTY is already explained by both PROCESS and DATA_STORE.

Among the independent variables, DATA_FLOW is the first one to reject due to insignificant effect to the size. As pointed out previously, data flow is used to connect components of DFDs showing the connections between components in functional primitives. After examination of data flow in DFDs, a data flow shows where the next process will be taken place after finishing the previous one, or where the next destination will be for retrieving the data from. Even in a large software project, it does not imply

that more designing effort is required accordingly, but from the occurrence of data flows in the software project, we can only know how the DFDs components are connected. If there are many data flows in the software projects, it means there are more other DFDs components are connected accordingly. However, since data flows don't reflect processing in the functional primitives. Therefore, the variable DATA_FLOW has no impact to the size of software project and is rejected.

For INTERACTION variable, some detailed processing steps may not be known to system designers at the system analysis stage of the development life cycle, especially when complexity of software projects is large and complex. At the early stage, we may not be very easy to investigate how DFDs components interact with each other. DFDs only show data movement from one state to another within an entire software project. It would not show the logic or complexity required in a module, even project designers have ideas about how modules interact with one another by passing data or control information from one to another. These ideas could be implemented using other programming techniques, for instance, structure chart or Warnier-Orr Diagram etc. Therefore, the variable INTERACTION is rejected.

With the completed model regression estimation, the regression variate specified, and the diagnostic tests that confirm the appropriateness of the results administered, we can now examine the predictive equation, which includes IN_ENTY, PROCESS, DATA_STORE and OUT_ENTY. The predictive equation is written as follows:

$$Y = -2008.689 + 37.330 (\text{IN_ENTY}) + 253.428 (\text{LOG}(\text{PROCESS})) + 207.779 (\text{LOG}(\text{DATA_STORE})) + 7.743 (\text{SQRT}(\text{OUT_ENTY}))$$

where Y is the dependent variable measured in thousands of LOC, IN_ENTY is the number of input entities, PROCESS is the number of processes after taking logarithms, DATA_STORE is the number of data stores after taking logarithms, and OUT_ENTY is the number of output entities after taking square root. By using this equation, the expected thousands of LOC can be calculated.

6. Validation

After developing the model using the main sample, a validation process is followed using the holdout sample. Before the estimated size of each software project is calculated, the independent variables of the holdout sample are transformed by taking logarithms and other transformation process if necessary.

There are some estimation errors introduced when the software projects were analyzed. The relative errors of

these projects are ± 0.2 but with some minor exceptions. It looks like a good model when the mean relative errors (.03) are calculated. A good model will lead to small values of relative errors and generally to a small mean relative error [5]. However, since it is possible that large positive relative errors can be balanced by large negative relative errors, a small mean relative error may not imply that a model is a good one. So the magnitude relative error is computed for each project. Thus, the smaller the value of magnitude relative error, the better the prediction. Even more important, positive and negative relation errors do not balance each other, so that the larger the value of magnitude relative error, the worse the prediction.

In order to produce a good set of project predictions, the mean magnitude relative error (.09) is calculated. The mean magnitude relative error is evaluated using a set of 36 projects whose mean magnitude relative error is $\leq .25$. The calculated PRED (.25) = .86. That is to say, in this model, 86% of the predictions for the cases in the set fall within 25% of their actual value. Therefore, this model is being accepted for software size estimation.

7. Conclusion and limitations

The paper studied the effect of the components of DFDs in determining the size of software projects. The analysis indicates the size components are accurate and reliable in predicting the size of software projects if they are extracted at the early stage of the development life cycle. Further, it shows that project managers have better understanding about planning and controlling the software development activities before the software projects are developed.

For project designers, the results of the study provide several insights for future software projects development. (1) the size components are easily extracted from DFDs during system analysis stage. Compared to other software metrics, development effort and duration are minimized without waiting until the entire software is fully developed. (2) the weights are determined after running linear multiple regression using a large sample, as a result, the weights are very reliable for representing the effort devoted to software engineering activities. (3) the model is easier to apply to similar environment. Since the results of the study are calibrated from large sample, the model can be generalized to other similar software projects. (4) the model is very suitable for both small and medium companies, especially for those which are lack of experience project designers and need better management and tighter control at lower cost.

The results in this study appeared promising. However, we should be aware of the following limitations. First, the software projects are small and medium in terms of program complexity. The results of the model are applicable to the similar software projects, such as transaction processing,

data retrieval and reporting generation. Second, the designers in the study are students, the final results of the model may be different if the software projects are developed by the experienced programmers. Third, the model developed in the study specifically emphasized on data-strong software projects, function-strong and hybrid-strong software projects may not be appropriate.

Abstract

International tourism is a highly competitive and information-intensive industry. Customers need volumes of information for decision aids. Moreover, the decision-making processes are quite sensitive to the variables of personal preferences, the tourist industrial ecosystem, the legal regulations and political environments of destinations, the regional or global economic situations, the natural matters, and so on. Hence, the owners of tourism are motivated to upgrade the competitiveness of their businesses with information technologies. This paper intends to design the architecture of Web Services in international tourism, which can contribute to the forward integration in international tourism supply chains. First, the authors conduct an in-depth case study of a regional tour operator in Thailand. In the case study, we examine the strength, weakness, challenges visions, and strategic approaches of international tourism, and their relationships with the information systems in the tourist business. Then, this paper designs the architecture of Web Services in international tourism. The architecture is expected to improve the information transparency through the global tourism supply chain, construct business-to-business collaboration mechanism, provide efficient and effective information to tourists, and consequently contribute to forward integration in international tourism supply chains.

Keywords: international tourism, Web Services, Business-to-Business collaboration, forward integration, case study.

1. Introduction

International tourism is a highly competitive and information-intensive industry. Customers need volumes of information for decision aids. Moreover, the decision-making processes are quite sensitive to the variables of personal preferences, the degree of competition inside the tourist industry, the legal regulations and political environments of destinations, the regional or global economic situations, the natural matters such as SARS, and so on. Hence, the owners of tourism are motivated to upgrade the competitiveness of their

businesses with information technologies.

The business owner's expectations toward information technologies are reflected on several aspects [1]. To compete with the new entrants, IT is expected to raise entry barriers, such as switching costs, product differentiations, and access to distribution channels. For the customer side, IT is expected to lift customers' selection, switching costs, differentiation, entry barriers, and the competence in forward integration. For the supplier side, businesses expect to increase their selection and competence in backward integration. To contend with the traditional intra-industry rivals, IT is expected to improve the cost-effectiveness, market access, service quality, differentiation in product, and finally the firm itself. IT is also supposed to generate new opportunities and competitive advantages throughout the value chain [2, 3]. The expected contributions of information technologies mentioned above apply to the international tourist industry as well, especially in companion with the Internet and communication technologies. Hence the authors are motivated to conduct a research of the competitive situation and design the architecture of Web Services in international tourism, which can contribute to the forward integration in international tourism supply chains.

In the remaining part of this paper, the authors first analyze an international tour operator in Thailand in section two. The tour operator receives inbound tourists mainly from Hong Kong and Taiwan. In section three, this study summarizes the strengths, weaknesses, challenges, visions, and strategies of information technologies to improve competitiveness in the international tourism. We extract a set of propositions from the case study with managerial implications and insights. In the fourth section, this study presents the architecture of web service for business-to-business collaboration to satisfy the information needs and even the forward integration in an international tourist company. The discussions and concluding comments will be given in the final section.

2. Case study: a regional tour operator in Thailand

Company M was founded in Bangkok, Thailand in August 1996. As a tour operator in the international

tourism supply chains, it provides packages of tourism-related services for the customers, including some combination of accommodation, transportation, restaurants and attraction visits [4]. Based on Gee, Makens & Choy [5], the distribution system of travel sales can be classified into four types: one-stage, two-stage, three-stage, and four-stage systems. (See Fig. 1). As shown in Fig. 1, a tour operator like Company M runs its business in the two-stage, three-stage, and four-stage systems. So Company M's direct customers may be the travel agents, tour wholesalers, and individual or group tourists. Most of its tourists travel from Hong Kong and Taiwan. As one of the top three tour operators in the same target markets, it received approximately thirty thousands tourists from Taiwan and fifteen thousands tourists from Hong Kong in 2002. Company M provides various services for various purposes of inbound tourists to Thailand, including sightseeing, business trips, educational communications or interchanges, and supporting some large special projects, such as Asia games in 2000.

As some businesses in the highly competitive international markets, the company has undergone many challenges as well as opportunities since its foundation, yet still erects in tourism and keeps growing continually from a small company toward a medium-sized enterprise. Now there are 15 staffs working at their newly decorated home-like office during the business hours. Outside the humane office, around 40 to 60 professional tour guides travel all over the country with the tourists and provide the first line services.

The attraction of traveling Thailand can be the abundant cultural assets, good natural conditions, fascinating social customs, friendly local residents, economic tour packages, etc. However, some tour packages in Thailand have gained notoriety in the price war and poor service quality. Since 1999, Company M made a critical decision to get out of the sick price war and competition, and positioned itself as a tour company that provides high-quality, customer-oriented and personalized services, at the reasonable prices.

"Our company has invested significant efforts in innovation." Said the CEO. "Since 1999, we have developed several high-quality tour packages and gained positive criticism from the customers. In addition to the conventional sources of tourists like group travelers, we also provide personalized packages for the individual travelers. Our goal and strategy is to ensure that all tourists with different purposes can be satisfied and experience the most comfortable stay in Thailand."

"On the other hand, the company regards the employees as our most valuable properties." Continued the CEO. "All the employees, including the supporting staffs and the tour guides on the sites, are compensated with competitive salaries and benefits. Compared to our competitors, we invest and provide more opportunities in employee development. There are regularly workshops or seminars, which may help upgrade the work performance,

broaden the mindset, exchange experiences and problem-solving skills, and so on. During the storm of SARS, other tour companies just laid off the tour guides and staffs to survive. However, we sustain the coldest season with our employees by cost-saving as well as internal education and training. After the SARS disaster, the backflows of sightseers increase dramatically in the latter half of 2003. Most of our competitors became short of manpower and called the tourist guides on mission anxiously, but our company just got everything back to the normal situation with ease."

Despite the bright sides mentioned above, Company M still has its challenges and even threats. Growing from a small business toward a medium-sized enterprise, Company M has undergone the pains of authorization and structure reformation. Besides, the information delay and non-transparency reduce the responsiveness in marketing and amplify the time pressures. "Quite our information of end customers and markets are collected through the travel agents or wholesalers. They are who interact with the end customer, not us." The middle layers of information distributions usually result in information delay and inefficiency. At the supplier sides, the poorly automated transaction processes also become a burden on operations.

During 2003, the prime minister of Thailand has announced several new policies to the industry and commerce, including more rigid control over the tourist business and stricter tax policy. "We understand that the government's vision to upgrade this country and the whole environments; however, it is really tough for the business to change the conventions overnight." Complained the CEO.

Talking about the visions of Company M, some brilliant rays of light flash at the CEO's eyes. As one member of the tourism systems, Company M does not limit its role at the current position. In 2002, it achieved a phase objective to lead and became the top company in its target markets. The next-step of the strategic plan is to expand its role from a tour operator to an international travel enterprise group. "We expect the information systems to provide a communication platform between the end customers and us. All the travelers' demands or special requirements can be collected and met firsthand. The customers can also understand our products or enterprise through the Internet and submit their orders directly. There are no more essential needs of the middlemen between the customers and us." At the supplier side, Company M expects that information systems and the Internet work effectively as they would in at the customer side. Besides, it is developing a plan of backward integration for the future 5 to 10 years. "No matter how world goes on, we just keep proceeding with our goals." The CEO said full of meaning.

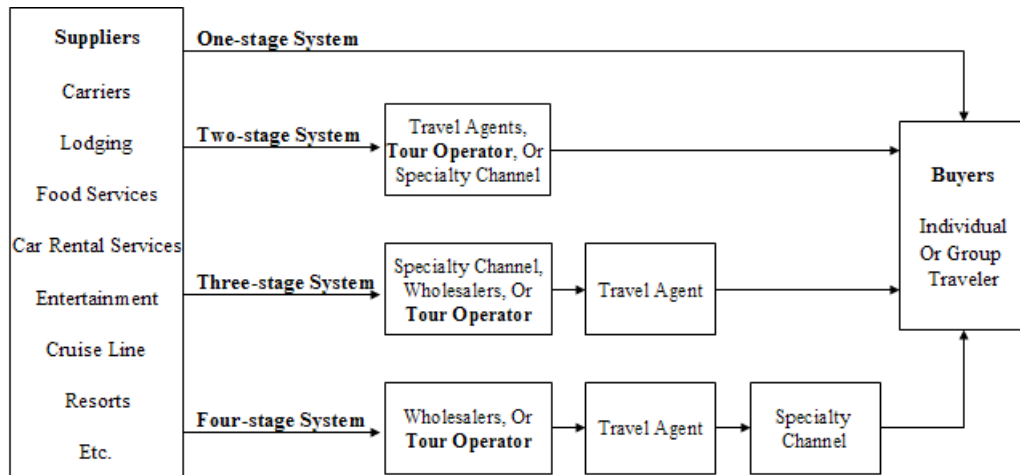

Fig. 1: Travel sales distribution system [5]

3. Implications and propositions from the case study

This study summarizes the strength, weakness, challenges, vision, and strategic approaches from the case company as Table 1.

Investigating the case deeply, this work extracts several propositions on the competition status of the international tourism and its impacts on the business investment and strategy forming. These propositions are listed as follow and illustrated as Fig. 2.

Proposition 1

The more aggressive the vision and more distinct the business objectives of the tour company, the stronger the intentions of the business owner to invest significantly in information systems and technologies—If the business owners have more strong initiative and more clear objectives in business vision, then they have stronger motivations to invest significantly in information systems and technologies.

Proposition 2

The more intensive competition inside the target market, the greater the likelihood for the tour operator to invest substantially in information systems and technologies—If the competition inside the target market are more intense, then the business will sense much more deeply the essentiality to maintain and upgrade their competitive advantages in the industry, compared to the opposite circumstances.

Proposition 3(a)

The greater the degree of substitution from the potential competitors (such as airway holidays), the greater investment of employee development the tour operator willing to make—If the potential competitors are more likely to provide packages or services with equal or similar utilities at competitive costs, then the potential

competitors will become more threatening. Hence the business owner will have more motivation to make investment in information systems and technologies to ensure their competitiveness.

Proposition 3(b)

The greater the degree of substitution from the indirect competitors/substitutes (such as the tour packages whose destinations are in other Southeast Asian areas, Northeast Asian, Australia and New Zealand, Oceania, etc), the greater investment of employee development the tour operator willing to make—Similarly, if the indirect competitors are more likely to provide products or services with equal or similar utilities at attractive prices, then the indirect competitors or substitutes will become more threatening. Hence the business owner will have more motivation to make investment in information systems and technologies to assure their competitiveness.

Proposition 4(a)

The more aggressive the tour operator's objectives toward forward vertical integration in the tour industry, the more significant investment the tour operator willing to put into the business-to-business integration technologies—Intuitively, if the tour operator has clear and strong objectives toward forward vertical integration, then the business-to-business integration technologies will be a powerful instrument for this goal.

Proposition 4(b)

The more aggressive the tour operator's objectives toward backward vertical collaboration in the tour industry, the more significant investment the tour operator willing to put into the business-to-business collaboration technologies—Similarly, if the tour operator has aimed aggressively at backward vertical collaboration, then the business-to-business collaboration technologies will be a powerful instrument for this target.

Proposition 5

The more clear and definite the tour operator's objectives toward backward vertical collaboration in the tour industry, the more likelihood that the tour operator makes efforts to persuade its suppliers (such as hotels, restaurants, etc) into the business-to-business collaboration technologies—This proposition is interrelated to Proposition 4(b). If the tour operator has definite objectives toward backward vertical collaboration, then the agreement and cooperation from the supplier side are very critical success factors. Therefore it will be motivated to win the supports from the supplier in business-to-business collaboration.

Proposition 6

The more rigid control from the government, the more likelihood that the tour operator will diversify their capital investments and business operations—The stricter legal and governmental environments cause the tour operator to diversify their business and capital investment for risk consideration.

In the following section, this paper will present the information system evolution in Company M, and how the information technologies, especially Web Services, can contribute to its vision from present through its long-term planning horizon.

Factor	Description
Vision	<ul style="list-style-type: none">● Maintaining the leading position in the market.● Forward integration from the current limited role of a tour operator, and get more control of the market through direct contact and communications with the end customers.● Backward integration with the suppliers, such as hotels, restaurants, entertainments, etc, to provide more guaranteed service quality for the tourists in the whole traveling processes.● Expand toward an integrated tourist enterprise group.
Approaches	<ul style="list-style-type: none">● Advances for more effective and efficient knowledge management systems.● Establishing a learning organization to accelerate the improvement of the manpower as well as the company.● New information platform and new information architecture for business-to-business collaboration and forward integration.

Table 1: Summaries of the case tour operator

Factor	Description
Strength	<ul style="list-style-type: none">● Good competition position in the industry.● Good relationships with the employees and competitive employee development strategies.● Innovations in product design.● Personalized services and customer oriented strategies.
Weakness	<ul style="list-style-type: none">● Immature authorization.● Lack of professional expertise in information technologies and technical supports.
Challenges	<ul style="list-style-type: none">● Pressures from business growth and transformation.● Changing governmental policies and more rigid legal environment.● Unpredictable natural disasters, such as SARS.● Uncontrollable economic depression or crises.● Vicious means from the competitors, such as the harmful price war.

4. Architecture of Web Services in international tourism.

In this section, we first describe the past and current information system architecture of Company M and then design a new architecture based on Web Services, which contributes to the vertical collaboration and integration in international tourism supply chains.

The information system architecture of the company has evolved in three phases: (1) stand-alone file system, (2) client-server architecture, and (3) Business-to-Business integration model.

At the first phase from Aug. 1996 to Dec. 1999, the CEO of Company M focused on the requirements of financial accounting and arrangement of tour packages. Thus, the information system was simply stand-alone file systems. The specifications were as follow:

- Platform: Microsoft DOS.
- Programming Language: CA Clipper.
- Database: dBase III.
- Network Connection: Not available.

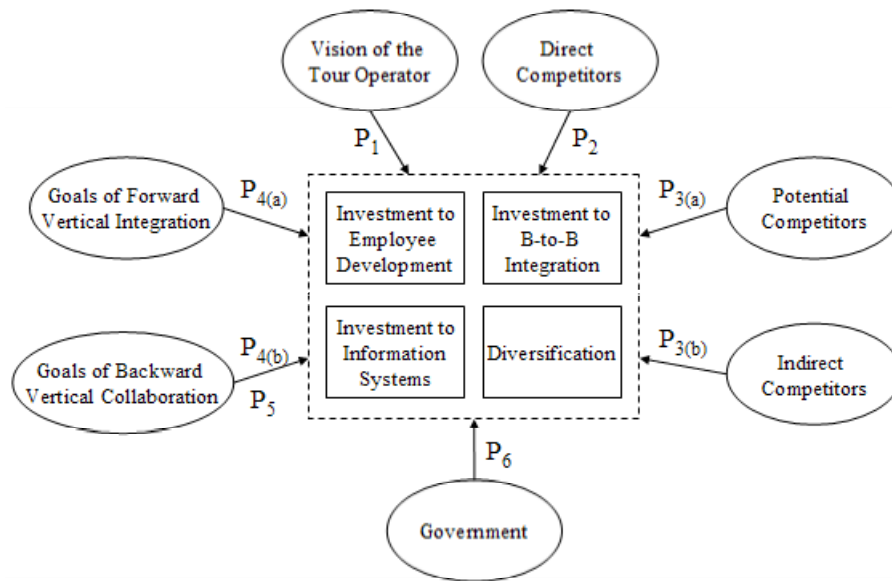

Fig. 2: A model of forming competitive strategy in the international markets

The drawbacks of the file system at this stage were:

- Data without synchronization and integrity.
- Lack of network connection.
- Difficulty to maintain and upgrade software.
- Lack of data management capabilities.

Since 2000, due to the drawbacks listed above, the CEO took the advice from one local information consulting company and decided to migrate the information system to client-server architecture (See Fig. 3).

Fig. 3: Client-and-Server Architecture

Based upon this idea, the information system at the second phase included:

- Platform: Microsoft Windows.
- Programming Language: Borland Delphi.

- Database Server: Microsoft SQL Server.
- Network Connection: with LAN Connection.

Although the client-server architecture resolved the problem of data synchronization and integrity intra-company, however, the information sharing extra-companies, such as among hotels, airlines, tour agents and tourists is still completed in the traditional ways, such as fax, e-mail, telephone and mail, which are inefficient and involving high transaction costs. Hence, seeking an efficient way to exchange information among business partners become a critical issue.

Although the World Wide Web (WWW) is a simple way to share information, WWW involves lots of human efforts to parse the HTML-format document. The web pages may appear informative to readers, but their logic behind are highly unstructured and lack a predefined schema. Thus, it is difficult to understand the semantic meaning of diverse web pages and structure them in an organized way for systematic information retrieval.

The objective of Business-to-Business integration (B2Bi) is to eliminate the manual processes by allowing internal applications of different companies to directly exchange information. Additionally, there are enormous advantages of B2Bi [6]:

- Strengthen business relationships with partners and customers.
- Fast to market.
- Reduced cycle times and increase operational efficiencies.
- Enhance customer relationship.
- Reduce operational costs.

Although many B2Bi vendors provide application packages to support the B2Bi activities and particular industrial standards, such as EDI, RosettaNet, ebXML, cXML and etc., it is still expensive, proprietary, and lacks of flexibility due to the difficulty in achieving consistency and consensus for the business model of the entire organization. Therefore, the B2Bi models are often implemented in larger-scale enterprises.

Opposed to the problems of B2Bi, Web Services have the following potentials in revolution of business process collaboration [6]:

- **Interoperability:** Web Services can be written in any language, and any Web Services can interact with any other Web Services easily with the open standard protocols such as Hypertext Transport Protocol (HTTP), XML, Simple Object Access Protocol (SOAP), Web Services Description Language (WSDL) and Universal Description, Discovery and Integration (UDDI).
- **Industry Support:** Web Services address the Interoperability issue by having the widest industry support. Many major software vendors have involved in supporting the Web Services standard.
- **Ubiquity:** Since Web Services communicate with open standard protocols, any platform that supports these protocols can host and access Web Services.

Web Services has the following advantages [7]:

- **Open Standards:** Unlike proprietary enterprise solutions, Web Services are based on open standards. The fact that they are built on existing and ubiquitous protocols eliminates the need for companies to invest in supporting new network protocols.
- **Simple:** Web Services are easy to design, develop, maintain, and use as compared to the existing solutions which may involve distributed technology.
- **Flexible:** Since proprietary enterprise solutions may require point-to-point integration, changes made at one end have to be propagated to the other end, making them very rigid and time consuming in nature. Web Services-based integration is quite flexible, as it is built on loose-coupling between the applications.
- **Efficient:** Web Services allow applications to be broken down into smaller components, which make the integration of applications easier as it is done on a granular basis.
- **Dynamic:** Web Services provide a dynamic approach to integration by offering dynamic interfaces, whereas traditional EAI solutions are pretty much static in nature.

Web Services are a common program-to-program communications model, built on existing standards. The Web Services model is based upon the interactions among Service Registry, Service Provider and Service Requestor. The interactions involve the Publish, Find and Bind operations. Web Services use SOAP based messages to achieve dynamic integration between two different applications. Using WSDL describes the public and private application services. Fig. 4 shows the relationships among the relevant standards:

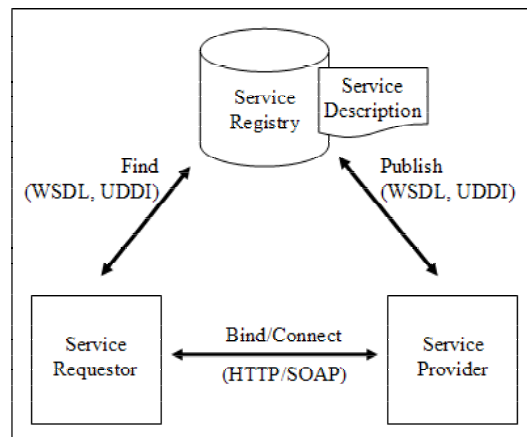

Fig. 4: Web Services Model [8]

The following summaries are the additional requirements from CEO of Company M at the third phase for Business-to-Business integration:

- Rapidly deployment.
- Reduce operational cost.
- Increase competitive advantage.
- Forward compatibility.
- Ease of installation and management.

Thus, based upon the summaries above, the Web Services Business-to-Business integration model is designed (Fig. 5):

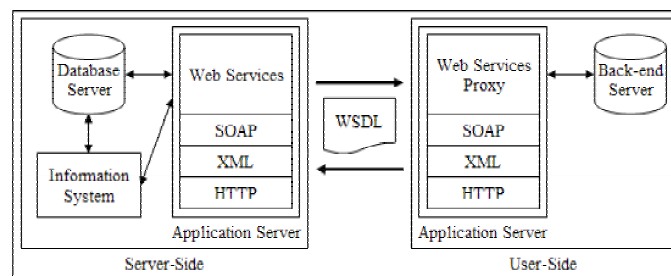

Fig. 5: Web Services B2Bi Model

The specifications of Web Services B2Bi model are:

- Platform: Microsoft Windows .NET platform.
- Application Server: Microsoft Internet Information Server.
- Database Server: Microsoft SQL Server.
- Program Language for Web Services: Visual Basic .NET.

Fig 6 shows the example of sequence diagram for the activities in this model to describe how the groups of objects interact with each other among tour operator, airlines and customers including tour wholesalers, tour agents and end travelers.

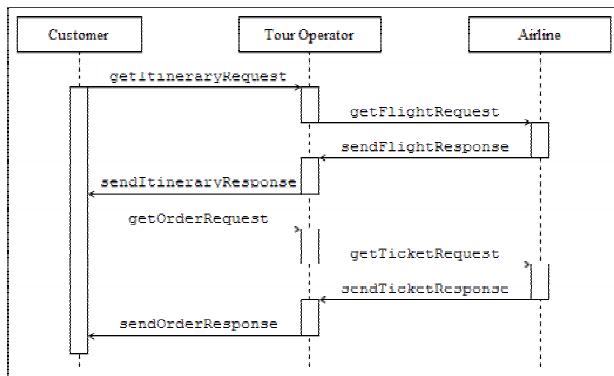

Fig. 6: Sequence diagram

Web Services represent a significant step in the evolution of Business-to-Business integration. The capabilities of Web Services allow companies to provide a front-end integration with existing application services, wrap up back-end enterprise systems as Web Services and integrate intra- and extra-services as a whole business process.

5. Discussions and conclusions

This study investigates a regional tour operator in Thailand specializing in providing tour packages for the inbound tourists from Asia, especially Taiwan and Hong Kong. Observing from various dimensions, the authors summarize the strength, weakness, challenges, vision and strategies of the case company. Then, this research extracts several managerial implications and propositions through the case analysis, and designs the architecture of business-to-business collaboration and integration for an international tourist enterprise to ensure its competitive advantages. This study develops the architecture under the belief that information systems and technologies can ensure and upgrade the competitiveness in highly competitive international tourist markets.

A VIRTUAL BUSINESS MODEL FOR THE NEW ECONOMY

David Walters
Sydney Graduate School of Management
Sydney, NSW, Australia

Abstract

The new economy brought with it a new approach to designing business models. Not too many years ago the familiar organization structure was dominated by a traditional view

Key words: new economy firm, cash flow driven, return on investment, distributed assets (low capital intensity), core assets and distinctive capabilities, value chain positioning.

INTRODUCTION

Normann (2001) discusses "a new strategic logic". and suggests that: "...managers need to be good at *mobilizing, managing, and using* resources rather than at formally *acquiring* and necessarily *owning* resources"

This new strategic logic is well expressed by McHugh et al (1995) who describe the emergence of holonic, or virtual, organisation structures where :

"...a set of companies that acts integratedly and organically; it is constantly re-configured to manage each business opportunity a customer presents. Each company in the network provides a different process capability and is called a holon" McHugh et al (1995)

An example of the approach to the "new economy is provided by Millennium Pharmaceuticals. This company was founded in 1993 and is specializing in performing basic research on genes and proteins using automated R&D technologies. In an interview with the CEO, Mark Levin, (Champion: 2001)

of managers that was based upon asset ownership and vertical organization structures. The prevalent view was that ownership enhanced control and profit margins. More recently flexibility, cooperation and collaboration have become important features for success. The success of organizations such as Dell and the move by some of the largest corporations in the world towards a model within which assets are managed rather than owned has led to significant changes not only in structure but also in attitudes and managerial behaviour. As a result the "new business model" has five common attributes: the firm should be *cash flow driven*, it should focus on *return on investment*, it should function with *distributed (leveraged) assets or low capital intensity*, to do so with a single minded view on *core assets and distinctive capabilities*, and develop competitive advantage by *relevant positioning within its industry value chain*.

This article reviews these developments and uses the Australian wine industry as an example of the new business model.

described how the value in his particular industry has changed. In particular he suggested that Value has migrated:

"Value has started to migrate downstream, toward the more mechanical tasks of identifying, testing, and manufacturing molecules that will affect the proteins produced by the genes, and which become the pills and serums we sell. At Millennium, we've anticipated this shift by expanding into downstream activities across several major product categories. Our ultimate goal is to develop capabilities and a strong presence in every stage of the industry's value chain-from gene to patient".

Levin argues that the value chain for other high-tech products has, after all, tended to break down into a few separate, largely independent markets (each majoring on specific value positioning characteristics). The computer industry is used as an example with chip manufacturing, computer assembly and delivery, software and support services are now all quite independently distinguishable but interlinked markets. Where once IBM was dominant across the whole industry, Intel, Dell and Microsoft

now coexist as a value chain. Millennium sees problems with the current structure of its industry, particularly as the profitable areas of the value chain are not in the R&D process alone. Levin suggests the future instead lies in personalized medicine: "One day, everyone will have their own genomes mapped out and stored in memory chips, and doctors will look at the information in those chips and prescribe accordingly".

And:

"We want to be the leader in personalized drug therapies ...our expressed goal is to be the first company to deliver health care tailored to the patient's genetic profile. To achieve that goal we need to reach all the way to the doctors and the patients".

A strategy to achieve this goal is based on extending the alliance and partnership models that have proven to be successful. Initially these partnerships were based upon Millennium's strong R&D capability, the relationship with the partner being simply one of contract researcher. However as the company has moved further along the value chain this has changed with the partnerships becoming fifty/fifty alliances with an increasing ownership stake in the products. This strategy has been based upon identifying and "acquiring" the capabilities that will be required. Levin in fact identifies a major problem for the industry – the huge investment required in R&D, \$2b to \$5 b, sums that are encouraging mergers and acquisitions where individual companies are losing their identities. In contrast he suggests that Millennium will emerge with a strong position in the industry value chain based on this networked R&D.

A NEW PERSPECTIVE ON BUSINESS STRUCTURE

This raises interesting questions of what business structures are best suited to take advantage of these emerging trends. It is suggested that traditional hierarchical models based on the deployment of ever increasing amounts of capital to achieve market dominance through large scale virtual or horizontal market integration are unlikely to be flexible or adaptable enough. While size still matters and it is not suggested that the large corporates are yet heading the way of the dinosaur, traditional models require re-examination.

In particular it is suggested that the "new economy firm" should focus on five key attributes in developing and designing their business models, all of which are discussed in detail below. These attributes are:

The firm should be *cash flow driven*,

- It should focus on *return on investment*
- It should function with '*distributed assets*' (*low capital intensity*),
- It should develop a more single minded *focus on core assets (R&D, brands) and distinctive capabilities only*,
- A principal element of its competitive advantage should come from successfully and appropriately *positioning itself in its industry value chain*.

Clearly these components are all quite interdependent. See **figure one**

Cash Flow Driven

The first of these structural imperatives is a focus on cash flow as opposed to traditional notions of profitability. There have been a number of global accounting based crises that suggest the often cited quotation "profit is opinion, cash flow is fact" is a major consideration for corporate governance regardless of size and structure.

It should be pointed out that even the conventional (accounting based) approach to cash flow management is limited, being developed for statutory reporting purposes. An alternative model is offered as **figure two**. This model identifies the operational and strategic decision areas that impact on cash flow planning and management and breaks these down into three broad categories the sum of which gives the firms *Free Cash Flow*.

The first category is quite familiar - *Operating Cash Flow*. Cash flow analysis at this level in the context of a "new economy" business structure allows the identification of options based around delivering both customer and corporate value either by enhancing product features or by reducing costs. These options may be internal to the organization or may be external. Basic options such as outsourcing production to lower component costs or to obtain a more reliable component can be evaluated, as can the impact on both customer service (and cash flow) that may result from a shift in the companies policy towards intermediaries.

At the second level the model enables the impact on assets of alternative production and distribution strategies to be evaluated. *Cash Flow From Assets* describes the cash flow profiles that may result from alternative decisions. The options available each have significant implications for inventory, receivables and payables together with cash flow impacts from changes in the “structure and ownership” of production and logistics in the organization.

Strategic Cash Flow decisions include investment in long term fixed tangible and intangible assets. They also concern working capital to the extent these are essentially long term, considering not simply work in progress and finished goods inventories but strategic sourcing issues that are involved with the design of products to benefit from the advantages of product platforms and buying exchanges established on an industry wide basis. In addition we are also concerned with the difficult, but nonetheless important, entry and exit costs that are associated with strategic cost decisions.

The eventual success of the business is the *Free Cash Flow* that is generated. To calculate this we need to consider the additional funding required by the business if it is to achieve its objectives. These will be equity and/or debt combinations. This introduces not only the cost considerations but also the perceptions of risk that the “market” may assume and issues of corporate control. The “value of the business” then becomes the discounted value of the free cash flow at a discount rate that is judged to be appropriate reflecting this risk.

The characteristics of the target market have a strong impact on cash flow management decisions. For example highly competitive markets in which margins are ‘difficult’ due to market structure (in which concentration has resulted in a few influential companies with large market shares, seasonal and fashion driven products, or ‘luxury’ products that are prone to mark downs) may require equally competitive pricing strategies if positive cash flow are to be maintained,

A Focus on Return on Investment

While we maintain that free cash flow should be the primary measure of success there are a number of reasons for including ROI within a ‘portfolio’ of performance measures. Using an

ROI measure facilitates comparisons between not only businesses but also components within a business. This is particularly important when considering the potential returns from alternative investments within an organization. The efficiency of capital within specific functions, such as physical distribution and manufacturing within a virtual organization differ widely, and it is for these reasons that decisions to seek partner organizations occur.

Rappaport (1983) offers the *value return on investment (VROI)*. VROI uses discounted cash flows to compare strategic alternatives, Rappaport’s approach is to measure the value created per discounted dollar of investment. Thus it offers management the means to evaluate which alternative offers the largest benefit. Rappaport’s model is simply stated by:

$$\text{VROI} = \frac{\text{Post-strategy Value} - \text{Pre-strategy Value}}{\text{Present Value of Projected Investments}}$$

The existing strategy value is derived by discounting the past year’s cash flow. The post-strategy value is similarly arrived at by using a DCF technique but being careful to consider planning horizons and by using a risk adjusted discount rate such as that used by the capital asset pricing model. (The consideration of risk is the subject of another contribution in this volume of readings). One further element is required - the present value of projected investments, which comprises the present value of the stream of incremental investments in fixed and working capital.

The VROI model offers a useful means by which the likely results of alternative business models may be evaluated. Income streams (and their capital and operating costs) can be compared using a *beta adjusted* discount rate to reflect the alternative perspectives of risk that each of the structures would involve. As an example, consider the partnership between an FMCG producer and a consumer durable manufacturer moving into industrial catering systems. Clearly they both lack specific experience in the industry sector and this inexperience should be reflected objectively by considering its impact on the venture. Investors’ views of risk would be reflected in the borrowing rates offered. In contrast in a scenario in which two or more organizations can bring a ‘synergy’ into the organization structure, and in doing so *lower* the risk rather than raise it, then discount rate used for the NPV calculation is likely to be lower.

Clearly VROI must be greater than zero if it is to create value for the shareholder. It can also be assumed that a negative value would indicate that not only is it not creating shareholder value, it is also unlikely that customer value expectations are being met, or if they are it suggests something is wrong with the project costings and that future activities are unsustainable. There are other considerations. An organisation's target ROI and its financial structure are closely related. In turn both are influenced by market characteristics. It follows that operational gearing is closely linked to the expected ROI of the business. If fixed costs are a relatively large proportion of total costs then pricing and gross margin ratios must be made to reflect the financial structure if a required ROI (and cash flow) are to be met. Sensitivity analysis on cause and effect relationships within alternative markets and market segments will add insight into the impact on ROI (and cash flow) on making changes in not only the financial variables but also the structure of alliances and partnerships within the virtual organization.

'Distributed Assets'/Low Capital Intensity

The benefits accruing to this aspect of the model have been well developed by firms such as Dell and Nike. Low capital intensity (investment/sales ratio) facilitates achieving maximised targeted cash flow and rate of return objectives. Furthermore, by adopting this strategy there is an implication that less funds have to be re-invested by each partner, making more funds available for discretionary purposes (i.e., reinforcing their distinctive competences, or distribution to shareholders).

A low level of capital intensity provides flexibility for marketing strategy options. It widens the price point options available by making lower price segments attractive and feasible. High growth markets may be funded from internal funding (with cash still available for discretionary purposes). It is difficult, usually impossible, for capital-intensive businesses to fund high growth rate from internal sources without the 'benefit' of monopolistic price advantages or perhaps some other characteristic that affords sustainable competitive advantage. Furthermore the low capital intensity model also offers operational flexibility. By maintaining an optimal balance between fixed and variable costs production

volumes can be made more responsive to market volumes thereby avoiding break-even crises. At the same time market response times are not inhibited. The application of FMS and JIT philosophies and techniques compensate for the loss of control that a shift from vertical integration to virtual integration may imply.

A Hypothetical Example

Developments in the Australian wine industry are typical of a model based upon distinctive capabilities (discussed below) with little or no fixed investment and the minimisation of working capital. The objective is to achieve a low investment to sales ratio. This takes into account assumptions concerning inventory levels that service target markets, realistic receivables and payables and a targeted pricing policy that generates target gross margins. The compelling philosophical attractiveness of the model can be demonstrated by the following two simple examples that compare a virtual wine business with a typical traditional wine business (which grows, makes and stores around 70% of its sales volumes).

In a low capital intensity (virtual winery) model the investment/sales ratio is typically lower than that of traditional models by a significant amount – 30 percent compared with as much as 120 percent. Assuming similar costs and product quality the *required* EBIT/Funds Employed ratio becomes a much lower figure. For example with a Capital Intensity Ratio of say 40/50 percent compared to the traditional level of between 100 to 200 percent the required EBIT/Funds Employed figure can be as low as 10 percent, considerably less than the 30 percent required for viability by the traditional model. It follows that target revenues are also lower, often by some 30 percent – in retail terms this may be as much as 25 percent less per bottle for the same quality wine! As a result the EBIT/Funds Employed ratio can show an impressive 75 percent for the 'virtual' model versus approximately five percent for the traditional winery model.

Cash flow improvements are equally significant. It can be calculated that, based on the assumptions of same revenues, EBIT/Funds Employed and debt, the cash generated can be shown to improve by a factor of between three and four times.

Clearly, the low capital intensity model begs the question as to whether a secure long term

supply of input product and supplementary services are available from third parties. In the context of the Australian wine industry historically, a significant proportion of the wine industry's production volume has been traded between industry members as bulk "commodity product" and specialist bulk businesses have been established whose sole purpose is to supply bulk inputs (to other businesses). Huge volumes enabled these businesses to supply input product at very attractive prices on flexible payment terms. Rosemount is an example. Until the early 1990's Rosemount was a traditional wine business. It effectively adopted the low capital intensity model in the mid 1990's in order to fund its growth. This was achieved during a period of relative under supply and rising grape prices. The strategy is particularly attractive if it is perceived that over supply and falling prices have at least 3-4 years yet to run.

Under such circumstances a *virtual winery* would adjust the proportion of requirements supplied between "spot" purchases (under short-term contracts), and longer-term contracts. Supplementary services are typically available from third party sources for operational tasks such as facilities where it can "fine tune" and store "product" prior to final processing and contract storage of finished goods.

A Focus on Core Resources/Assets

It follows that the emergent "new economy" focus on virtual structure encourages partners in an alliance to develop their core resources and assets. Indeed it is the reason that each component in an alliance has attraction for the other members. Kay (2000) identifies two categories. The first category are *distinctive capabilities* such as institutional sanctioned items - patents, copyrights, statutory monopolies and so on, but which also feature "... powerful idiosyncratic characteristics ... built by companies in competitive markets." These include strong brands, patterns of supplier and/or customer relationships, specialist skills, knowledge and processes.

In contrast *reproducible capabilities* can be created, purchased or leased by any company with reasonable management skills, skills of observation, and the financial resources. Both process and product technology are reproducible capabilities; the automotive industry is but one example.

Quinn (1992) emphasised the need to cultivate a core competence (capability) and suggests that manufacturing companies are becoming more and more dependent within the value chain on links consisting of services or intellectual activities. Olve *et al.* (1997) suggest that the underlying driver of long term strategic performance is intellectual capital and used Stewart's (1997) definition to give the term meaning, that is "packaged useful knowledge". They suggest it is this approach that is the reason why a company may be valued at more than the sum of its "hard" assets. Other approaches suggest the term "intangible assets" and this has the advantage of including or detailing specifics seen as brand values, R & D and management development.

This is an interesting concept for strategic organisational structures. Given the proposal that the dynamics of the business environment will lead to a situation where knowledge and core capabilities will be viewed as having specific shelf lives, the onus is on the company to identify the core capabilities necessary for its future. Olve *et al* (1997) extend their argument by describing a capability *balance sheet*. They argue that a traditional way of evaluating a company is to analyse its balance sheet and use the notion of gearing to explore the value of the business. A feature of the balance sheet is the ratio of shareholder equity to total assets, that is the financial gearing of the company. They cite the usual arguments concerning the extent, and influence of gearing, suggesting that if the company is overly self financed (i.e. it relies too heavily on its own capabilities), it will need to earn profits in excess of 'normal' levels to ensure shareholder satisfaction. Therefore, they suggest, few companies are totally self-financing.

The analogy of planning capability requirements uses the principles of financing for growth. The 'assets' required for success are identified as capabilities and the 'liabilities' indicate how the capabilities are to be financed - that is who is to provide them. The authors continue with the notion that capabilities have limited life expectancies and therefore suggest that the liabilities reflect a degree of 'capability leverage'. The capabilities are largely 'financed' by value chain partners. The contribution made by partners is large and is complemented by externally sourced temporary capabilities, required to meet specialist needs.

Hamel and Prahalad (1994) commented that:

“Preemptive investment in a core capability is not a leap into the dark ... it is the simple desire to build world leadership in the provision of a key customer benefit, and the imagination to envision the many ways in which that benefit can be delivered to customers, that drives the capability-building process.”

They continue by suggesting that capabilities that are most valuable are those representing a gateway to a wide range of potential product markets - a core capability leader possesses the option to be a major participant in a range of end-product markets. This is a particularly important issue for strategic operations management because the options become much wider when a value chains approach is considered. Hamel and Prahalad consider this with their capability matrix. Implicit in Hamel and Prahalad's original model is the requirement that some forward thinking be undertaken to determine the direction of “potential product markets” prior to investing in core capability leadership. Indeed the virtual organization/value chain approach offers an option to spread risk reflected by an even greater proportion of externally sourced temporary capabilities.

The link here with the cash flow and ‘distributed assets’/low capital intensity’ features of the model becomes quite clear. Organisations in virtual structures are able to focus investment on distinctive capabilities thereby reinforcing their differentiation and that of the alliance. There is a minimum of investment made into what Kay describes as “reproducible capabilities”. More importantly each member is not investing in ‘duplication’ of essential distinctive capabilities as these already exist.

Leveraging Competitive Advantage: a “Positioning” Decision

Potential competitive advantage in the market place and its potential for delivering superior shareholder value (as opposed to market positioning that attempts to deliver superior customer value) is very much based on adopting the low capital intensity model, but also identifying *where within the virtual network the capabilities of individual organisations can best be deployed*. Recognition of the fact that not all of the necessary capabilities and/or capacities are internally available leads the progressive business towards identifying where in the value chain its resources are most effectively applied. Value chain positioning and competitive advantage strategy is therefore a critical activity

In a qualitative context successful “leveraged competitive advantage” is assumed to be the successful management of one or more ‘market based’ characteristics that offer the organization a competitive edge. These may be located in either the demand chain or the supply chain, but for them to be significant they should be exclusive to the organization. It could be argued that effective strategic management identifies what these are and creates an appropriate virtual structure.

Normann and Ramirez (1993) suggested:

“ ... strategy is primarily the art of positioning a company in the right place on the value chain – the right business, the right segments, the right products and market segments, the right value-adding activities”. And: “The focus of strategic analysis is not the company or even the industry, but the value creating system (the value chain) itself, within which different economic actors – suppliers, business partners, allies, customers – work together to co-produce value. Their key strategic task is the reconfiguration of roles and relationships among this constellation of actors in order to mobilise the creation of value in new forms and by new players ... their underlying strategic goal is to create an ever improving fit between competencies and customers ... ”

Of more interest to shareholders and partners is a quantitative measure of ‘value’ delivered by this set of ‘competitive advantages’ Kay (1993) offered an approach. He suggested that the added value generated by an organization could be measured simply and effectively by deducting operating expenses and a ‘cost of capital’ from revenues. If the result is positive the organization is “adding value”, if not then it is “destroying value”. There is a similarity here with the Stern Stewart EVA measure (economic added value). Both approaches use a ‘comprehensive’ cost of capital that includes not just depreciation but interest and dividend payments, management and employee development, and investment in intangible assets.

However, Kay extends his argument by using it to provide a quantitative measure of competitive advantage. Kay's measure of competitive advantage is relatively simple; it is the added value divided by the operating costs and capital charges. **Figure three** illustrates both added value and competitive advantage. Kay argues that added value and competitive advantage may be calculated from published accounting information. However, it may take some searching of the “notes to the accounts” to identify some of the cost items.

Figure four suggests how, using Kay's model, competitive advantage may be further 'leveraged' by exploring the opportunities offered by the virtual organization model. In particular:

Revenues may be enhanced by partnerships that result in more effective responses to key customer value drivers (such as time-to-market, QR (logistics responses), flexibility, and customized service packages). Revenues may also be improved by such initiatives as cooperative R & D and product-market development with complementary and competitive organisations.

Labour cost profiles are influenced by outsourcing to obtain specialist skills or preferential labour rates. 'Capitalising' production processes is also a well-used alternative. Becoming more important is the use of design (for example by designing around 'platforms') to reduce intra and inter-organisational costs and in some circumstances eliminating duplications of process, activities and, therefore, costs.

Materials and services are also influenced by inter-organisational cooperation. The automotive, pharmaceutical and chemicals industries have pioneered web based supply chain partnerships. "Elemica" is a global electronic network comprising 22 of the largest international chemical corporations. By forming a negotiations/transactions hub interactions and transactions costs are significantly reduced and asset productivity throughout the "organization" was improved by the elimination of unnecessary inventories, automated transaction systems, reduced transportation costs (not to mention a vast improvement in 'mode' utilization) and storage costs.

Capital Costs are optimized or reduced by improving the productivity of tangible assets such as manufacturing facilities and distribution systems. Partnerships in product-market development or with the application of product innovations (e.g., the biotech industry) increase overall productivity and decreases unnecessary investment. Working capital productivity may be improved by optimizing inventory allocation and location supported by applying electronic systems to intra and inter-organisational interactions.

An effective value chain strategy, therefore, takes an organisation beyond its own boundaries. It involves identifying the core capabilities necessary to compete and to produce and deliver customer value expectations and to *coordinate* the value production process. The well-known examples, such as Dell and Nike have established models that are being implemented by a number of industries through a

value chain approach. But less well-known examples of value chain positioning exist.

Returning to the Australian wine industry, it has clearly undergone some significant changes that have resulted in the repositioning of a number of organisations within the industry value chain (for example, 'brand managers', producers, distributors etc). Given the importance of economies of scale, differentiation and integration, and the fact that lifestyle is an important consideration in wine marketing, the larger companies have been taking steps to acquire and manage major brand names. Companies in other sectors of the industry have driven much of the acquisition activity. Their knowledge and experience, together with a cost efficient infrastructure, has enabled them to invest in brand marketing and to manage the economies of scale and of integration by outsourcing wine production. The result then has been a major repositioning of organisations within the industry. The industry is moving towards brand management as being a major element in its value chain positioning and competitive advantage strategy. Wine production remains important but appears not to be as important as brand marketing when cash flow generation and contribution to earnings is considered

CONCLUDING COMMENT

The new management model is clearly one in which mutual dependency, cooperation, trust and transparency are major features. Without any of these components the model is unlikely to be successful. The results that are accruing to organizations that identify (and implement) the benefits of the 'new model' are becoming apparent. The potential savings for organizations within Elemica are beginning to appear. Within North America and Europe the potential savings from "e-market" initiatives are estimated to be at \$US 15-20 billion!

Abstract

Managing knowledge development is critical to the proper functioning of a learning organisation. Moreover, organisational learning should be incorporated into the strategic planning of such a learning organisation to ensure the long-term survival of the organisation. In this paper, these issues are critically discussed in the context of an international organisation. It is found that although the bulk of the organisation's work is knowledge-based, it faces problem in cultivating a "learning" culture within the organisation. There is little mutual learning between management and staff. The organisation also faces leadership and willingness problems. It would be critical for the organisation to come to terms with leveraging its knowledge base in planning for its sustainable development.

1. Introduction

According to Drucker (1993) [5], knowledge has become the resource leading to organisational uniqueness. Knowledge is a shared collection of principles, facts, skills and rules [8], and is a function of information, culture and skills [10]. The ability of organisation to compete will depend increasingly upon their ability to compete, develop new knowledge, and create maximum market value for the knowledge [6] [9]. In this paper, the organisation we choose to discuss is the International Telecommunication Union (ITU), a specialised agency of the United Nations at Geneva, Switzerland. In charge of regulating worldwide radiocommunications, setting up worldwide telecommunication standards and leading world telecommunication development, ITU is the world's oldest intergovernmental organisation. With a staff of more than 1,000 from all around the world, ITU has a very hierarchical structure. The Secretary-General and his deputy, together with the three directors of the bureaus, make up the top management, with department and unit heads reporting to them.

ITU may be said to be in a crisis. For more than a century, ITU's membership consisted mainly of national telecommunication administrations that contributed to most of ITU's financial and intellectual resources. These national telecommunication administrations had traditionally been (pseudo-) monopolies in their respective home countries, and could thus represent the

totality of the interest of the telecommunications industry in those countries. Since the early 1990s, however, most national telecommunication enterprises have been privatised, while the telecommunication industry has also been liberalised, allowing new entrants to the industry. These new entrants would also like to have their voices heard and their interests represented in an international forum such as the ITU. Additionally, the Internet phenomenon has also shifted the work focus of ITU from traditional telecommunications to novel information and communication technology. As such, planning to stay relevant in a world of privatised international telecommunication and advancing Internet connection, while maintaining the intergovernmental nature of the organisation becomes the top priority for ITU. ITU's strategic planning activities are carried out by the Strategies and Policy Unit (where the principal author served as administrative officer) within the Secretary-General's Office, which are then ratified by the Plenipotentiary Conference, the supreme organ of the ITU.

Based on the first-hand observations of ITU's functions and works by one of the authors who was an administrative officer in ITU's Strategies and Policy Unit, this paper attempts to capture the organisational learning process in a learning organisation, and the interaction between leadership and strategic planning (or the lack thereof) in such an organisation.

2. Managing Knowledge Development in a Learning Organisation

Knowledge and its management is central to ITU's works. The bulk of ITU's intellectual works are done by the "study groups", who are panels of experts from both inside and outside of ITU. ITU then disseminates and implements the fruits of their works. ITU will not survive without the crucial functions of knowledge development. As a knowledge-based organisation, ITU must then adapt itself to being a learning organisation.

Organisational learning has variously been defined as the process of improving actions through better knowledge and understanding [7] and interactions between adaptation at the *individual* level and adaptation at the organisational level [2]. Organisational learning may be conceptualised into single- and double-loop

learning [11]. In single-loop learning, the individual learns the “rules of the game” during his routine work in the organisation, while in double-loop learning, the changing of the rules and ultimately the organisation based on learning kicks in. While an individual learns to solve problems, the organisation develops systems and processes for attaining results. Organisational knowledge aids decision making, behaviour and actions, and is primarily developed from *individuals* in the organisation [8]. However, this is not always the case in practice. A newly elected ITU top management team typically settles in and tries to learn the “ropes” of ITU so as to effect change. Often, however, they are instead assimilated into the ITU “culture” and continues with the old ways of doing things. It may be argued that their level of learning is not profound enough so that they may discern ITU’s deficiency and cause change.

3. Organisational Learning in a Learning Organisation

Organisational learning is also about detecting errors or anomalies and correcting them by restructuring organisational theories in use [1]. In this respect, ITU’s managers have not done a good job. An average ITU manager simply slugs through his daily work without realising either the relevance or the correctness of his or his department’s course of actions. Moreover, despite a one-person internal audit department, there is no formal feedback mechanism for detecting and correcting administrative or substantial errors. The “feel good” and “save face” nature in a diplomatic environment also means that ITU staff and work participants are not exactly encouraged to voice their concerns. A small training department is more for window-dressing than offering any learning opportunities, such as scenario analysis.

Another issue which impacts ITU’s learning process is the dichotomy between explicit and implicit knowledge [4]. The former, being tangible, clearly stated and consisting of details which can be recorded and stored [8], resides primarily with ITU’s rank-and-file staff, who are mostly specialists in their various fields. The latter, which is often tacit, unstated, and based on individual experience, is often mastered by the managers, who have been wallowing in the ITU bureaucracy for years, who learned the dos and do-nots in ITU the “hard” way. Ideally, a mastery of both types of knowledge would be conducive to organisational learning, but in ITU’s case, there is scarcely any mutual learning process between the management and the staff.

4. Strategic Planning in a Learning Organisation

Strategic planning can be defined as the devising of a game plan consisting of the courses of action a company wants to take. It enables the organisation to follow a well-defined path in a turbulent environment. In

particular, in Greiner’s organisational life-cycle (cited in [12]) which postulates that organisation pass through 5 evolutionary growth stages and 5 revolutionary crisis points, the first crisis is that of *leadership*, after the solution of which the organisation learns to deal with this crisis and moves on to another evolutionary stage. In ITU’s case, there is indeed the crisis of *leadership*, as no clear goals are set and no inspirations are offered by either the top management or the middle-level managers. Both the organisation and the managers may thus be said to be yet to emerge from this leadership crisis, and therefore have not moved on to another evolutionary stage in the organisation’s growth.

Indeed, leadership is a critical issue for ITU. Senge (1990) [11] opines that a leader’s role in the learning organisation is that of a designer, teacher and steward who can build shared vision and challenge prevailing mentalities. Nevertheless, several factors exist to undermine this role for the leaders in ITU. In particular, ITU there exists the managerial sub-culture of over dependence on professional assistants to do the “learning” for the managers, rendering the latter often little more than presenters in public. The highly politicised atmosphere in an intergovernmental organisation also means that the differences in authority among the various heads are stiff, and they are very jealous in guarding their own “turf” of knowledge instead of sharing it with others.

De Geus (1995) [3] also said that a company that exists to survive needs a higher level of skill in dealing with the changing environment. As such the members of the organisation need to continually learn to adapt, manipulate and progress. This should have been the case with ITU, which is an organisation trying to find its place in a new and more variable environment. ITU should therefore incorporate a high degree of learning into its strategic planning. Although ITU does have a formal planning system in place, the system suffers from a number of deficiencies, ranging from specialist-domination of the planning process which abounds with details but lacks of vision, to an obsession in searching for the mythical “right” strategy while failing to assign ownership to any makeshift plans. And those plans are often not at all implemented. For example, during every recent ITU Plenipotentiary Conference (the highest governing organ of ITU), a Strategic Plan is typically adopted, but a new top management team which might not have drafted or been consulted about the Plan is typically not particularly interested in implementing it. It may thus be said that what ITU suffers from is not a lack of expertise or knowledge but a dearth of willingness, means and vision to incorporate them into the strategic planning process.

5. Conclusions

In summary, it is clear that an organisation that makes it its business the development and management of

knowledge should itself set an example as a learning organisation. The irony of the non-accomplishment of this task is amply observed in the case of ITU. It is critical that the managers in such an organisation should set the vision and the norm of learning in the organisation. If they fail to do so due to personal incapacity or unwillingness, the implication for the strategic survival of the organisation will indeed be profound. For the incorporation of learning into the strategic planning and implementation process of an organisation will like be the differentiating factor between those that survive and prosper on the one hand and those that become casualty of a changing environment on the other hand.

ei.oh@ties.itu.int

Abstract

The rapid rise of electronic commerce and the latter's increasing intrusion into everyday life has not been matched by an effective governance structure. The present paper proposes an evolving multi-faceted self-governance framework for the regulation of electronic commerce by, for and of the users and service providers of electronic commerce. The idea of "electronic commerce interest group" is proposed and described, together with their interactions. The framework takes into account the policy, ethical and economical aspects of electronic commerce development, and seeks to devise balanced and sensible electronic-commerce governance solutions.

1. Introduction

The advent of the Internet over the past decade has created new possibilities for business dealings, be they transactions of products or provisions of services. As a result, tremendous convenience and savings have been enabled by electronic commerce. Nevertheless, the proliferation and invasiveness of electronic commerce into both business and individual lives have also engendered opportunities for unscrupulous parties to engage in malicious activities over the electronic medium, often with greater ease, speed as well as harms to society. A typical knee-jerk reaction to these perceived electronic endemic is the tightening of Internet regulations by authorities. This paper attempts to explore an alternative answer. Part I of the paper discusses the policy, ethical, economical and social dimensions of electronic commerce specifically and Internet in general. Based on these observations, Part II proposes a multi-faceted self-governance framework for electronic commerce activities and compares its strengths and weaknesses.

2. Some Issues in Electronic Commerce

2.1 Policy

Despite the seemingly democratic nature of the Internet, sound public policy over the Internet can make or break the healthy development of electronic commerce. A public policy which restricts both the access and the contents of the Internet, for example, will almost certainly strangle the growth of electronic commerce. Some of the important public-policy issues on electronic commerce

may be divided into three categories: intellectual property, content and privacy.

2.1.1 Intellectual Property

The property rights over intangible "property" which is the result of creativity and/or innovation are often referred to as intellectual property (IP). On the Internet, the main IP debates concerns domain names and copyrights.

2.1.1.1 Internet Domain Names

Internet "domain names" have seen intense "turf fights" during the last decade. Domain names are unique Internet "addresses" which indicate a web page. A domain name consists of at least two components – a designation of the organisation (e.g., "ums") and an abbreviation for the nature of the organisation (e.g., "edu"). The latter is known as "top-level domain" (TLD). A domain name registered in a country other than the United States usually has an additional country-designating component (e.g., "my" for Malaysia). In the United States, on the other hand, the domain names usually do not have an additional country-designating component, and these TLD's are known as "generic" TLD's (gTLD). For the electronic commerce communities worldwide, the ".com" gTLD has become a priced commodity, with its subtle phenomenological implications of commercial superiority. Nevertheless, confusion may arise out of similar gTLD. To illustrate, both University of Malaysia Sabah and University of Malaysia Sarawak may arguably have a legitimate claim to the domain name "ums.edu" provided proper registration is made.

During the latter part of 1990's, two initiatives have been made to resolve the gTLD disputes. There was initially the "gTLD Memorandum of Understanding" (gTLD-MoU) [9] developed by an international ad hoc body in 1997, with participations from both the World Intellectual Property Organization (WIPO) and the International Telecommunication Union (ITU). The gTLD-MoU proposed a seemingly autonomous gTLD governing structure with various functioning arms such as a policy advisory body, a policy oversight committee, a depositary for the MoU, a council of registrar, and an administrative challenge panel. Despite its limitations, the

gTLD-MoU may be viewed as one of the first international efforts in arriving at a self-governing structure for electronic commerce. The main advantage of gTLD-MoU is that it is a truly international attempt to resolve an international problem. The main disadvantage, on the other hand, is a lack of criteria to separate the genuine, interested participants of the gTLD debate from those who incidentally avail themselves of the benefits of the MoU.

In response, the United States proposed its own domain name system reform policy in 1998 [11]. Under the American initiative, a non-profit corporation was formed with headquarters in the United States to manage gTLDs and to resolve international gTLD disputes. Both the strength and the weakness of this structure is its backing by the American government. While US backing lent credibility to the proposal, a significant amount of suspicion has also been raised. The European Union has criticized that the American proposal was not arrived at with sufficient international consensus. Others view the US proposal as the extension of US domain name policy to the Internet community in the rest of the world. Over the past few years, however, the US proposal has more or less been grudgingly accepted and practices around the world.

2.1.1.2 Copyrights

Another contentious IP issue concerning electronic commerce is the issue of copyrights. The history of copyright law witnessed the conflicting demands between, on the one hand, the authors of protected creative works who would like to exact their due shares whenever their protected works are reproduced, and, on the other hand, the user of the protected works who would like to ensure his access to the greatest amount of materials, protected or otherwise, with as little charges as possible. This constant struggle is magnified on the Internet, as was the case with peer-to-peer electronic file swapping services, which provided a means for their members to exchange digital music files which may or may not be protected. The Internet has made reproduction of protected works relatively effortless. A further complication is that the global reach of the Internet implies that restructuring of the copyright law and policy must necessary be universal. In addition, the debates over copyrights between the developed and developing countries often assume a non-economic and political nature. Some argue that the present copyrights system protects the interests of developed countries who limit the flow of “protected” information to developing countries which cannot afford to pay the often stiff royalties for the vital information necessary for the latter’s national development. The Internet thus enables the developing countries to obtain crucial “protected” information with relatively low costs.

2.1.2 Content

The huge amount and diversity of opinion and materials expressed and exchanged on the Internet constitutes a main reason for the tremendous development of electronic commerce. Governments around the world are gently waking up to the potential of the Internet in providing essential services. They are also rudely awakened by the poorer taste or appropriateness of some of the Internet contents. The governmental impulse, then, is to regulate Internet content allegedly for the public good. This was the case, for example, in Germany [8] and China [5]. It remains to be seen whether these draconian policies would hamper the healthy electronic commerce development in those countries. Nevertheless, these measures may not be as effective in eradicating “harmful” material as they first seemed. The global nature of the Internet means that a prohibition on certain content production in one country would help the content-creation industry in another country, since the demand for the content remains the same. Therefore, a more effective system may be a self-regulatory “content” framework, such as the “content forum” with industry and expert representation such as that proposed under the Malaysian Communication and Multimedia Act 1998.

2.1.3 Privacy

The protection of personal Information is essential to integrity to both human dignity and commercial integrity. Therefore, the protection of Internet users’ and producers’ information privacy is important for the continuous development of electronic commerce. Without an adequate privacy protection framework, potential participants would be deterred from engaging in electronic commerce, lest their personal data become tradable commodity. To answer this concern, most developed countries, such as the European Union [6] [7] and Organisation of Economic Cooperation and Development [13], have been drawing up their respective data privacy laws, policy and guidelines.

2.2 Ethics

The moral outlook of the “Internet community” should be examined before a meaningful proposal of a self-governance framework for electronic commerce. This determination of the ethical attitude of those who use and who provide services over the Internet is crucial in determining the best Internet self-governing structure and in avoiding self-regulatory pitfalls.

Using ethical principles distilled from various philosophical and sociological literature, Oh et al. (1998) [12] designed a survey on the attitude of the of Internet community. The survey requested participants to rank these ethical principles in the order of their preference in utilizing the principles in resolving the moral dilemmas which the participants may encounter in the course of their Internet usage or service provision. Table 1 summarises and adapts the results of the survey in descending order of the preferences of ethical principles by the Oh et al. (1998)

[12] survey participants.

Table 1. Ethical principles and their descriptions (Oh et al., 1998)

Ethical Principle	Description
Means-Ends Ethic	If the end justifies the means, then you should act.
Might-Equals-Right Ethic	You should take whatever advantage you are strong enough and powerful enough to take without respect for ordinary social conventions and laws.
Intuition Ethic	You do what your "gut feeling" tells you to do.
Professional Ethics	You should do only that which can be explained before a committee of your professional peers.
Conventionalist Ethics	Individuals should act to further their self-interests so long as they do not violate the law.
Organization Ethics	This is an age of large-scale organizations – be loyal to the organization.
Hedonistic Rule	If it feels good, do it.
Disclosure Rule	If you are comfortable with an action or decision after asking yourself whether you would mind if all your associates, friends, and family were aware of it, then you should act or decide.
Golden Rule	Do unto others as you would have them do unto you.
Utilitarian Principle	You should follow the principle of "the greatest good for the greatest number."
Categorical Imperative	You should not adopt principles of action unless they can, without inconsistency, be adopted by everyone else.

In Table 1, it could be noted that the top two preferences in ethical principles of Internet users and producers, assuming the survey results as representative of the attitude of the Internet community, for utilization in resolving on-line moral dilemmas are Means-Ends Ethics and Might-Equals-Right Ethics which are not so positive. Oh et al. (1998) [12] pointed out that similar top preferences were also found in surveys of business school students and business managers. In other words, while the Internet community may be viewed (based on the Oh et al. (1998) [12] survey) as ruthless and aggressive, their attitude is no worse or better than the rest of the "real life" business community. Human selfishness and combativeness are just features of human characters that any regulatory framework has to work with.

Moreover, if those ethical principles in Table 1 which

may be deemed more or less "anti-social" (Means-Ends Ethics and Might-Equals-Right Ethics), "compulsive" (Intuition Ethic and Hedonistic Principle) or generally "problematic" (Conventionalist Ethics and Organizational Ethics), we are left with the moral/ethical principles in Table 2 (again in descending order of their preferences).

Table 2. "Preferred" ethical principles based on Oh et al. (1998)

Ethical Principle	Description
Professional Ethics	You should do only that which can be explained before a committee of your professional peers.
Disclosure Rule	If you are comfortable with an action or decision after asking yourself whether you would mind if all your associates, friends, and family were aware of it, then you should act or decide.
Golden Rule	Do unto others as you would have them do unto you.
Utilitarian Principle	You should follow the principle of "the greatest good for the greatest number."
Categorical Imperative	You should not adopt principles of action unless they can, without inconsistency, be adopted by everyone else.

In Table 2, it could be noted that the top two "good" ethical preferences of the Internet community, Professional Ethics and Disclosure Rule, are both dependant on the establishment of either professional or specialized bodies – "professional peers" and/or "associates." This may give us a hint that an effective Internet self-governing structure must entail, as one of its most important components, professional or specialized bodies. They may be the most effective means to counter the more "sinister" human tendencies as discussed above.

2.3 Economics

The momentous growth in the number of Internet service providers (ISP's) implies the strength of electronic commerce. It can, however, be observed that the economic growth of the Internet has been concentrated in too few hands; there is a lack of competition among the major ISP's. In the wholesale Internet market, for example, the top three US ISP's accounted for about 73% of US market share. [3] In the retail Internet market, the number of AOL subscribers outdid that of its top ten competitors. [10] The fear is that with their overwhelming market shares, giant ISP's may squeeze out smaller competitors and thereafter inflate service prices. Governmental regulation in the form of anti-trust policy is often suggested as a suggestion. But is this an effective

solution?

Not for Ronald Coase, the 1991 Nobel laureate in economics, who once said, "All solutions have costs and there is no reason to suppose that government regulation is called for simply because the problem is not well handled by the market or the firm". [4] One version of the Coase theorem states if transaction costs are zero (i.e., if the parties involved are able to make any agreement that is in the mutual benefit of the parties), an economically efficient outcome will be reached regardless of any initial definition of property rights. For example, in the case of pollution, if left alone to bargain, both the polluter and polluter will reach an economically efficient settlement, regardless of their initial entitlements.

The chief criticism of Coase Theorem is that in reality all transactions entail cost. For example, Arrow (1969) [2] demonstrated that there is a priori no market where the transaction cost is zero. However, others have argued that at the least Coase showed that for some problems there is no fixed rule or best regulation that will generate an economically efficient solution. [1]

3. Elements of A Proposed Internet Self-Regulatory Framework

The lessons learned from the extended discussions above indicate that the most important elements of a proposed self-governance framework for electronic commerce may be referred to as "electronic commerce interest groups" (ECIG), representing the interests of the various members of the electronic commerce community. The chief beneficiaries of such self-governance will be the Internet users and service providers.

One ECIG crucial for self-regulation will be a Commercial ECIG, an on-line chamber of commerce. The Commercial ECIG will enable e-merchants to act in concert to safeguard their commercial interests while the diversity of opinions and modes of business within the ECIG will prevent them from developing into a self-perpetuating monopoly. In many circumstances, the commercial ECIG may also resolve commercial disputes among its members in the form of alternative dispute resolutions, to avoid the high costs and long delays of the traditional judicial systems.

Another "interest groups" should be a Professional ECIG akin to the professional societies in the real-life community, such as Medical and Bar Associations. These professional bodies set the crucial standards for their members, as they are in the best position to know what is sound for the healthy development of their trades. Electronic commerce today is highly specialized, just as the regular working world. The hardware technicians, the software designers, the chat room moderators and the on-line auctioneers should all establish their professional associations, much like the medieval masters and their

guilds. The professional ECIG may, for example, adjudge cases of breaches in professional ethics.

Yet another, and probably the largest, ECIG is the Consumers ECIG, which is made up of electronic commerce consumers. As a consumer advocacy group, this ECIG should act as a watchdog in ensuring the quality of service delivered to the consumers.

An Experts ECIG should also be formed including prominent electronic commerce academics and researchers who have contributed and continue to contribute significantly to the development of electronic commerce. The role of this ECIG is to render learned advice in charting the future course of the Internet.

A Workers ECIG, like a union, may also be formed to look after the welfare and benefits of those who rely on electronic commerce as their means of livelihood. A healthy functioning of this ECIG is crucial to the morale and hence the productivity of electronic commerce work force.

The last ECIG, the Development ECIG, takes care of the special needs of the developing countries, representing the interests of the majority of earth's population who yearn to accede to the Internet community.

It is important that the memberships in these ECIGs are not exclusive of each other. A member of the professional ECIG, i.e., a prominent electronic commerce practitioner, may indeed also be a member of the experts' ECIG. Relatedly, ECIG memberships are not limited to natural persons, but are open to companies, organizations, or other interested entities. However, each ECIG should devise rules for the eligibility of its membership. These ECIGs are also not exhaustive, and will evolve over time. As both the mode and speed of electronic commerce evolves, new ECIGs may be formed, and some or all of the existing ECIG may be replaced. The ECIGs should be formed at local, national, regional and international levels.

The overall governance structure of electronic commerce can best be based on so-called informal consultations among the various ECIGs. The informality of decision-making by informal consultations preserves the great Internet tradition of "off-handedness" and casualness which has been vital to the continuing survival of the Internet, while providing a flexible means of resolving problems or seizing opportunity as an online community. In addition to real-life meetings, the informal consultations may be held continuously via electronic means. In this way, issues may be brought to the electronic bulletin boards in a less confrontational manner. It is hoped that sound and practical policy will subsume from the benefits of informal consultations, much as they have been so throughout the history of the Internet. A conceptual framework of interactions by informal consultation among the various ECIGs is depicted in

Figure 1.

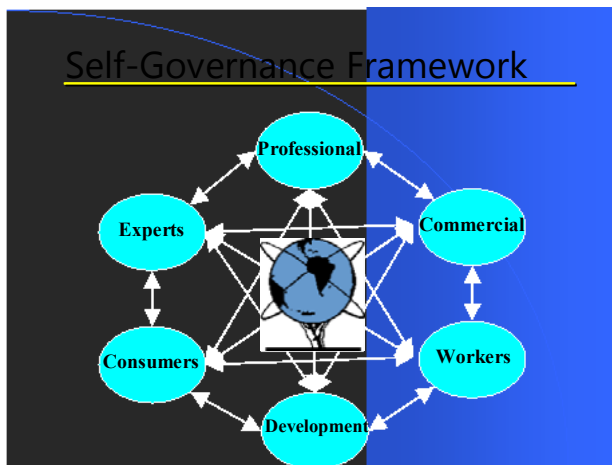

Figure 1: Conceptual depiction of a self-governance framework for electronic commerce

Criticisms may be voiced on such a self-governance system. For example, the system lacks a enforcing authorities (such as governments), and may hence be ineffective in handling serious challenges, either technical or policy, to electronic commerce. It should be kept in mind, however, that the electronic commerce community are reputedly quite proactive and would more readily rise up to challenges or accept responsibility, which is the basis for the self-governing framework is proposed for electronic commerce. Besides, just as in an off-line community, those who broke the ECIG rules, though not sanctioned by law, will often face alienation, ostracization, or outright expulsion.

4. Conclusions

The present paper discusses some of the policy, ethical and economical concerns of the Internet and then proposes a self-governance structure for electronic commerce based on policy formulation through informal consultations among the various electronic commerce interest groups. The self-governance framework proposed is not a perfect one, and will require constant refinement. It is, nevertheless, a baby step toward responsible governance of electronic commerce.

Customer Expectations of Internet Banking in South Africa

Simone Green & Jean-Paul Van Belle

Department of Information Systems

University of Cape Town

South Africa

jvbelle@commerce.uct.ac.za

Abstract.

The Internet has fundamentally changed the banking industry in South Africa by giving people more immediate control over the management of their finances. This research investigated whether a gap exists between customer expectations of Internet Banking and the satisfaction of these expectations in the virtual environment by South African banking institutions. The research was operationalized by means of a survey amongst internet banking users. The research focused specifically on the way customers of Internet banking sites felt about the service and functionality they received on the Internet and whether their expectations of this banking service were being met.

What emerged from the research was that customers were happy with their basic Internet banking experience. What they were not satisfied with, were cost issues and the lack of personalised service. Issues such as speed and more advanced functionality also played a minor part. In addition, Internet banking customers felt there was a lack of integration across banking channels. Overall, the research indicates that basic user expectations are being met by Internet banks in South Africa. However, unless this satisfaction is maintained and extended, banks could possibly lose customers to the already emerging virtual, innovative and more cost-effective alternative banks of the future.

1. Introduction.

Changing consumer needs, innovative financial products, changes in the industry structure and a mix of delivery channels are reshaping the banking industry. An important factor and enabler in this process of fast-paced change and innovation is the Internet. The Internet has revolutionized the banking sector by offering customers additional functionality, 24-hour access to their money as well as time and cost savings. [1] The Internet dissolves traditional boundaries between financial institutions and empowers individuals to choose and define their own financial futures. [2] [3]

One of the effects is a growing convergence in the financial services industry, whereby traditionally specialized organizations are now offering financial services that cross all sections of the population. [4] This means that traditional banks are fast losing their key differentiating characteristics. A great challenge, therefore, is to refocus their attention on their customers and gain a much better understanding what they want from a

financial services perspective. This has forced banks to look at their internal procedures in order to cope with the fast-evolving needs and expectations of their customers: cost savings, customized products and services and more personalized attention.

This research aims to determine whether a gap exists between the customer expectations of Internet-based banking services and the delivery, by South African banking institutions, to these expectations as part of an integrated banking offering. Although some South African banks have undertaken their own studies, these are often focussed on particular aspects and often driven by various strategic and (internal) political objectives. In addition, the results of these studies are not commonly made public. Finally, these studies are often commissioned by individual institutions and fail to represent an industry-wide picture. It is important to realize that the South African situation differs fairly dramatically from that in other countries due to its very specific industry configuration and regulations, population characteristics, banking information technologies and Internet infrastructure. Thus the results from international studies are not likely to be usable in a South African context.

2. How the Internet affects Banking.

The Internet has driven a number of changes in the financial services sector.

2.1 Convergence between financial service providers.

By dissolving the boundaries between information publishers, independent advisers and traditional product providers, each group is attempting to extend their offerings in order to provide a more complete service to their customers. As specialised organisations move beyond their core competencies, this convergence poses a threat to traditional banks, especially in the light of innovative institutions offering more customer-centric services. [4] [5]

2.2 Empowered customers.

Customers are quickly coming to expect Internet access to information and products. Face-to-face contact at branches and sales offices is losing importance as more information becomes available on-line. The increased competition from innovative, virtual financial institutions

is making customers more price-sensitive. These empowered users are now demanding better Internet experiences from traditional banks and becoming less tolerant of the inferior offering given to them in the past.

“Round-the-clock access to content and commerce gives users a hyperactive sense of entitlement. Customers demand what they want and when they want it: at home, at work, across channels.” [6]

2.3 Banks focus on the future but often overlook current customers.

Banks are often racing to outdo each other in an attempt to be “first-to-market” with innovative new services. Due to the technical complexities underlying these Internet-based services, usability issues are often overlooked and this may lead to overlook the needs and satisfaction of their existing customer base. [4]

2.4 Personalization online.

A lot of effort is spent on personalisation. However, many of these efforts have not been particularly successful because they currently add little real value to the user nor do they simplify the overall user experience. Indeed, much of the current Internet-based personalisation appears to be limited to customised homepages, more targeted marketing messages, basic advice and generic recommendations. As long as they fail to deliver real and significant added value to their customer’s overall financial experience, banks will not reap the somewhat naïvely expected rewards of improved customer loyalty and account growth. [2]

3. Current state and drivers of the South African banking industry.

An interesting study by Price-Waterhouse-Coopers [7] in the state of South African banking uncovered a number of important issues. It emerged that change in the banking industry was mainly driven by technology (getting the right balance between “clicks and bricks”), consolidation (to achieve economies of scale) and globalisation. Competition was driven by IT developments and the emergence of alternative delivery channels. Internet banking was seen as one of the more successful markets. Change enablers were client sophistication (and consequent demand), new information technologies and the Internet. However, the most pressing issues were service quality, client focus and profit performance.

Eight out of nine commercial banks had a formal strategy in place to switch customers to electronic channels, against only half of the investment banks. Of the nine banks that offered Internet banking facilities, only one believed this area to be profitable. However, most banks believed that the Internet could be used to reduce costs and generate revenues. At a less than 1% penetration rate, web enabled mobile phones were experiencing limited acceptance by bank customers who believed the

technology to be slow and cumbersome.

3.1 Issues facing Internet banking customers.

Currently, there are a number of issues hampering the acceptance of Internet-based money management. These include customer satisfaction with existing service channels, security concerns, and a perceived lack of utility in the Internet channel. [7] For newcomers to the Internet, issues such as security and privacy concerns are still the greatest barriers to entry. [8] Banking organisations have a big role to play in helping to make their customers feel safe on the Internet.

Another issue facing Internet banking customers is that they perceive the Internet channel to lack functionality. Financial service providers appear to have, so far, failed to communicate a clear value proposition to customers. Most consumers reported that they do not use Internet-based financial services nor expect to use them in the near future. [1] Financial institutions thus face a challenge in demonstrating that using the Internet as a service channel will be worthwhile and functionality will be delivered.

3.2 Specific challenges facing the Internet banking service providers.

The greatest challenge for banking institutions will be to move beyond traditional ideas of banking by redefining, streamlining and integrating their core business focus to suit customers needs. [5] They need to reinvent themselves by critically examining their existing infrastructures and focusing on the key areas that directly benefit their customers. This strategy requires the banks to replace their traditional product and channel silos with a customer-centric approach, entailing enormous changes in corporate culture and operational procedures for most institutions. [3]

Perhaps the most critical challenge is to get customer service right, not just on the Internet, but across all communication channels. Customer service is currently considered the Achilles heel of most South African banks.

A second challenge is to find the right balance between “bricks and clicks” by moving cautiously in reducing the size of physical branch networks. [9] Retaining the existing physical infrastructure prevents immediate cost-savings but remains the greatest point of difference between traditional and virtual banks. This is of particular relevance in South Africa which struggles with relatively low Internet penetration rates.

Another challenge is that of channel integration. Traditional banking institutions are still struggling to integrate customer data across all the points of contact customers have with them. Even where this is achieved, they must ensure consistency in the functionality across banking channels. If the strategy is that the Internet could become the main communication channel in the banking context, this requires that a core Internet service offers comprehensive transaction, financial management and advice functionality. This functionality should become the

backbone of their channel management and can then be extended with other channels playing a supporting and complementary role. [3] Unfortunately, this strategy requires an IT architecture which is often not possible given the banks' proprietary and legacy systems. The latter often limits the Internet service functionality. This creates a vicious circle whereby the Internet value proposition is too small to move customers online, and limits the financial viability of the Internet channel. This in turn discourages the bank from investing sufficient funds to further develop the channel.

Another challenge faced by banks is the new type of Internet customers, the youth, and their very different demands and expectations. These early adopters have internalised the Internet technology, are highly active, autonomous and willing to experiment. On the other hand, they expect low fees and have no respect for the traditional distinction between banks and technology brands such as IBM and Microsoft whom they are equally willing to trust with their money. This market is important because they constitute the next generation of banking customers and, once lost, may be extremely difficult to win back. However, banks cannot focus their Internet channels entirely on this market without alienating their more techno-phobic mainstream customers who tolerate less risk and require better guidance. [5]

Finally, a major challenge is that new entrants in the Internet banking arena, such as retailers, investment companies and brokers, are seeing banking as a tool to retain and acquire customers for their core business rather than as an independent profit centre. In addition, they often have a far more streamlined technical and business process infrastructure. As a result, they are likely to market and price their banking products aggressively and can offer extremely competitive rates. [4]

4. Research methodology.

The working hypothesis for this research is that there exists a gap between customer expectations of Internet banking and the satisfaction of these expectations by banking institutions in South Africa.

4.1 Definitions.

The concept of "user expectations" as used in this research must be seen the context an interactive Internet environment and is based on the research of several authors. [7] [10] [11] [12] The following specific qualities are considered to make up the user expectations of Internet banking customers:

- Basic functionality, convenience and speed of website.
- Service levels both online and offline.
- Integration across banking channels.
- Cost of transactions.
- Quality of information on the website.
- Actual website usability.
- Personal contact independent of the Internet banking channel.
- Added value for the end user in terms of the

product/service offering.

The term "Internet banking customers", hereafter usually referred to as "users", will be understood to refer to persons who make use of Internet-based banking facilities offered by their bank, enabling them to perform real-time transactions on their bank accounts in a secure and private environment.

4.2 Research approach.

The research has been approached from a functional, practical and emotional perspective. The research methodology reflects these perspectives. The research itself was exploratory in nature. Exploratory research studies are suitable for finding out what is happening at a high level; seeking new insights and knowing what questions to ask.

The study combined qualitative and quantitative data analysis. This was necessary since the aim was to establish how people feel about Internet banking from both an emotional and practical perspective. The qualitative approach assisted in gaining an insight into the more emotive issues that cause the formulation of these opinions.

The research process began with a series of in-depth interviews with a group of ten Internet banking customers. The group was stratified according to gender, a general or private banking relationship, dial-up versus corporate access, and some spread in banking institutions. The interviews were conducted using a structured discussion guide. The aim was to uncover specific issues, feelings and thoughts people had regarding their Internet banking as well as to gauge their current and immediate banking needs and future expectations.

These results were then tested more rigorously with the help of quantitative research by means of a web-based questionnaire. This questionnaire was accessible by means of a URL sent to respondents via e-mail. The sampling was done using a combination of convenience and snowball sampling. It was felt that this was acceptable for purposes of exploratory research. This approach resulted in a larger sample that would otherwise have been possible, but introduced some significant biases.

5. Sample description and representativeness.

The in-depth interview sample consisted of 4 women and 6 men, with a length of Internet banking experience ranging from 1 to 18 months. They came from a wide variety of job functions and there was a mix of dial-up and corporate users. Half of them had a personal banker. This sample was not intended to be representative.

77 usable responses were obtained from the online questionnaire. Table 1 shows the sample demographics and compares it to the sample of a commercial survey undertaken by Webcheck. Although the detailed data results of the latter were confidential, approximate sample demographics could be calculated from the management report. It must be noted that the use of rounded values and reasonable assumptions implies that some of the figures in

the Webcheck column are approximate.

Table 1: Comparison of sample demographics.

Characteristic	Green & Van Belle July'02	Webcheck July'01
Sample size: n =	77	400
Gender: male:female	73%:27%	53%:47%
Age: 18-30:31-39:40+	45%:30%:25%	22%:32%:46%
Access type: Dial-up:corporate:both	57%:72%:29%	? : ? : 35%
Banking institution:		
□ □ Standard Bank	42%	41%
□ □ Nedbank	22%	19%
□ □ ABSA	14%	16%
□ □ FNB	12%	17%
□ □ Other	10%	(10%)

Although the sample is not random and less than one-fifth of the size of Webcheck's, some of the demographics appear to be very comparable, notably the banking institution and the type of Internet access. However, our sample has a significantly smaller proportion of 40+ year olds, off-set by the thirty-and-less group, as well as a very strong male dominance. The probability of the samples reflecting the same population is extremely improbable (p-values for χ^2 is less than 0.1%). However, despite the larger sample size of Webcheck, there are some indications that their sampling frame – especially in terms of gender and age distribution – may also not be representative of the internet banking users. Unfortunately, no information was available on their sampling methodology.

6. Opinions about banking in general.

In the in-depth interviews, most people expressed unhappiness with their physical bank, but appeared to be much more content with their Internet bank. Consequently, a number of questions were included in the questionnaire to probe the respondents' opinions about banking in general.

Important in explaining some of the dynamics in the South African banking industry is the fact that, when asked for their reasons for staying with their bank, by far the most people (42%) found that it was "too much effort to change". This was consistent across gender and age group. Other reasons given were service (17%), loyalty (10%) and competitive rates (5%). This certainly seems to rationalize a popular perception that banks appear to invest more resources into attracting new customers than they seem to invest in retaining existing customers e.g. by means of increasing service levels. However, there appears to be some conflict with the responses on a later question where 65% of respondents said that they would move their accounts if they were offered cheaper banking fees. This highlights the potential threat posed by new low-cost entrants in the financial market.

When asked whether the bank was meeting their financial expectations, 60% of overall respondents said

that their bank did not, although this ratio was more than reversed within the 31-39 age group (only 35%). This difference is statistically significant ($Z = -2.1$) and demonstrates how perceptions (and perhaps service levels) differ at this age group.

Almost everyone (86%) would like to be able to open new accounts over the Internet, without having to go to a physical branch.

Interestingly, although 58% of the sample did not want their bank more involved in their financial life, 49% said they would like more financial advice. There were two sub-groups who liked significantly ($p < 5\%$) more financial advice: 76% of women and 82% of those banking with one particular bank said that they would have liked more help in choosing additional banking products. This again emphasizes the need to segment the markets and engage in some data mining.

7. Opinions and views on Internet banking.

7.1 Levels of satisfaction.

Contrary to the relatively low levels of satisfaction with their physical banking channels, 82% of respondents said that they were happy with their Internet Bank. 100% of respondents confirmed that Internet banking made their lives easier.

Rating the advantages of Internet banking using a multiple response question, convenience (73%) was rated significantly higher than time saving (56%). 30% said it gave them more control over their money. Figure 1 gives an overview of all the advantage ratings.

Figure 1: Perceived advantages of Internet banking.

This relates directly to the most important thing people wanted their bank to deliver on the internet: 74% said speed, 56% of the sample said convenience, 38% said functionality and 35% said cost; although there were some minor differences between banking institutions. 71% of respondents felt that their bank delivered on their requirements.

The biggest problem with Internet banking was speed – cited by half of the respondents. Figure 2 shows a ranking for the other problems.

Figure 2: Perceived problems with Internet banking.

However, there was a marked difference between banking institutions (statistically significant at a 95% level of confidence). The main problem with the largest Internet Bank (Standard Bank, 56%) was perceived to be speed. For two other banks (ABSA and Nedbank) limited functionality was the main problem, though much more significantly so for the former (91% versus 53%). 67% of FNB users had a problem with cost and 44% with security and the lack of integration with existing bank channels. It must be noted that the bank websites evolve all the time and some of these issues have been addressed since the survey was undertaken.

7.2 Use, usability and safety.

Internet banking was mostly used for inter-account transfers (62%) and payments (61%), not statements (48%) or checking balances (44%). Overall, most respondents felt that their Internet banking site was easy to use, though 62% wanted to have the ability to customize their banking site. 55% of respondents felt that Internet service, in terms of feedback, solving technical errors and rectifying problems, was generally good. The great majority (77%) felt that their personal information was “safe”.

7.3 Qualitative data analysis.

The in-depth interviews as well as the many open-ended questions on the questionnaire allowed an investigation of the more emotional reasons for the way people perceived and actually experienced their Internet bank.

Although usability was not a major problem, a number of suggestions for improvement were made. Not surprisingly in terms of the speed problem, users demanded sites to be less graphically intensive to reduce download times. Simpler navigation and better information display/layout were also suggested, as were more intuitive menu options that described specific content sections better. A less complex login procedure was a requirement which may be in conflict with the security requirements.

More problematic – especially for the two institutions mentioned higher – and a lot more difficult to achieve, are

the needs relating to better functionality. Users wanted an integrated view of the different accounts, with a single point of access. They also wanted additional functionality, especially the ability to open new accounts and add new beneficiaries online. Greater access to transactional history was also mentioned. Channel integration came up as well with being able to communicate with the bank via e-mail being mentioned very frequently, as well as improved call centres with operators who are empowered to conduct transactions. Finally, some users would like to see more useful and interactive financial tools.

One of the respondents described her vision as follows:

“[I’d like to see] a management tool that helps me analyse my budgeted expenses against my income. A system that mails me warnings when funds are low and stop orders are likely to bounce. Something that lets me assess whether I can afford a new purchase. Banks make their money off interest and I am sick of them letting my overdraft and credit spiral. I want a partner that helps me control my money.”

An overriding feeling was the desire of customers to feel treated like individuals. This was validated by the questionnaire responses where 74% wanted to maintain a personal relationship with their bank, no matter how automated and electronic banking became. People were looking for added value from their banking institutions in the form of:

- Pro-active advice through personal service regarding available products and additional services available to them.
- Investment advice, recommendations and feedback on the way their accounts were performing.
- Accessibility to persons who could answer technical (Internet problems) and financial (account based) questions but were empowered to effect certain changes.

On the issues of trust and safety, most people said that they assumed that the banks would be more concerned with data privacy and safety than e-commerce shopping sites. They also saw banks to have always been on the forefront of developing secure technology, and as a result assumed that they were safer to use. It was felt that a lot of this trust had to do with banks working hard to create this perception of safety and trust.

7.4 The future of electronic banking.

When asked where people would like to see Internet banking moving, the following threads were raised.

- Transparency of service as captured nicely by one respondent into “open access” – can opt out or leave the site in seconds; “open information” – giving a choice and info about competitors; “open communication” – direct on-line contact to a human being; and “open rates” – a clear view of their charges, possibly motivated in terms of their cost structure.
- Integrated money management. Some respondents and interviewees were aware of the trend towards convergence and more integrated financial service

offerings. This trend – as already evidenced by one retailer and one life insurance company launching an Internet bank – was welcomed by respondents.

- Retaining personalized service. Many people, especially those older than 30 years, expressed the fear that there was the potential “death of personal relationships” due to banking become more and more driven by technology.
- Future costs. There was a strong concern that banks needed to pass on the (long term?) cost saving from Internet banking onto their customers.

8. Conclusions.

The original research hypothesis was that there currently exists a gap between expectations of Internet banking customers, and the satisfaction of these expectations by South African banking institutions. The results of this study indicated that Internet banking customers in general were happy with their Internet banking facility, and that their basic expectations were being met through the Internet channel.

Internet banking has delivered functionality and convenience to Internet banking customers. It has improved the service offered by traditional banking institutions and has delivered to basic Internet banking customers’ expectations. However, since people are still struggling with basic Internet issues such as cost of connection, security fears and actual operational speed, their expectations from Internet banking have been relatively simple to date and essentially needs driven.

In terms of convenience, time saving and basic functionality which Internet banking offers, users’ expectations were being met. The Internet has raised the standards of service which customers have come to expect from their banking institutions. Internet banking, by its very nature, offers basic functionality in the form of payments, transactions and general account management. It is this “added value” which banks of the future need to focus on if they are to differentiate themselves in the market, not just in an attempt to acquire new customers, but to retain their existing customers. This research study indicated that although people were relatively content with their Internet bank at the time of the study, they still had fundamental issues with their actual “brick and mortar” bank in terms of the products they offered, service levels and integration with the Internet banking channel.

Speed was one of the areas where customer expectations were not being met on the Internet. This is not entirely the fault of banking institutions in South Africa because the infrastructural problems of hardware and bandwidth within South Africa have a fundamental effect on how fast people can transact on the Internet.

43% of the sample said there was integration across banking channels. However, the open questions and interviews revealed that many people felt there was not enough integration especially between branches and the Internet.

The issue of additional costs associated with banking

on the Internet, is one of the areas in which customer expectations are not being met. From the interviews and open questions, there was an overwhelming feeling that the costs associated with Internet banking were high and unnecessary. Most people felt Internet banking should be a free, added value service integrated into their entire banking experience. Additionally, people felt that one of the main reasons they would consider leaving their bank would be due to another bank offering reduced fees.

In terms of information quality on the Internet, most people were not aware of many of the services and products offered by their banking institution. Women particularly spoke about wanting help and advice in choosing new banking products. This is interesting as the Internet is a good medium for the transmission of information to people in the most cost effective and interactive way. It is felt that banking institutions should ensure that relevant information is made available to their customers on the Internet to compliment the service. Until then, email communication and clearly organised Frequently Asked Questions (FAQ’s) can go along way to solving this problem in a cost effective way.

Most people seemed happy with the actual usability on their Internet banking site. Minor issues included comments of complex login processes, as well as not having the ability to view all accounts within one window.

The final area of customer expectation involved providing banking customers with added value services online. People felt that although basic functionality issues were being addressed, there was the potential for more in terms of what they could be offered on the Internet. People were looking for personalised communication from effective and efficient organisations to help add value to their financial lives. It is felt that banking institutions could benefit from Customer Relationship Management (CRM) programmes, to better understand their customers. Relationship building between financial institutions and their customers is vital.

In terms of the actual research methodology, it is felt that the study was appropriately designed, but lacked both sample numbers and specifically selected sample groups that would have been more representative of the banking population in South Africa at the time of the study. Additionally, the research was limited by both cost restrictions and time constraints. It is felt that in addition to the actual research methodology followed, there was the potential to conduct more extensive qualitative interviews with a more specific sample group as well as with South African banking institutions. It is felt that this additional information would have given the study a greater depth: it would have provided a deeper insight into what people were expecting from an Internet-based service as well as would have offered an insight into how banking institutions perceived their Internet offering.

9. Future research.

It is felt that the potential for future research lies particularly in the area of delivering banking services and

products to the majority of South Africans through the better utilisation of the Internet as the ubiquitous medium it has the potential to be.

In addition, future research could focus on areas such as the effect on traditional banking institutions by innovative, virtual financial institutions that are able to offer better services, competitive rates and unique products; on defining new ways of delivering value added services at reduced costs; and on understanding which financial product categories are growing or changing most rapidly online and why. Additionally, from the research itself a number of interesting issues emerged which definitely warrant future research. These include understanding the way different age groups respond to financial products and services and the differences between men and women in terms of where and how they see their banking institution fitting into their financial lives.

Abstract

Under the prerequisite that virtual markets need a unit of analysis other than traditional markets, business model is set as the unit of analysis of this research. In this research, in order to help choose Internet business model that creates the most value, evaluation indexes for value-creation potential of Internet business models are developed. As research methods, deductive method and analytic hierarchy process (AHP) are used.

As the first stage of deduction process, the improved profits and the reduced costs, which factors are classified and quantitative and qualitative evaluation indexes of two dimensions are extracted by related studies. Then, evaluation indexes are corrected, complemented and verified through the expert interview, and analytic hierarchy is documented.

As the result, the improved profits dimension outweighed the reduced costs dimension, and each qualitative effect outweighed each quantitative effect. The overall consistency index showed to be 2%, which means that all the experts are determined to have rational consistency.

I. Introduction

As the recent development of digital technology has brought about the construction of an open-type digital network, that is Internet, an increasing number of people come to exchange a great quantity of information. Therefore, the problems involving the inverse proportion between the reachness and faithfulness of information become increasingly solved [19]. This solution in turn heightens the level of spreadability and accessibility of information, which in turn can empower customers and promote the fundamental change of the business logic of firms [35]. By using Internet, consumers are enabled to

choose the firm that is likely to offer the best quality of products and services, since they can acquire and exchange enormous information about products and services of all related firms quickly and freely.

On the other hand, the existing elements for predominance in competition - such as distribution channels and chain stores constructed through immense investment - became in name only owing to the alleviating of the inverse proportion between reachness and faithfulness of information. Furthermore, a fundamental change is appeared in the distribution channel selection for an efficient approach about suppliers and customers and in the interchange method between a firm's internal and external functions because transaction cost is decreased [17]. This fact means that the business models including a firm's operation method have been changed drastically by an emergence of the Internet.

Firms should select the most suitable business model in order to create more values in a digital economy environment. Specially, it is related with enhancing competitiveness of the existing core business and securing new business opportunities to select the most suitable business model in Internet business. The competitiveness of a firm is depending on selecting suitable Internet business models and strategies in the digital economy that is new economic environment.

However, most studies of the Internet business model have been suggested just taxonomy and some success factors or analyzed some cases. There were not the studies of a tool that can evaluate the value-creation potential of Internet business models systematically.

Therefore, this study aims to develop the evaluation indexes that can evaluate the potential of the value-creation of a business model for firms in the beginning

and help the firms select suitable business models.

II. Literature Review

1. The Definitions of Internet Business and the Business Model

The concept of Internet business is different from that of electronic commerce. Electronic commerce means that products, information or services are sold and bought on the Internet, whereas Internet business means that all processes of a value chain following by planning, development, manufacture, production, distribution and consumption of a product are connected with Internet.

The goal of Internet business is suggested on improving profits or creating values in most definitions about a business model. This study defines the business model as “structural form of the components of transactions that was designed in order to create values” by modifying the definition of Amit & Zott (2000) that structural form of the components of transactions that was designed in order to develop business opportunities.

2. The Classification of Internet Business Models

The main researches on Internet business model are as follows. Bambury (1998) divided Internet business models into the Internet unique business models and the traditional business models transplanted to the Internet. He insisted that a lot of traditional business models are applied compositely to the Internet.

Timmers (1998) found out the method to integrate information along a value chain by confirming the elements on a value chain and analyzing a interaction pattern of participants of a transaction. Through this, he classified business models into e-shop, e-procurement, e-auction, e-mall, third party marketplace, virtual community, value chain service provider, value chain integrator, collaboration platform, information brokerage, and trust services.

Rappa (2000) presented general business models such as brokerage, advertising, infomediary, merchant, manufacturer, affiliate, community, subscription, utility, and more concrete models according to business methods operated by each business model.

Yang (2000) classified business models into the type of advertisement, the type of retail shop, the type of channel, the type of cooperation, the type of franchise, and the type of joining according to main income sources.

2.1. The Value Creation of Internet Business Models

Bloniarz & Larsen (1997), Ghosh (1998), Jarvenpaa & Tiller (1999), Amit & Zott (2000), Bielski (2000), and Ethiraj et al. (2000) studied the factors that affect value creation of a business model.

Among them, the studies of Amit & Zott (2000) and Ethiraj et al. (2000) are similar to this study and provided some important factors. Amit & Zott (2000) observed the value-creation potential of business models of 59 Internet business firms in the United States and Europe.

They developed a value drive model that can evaluate the value-creation potential of Internet business model according to four dimensions of novelty, lock-in, complementarities, and efficiency. The Ethiraj et al. (2000) suggested scalability, complementary resources and ability, related specific assets, a knowledge sharing routine as success factors of Internet business model. The scalability means the ability that is able to extend a merit of a business model according to a value chain. Besides, it means using a unique complementarity of a business model in order to diversify markets, products and customers [30]. Cooperative firms develop a knowledge sharing routine in order to use a mutual ability efficiently. The knowledge sharing routine means a regular pattern of interaction between the firms transferring, recombining, and creating related specific assets [16].

III. Research Methodology

1. Analytic Hierarchy Process

The Analytic Hierarchy Process (AHP), which enables the user to determine the relative importance of criteria sets underlying their choice behaviors [5], is selected as the appropriate analysis tool. The AHP of Saaty (1977, 1980)-is theory and reality-an often used to solve strategic decision problems [3] [4] [5] [12] [28] [29] [32] [49] [53].

According to Saaty's original proposal, a complex system is decomposed into subsystems and represented in the hierarchical form. The element at the highest level is called the goal. The elements at each level are the criteria (factors) of the elements at the level below. The elements at the bottom level are called the alternatives. In this way, AHP organizes the basic rationality of the priority setting process by breaking down a multi-element complex system into its smaller constituent parts called components (or levels). The process can be divided into three phases, which are structuring a system, comparing pair-wise and synthesizing priorities.

The principle of comparative judgment is setting up a matrix to carry out the pair-wise comparisons of the relative importance of the elements in a component with respect to the criteria, elements in a dominating component at a higher level in the hierarchy. This matrix, denoted by A in our notation, is called the pair-wise comparison matrix. Let the pair-wise comparison matrix be

$$A = \begin{pmatrix} 1 & A_{1,2} & \dots & A_{1,n} \\ A_{2,1} & 1 & \dots & A_{2,n} \\ \dots & \dots & \dots & \dots \\ A_{n,1} & \dots & \dots & 1 \end{pmatrix} \quad (1)$$

where N is the number of elements in the component. The entry $A_{ij} > 0$ measures the relative importance of the impact on the criterion from element i against that from element j . There are some obvious properties of A (1),

among which the consistency is the most important one. When matrix A satisfies the following equation, it is said to be consistent.

$$A_{ij} = A_{ik} A_{kj} \quad \text{for any } k. \quad (2)$$

It is straightforward to show that when A is consistent, the weight vector W, which gives the relative priorities of the elements, is identical to any one of the columns of A within a normalization factor. One can further show that W is the dominant eigenvector of the matrix, namely

$$A * W = N * W \quad (3)$$

Since the relative importance of the elements depends only on the relative amplitudes of the components of the vector W, we may normalize W by requiring

$$\sum_i W_i = 1 \quad (4)$$

Generally, a vector is said to be normalized if it satisfies the above equation.

In fact, the inadequate nature of the comparison process dictates that inconsistency cannot be completely eliminated. It has been argued that even when A is not consistent, the weight vector W is still determined by the dominant eigenvector of A, namely

$$A * W = \lambda_{\max} W \quad (5)$$

where λ_{\max} is the largest eigenvalue of the matrix A. It can be shown that $\lambda_{\max} \geq N$ for any positive reciprocal matrix. The equality is reached only when the matrix is consistent. To measure the consistency of the matrix A, we define the Consistency Index (C.I.) as follows:

$$C.I. = \lambda_{\max} - N / N - 1 \quad (6)$$

In practice, we consider A is very consistent if the consistency index ratio C.R. = (C.I.)/(R.I.) is less than 0.1(Random Index: R.I.), which is the average consistency index of a random reciprocal matrix of the same dimension. And also the consistency of A is acceptable if the ratio of C.I. is about 10% or less, we accept the estimate of W. Otherwise, we attempt to improve consistency [29] [38].

The general analyzing process of AHP is presented in Table 1.

IV. Development of Evaluation Indexes

1. Generating the Evaluation Indexes for Value-Creation

The study found out the evaluation indexes for value-creation. Those were consisted of improved profits and reduced costs extracted by previous studies and interviews with experts and made the analytic hierarchy.

1.1. The Framework for the Development of Evaluation Indexes

To develop the evaluation indexes for value-creation potential of Internet business models, the study selected two factors such as improved profits and reduced costs that affect value-creation. Furthermore, the evaluation indexes were developed based on profit drives, expected profits, cost drives, and expected costs that were factors to measure improved profits and reduced costs. The profit drives and the cost drives were suggested as the

qualitative effect and the expected profits and expected costs as the quantitative effect.

----- Insert Figure 1 about here -----

1.2. The Analytic Hierarchy

The analytic hierarchy was presented in Figure 2. It was composed of the evaluation indexes that were extracted by previous studies and interviews with experts based on the framework for the development of evaluation indexes.

----- Insert Figure 2 about here -----

2. Defining the Evaluation Indexes

The evaluation indexes for value-creation potential of Internet business models were explained as follows.

2.1. Improved Profits

The indexes to evaluate improved profits were composed of a qualitative effect and a quantitative effect. The qualitative effect means the qualitative factor that raises total profit that a business model creates. There were complementarities, Lock-in, and novelty as indexes to evaluate the qualitative effect. The quantitative effect means expected total profit that a business model creates. There were things about potential customers and marginal incomes as indexes to measure the quantitative effect.

2.2. Reduced Costs

The indexes to evaluate reduced costs were composed of a qualitative effect and a quantitative effect. The qualitative effect means the qualitative factor that decreases total cost that a business model generates. There were transactional efficiency, marginal productivity, and reusability as indexes to evaluate the qualitative effect. The quantitative effect means expected total cost that a business model generates. There were labor cost, contents developing cost, operating cost, and marketing and selling cost as indexes to measure the quantitative effect.

3. Assigning the Importance of the Development of Evaluation Indexes and Analysis

To assign the importance of each evaluation index extracted by prior studies and interviews with experts, the related data were collected from the experts who had participated in the interview.

3.1. The Process of Survey

The questionnaire was made out based on the analytic hierarchy presented in the Figure 2. It was consisted of 52 items in five levels from goal in the highest level to final level. Two items in the same level were arranged to be able to compare. The relative importance between two items was measured on a nine-point scale.

The persons who participated in the survey were consisted of seven experts who had participated in the interview in the generating process of evaluation indexes. They were working-level officials who are in charge of developing Internet business model and consulting, and investing Internet business firms.

Two survey methods were used for the study. First, e-mails were sent to each of the experts. The e-mails included an explanation about the way to respond to the questionnaire. The completed questionnaires that the experts assigned the relative importance were sent to the researchers through e-mails.

Second, the researchers visited the experts and explained the way to respond to the questionnaires. Then they collected the questionnaires that the experts assigned the relative importance immediately. Team Expert Choice Ver. 9.5 was used for analysis. It is a software program supporting the analysis of AHP

3.2. The Results

The consistency index of the questionnaires collected from seven experts was analyzed. That of one questionnaire was exceeded the permitted limit. Then it was excluded and six questionnaires were analyzed. The results are as follows.

----- Insert Table 2 about here -----

Overall consistency index of six experts was 2%. The consistency index of each one was expert 1 (6%), expert 2 (5%), expert 3 (7%), expert 4 (9%), expert 5 (7%), and expert 6 (4%) respectively. All the experts had rational consistency because the consistency indexes of everyone were within 10% [38].

Through the result of synthesizing opinions of the experts who evaluated actual Internet business model in practical business, the study has the following conclusions.

First, the improved profits of a business model outweighed the reduced costs. It shows that how much the business model can create profits is a key point to select a business model before starting a business.

Second, the qualitative effect outweighed the quantitative effect in the improved profits and the reduced costs. It means that the qualitative effect was important than the quantitative effect to evaluate the value-creation potential of Internet business models.

Third, the order of importance was calculated that novelty is the first, complementarities, the second, and lock-in, the last among the qualitative indexes evaluating the improved profits. That is, it shows that the degree that a business model introduces a new way of transactions affects the improved profits highly, and then providing products and services in bundle and motivating customers to re-transact affect profits less.

Fourth, among the quantitative indexes evaluating the improved profits, the order of importance was calculated that marginal revenue is the first and potential customers, the second. It means that the marginal revenue affects qualitative profits highly.

Fifth, the order of importance was calculated that transactional efficiency is the first, reusability, the second, and marginal productivity, the last among the qualitative indexes evaluating the reduced costs. It shows that the degree that the transaction cost is decreased affects the improved profits highly. However, it affects profits less than the degree of the additional output as a result of adding one unit of variable factor and that of possibility of use services/information with other objectives.

Sixth, marketing/selling cost is the most important, and labor cost, the second, contents developing cost, the third, and operating cost, the least in qualitative indexes evaluating the reduced costs. That is, marketing/selling cost is produced highly, and then labor cost, contents developing cost, and operating cost are generated less.

V. Conclusions and Implications

The importance of an each index and a consistency level applying to AHP are as follows.

----- Insert Table 3 about here -----

Internet business firms must select suitable business models to create values. The competitiveness of firms is depending on selection and strategies of suitable Internet business models. However, most studies of the Internet business model have been suggested just taxonomy and some success factors or analyzed some cases. There were not studies of the evaluation index, which is able to evaluate the potential of the value-creation of Internet business models systematically.

Therefore, this study has contributions to practitioners as well as academics. As for a practical contribution, this study provides firms with evaluation indexes that can diagnose value creation potential of Internet business models and a relative importance between the evaluation indexes. As for academic contributions, this study presents a cornerstone of the study of evaluation criteria of the Internet business model.

However, the study was not able to consider on the difference of the indexes and the importance by industry. Therefore, it should be deliberated in future study.

Appendices

Table 1. The Analyzing Process of AHP

Step 1.	Problems should be defined exactly and then requirements of problems are clarified.
Step 2.	A Hierarchical structure is consisted of from goal of problems, evaluation criteria, to comparison of alternatives considering all elements related to the problems.
Step 3.	A relative importance about all evaluation criteria is marked and a comparative matrix is made out after executing pairwise comparison between evaluation criteria.
Step 4.	The consistency level(C.R.) is calculated to check matrix consistency after finding out the relative estimate weights (W) of all evaluation criteria. If C.R. exceeds 10%, the results of pairwise comparison should be reexamined.
Step 5.	The process of step 3 and step 4 are repeated toward all evaluation criteria included the hierarchical structure made in step 2.
Step 6.	The relative estimates of alternatives calculated by each evaluation criterion are added by each alternative. It is that relative weight between the alternatives that considered all evaluation criteria generally.
Step 7.	The alternative that got most a lot of scores is selected after comparing an evaluation score of each alternative that calculated in step 6.
Step 8.	If C.R. of all evaluation results exceeds 10%, You must examine whether a mistake was with configuration of hierarchical structure of problems in the beginning or consistency lack on comparative judgment.

Abstract

Many business decisions can be modeled as multiple objective linear programming (MOLP) problems. When formulating a MOLP problem, objective functions and constraints involve many parameters which possible values are assigned by the experts who are often imprecisely or ambiguously known. So, it would be certainly more appropriate to interpret the experts' understanding of the parameters as fuzzy numerical data which can be represented by fuzzy numbers. This paper focuses on fuzzy multiple objective linear programming (FMOLP) problems with fuzzy parameters in any form of membership function in both objective functions and constraints. Based on the related results of fuzzy linear programming (FLP) and linear programming problems with fuzzy equality and inequality constraints proposed by Zhang et al, this paper firstly proposes related definitions and concepts about FMOLP problems with fuzzy parameters. It then proposes a new approximate algorithm developed for solving the corresponding MOLP problems and the FMOLP problems. Finally, the use of related concepts, theorems, and the proposed approximate algorithm is illustrated by an example involving different cases which include setting various iterate steps, tolerances, weights, and satisfaction levels.

Keywords: Optimization; Decision support technology; Multiple objective linear programming; Fuzzy multiple objective linear programming, Approximate algorithm.

1. Introduction

Most of decision-making problems in the real world take place in an environment in which the goals, the constraints and consequences of possible actions are not known precisely [1]. In order to deal with such decision situations, fuzzy set theory has been applied into decision-making models.

Multiple objective linear programming (MOLP) is one of the popular methods to deal with complex and ill-structured decision-making. When formulating a MOLP problem, various factors of the real world system should be reflected in the description of the objective

functions and the constraints. Naturally, these objective functions and constraints involve many parameters which possible values are assigned by the experts who are often imprecisely or ambiguously known [2] [8]

With this observation, it would be certainly more appropriate to interpret the experts' understanding of the parameters as fuzzy numerical data which can be represented by fuzzy numbers. The fuzzy multiple objective linear programming (FMOLP) problems involving fuzzy parameters would be viewed as a more realistic version than the conventional one [2] [8].

Various kinds of FMOLP models have been proposed to deal with different decision-making situations which involve fuzzy values in objective function parameters, constraints parameters, or relationships. Transforming a FMOLP problem into a crisp programming problem is still employed by researchers [3] including methods proposed by Tanaka and Asai [9], Lai and Hwang [4], Luhadjula [5], Wierzchon [10]. Although various approaches have been made to solve a FMOLP problem with fuzzy parameter, however, most of works listed above are dealt with the fuzzy parameters with symmetric triangular, trapezoidal, or some kind of symmetric membership functions. Zhang et al [11] [12] proposed one method to solve a fuzzy linear programming (FLP) problem by transforming it into a corresponding four-objective constrained optimization problems and another method to formulate linear programming problems with fuzzy equality and inequality constraints. Based on that, this paper develops an approximate algorithm for solving the proposed FMOLP problems with fuzzy parameters in any form of membership function in both objective functions and constraints..

This paper is organized in five sections. The introduction of the related concepts about fuzzy set theory is made in Section 2. A review of related definitions and theorems for solving FMOLP problems with fuzzy parameters in objective functions and constraints are described in Section 3. The core idea of the approximate algorithm proposed for solving FMOLP problems is described in Section 4. An example is presented in Section 5 and aimed at demonstrating the concepts and methods for solving a FMOLP problem.

2. Related Definitions Used in the Paper

Definition 2.1 Let X denotes a universal set. Then a fuzzy subset \tilde{A} of X is defined by its membership function

$$\mu_{\tilde{A}} : X \rightarrow [0,1], \quad (1)$$

which assigns to each element $x \in X$ a real number $\mu_{\tilde{A}}(x)$ in the interval $[0, 1]$ where the value of $\mu_{\tilde{A}}(x)$ represents the grade of membership of x in \tilde{A} [6] [11].

Definition 2.2 A fuzzy set \tilde{A} is convex if and only if

$$\mu_{\tilde{A}}(\lambda x_1 + (1-\lambda)x_2) \geq \min(\mu_{\tilde{A}}(x_1), \mu_{\tilde{A}}(x_2)) \quad (2)$$

for every $x_1, x_2 \in X$ and $\lambda \in [0,1]$ [6] [11].

Definition 2.3 A fuzzy number is a convex normalized fuzzy set of the real line R^1 whose membership function is piecewise continuous [6] [11].

Let F and F^* be the set of all fuzzy numbers and the set of all finite fuzzy numbers on R respectively. According to the decomposition theorem of fuzzy set, we have

$$\tilde{A} = \int_{\lambda \in [0,1]} \lambda \tilde{A}_\lambda \quad (3)$$

$$\tilde{A} = \int_{\lambda \in R_0} \lambda \tilde{A}_\lambda \quad (4)$$

for all $\tilde{A} \in F$, where R_0 is all rational numbers in $(0, 1]$ [11]. $F \subset R$

Definition 2.4 Let \tilde{A} and \tilde{B} with the membership functions $\mu_{\tilde{A}}$ and $\mu_{\tilde{B}}$ respectively, and $0 \leq \alpha, \beta \leq 1$. The addition of two fuzzy number $\tilde{A} + \tilde{B}$ and the scalar product of $\alpha \tilde{A}$ are defined by the membership functions

$$\mu_{\tilde{A} + \tilde{B}}(z) = \sup_{z=x+y} \min(\mu_{\tilde{A}}(x), \mu_{\tilde{B}}(y)) \quad (5)$$

$$\mu_{\alpha \tilde{A}}(z) = \sup_{z=\lambda x} \min(\mu_{\tilde{A}}(x), \alpha) \quad (6)$$

Form the decomposition theorem of fuzzy set and the Definition 2.4, for any two fuzzy number \tilde{A} and \tilde{B} , and $0 \leq \alpha \in R$, $0 \leq \beta \in R$

$$\tilde{A} + \tilde{B} = \int_{\lambda \in [0,1]} (\alpha_\lambda^L + \beta_\lambda^L, \alpha_\lambda^R + \beta_\lambda^R) \quad (7)$$

$$\alpha \tilde{A} = \int_{\lambda \in [0,1]} (\alpha \alpha_\lambda^L, \alpha \alpha_\lambda^R) \quad (8)$$

$$\tilde{A} \tilde{B} = \int_{\lambda \in [0,1]} (\alpha_\lambda^L \beta_\lambda^L, \alpha_\lambda^R \beta_\lambda^R) \quad (9)$$

Let F^n and F^{*n} be the set of all n -dimensional fuzzy numbers and the set of all n -dimensional finite fuzzy numbers on R respectively [11].

Definition 2.5 For any two n -dimensional fuzzy numbers \tilde{A} and \tilde{B} define

- (1) $\tilde{A} \leq \tilde{B}$ iff $\alpha_i^L \geq \beta_i^L$ and $\alpha_i^R \geq \beta_i^R$, $i = 1, \dots, n$
 - (2) $\tilde{A} \leq \tilde{B}$ iff $\alpha_i^L \geq \beta_i^L$ and $\alpha_i^R \geq \beta_i^R$, $i = 1, \dots, n$
 - (3) $\tilde{A} \leq \tilde{B}$ iff $\alpha_i^L \geq \beta_i^L$ and $\alpha_i^R \geq \beta_i^R$, $i = 1, \dots, n$
- [11].

3. Fuzzy Multiple Objective Linear Programming and Related Definition and Theorems

In this paper, we now consider the situation that all coefficients of the objective functions and constraints are fuzzy numbers parameters in any form of membership function, then such FMOLP problems can be formulated as follows:

$$(FMOLP) \begin{cases} \text{Maximize} & \tilde{f}x = \tilde{C}x \\ \text{s.t.} & x \in X = \{x \in R^n \mid \tilde{A}x = \tilde{b}, x \geq 0\} \end{cases} \quad (10)$$

where \tilde{C} is an $k \times n$ matrix, each element of which \tilde{c}_{ij} is fuzzy number represented by membership function $\mu_{\tilde{c}_{ij}}$. \tilde{A} is an $m \times n$ matrix coefficients of the constraints, each element of which \tilde{a}_{ij} is fuzzy number represented by membership function $\mu_{\tilde{a}_{ij}}$. \tilde{b} is an m -vector of the rhs, each element of which \tilde{b}_i is fuzzy number represented by membership function $\mu_{\tilde{b}_i}$ and x is an n -vector of decision variables, $x \in R^n$.

In the proposed FMOLP problems, for each $x \in X$ the values of objective function $\tilde{f}x$ are fuzzy numbers. According to the definition 2.5, we have the following definitions about FMOLP problems.

Definition 3.1 x^* is said to be a complete optimal solution, if and only if there exists $x^* \in X$ such that $\tilde{f}_i x^* \leq \tilde{f}_i x$, $i = 1, \dots, k$ for all $x \in X$.

Definition 3.2 x^* is said to be a Pareto optimal solution, if and only if there does not exists another $x \in X$ such that $\tilde{f}_i x^* < \tilde{f}_i x$, for all i .

Definition 3.3 x^* is said to be a weak Pareto optimal solution, if and only if there does not exists another $x \in X$ such that $\tilde{f}_i x^* < \tilde{f}_i x$, for all i .

Associated with the FMOLP problems, let's consider the following multiple objective linear programming (MOLP _{λ}) problems:

$$(MOLP_\lambda) \begin{cases} \text{Maximize} & \langle \tilde{c}_{\lambda_i}^L, x \rangle, \langle \tilde{c}_{\lambda_i}^R, x \rangle, \lambda \in [0,1] \\ \text{s.t.} & x \in X = \left\{ x \in R^n \mid A_\lambda^L x \leq b_\lambda^L, A_\lambda^R x \leq b_\lambda^R, \right. \\ & \left. x \geq 0, \forall \lambda \in [0,1] \right\} \end{cases} \quad (11)$$

where

$$C_\lambda^L = \begin{bmatrix} c_{11\lambda}^L & c_{12\lambda}^L & \dots & c_{1n\lambda}^L \\ c_{21\lambda}^L & c_{22\lambda}^L & \dots & c_{2n\lambda}^L \\ \vdots & \vdots & \ddots & \vdots \\ c_{k1\lambda}^L & c_{k2\lambda}^L & \dots & c_{kn\lambda}^L \end{bmatrix}, C_\lambda^R = \begin{bmatrix} c_{11\lambda}^R & c_{12\lambda}^R & \dots & c_{1n\lambda}^R \\ c_{21\lambda}^R & c_{22\lambda}^R & \dots & c_{2n\lambda}^R \\ \vdots & \vdots & \ddots & \vdots \\ c_{k1\lambda}^R & c_{k2\lambda}^R & \dots & c_{kn\lambda}^R \end{bmatrix}$$

$$A_\lambda^L = \begin{bmatrix} a_{11\lambda}^L & a_{12\lambda}^L & \dots & a_{1n\lambda}^L \\ a_{21\lambda}^L & a_{22\lambda}^L & \dots & a_{2n\lambda}^L \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1\lambda}^L & a_{m2\lambda}^L & \dots & a_{mn\lambda}^L \end{bmatrix}, A_\lambda^R = \begin{bmatrix} a_{11\lambda}^R & a_{12\lambda}^R & \dots & a_{1n\lambda}^R \\ a_{21\lambda}^R & a_{22\lambda}^R & \dots & a_{2n\lambda}^R \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1\lambda}^R & a_{m2\lambda}^R & \dots & a_{mn\lambda}^R \end{bmatrix}$$

$$b_{\lambda}^L = \langle c_{1\lambda}^L, b_{1\lambda}^L, \dots, b_{m\lambda}^L \rangle^T, \quad b_{\lambda}^R = \langle c_{1\lambda}^R, b_{1\lambda}^R, \dots, b_{m\lambda}^R \rangle^T.$$

Definition 3.4 x^* is said to be a complete optimal solution, if and only if there exists $x^* \in X$ such that $f_i(x^*) \geq f_i(x)$, $i = 1, \dots, k$, for all $x \in X$ [7].

Definition 3.5 x^* is said to be a Pareto optimal solution, if and only if there does not exist another $x \in X$ such that $f_i(x) \geq f_i(x^*)$, for all i and $f_j(x) > f_j(x^*)$ for at least one j [7].

Definition 3.6 x^* is said to be a weak Pareto optimal solution, if and only if there does not exist another $x \in X$ such that $f_i(x) > f_i(x^*)$, $i = 1, \dots, k$ [7].

Theorem 3.1 Let x^* be a feasible solution to the FMOLP problem. Then

1. x^* is a complete optimal solution to the problem if and only if x^* is a complete optimal solution to the MOLP $_{\lambda}$ problem.
2. x^* is a Pareto optimal solution to the problem if and only if x^* is a Pareto optimal solution to the MOLP $_{\lambda}$ problem.
3. x^* is a weak Pareto optimal solution to the problem if and only if x^* is a weak Pareto optimal solution to the MOLP $_{\lambda}$ problem.

Proof. The proof is obvious from Definition 2.5.

In the next section, we will propose an approximation algorithm to solve the MOLP $_{\lambda}$ problem and the FMOLP problem.

4. An Approximation Algorithm for Solving FMOLP Problem

Based on the definition of FMOLP problem and MOLP $_{\lambda}$ problem and Theorem 3.1, an approximation algorithm is proposed as following for solving MOLP $_{\lambda}$ problem, the solution of which is equally the solution of FMOLP problem.

For the simplicity in presentation, we define

$$X_{\lambda} = \{x \in R_n \mid A_{\lambda} x \leq b_{\lambda}^R, A_{\lambda} x \geq b_{\lambda}^L, x \in X\}$$

The main steps of the approximation algorithm are described as follows:

Let the interval $[0,1]$ be decomposed into m mean sub-intervals with $(m+1)$ nodes λ_i , $i = 0, \dots, m$ which are arranged in the order of $0 = \lambda_0 < \lambda_1 < \dots < \lambda_m = 1$, then define $X^m = \bigcup_{i=0}^m X_{\lambda_i}$, and denote

$$(MOLP_{\lambda})_m \begin{cases} \text{Max } \langle c_{\lambda_i}^L, x \rangle, \langle c_{\lambda_i}^R, x \rangle \\ \text{s.t. } x \in X^m \end{cases} \quad \lambda_0 < \dots < \lambda_m = 1 \quad (12)$$

Step 1: Set $m = 1$, then solve $(MOLP_{\lambda})_m$ for λ_m , where $\lambda_m = \lambda_1, x_2, \dots, x_m$ and the solution is obtained subject to constraint $x \in X^m$.

Step 2: Solve $(MOLP_{\lambda})_{2m}$ for λ_{2m} .

Step 3: If $\|x_m - x_{2m}\| \leq \epsilon$ the solution x^* of MOLP $_{\lambda}$ problem is x_m . Otherwise, update m to $2m$ and go to Step 2.

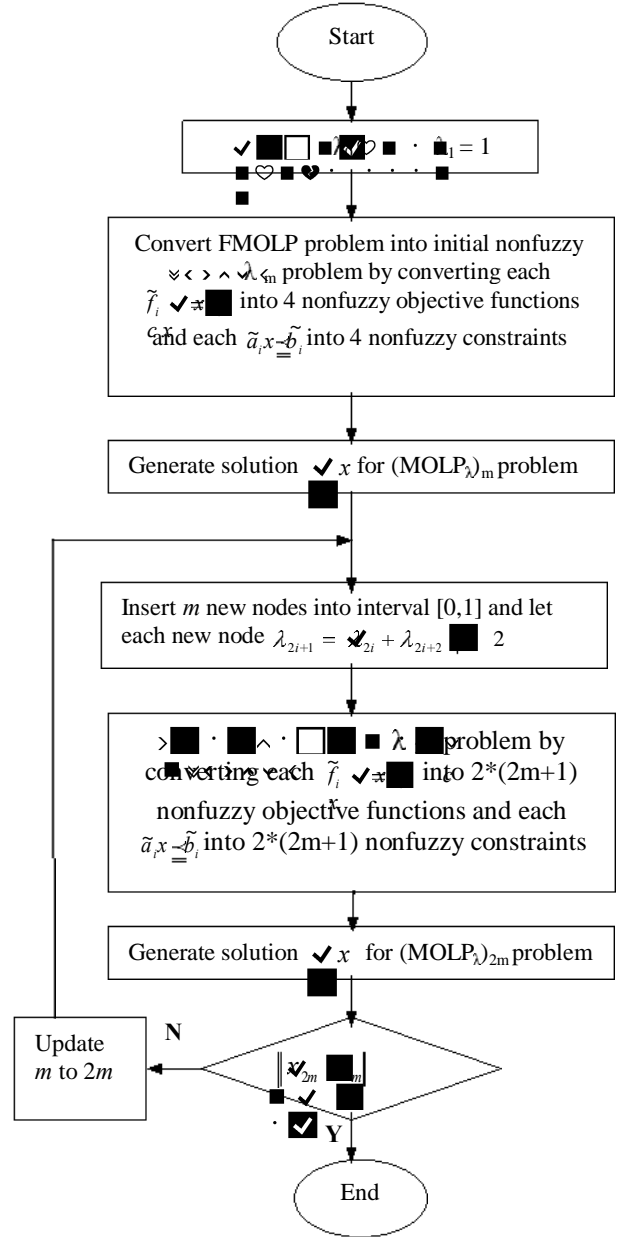

Diagram 1: The data flow diagram for the approximate algorithm

Initially, in step 1, the interval $[0,1]$ is not split, only 0 and 1 are considered, then, each fuzzy objective function f_i is converted into four corresponding nonfuzzy objective functions $\langle c_{i0}^L, x \rangle, \langle c_{i1}^L, x \rangle, \langle c_{i0}^R, x \rangle, \langle c_{i1}^R, x \rangle$, $i = 1, \dots, k$. This conversion also applies on constraints in the same way. The solution x_m is based on new nonfuzzy objective functions and constraints.

The detail data flow diagram is listed in Diagram 1.

5.1 The description of an example of FMOLP

$$\max_{\tilde{f}} \cdot \max_{\tilde{f}_1, \tilde{f}_2} \cdot \max_{\tilde{c}_1, \tilde{c}_2} \begin{matrix} \checkmark & \checkmark & \checkmark \\ \blacksquare & \blacksquare & \checkmark \\ \checkmark & \checkmark & \checkmark \end{matrix} \begin{matrix} \tilde{f}_1 \\ \tilde{f}_2 \\ \tilde{c}_1 x_1 \\ \tilde{c}_2 x_1 \end{matrix} \cdot \begin{matrix} \checkmark \\ \blacksquare \\ \checkmark \\ \checkmark \end{matrix} \begin{matrix} x_1 \\ x_2 \\ x_1 \\ x_2 \end{matrix} \cdot \begin{matrix} \checkmark \\ \blacksquare \\ \checkmark \\ \checkmark \end{matrix} \begin{matrix} x_2 \\ x_1 \\ x_2 \\ x_2 \end{matrix} \quad (13)$$

$$\text{s.t.} \quad \begin{cases} \tilde{a}_{11}x_1 + \tilde{a}_{12}x_2 \leq \tilde{b}_1 \\ \tilde{a}_{21}x_1 + \tilde{a}_{22}x_2 \leq \tilde{b}_2 \\ \tilde{a}_{31}x_1 + \tilde{a}_{32}x_2 \leq \tilde{b}_3 \\ \tilde{a}_{41}x_1 + \tilde{a}_{42}x_2 \leq \tilde{b}_4 \end{cases} \quad (14)$$

$$\mu_{\tilde{c}_{11}} = \begin{cases} 0 & x < 1 \\ \checkmark - 1 & 1 \leq x < 2 \\ 1 & 2 \leq x \leq 3 \\ \cancel{2} 6 - x^2 & 3 < x \leq 16 \\ 0 & 16 < x \end{cases}$$

$\mu_{\tilde{c}_{22}} =$	$\begin{cases} 0 & x < 1 \\ \checkmark - 1 & 1 \leq x < 2 \\ 1 & 2 \leq x \leq 3 \\ 5 - x & 3 < x \leq 25 \\ 0 & 25 < x \end{cases}$
$\mu_{\tilde{a}_{11}} =$	$\begin{cases} 0 & x < -2 \\ 2x + 4 & -2 \leq x < -1.5 \\ 1 & -1.5 \leq x \leq -0.5 \\ 4x^2 & -0.5 < x \leq 0 \\ 0 & 0 < x \end{cases}$
$\mu_{\tilde{a}_{12}} =$	$\begin{cases} 0 & x < 0 \\ x/4 & 0 \leq x < 2 \\ 1 & 2 \leq x \leq 4 \\ \checkmark - e^x & 4 < x \leq 12 \\ 0 & 12 < x \end{cases}$
$\mu_{\tilde{a}_{21}} =$	$\begin{cases} 0 & x < 0 \\ 2x & 0 \leq x < 0.5 \\ 1 & 0.5 \leq x \leq 1.5 \\ \checkmark - e^x & 1.5 < x \leq 10 \\ 0 & 10 < x \end{cases}$
$\mu_{\tilde{a}_{22}} =$	$\begin{cases} 0 & x < 0 \\ \checkmark - 1 & 0 \leq x < 2 \\ 1 & 2 \leq x \leq 4 \\ \checkmark - e^x & 4 < x \leq 18 \\ 0 & 18 < x \end{cases}$
$\mu_{\tilde{a}_{31}} =$	$\begin{cases} 0 & x < 1 \\ \checkmark - e^1 & 1 \leq x < 3 \\ 1 & 3 \leq x \leq 5 \\ 6 - x & 5 < x \leq 18 \\ 0 & 18 < x \end{cases}$
$\mu_{\tilde{a}_{32}} =$	$\begin{cases} 0 & x < 0 \\ x^2/4 & 0 \leq x < 2 \\ 1 & 2 \leq x \leq 4 \\ 10 - x & 4 < x \leq 10 \\ 0 & 10 < x \end{cases}$
$\mu_{\tilde{a}_{41}} =$	$\begin{cases} 0 & x < 0 \\ x/2 & 0 \leq x < 2 \\ 1 & 2 \leq x \leq 4 \\ \checkmark - e^x & 4 < x \leq 10 \\ 0 & 10 < x \end{cases}$
$\mu_{\tilde{a}_{42}} =$	$\begin{cases} 0 & x < 0 \\ 2x & 0 \leq x < 0.5 \\ 1 & 0.5 \leq x \leq 1.5 \\ 100 - x^3 & 1.5 < x \leq 10 \\ 0 & 10 < x \end{cases}$
$\mu_{\tilde{b}_1} =$	$\begin{cases} 0 & x < 18 \\ \checkmark - e^{18} & 18 \leq x < 20 \\ 1 & 20 \leq x \leq 22 \\ 2000 - x^3 & 22 < x \leq 30 \\ 0 & 30 < x \end{cases}$

$$\begin{aligned} \mu_{\tilde{b}_2}^{\checkmark} &= \begin{cases} 0 & x < 24 \\ \checkmark - e^{24} \blacksquare^{26} - e^{24} \blacksquare & 24 \leq x < 26 \\ 1 & 26 \leq x \leq 28 \\ \checkmark - x \blacksquare^2 & 28 < x \leq 40 \\ 0 & 40 < x \end{cases} \\ \mu_{\tilde{b}_3}^{\checkmark} &= \begin{cases} 0 & x < 42 \\ \checkmark - 42 \blacksquare & 42 \leq x < 44 \\ 1 & 44 \leq x \leq 46 \\ \checkmark - e^x \blacksquare^{60} - e^{46} \blacksquare & 46 < x \leq 60 \\ 0 & 60 < x \end{cases} \\ \mu_{\tilde{b}_1}^{\checkmark} &= \begin{cases} 0 & x < 27 \\ \checkmark - 729 \blacksquare^2 & 27 \leq x < 29 \\ 1 & 29 \leq x \leq 31 \\ \checkmark - 4000 - x^3 \blacksquare^{209} & 31 < x \leq 40 \\ 0 & 40 < x \end{cases} \end{aligned}$$

Associate with the FMOLP problem, the corresponding MOIP₃ problem is listed as follows:

Table 1: Summary of the running solution by the approximate algorithm

Table 2: Summary of the running solution by setting different weights of objective functions

According to Theorem 3.1, the solution to the MOLP $_{\lambda}$ problem is also a solution to the FMOLP problem. Here, we recommend using weighting maxmin method to solve the MOLP $_{\lambda}$ problem.

5.2 Solving MOLP $_{\lambda}$ problem by the approximate algorithm

Refer to MOLP $_{\lambda}$ problem, in step 1, the interval [0,1] is not split, only $\lambda = 0$ and $\lambda = 1$ are be considered, then totally 8 nonfuzzy objective functions and 16 nonfuzzy constraints are generated. By weighting maximum method, the solution is $(x_1^*, x_2^*) = (3.2260, 0.1932)$.

In step 2, one node is inserted in the interval [0,1], then totally 12 nonfuzzy objective functions and 24 nonfuzzy constraints are generated. By weighting maximum method, the solution is $(x_1^*, x_2^*) = (4.5985, 1.1049)$. The more detail information about further steps is listed in Table 1.

From Table 1, we can find that if the tolerance $\epsilon = 10^{-3}$, the approximate algorithm stops at step 5, if the tolerance $\epsilon = 10^{-5}$ the approximate algorithm will stop at step 8, and the number of nonfuzzy objective functions and constraints will increase dramatically.

When choose different weights w_1 and w_2 for objective functions, the different results are summarized in Table 2:

It can be found from Table 2, when $w_1 = 1$ and $w_2 = 0$, the solution (3.2260, 0.1932) is only concerned about the first objective function. When $w_1 = 0$ and $w_2 = 1$, the solution (0, 1.8506) is only concerned about the second objective function. When w_1 decreases from 1 to 0 and w_2 increases from 0 to 1 simultaneously, the solution will move from (3.2260, 0.1932) to (0, 1.8506) gradually.

Multi-language Websites in a Multi-cultural Country: a South African Perspective.

Abstract

This paper reports on an exploratory study done to assess the demand for multi-language websites by South Africans who do not have English as their home language but speak English proficiently. South Africa makes an interesting case study because, in spite of its eleven official languages, English is used as the default language in most business communications and for websites in particular. The unspoken – and empirically unverified – argument appears to be that most educated South Africans are fluent enough in English not to need non-English sites. This myth is soundly debunked in our exploratory study and it can be conjectured that organisations who will cater for the pent-up demand for native language websites should be able to attract a captive audience. It is suggested that the study is of particular interest to other nations who have multiple official languages but where a single language dominates the internet communications, as appears to be the case in many African and a number of Asian countries.

1. Introduction

South Africa is proud of its cultural diversity, which lends the country its unique character and constitutes one of its many strengths. The South African Constitution aims to protect cultural heritage and promote equity by proclaiming eleven official languages and guaranteeing the right to education and information in one's own language of preference.

However, it seems that there are very few South African websites available in languages other than English. In particular, apart from a small number of government sites, virtually no websites are available in the home languages of significant portions of the population, such as Zulu or Xhosa. South Africa still has, with its roughly 2.5 to 3 million internet users, a very low Internet penetration rate of well below 10%. No conclusive statistics are available on the home language of the internet users, although a large proportion of these users can be assumed to have English as a home language. However, this still leaves a huge number of users with another home language and, in the light of the economic empowerment trends, this number is expected to increase dramatically in the next few years.

A number of technical options exist to implement and maintain websites with multiple-language content, but

these generally involve not insignificant resource investments. [1] [2] (This paper does not explore the various technical approaches for multi-language websites.). It was felt that this situation therefore called for an exploratory study of empirical nature to assess whether there really is a demand by non-native English speakers. The focus is to gauge the demand for non-English websites amongst experienced internet users who have a good command of English and who work or study in a predominantly English language environment, but use a different language at home (hereafter referred to, somewhat misleadingly, as “non-English” web-users).

Interestingly, significant work has already been accomplished in the open source software arena on porting internet browser software to interfaces sporting traditional languages such as Zulu and Xhosa. This work will be extended to the OSS office suite. [3]

It must be noted that the emphasis of this research was on the language of the websites. It is acknowledged that there are many other cultural aspects which need to be given attention in interface design, such as the use and meaning of symbols and icons, colours, layouts. It was felt that many of these non-language cultural issues are still in early stages of research. In addition, it is much more straightforward to investigate language than to deal with the various methodological issues relating to empirical constructs for measuring culture.

2. Previous work relating to multi-language websites.

The internet is a medium that transcends traditional geographical boundaries. It is therefore not surprising that considerable research and development has already been devoted to multi-language sites. Not surprisingly, much of this research has been encouraged by the European Commission, although several US agencies and Asian researchers have also looked into this issue.

It is a disconcerting fact that about 85% of websites are in English, even though the non-English web users outnumber their English-speaking counterparts almost two to one (figure 1). [4]

Figure 1: Online Language Populations Mar-03

Designing a site in a language other than English is easy enough. However, there is obviously also an urgent need to investigate the issues related to website design targeting users across different languages i.e. multi-language websites. Three main needs of these users were identified by Van Dijk [5]:

- Users expect the same information and functionality for each of the languages, without a bias towards the dominant language.
- Not only the information but also the instructions for navigating the website should be multi-lingual. The naïve practice of displaying a national flag icon to choose language causes confusion in countries with multiple official languages, such as South Africa.
- The website should be tested by native language speakers to avoid unnecessary language (and sometimes cultural) mistakes.

3. Multi-lingualism in South Africa

Until 1994, South Africa was officially bilingual (English and Afrikaans). Since the formal abolishment of apartheid in 1994, South African language diversity has been guaranteed in the constitution:

“recognising the historically diminished use and status of the indigenous languages of our people, the state must take practical and positive measures to elevate the status and advance the use of these languages”

The aim is clearly to empower all people and not to prejudice people from African origins. So, apart from commercial marketing considerations, there is also a strong moral obligation on South African organisations to establish multilingual websites. On the other hand, it must be recognised that not all of the eleven official languages are spoken equally widely, as shown in figure 2.

Figure 2: Home language as spoken by % of population

Although the accuracy of these figures is subject to some debate, it can be seen clearly that English is not as dominant a language as it is sometimes perceived to be. Zulu, Xhosa, Afrikaans and Pedi are more predominant as home language than English. [6] [7] It must be reiterated that these figures are not at all representative of the South African internet users. However, apart from any direct commercial advantages, the implementation of multi-language websites in South Africa would stimulate further development of these languages, exploit and promote the multi-cultural diversity of the nation, and ensure more equal access to information and education.

Despite the increased awareness about language and notwithstanding the Constitutional provisions, there is an extreme paucity of indigenous language websites. A non-systematic survey reveals a fair number of Afrikaans-only and mixed Afrikaans/English websites but only a handful websites catering for the other nine official languages. The latter are mainly central and local government sites although a few large parastatal and commercial organisations are beginning to make selected (usually pre-existing static) documents available in other languages. A more systematic census of these websites remains a useful research challenge, although it is probably a fast moving target.

4. Research approach

As seen above, there are strong ethical motivations and public relation aspects to providing multi-language websites in South Africa. However, it is believed that website providers will embark on the development of multi-language website much more readily if actual demand from existing internet users can be demonstrated.

The following research hypothesis was therefore suggested.

H₀: There is a demand for multi-language websites from current internet users whose speak English well but whose home-language is not English.

A proper full-scale survey was beyond the means of a small research effort, but it was felt that a fully representative survey should in any case only be considered after an exploratory survey has demonstrated

at least some initial support for the hypothesis and piloted some of the methodological issues.

It was decided to use a convenience sampling frame and two samples were drawn: one from a life insurance company, Momentum Life, in Cape Town, and the other first-year Information Systems students in the Commerce Faculty of the University of Cape Town (UCT). The language of conduct in both organisations is English. Since the official languages are not symmetrically distributed across provinces, this introduces a definite bias in the sample but it was felt that the exploratory nature of the research justified this pragmatic decision. In the end, 100 questionnaires were distributed in the commercial company Momentum Life and 280 to first year information systems students.

In the end, 48 completed questionnaires were returned from Momentum Life of which 38 were usable, and 97 from UCT, of which 87 were usable. This led to a total of 125 usable responses i.e. a net response rate of just under 33%.

No existing instrument was found so a new instrument was designed. First, a number of issues were identified from the literature survey. These were written down and served as the basis for the formulation of the initial questions. These were supplemented by other relevant questions in a iterative manner. Finally, a focus group session with 10 participants was asked to complete the pilot questionnaire while at the same time discussing their thoughts on various topics raised by the researchers. This resulted in an interactive discussion which was used to finalize the final questionnaire. Considerable effort was made not to give offence by clearly stipulating the ultimate objectives of the research, although native-English speakers were asked not to complete the questionnaire. People who did not use any of the other 10 official languages were, however, not prejudiced and could complete the questionnaire.

Although some of the questions were factual, most of the questions sampled opinions, beliefs and attitudes. No conceptual or theoretical constructs were employed so the questionnaire was not statistically validated. The usual confidentiality principles were observed and the normal reservations about the deficiencies of empirical sampling methods apply.

5. Sample characteristics and representativeness.

Of the 125 respondents, the male-female ratio was 52%/48%. Because 87 usable questionnaires were returned by students, almost two-thirds (63.2%) were between 18 and 25 years of age. Only 8.8% of respondents were above 35% of age. 10% of respondents were foreigners and a further 3% permanent resident non-citizens.

Only 8% of respondents declined to answer the optional race question, despite its sensitive nature. Of those who answered the question, 68% of respondents voluntarily identified themselves as black, 15% as coloured,

15% as white and 3% as Asian.

In order to qualify for the research, respondents had to access the internet at least once a month, although 49% accessed the internet daily and a further 42% at least once or twice per week. Not surprisingly, 90% rated their knowledge of the Internet average or above average.

Figure 3: Home Language of Respondents

The three major home languages, comprising a full 77% of the respondents, were Xhosa, Afrikaans and Zulu. 11% of respondents have a home language which is not one of the eleven national South African languages. This is testimony to the fact that some workers and students originate from other African, European or Asian countries. The other 22% represent the 7 remaining national languages, each claiming less than 5%. Because of the predominance of Xhosa and Afrikaans speakers, most results will be presented those two sub-groups as well as for the entire group. It must be noted that especially the “Afrikaans” speakers are not likely to represent a single homogenous cultural group.

Extremely important for this research was the English fluency level of the respondents. 96% of respondents considered themselves fluent English speakers: they rated their own fluency average (34%), above average (30%) or excellent (32%). Two important conclusions can be drawn from this statistic. Firstly, there should not have been a problem with the understanding and interpretation of the questionnaire. Secondly, the understanding of English is sufficient to ensure that respondents can, in principle, navigate English websites.

It is of interest that most of the respondents are, in fact, multilingual. Of all respondents, 42% spoke Afrikaans, 39% spoke Xhosa and 36% Zulu. For instance, of all native Xhosa speakers, 52% also spoke Zulu and 21% spoke Afrikaans in addition to English.

Overall, it appears that the sample is fairly representative of the sampling frame and displays the desired characteristics for purposes of the research. However, it must be borne in mind that the sampling frame is biased in terms of geographical region, which implies a bias towards Xhosa and Afrikaans speakers, as well as exhibiting a bias in terms of the relatively young average age of the respondents.

6. Analysis of Results

6.1 Quality and lack of multi-language websites.

Respondents were asked to indicate which problems they experienced with non-English websites as compared to English websites. Although a very few people ticked specific issues (lack of content, poor usability, language errors, outdated information, poor graphics, poor translation), 78% said they had never tried to access non-English sites. Unfortunately, it is not entirely clear whether the 16% of respondents who experienced “no problems” with non-English sites did in fact access such sites. This points towards a severe dearth of non-English sites and appears to skew the value of some of the questions that follow by replacing actual user experiences with hypothesized opinions.

One particular quality concern in respect of multi-language sites is whether the translated website contains the same information. It appears that, for those multi-language sites that do exist, there appears to be quite a few problems in terms of quality or overall standard, with 25% responding “no” against a 17% responding “yes” (58% didn’t know). Although there is no statistically significant difference between the different language groups, only 9% the Afrikaans group responded “yes”. This may be explained by the fact that some Afrikaans speakers are historically very proud of their language (they have even erected a language monument) and may be quite sensitive about their language in the light of the recent “demotion” of the language from one of two to one of 11 national languages. Although this is speculation, this sensitivity seems to fit differences in the other questions as well.

6.2 Need for multi-language sites.

When asked if they would change the language of a website to their home language, if such an option is/were available, the vast majority of respondents reacted positively i.e. said they did so all the time, sometimes, or would if such an option was possible. However, this large proportion of 53% who would if it were possible, is perhaps the strongest indication of the pent-up demand for multi-language websites.

Table 1: if there’s an option to change the website language – do you do this?

Yes	No	Sometimes	Would if possible
10%	27%	10%	53%

Most interestingly, the proportion of Xhosa speakers who would do so (8%), is far less than that of the Afrikaans speakers, where a full 23% would change to Afrikaans if they could, although this difference is again not statistically significant (when using the χ^2 -test).

Survey participants were asked whether they had experienced any problems surfing the internet due to the fact that websites were predominantly in English and not available in their home language. This appeared to be the case for a full three quarters of the respondents. Overall, one quarter (26%) answered “Yes” and a further half (50%) answered “Sometimes”. Only 24% said that they did not experience such problems.

6.3 Differentiation of multi-language use.

In a society where multiple languages are spoken, the home language cannot always be used for communication. In this case, the Internet must be seen as just another communication channel. Therefore, it is interesting to check to what extent the various media and communication channels are dominated by individual’s home language. Note that it must be borne in mind that in a number of cases, the alternative language used may not necessarily be English. Participants were asked to rank their use of certain communications and media channels in their home language. Figure 4 summarizes the results for those who selected that they performed the given activities in their home language either “Often” or “Always”.

Figure 4: Use of media in home language.

Although, as might be expected, conversation is the highest with 53%, and none of the others are used by more than 50% of the sample. The fact that 47% of respondents only engages in conversation in their home language “sometimes” or even less frequently, testifies to the multi-cultural nature of interactions in South Africa, as well as the dominance of English in the work/study environment.

On the other hand, it is evident that the participants are becoming used to channels being available in their home language. For instance, 47% of the Xhosa speakers indicated that they listened to Xhosa radio stations, despite the fact that English broadcasts outweigh those in Xhosa by a huge margin. Even the least used facility, movies, has just short of 20% of the participants watching in their home language.

6.4 Desired types of home language websites.

From the open-ended feedback, and as anyone who has operated in multi-language environments knows, not all types of information lend themselves equally well for translation or digestion in home language. Financial, technology or work-related information is more likely to be acceptable in English than, say news items. This is reflected in the rankings of which internet facilities respondents would like to see available in their home language (this was a multiple response item).

Figure 5: Ranking of internet facilities required in home language.

News was the most popular choice with 68%. Academic was next, but this response is likely to be biased by the large number of students in the sample. However, it does stress the importance of not just making commercial but also educational and informational sites available in multiple languages. Other desired categories were entertainment and competitions. Although it could be expected that finance and jobs would rank lower in importance, it is interesting to note the low weight given to sport and literature. However, the figures given for online chat, email and literature validate the percentages given in the home language use of the various communication media in the previous figure.

As an interesting aside, participants were asked whether they would be willing to pay a subscription charge to have a website made available in their home language. Despite the large percentage of people wanting such websites, 78% of the sample was not willing to pay for such a facility. Again, this figure may be overstated due to the large number of (non-income earning) students in the sample.

When asked about the desirability of banner advertising in one's home language, 43% of the respondents indicated that they would prefer banner advertising in their home language and another quarter didn't care. By contrast, 22% indicated that they wouldn't want such advertising and 8% believed it to be a waste of time. Finally, it appeared as if only 8% of the respondents had received spam (unsolicited commercial e-mail) in a language other than English. In all cases, the other language turned out to be a European language, not one of the other South African languages.

The lack of banner advertising and commercial e-mail in home languages indicate the possibility of exploring less expensive avenues where companies are hesitant of making their entire website available in other languages. Piloting with home language banner adverts – and possibly the use of opt-in mailing lists – would serve as a good feasibility test for companies prior to translating their entire websites.

7. Conclusion and further research.

South Africa is a country with many cultures and languages. The diversity of cultures is widely seen as one of South Africa's strengths, and the right to receive education and information in one of eleven official home language is enshrined in the country's new Constitution. However, unlike in Europe, there is a dearth of multi-language websites catering for the South African official languages. This is also in strong contrast to the other communication and media channels in South Africa, which provide significant home language support.

Exploratory empirical research indicates that there is a very definite demand for websites in languages other than English, even among regular internet users that speak English fluently and access many other communication media in English. 78% of respondents had never used a non-English website even though the majority has experienced language related problems on the web and would like to have a facility to change the language.

Although this demand is fairly strong, not all users see the need for non-English websites. There are also indications that some differences may exist between different cultures and language communities, but the sample was not representative or large enough to confirm these differences statistically. It is also clear that the demand also depends on the type of website: especially news, academic, entertainment and competition websites would benefit most from multi-language capability.

The implication for the researchers is that there is an urgent need to confirm these results with a larger and more representative sample. There is still much uncertainty to what extent specific requirements differ between cultures and language groups. A secondary research objective will be to investigate other cultural-specific but non-language related aspects of websites such as the manner of navigation, use of non-English browsers, symbols and overall site organisation and other underlying design assumptions.

The implications for the site providers is clear: there is a large and pent-up demand – specifically in the areas of education, news, entertainment and competitions – for multi-language websites and there is a great potential for first-mover advantages to be realised in the short term. A less costly entry strategy would be to test the water with home-language banner and e-mail advertising, although this is likely to produce some dissonance when the recipient attempts to access the English website. Finally, it is believed that there are not only a direct value and public relations proposition in providing multi-language websites. The researchers are of the conviction that there is also a strong ethical obligation towards the eradication of historical inequities and the active development of a multi-cultural sense of community as part of the nation-building process in our country by providing these websites. Most appropriately, the central and some local governments as well as some parastatals have taken the lead, albeit in a somewhat modest way. It is hereby hoped

that this research will prompt commercial and educational institutions to adopt a more engaging stance and accord the provision of a multi-language website a high priority.

8. Appendix: Some illustrative comments .

This appendix gives some qualitative responses to the questionnaire. They have been selected to indicate the wide range of emotional attitudes respondents had towards multi-language websites.

The comments of people in favour of multi-language websites range from the political, site navigation (instructions) to the actual content.

- “We need transformation; we need websites in our own languages. This in return will see us growing and going towards the African renaissance.”
- “Other language Internet should be a right, not a privilege.”
- “In the New South Africa, I would expect companies to be offering their services in Xhosa and all of the other official languages.
- “I would love to access the Internet using my own language because many times I find it hard to understand what is required of me. Thanks, God bless you!”
- “I find it extremely difficult to use some websites because their instructions are hard to follow. If they at least gave us some parts in Zulu, it would make it much easier for me.”
- “I would use the Internet for much more if I could do things in Xhosa.”
- “Although my English is improving, it would have been much easier to learn to use the Internet if they had made tutorials in Zulu.”
- “I think school and now university would be much easier if they put information into other languages. I can only ever find information in English.”
- “English is far more difficult to understand than people think. I often avoid going on the Internet because it takes me so long to find information.”
- A sensitive issue is “Afrikaans” whose official status was diluted significantly. Contrast “If Internet sites can be in Afrikaans [...] I feel we have the right to all languages.” with “Afrikaans used to be such a popular language in South Africa (pre 1994), yet there are no

Afrikaans websites available for the Afrikaans speakers.”

However, not everyone would applaud a concerted effort to move to multi-language sites.

- “English is the universal language, so don’t bother changing anything.”
- “Why learn a language that will not provide a job?”
- “I don’t fee it would make a difference if certain websites were in Zulu. [E.g. the] SuperSport website is in English and it would be much harder for me to use if it was in Zulu.”

Still others give a more balanced view:

- “To become globally competitive, English (Internet or other) is imperative since it is the international language of business. However, for entertainment purposes, other languages in SA could be used on the Internet.”
- “I would love to see my language being used, but not in all cases. I prefer English most because we [live] in a modern world.”

Designing Business Models for Mobile Payment Services

Edward Faber* and Harry Bouwman**

*Telematica Instituut, Enschede, The Netherlands, edward.faber@telin.nl

**Delft University of Technology, The Netherlands w.a.g.a.bouwman@tbm.tudelft.nl

Abstract[♦]

Designing business models for mobile services is a complex undertaking because it requires multiple actors to balance different requirements and interests such that a 'win-win' situation is created. A business model can be seen as a blueprint of four interrelated components: service offering, technical architecture, and organizational and financial arrangements. Although little attention has been paid to how these different components are related to one another, this knowledge is needed to enhance our understanding of what constitutes a viable business model. In this paper the connections between two of these components, namely service offering and organizational arrangements, are explored by analyzing the business models of three recent mobile payment initiatives. The cases reveal that similar value elements can be realized in different ways and that, depending on the target group, dominant actors can be bypassed in the value network.

1 Introduction

The mobile telecom industry currently faces a number of opportunities that may radically change the field of mobile telecommunication. The development of new networks like GPRS (2,5 G), UMTS (3G) WLAN (WiFi), and Personal Area Networks (beyond 3G) will spark the development of mobile services. With 'mobile services' we mean all kinds of innovative services that combine technologies from the domains of telecommunication (e.g. mobile services), information technology (e.g. the Internet, PDA's) and consumer electronics (e.g. cameras). These new technologies, in combination with the

'convergence' of these domains, and concepts of content and services providers, offer opportunities for the mobile telecom industry.

To exploit the opportunities companies need to buy licenses, build networks and develop new services. Since most industry players currently lack the resources and capabilities to do so, mobile services are increasingly being developed and provided by networks of cooperating organizations. It is assumed that flexible 'value webs' will arise and replace traditional, static and linear 'value chains'. In such a 'value web' each player has different capabilities and resources, and innovation thrives on the combination of these capabilities and resources. Compaq HP, Microsoft and KPN Mobile, for instance, recently started the joint development and marketing of a mobile office application called Lucio.

Cooperation in value webs is by no means straightforward. Various studies [20,15,3] indicate that companies encounter serious difficulties in achieving the anticipated benefits from cooperation. First of all, partner organizations may use the cooperation to pursue different strategic goals, which may induce partners to act against what is agreed upon, hide the truth or try to extract confidential information from their partners. Secondly, partner organizations often come from different industries (e.g. network operators, financial institutions, and retailers) each with their own peculiar business logic. Such diversity may be necessary for the development of new innovative services, yet at the same time disrupt cooperation. Finally, cooperation gives rise to complex interdependencies between organizations because none of the partners has formal authority over the others. Hence, every adjustment has to be discussed and jointly agreed upon [17].

Given the disappointing success rates of inter-firm co-operations and the risks and cost involved in the introduction of new mobile services, it is not surprising that practitioners and academics pay a great deal of attention to the concept of business models. In our view a business model is a blueprint for how a network of

[♦] The research presented here has been conducted within the government funded BITA and B4U project. The authors would like to thank Roel Stap, Sander Hille and Paul Oude Luttighuis for their insightful comments on previous versions of this paper and acknowledge Roel Stap for his contribution to the case study research.

organizations co-operates in creating and capturing value from technological innovation [10]. Designing business models is a complex issue because technical, financial, organizational and professional user or consumer's needs and requirements need to be balanced. For instance, what makes sense from a technical point of view (better specs of positioning technology) may not make sense from a financial (higher costs) and user perspective (privacy concerns). Moreover, organizations have to balance their different interests and business logics to create a 'win-win' situation, in which each player has incentives to co-operate, and in which the combined benefits are higher and the combined efforts are smaller compared to each player working separately.

Although extensive literature on strategic alliances [7], network formation [24] is available it fails to provide insight into the subtleties involved in the design of viable business models for the provisioning of mobile services in value webs. Existing literature on business models is extensive [1,16,21,26,32]. However the predominant focus has thus far been on defining and classifying business models. Little attention has been paid to the way the various elements of a business model are and have to be related to one another. This knowledge is needed to enhance our understanding of what constitutes a viable business model.

The objective of this paper is to explore the relationship between two important business model elements: customer value and value network. The paper is structured as follows: first, a descriptive framework for studying the interrelatedness of business models elements is developed. This framework is then used to analyze the business models of three recent mobile payment initiatives, focusing on the relationship between the customer value of service offerings and the value network required to realize a service offering. The paper concludes with drawing conclusions on important issues regarding the design of viable business models and providing directions for further research.

2 A descriptive framework for studying business models

We view a business model as a blueprint of the way a network of organizations co-operates to create and capture value from the implementation of technological innovations. We look beyond the individual firm and consider the business model for a network of companies: a collaborative effort of a number of companies to offer a joint proposition to their customers. When comparing the various existing definitions of business models it is possible to distinguish some common components that are network-oriented or can easily be extended to be so [13]:

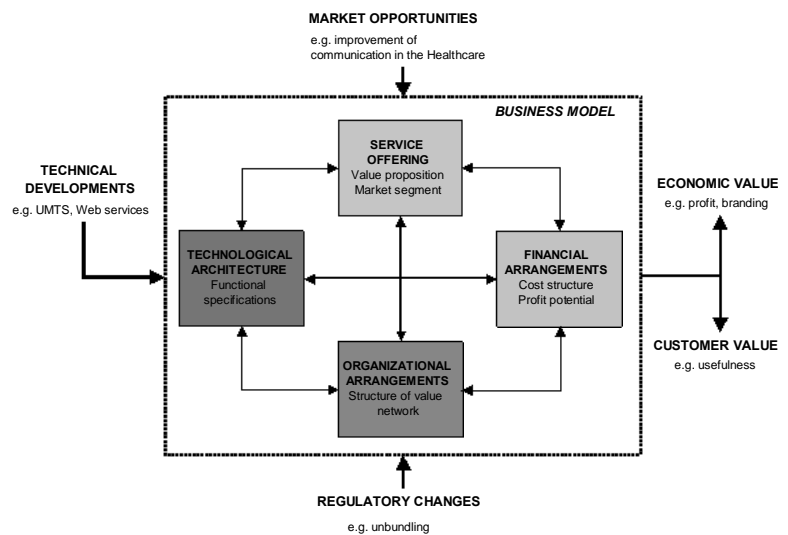

- *Service offering*: a description of the value proposition (added value of a service offering) and the market segment at which the offering is targeted

- *Technological architecture*: a description of the technical functionality required to realise the service offering
- *Organizational arrangements*: a description of the structure of the multi-actor value network required to create and distribute the service offering, and to describe the focal firm's position within this value network
- *Financial arrangements*: a description of the way a value network intends to generate revenues from a particular service offering and of the way risks, investments and revenues are divided across the different actors in a value network.

Furthermore the governance of the process of developing a business case has to be taken care for. The challenging aspect of analyzing and designing business models is that it requires managers to connect and balance different business model components (technological architecture, service offering, organizational arrangements, and financial arrangements) in the face of technical, market, and legal developments (see Figure 1), the ultimate aim being to create sufficient economic and customer value.

As the focus of this paper is on the connection between the customer value of services and the value network offering them, these components are elaborated in more detail below.

Figure 1: high level descriptive framework

An important element of a *service offering* is customer value. Value is seen as part of an equation in which customers in target markets compare the perceived benefits and total costs (or sacrifice) of (obtaining) a product or service [9, 27]. The value proposition must be

considered better at delivering the desired satisfaction more effectively and efficiently than competitors. Customer experience is the key factor here [5]. In many cases customer value as perceived by the end-user has little to do with the customer value that is envisaged in initial business models and greatly depends on the user's context as a person, professional or consumer [9]. In general, we will draw the distinction between new-to-the-world products or services and new versions of existing products or services (see also the concept of versioning: [29]). Newness is quite a troublesome concept. It concerns products that are new to the world [4], or disruptive innovations [11].

In general, *organizational arrangements* revolve around the resources and capabilities that have to be made available. In their analysis of business models Hedman and Kalling [16] conclude that in the final analysis economic value is determined by a firm's ability to trade and absorb ICT-resources, to align (and embed) them with other resources, to diffuse them in activities and manage the activities in such a way as to create a proposition at uniquely low costs or with unique qualities in relation to the industry in which the company is operating. Increasingly, organizations have to work together to deliver customer value in so-called 'value networks'. Depending upon which actor(s) contribute key assets in the creation of value and the operating risks involved, different configurations of actors are likely to result, with some taking on structural, integrative roles in the alliance and others taking supporting, facilitating roles [8,14,18,28,30,31,33].

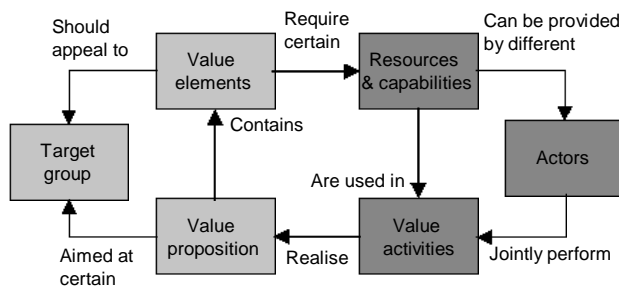

Figure 2: Connection between customer value and value network

The customer value of service offerings and the value network needed to realize customer value are closely related, as depicted in Figure 2. An important research question is how the design of a value network influences the customer value of a service offering and vice versa. This relationship will be explored by analyzing the business models of three mobile payment services. Before doing so we will first elaborate on mobile payment services.

3 Mobile payment

Mobile payment services are payment services using a mobile device, such as a PDA or a mobile phone, to initiate and confirm electronic payments. Mobile devices can be used to pay for goods and services on the Internet, ticketing machines, and at payment terminals in stores. Mobile devices are generally expected (see e.g. Krueger, 2001) to play an important role in commercial transactions. This expectation is based on the high penetration of mobile phones in many countries, the opportunities provided by 2.5 (GPRS) and 3rd generation telecommunication networks (e.g. UMTS) and applications (such as WAP and I-mode), and the positive market forecasts for m-commerce. A recent international survey conducted among 5600 mobile phone users by AT Kearny [23] indicates that 46% of the respondents would use mobile payment if it becomes widely available.

Given these high expectations it is not surprising that there have been many mobile payment initiatives in the past few years. However, the introduction of mobile payment proceeds at a slow pace, not in the last place because of the difficulty of developing feasible and viable business models. Any provider of mobile payment services has to come up with a proposition that is interesting to both consumers and merchants. This dual focus and the subsequent 'critical-mass problem' complicate the introduction [22,25]. Moreover, businesses need to account for the business logic not only of the financial services sector, but of the business logic of the retail and telecommunication sector as well. This creates a multi-party, cross-sector problem whose solution is fundamental for the successful development of mobile payment services.

An important issue in designing business models for mobile payment services is how to create enough customer value and who to involve in the value network. With respect to customer value, trust, ease of use, cost and reach are generally accepted as important elements in the value proposition of a mobile payment service. With respect to value network design an important question is the indispensability of financial institutions in offering a mobile payment service.

4 Research method

The research reported in this paper has been conducted within the BITA and B4U project¹, in which not only mobile payments cases, but also cases dealing with mobile information and entertainment services, location based services, community's, tracking and tracing, and personalised instant messaging. The findings that are discussed in this paper are based on an exploration of three mobile payment services initiatives. Before the

¹For more background information on the BITA project see: <http://www.telin.nl/NetworkedBusiness/BITA> and for the B4U project see: <http://www.freeband.nl/projecten/b4u/>

actual cases were being researched, industry reports, academic literature and company web sites have been consulted. This exploration allowed us to produce an overview of mobile payment initiatives and to narrow down the scope of the case studies. For every case representatives from mobile payment providers, retailers, and financial institutions were consulted. We conducted semi-structured interviews and talked informally with dozens of company representatives. Given the exploratory nature of the subject the interviews were semi-structured [2]. The interviews were recorded and transcribed. The data from the interviews were supplemented with information from company websites, industry reports and academic literature. We made case descriptions, which we used for cross-case analyses. To ensure internal validity, all involved researchers used the same interview and case description templates. In addition, the researchers conducted the interviews in different combinations and reviewed and discussed each other's case descriptions. The informants reviewed the case descriptions. Cases were stored in a database that was accessible for all involved researchers, for analysis.

5 Cases

In the remainder of this paper we will take a closer look at the business models of Mobipay, Moxmo and Mobile2pay in terms of service design and value network. The cases have been selected because they represent different market introduction strategies.

Table 1: cases

Case	Characterization
Mobipay	Bank-oriented: customer base of financial institutions is used to introduce mobile payment
Moxmo	Independent: customer base is built independent of financial institutions, existing payment infrastructure is bypassed
Mobile2Pay	Independent: customer base is built independently from financial institutions. Financial institution has role as trusted third party

Since both consumers and merchants play an important role in the distribution and acceptance of mobile payment products, the value proposition has been analyzed from the perspective of both actors.

5.1 Mobipay

Mobipay is a mobile payment initiative started in December, 2000, initiated by the leading Spanish financial institutions Banco Bilbao Vizcaya Argentaria (BBVA) and Santander Central Hispano (SCH), as well as all Spanish mobile telephone operators: Telefónica Móviles, Vodafone and Amena. The initiative's objective is to develop and promote an international mobile

payment solution, based on a co-operative model between mobile operators and financial institutions. Mobipay International is the holding company that owns the local initiatives in different countries.

5.1.1 Value proposition

Mobipay's value proposition provides mobile and single access to the existing payment infrastructure. Mobipay provides a transaction platform capable of supporting all kinds of payment methods. With Mobipay the consumer can pay through existing and trusted electronic payment methods using their private mobile phone as an authentication terminal. Mobipay focuses primarily on the financial institutions and telecom operators. Although Mobipay provides banks and telecom operators with reasons as to why mobile payment is of added value to end-users it does not directly offer a value proposition to these end-users. In Spain the main selling argument towards financial institutions is increased intermediated payments.

5.1.2 Value network

Mobipay provides a mobile transaction platform to financial institutions that can be used with existing payment methods. The mobile operators are more or less part of the distributed platform by integrating their mobile access services in this platform. The mobile network operator provides mobile communication services to Mobipay, which are used to access the payers' verification terminal. Mobipay offers financial institutions single and mobile access to the existing payment infrastructure. For Mobipay the support of financial institutions is important because of their relationship with customers and retailers, the users and acceptors of mobile payment solutions. Mobipay receives a fee per transaction for its services. The financial institutions handle the payment of the transactions. Mobipay is responsible for the authorization, authentication, electronic assembly and delivery of payment transactions. Financial institutions are also responsible for the distribution of mobile payment. The retailer's role is to provide payment methods to the consumer and in return is paid for the products and services in an appropriate way. The payment services are provided by the financial institutions (or third party payment providers) and will be paid for by the retailer.

Table 2 and 3 summarize the value configuration of Mobipay in terms of target group, value elements, resources & capabilities, and actors.

Table 2: Value configuration consumer side

Value element	Customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Mobipay
	Control over transactions	Transaction management	Financial institutions
	Trusted Third Party	Institutional rules of conduct	Financial institutions
Ease of use	Mobile phone as access device	System integration	Mobipay
Cost	Not different from normal transactions	Cost efficient payment infrastructure	Different financial institutions
Reach	Increasing number of retailers in different countries	Customer base	Financial institutions and mobile operators

Table 3: Value configuration merchant side

Value element	Customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Mobipay
	Trusted Third Party	Institutional rules of conduct	Financial institutions
Ease of use	No changes needed in POS	System integration	Mobipay
Cost	Cheap electronic point of sale	Secure authentication & authorization	Mobile operators and financial institutions
Reach	Increasing number of retailers in different countries	Customer base	Financial institutions and mobile operators

5.2 Moxmo

Moxmo is a recent Dutch payment initiative that provides mobile payment solutions to merchants, primarily on the Internet and non-POS situations. Moxmo was introduced by Global Payways and operates independently from banks and (mobile) telecom operators, which distinguishes it from most other mobile payment solutions.

5.2.1 Customer value

Moxmo is a mobile wallet service that allows consumers to make secure and direct payments to anyone who has a mobile or accepts Moxmo as a method of payment. Since mobile payment itself is not a product, Moxmo is collaborating closely with service providers to develop new innovative service concepts that may incorporate mobile payment. This is seen as an important prerequisite for the further growth of mobile payment, and thus of Moxmo in particular. The value proposition of Moxmo towards consumers is that it offers convenient (any time any place) and secure electronic payment.

Moxmo currently focuses on the micro-payment product-market segment. It focuses in particular on person-to-person payments, Internet payments, topping-up of prepaid accounts and ticketing. At a later stage Moxmo aims to extend these services to include parking, international transfers, debit card payments, customer cards, and ultimately payments in stores.

5.2.2 Value network

Moxmo is a start-up company owned by Global Payways. Global Payways plays three roles in Moxmo, which are divided into distinct business units. First, it is involved in developing service propositions in co-operation with third parties. These propositions should result in high-end value services and products using Moxmo. Second, it processes the transactions generated by Moxmo. Third, it wants to control the deposits stored on the electronic wallets of its customers. To do this Moxmo needs to acquire a license for Electronic Money Institution (EMI). As far as we know Moxmo is still in the process of obtaining such a license. In the meantime customer deposits are controlled by ABN-Amro. Retailers may play a role as acceptor and distributor of Moxmo. In their capacity as distributors retailers are actively promoting the Moxmo payment method to their consumers. Moxmo offers revenue sharing for each payment that is performed by consumers acquired by the retailer. Thus Moxmo hopes to win over consumers and merchants, and thus build its brand. Recently, it also took over the customer base of Paybox in Germany, which cancelled all its activities. The operational management of transaction platform and mobile wallet administrator is outsourced to an Application Service Provider. Finally, mobile operators facilitate the mobile access between the users' mobile phone and the Moxmo transaction platform.

Table 4 and 5 summarize the value configuration of Moxmo in terms of target group, value elements, resources & capabilities, and actors.

Table 4: Value configuration consumer side

Value element	Customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Moxmo
	Control over transactions	Transaction management	ABN-Amro
Ease of use	Mobile phone as prepaid wallet	License for EMI	Moxmo
Cost	Low cost through bypassing of existing payment infrastructure	Cost efficient independent payment infrastructure	Moxmo
Reach	Increasing number of retailers in the Netherlands and Germany	Access to customer base	Moxmo and retailers

Table 5: Value configuration merchant side

Value element	Customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Moxmo
	Guaranteed payment	Risk management	Moxmo
Ease of use	No clear value offering	No clear value offering	No clear value offering
Cost	Low cost through bypassing of existing payment infrastructure	Cost-efficient independent payment infrastructure	Moxmo
Reach	Revenue sharing is offered for those that become a distributor	Distribution channel	Retailers themselves

5.3 Mobile2pay

Mobile2Pay is a mobile payment initiative initiated in October 2002 by Smart Concepts. Its main objective is to create an interactive mobile sales channel that enables the payment and delivery of goods, in particular impulse purchases.

5.3.1 Customer value

Mobile2pay formulates its value proposition as ‘seeing is having’. Consumers can respond directly to advertisements published in magazines or broadcast on radio, using their mobile phone as a transaction device. The main advantages of Mobile2pay for consumers are speed of use (impulse buying and fast processing), ease of use (small smart device) and benefits (discounts).

Mobile2pay focuses on retailers, and its main objective is to set up a mobile sales channel rather than to provide a mobile payment system. With this idea Mobile2Pay defines a strategy for mobile commerce in general and uses mobile payment as an enabling functionality. Mobile2pay focuses on medium-sized and macro payments.

5.3.2 Value network

The retailers’ role is to provide payment methods to the consumer to get paid for their products and services. By offering an interactive transaction channel to its consumers retailers are able to improve their service to consumers. Fortis bank acts as trusted third party in the payment transaction between the consumer and the retailer. The bank receives an authorized and complete payment transaction from Mobile2Pay, and returns a bank guarantee. This guarantee is based on the consumer’s creditworthiness. After receiving the guarantee the retailer will ship the goods. If the retailer receives confirmation from the consumer, the bank will transfer the money to the retailers account. By deploying a dynamic spending limit, Mobile2pay filters out defaulters. Customers are rewarded for keeping their promises (faithful payment) by an increased spending limit. Mobile2Pay handles the consumer authentication and the authorization of the payment process. Finally, mobile operators facilitate the mobile access between the users’ mobile phone and the transaction platform of Mobile2Pay.

Table 6 and 7 summarize the value configuration of Moxmo in terms of target group, value elements, resources & capabilities, and actors.

Table 6: Value configuration consumer side

Value element	Customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Mobile2pay
	Control over transactions	Transaction management	Mobile2pay
	Guaranteed delivery	Trusted Third Party	Financial institution (Fortis)
Ease of use	Mobile device as debit card	Automatic collection	Mobile2pay
Cost	Price reductions when ordered with mobile phone	Access to customer base	Retailers
Reach	Increasing number of retailers in the Netherlands	Access to customer base	Retailers

Table 7: Value configuration merchant side

Value element	customer value offered	Resources and capabilities	Actors
Trust	Secure payment	Secure authentication & authorization	Mobile2pay
	Guaranteed payment	Trusted Third Party	Financial institution (Fortis)
	Guaranteed payment	Dynamic spending limit for users	Mobile2pay
Ease of use	No clear value offering	No clear value offering	No clear value offering
Cost	Increased sales through impulse buying	Anytime and anywhere payment	Mobile2pay
Reach	No clear value offering	No clear value offering	No clear value offering

6 Discussion and conclusion

The mobile payment providers we examined in this study follow different strategies to obtain critical mass. Whereas Mobipay invests most of its effort in bringing together financial institutions and telecom operators, Moxmo and Mobile2pay directly try to convince merchants and customers of the added value of mobile payment. However customer groups have different needs and wishes.

Trust All mobile payment providers are aware that trust is of crucial importance. However, they make use of different mechanisms. In the case of Mobipay, consumers deal with their trusted home banks. Due to this Mobipay can profit from the generally trusted laws and codes of conduct of banks and the relationship that already exists between the banks and their consumers. Moxmo, on the other hand, has to prove its trustworthiness to consumers by recurrent positive experiences. To merchants it promises guaranteed payment. However, it is not clear if it can live up to its promises. Finally, Mobile2Pay uses an escrow service to eliminate the risks for consumers and merchants. By doing so it can guarantee product delivery to consumers and guarantee payment to merchants. Moreover, by deploying a dynamic spending limit Mobile2pay filters out defaulters.

Ease of use The entry barriers for consumers vary among the studied payment initiatives. With Mobipay consumers do not need to register at all, provided that they have opened a bank account. With Moxmo users need to register and open a new bank account and with Mobile2Pay they need to register and authorise an automatic direct debit. One thing that remains to be seen is how users will value these entry barriers. For merchants the integration with existing payment products is an important issue. They are not all that eager to implement a new payment product in addition to already existing payment products such as debit and credit card payments. Mobipay is the only initiative that presents a convincing case with respect to this value element.

Cost Mobipay focuses primarily on financial institutions (banks and payment brands) and to a lesser extent on telecom operators. It leaves the promotion of mobile payment to the financial institutions and telecom operators. Moxmo sees mobile payment not as a product in itself and is collaborating closely with service providers to develop new innovative service concepts in which mobile payment can play a role. Moxmo offers revenue sharing and new service concepts to merchants. Consumers are offered convenient and secure payment. These elements of the value proposition can hardly be regarded as order winners but rather are 'dissatisfiers' (their absence provides a negative experience). Mobile2pay tries to provoke consumers into purchasing goods by offering price reductions on products that are paid for with its payment service. The impulse character of purchases is stressed ('seeing is having') and promoted as a valuable experience for consumers. Mobile2pay offers merchants an interactive transaction channel next to the Internet and attended points of sale.

Reach Mobile payment providers use different strategies to acquire merchants and consumers. Mobipay relies on financial institutions to convince merchants and consumers of the value of mobile payment. Moxmo and Mobile2pay cannot rely on the customer base of financial institutions and have to acquire customers themselves.

Merchants regard mobile payment as yet another payment product that they need to support. They seem to be willing to adopt mobile payment if it resolves some of the problems they have with existing payment products. Guaranteed payment is especially valued highly. This can be realized in different ways, as illustrated by the Moxmo and Mobile2Pay cases.

Consumers do not consider payment a service but instead they see it as "a necessary evil". Low transaction fees, ease of use, guaranteed delivery are therefore 'dissatisfiers' rather than order winners. For mobile payment providers this means that it is important not to promote payment as a product in itself but as an enabler of new value adding services. The two independent initiatives provide nice examples of this.

Although both Moxmo and Mobile2pay were typified as independent initiatives, the findings show that financial institutions *do* play important roles in both initiatives. Until it is given an EMI-license Moxmo has to rely on the ABN-Amro for the management of wallet deposits. By making use of escrow services Mobile2Pay is able to guarantee payment to merchants as well as delivery to consumers. By including financial institutions in the value network mobile payment providers are able to reduce the risks for both merchants (guaranteed payment) and consumers (guaranteed delivery). This comes, however, at the expense of increased transaction costs.

An important decision is whether or not to include financial institutions in the value network. Required guarantees and transaction costs are important influence

factors. For micro payments, which require less guarantees and low transaction costs, it does not seem to be useful to consider including financial institutions. Financial institutions do seem to be required for medium and macro payments. However it can be debated if mobile payments limited to only micro-payments will be attractive enough for consumers. The cases reveal that certain value elements can be realized in different ways and that depending on the target group it is possible to bypass dominant actors in the value network. Still the financial institutions have a strong position and bypassing financial institutions is problematic.

Based on the three cases we can draw some conclusions on customer value. First of all it is important to realise that the customer value of the services offered although technically innovative, are not experienced as very innovative to the customer. The mobile services in itself are yet another way, next to money, credit and debit cards, to take care for payments. So the positioning of a mobile payment channel next to already existing payments channels is problematic. Although new to the world from a technical point of new customers don't see the customer value very clearly. Furthermore merchants, who have control over the customer relation between the mobile payment services and the end user: the customer will only accept the mobile payment channel as it solves some of their problems. So in the service offering the issue of value have to be addressed very carefully for both customers and merchants. A possible alternative is to make mobile payments an integral part of other innovative mobile services. The mobile payment service can be presented as an additional feature of the new service.

With regard to the value network we see that bypassing financial institutions is rather problematic. Seen their powerful position within the value network it is almost impossible to by-pass banks, especially if the service will not be limited to micro-payments.

As far as our conceptualization of the design of businesses models is concerned, it is clear that we not only have to look into the value of a service from the perspective of the customer but also from the perspective of the service provider. The mobile cases show that the mobile payment provider has to position it services in a relation between financial institutions and their customers, where there are many alternatives and the dominant role of players in the existing value networks leave ample space for new entrants.

We realise that our conclusions are based on only a limited set of cases. Yet some of the identified patterns are similar to those identified in other case studies conducted in the B4U and BITA project. We hope that this article inspires other researchers to study the complex interplay between the four business model domains and their impact on customer and economic value.

Case Study of Data Mining Application in Banking Industry

Yongping Liu

Applied Mathematics Department
South China University of Technology
maypliu@scut.edu.cn

Abstract

In this paper, we study the usages of data mining in banking industry and its related impacts. Great changes in banking services emerged from the application of data mining especially in retailing banking. We present China Merchant Bank (CMB) as an example to do case analysis, in which we explore data environment evaluation analysis model, operational efficiency model and profitability model to analysis the application performance for CMB. Finally we provide some advices of future development to CMB.

1. Introduction

Data warehouse (DW) is like a box, in which vast of data are included and processed into useful information by using various kinds of tools, such as data mining (DM), OLAP, ERP. Banking industry is the pioneer who adopts DW as tool in decision-making. DW makes it possible for business to store large amounts of disparate data in one location. DW consolidates many types of data from many data sources in order to facilitate data analysis for fact-based decision-making.

DW expanded dramatically in the late 1980s, when businesses began realizing the value of their data. Before then, the focus was more on how to integrate DW into a company's existing IT infrastructure than it was about business value. The real value of a DW is to make new business knowledge available literally at the touch of a button. Finding, collecting, and synchronizing data is all performed electronically. Thus, the e-data way of information retrieval provides the needed information in a direct, rapid, and meaningful way, in which queries and answers can be sent and retrieved directly through users and DW. Business intelligence is one of those monikers that encompass the set of products and services for accessing and analyzing data and turning it into

information. In early days DW was motivated by a number of separate factors:

1) Mainframes offload. Frequently, a company's mainframe system was busy enough already, and upgrading could be just as expensive as buying a brand-new DW. These mainframes were often transactional systems performing mission critical functions such as customer billing or banking deposits. Companies were loath to tax their mainframes any further, and the data redundancy and separate processing DW provided were enticing.

2) Dirty data. Different data from all over the enterprise, from accounts payable in compensation to customer information, was often not only hard to find but impossible to understand and often just plain wrong. The DW provided a single platform for loading this "heterogeneous" data. It also offered a pretext for data cleaning---checking it for quality and accuracy, and reformatting it so that it was comprehensive and useful before it was loaded into the warehouse.

3) Security. In order to protect their mission-critical operational systems [6], most companies limit their access to a few experts. DW offered a most generally accessible environment for frequently sought-after information.

In this paper, we study the usages of DM in banking industry and its related impacts. There are 4 parts. In part one and two we explain some background literatures, such as DM, banking services changes emerged from the uses of DM into banking services and retailing banking. In part three and four, we present China Merchant Bank (CMB)[13] as an example to do case analysis, in which we explore 3 models (data environment analysis model , operational efficiency model and profitability models) to make an analysis for CMB. We mention the customer relationship management and personalization in

marketing. At last we provide some advices of future development to CMB.

2. Background literatures

DM is the automatic extraction of hidden predictive information from databases[11]. Like statistics, DM is a technology rather than a business solution. For example, consider a catalog retailer who needs to decide who should receive information about a new product. The information operated on by the DM process is contained in a historical database of previous interactions with customers and the features associated with the customers, such as age, zip code, their responses. DM would use this historical information to build a model of customer behavior that could be used to predict which customers would be likely to respond to the new product. By using this information a marketing manager can select only the customers who are most likely to respond. The operational business software can then feed the results of the decision to the appropriate touch point systems such as call centers, web servers, email systems so that the right customers receive the right offers.

Banking industry is the pioneer to adopt DM and its related technology into application. The products banks provide to customers are financial services. Financial services are different from traditional product-making industries. Products provided by financial services are mostly intangible and customer-oriented. To gain greater profit needs maintaining customers' loyalty, which is regarded as customer satisfaction [8]. There are mainly two reasons for banks to adopted DW urgently and necessarily.

1) More and more payment options are available to customers.

New payment technologies and specifications [5] are emerging and need to gain both customers and business acceptance. The ultimate benefits include reduced processing cost, reduced lead times, increased interoperability, and increased flexibility in choosing a payment mechanism. As with any emerging technologies, some will become mainstreams and other products will wither on the vine. Therefore to gain the advantages listed above, banks should equip themselves with solid DW and related technologies to accomplished the task.

2) Rapidly changing customer requirements

The information age is characterized by rapidly changing customer requirements, market niches and focused, global competitors. The information age has greatly influenced strategies business decisions processes, SCM, CRM. The environmental changes experienced by firms in the past decade have been drastic and unpredictable. The innovation of information technology makes huge amounts of customer, market and product data available and accessible to knowledge workers [3].

3. Case Analysis of CMB

3.1 General history of CMB

CMB was established in 1987 in Shenzhen. With current assets over US\$50 billion and with US\$43.5 billion of deposits, it ranks as the 6th largest bank in China. CMB earns good reputation in domestic and abroad markets. Bankers' journal ranked CMB 187th in the top 1000 biggest banks in the world in 2002. CMB was the first bank with public shareholder ownership in China. As the pioneer in China's banking reform, CMB was the first Chinese bank to enter offshore banking and has established international banking agreements with 571 banks in 40 countries worldwide. Within China, CMB has 355 branches with its own nation-wide commercial banking network. CMB is also the first China bank to officially establish investment-banking operations in the Chinese banking industry, and more recently, has set up the first China Internet banking service. CMB was also the first bank in China to obtain ISO9001 certification.

3.2 Technology advantages of CMB

During 16 years development, CMB has been consistently adopting the technology driven strategy. In 1995 CMB put all-in-one credit card into market, which was regarded as a milestone of personal financial management in China banking industry. In the next year, CMB was the first bank to turn nationally credit and debit into reality, while in the same year, it launched IC card, which makes it possible to withdraw and deposit without distance and time limitation among companies. In addition, CMB also built the website of national ATM and domestic consumptions of POS, both of which

compose modernized and national personal financial service network supported by powerful and advanced technology, the volume of all-in-one credit card has been drastically increase and becomes the shining product of CMB. In Feb 1998, all-in-net service is developed by CMB, which is the first bank to launch on-line banking service in China. 21 months later CMB became perfect on-line corporation banks, on-line personal banks, on-line trading mall and on-line security investment and on-line payment. Till now, CMB's on-line banking is occupying an absolutely leading place in technology domain and service income area in banking sector of China. About 80% famous web sites, for instance, www.sohu.com, www.sina.com.cn , www.8848.com, choose "all-in-net" as the first or even the unique choice as payment tool. The achievement CMB has gained is not accidental. It is due to its strong and solid DW system. Moreover, In 2000 China Merchant Bank joined the ESS Technology corp., a leader in Internet, communications, PC audio and digital video, and China E-Commerce Technology Co. Ltd. (CECT) and announces a major breakthrough in Chinese Internet e-Commerce by creating the first secure e-Commerce payment gateway in China. The three companies jointly announced the new solution to facilitate payments through an Internet Set-Top-Box designed by ESS using ESS's technologies and products. The solution utilizes ESS's Internet Set-Top-Box to protect both the account holders and the bank. The Set-Top-Box automatically connects to CECT's portal and ICP website that operates the CMB gateway. CMB serves as the clearing bank, which settles all e-Commerce transactions through a debit system for each customer's account.

3.3 Why CMB use DW and DM

The DW is a site, which combines information from different, separate systems in one location. Because the information is stored together, it is easy to access. Data in the warehouse comes from a number of sources. At this point, the warehouse of CMB contains four main types of information identified by the business area: financial, general, individuals and corporations. The DW is a read-only database, which guarantees its stability over time. To do customer segmentation, CMB needs DM

urgently. For example, a pattern might indicate that married males with children are twice as likely to drive a particular sports car than married males with no children. If you are a marketing manager for an auto manufacturer, this somewhat surprising pattern might be quite valuable. DM uses well-established statistical and machine learning techniques to build models that predict customer behavior. The technology enhances the procedure by automating the mining process, integrating it with commercial DW, and presenting it in a relevant way for business users. DM helps banks improve their understanding of customer behavior so as to target marketing campaigns more accurately and to align campaigns more closely with the needs, wants and attitudes of customers and prospects. The key is to find patterns relevant to current business problems.

3.4 Principles of DM application in CMB

According to a report that released by CMB in 2002, there are several thoughts on the current state of DM software applications in CMB:

1) Automated Model Scoring

Scoring models against a database is currently a time consuming, error prone activity that hasn't been given enough consideration [2]. When someone in marketing needs to have a database scored, they usually have to call someone in IT and cross their fingers that it will be done correctly. If the marketing campaigns that rely on the scores are run on daily basis, this means a lot of phone calls and lot of manual processing. Instead, the process that makes use of the scores should drive the model scoring. Scoring should be integrated with the driving applications via published API and run-time-library scoring engines. Automation will reduce processing time, allow for the most up-to-date data to be used, and reduce error.

2) Time-Series Data

Much of the data that exists in DW has a time-based component. A year's worth of monthly balance information is qualitatively different than twelve distinct non-time-series variables. DM applications need to understand that fact and use it to create better models. Knowing that a set of variables is a time-series allows for calculations to be done that make sense only for time

series data: trends, slopes, etc.

3) Incorporate Financial Information

The results of the DM process will drive efforts in areas such as marketing, risk management, and credit scoring. Each of these areas is influenced by financial considerations that need to be incorporated in the DM modeling process. The information necessary to make these financial decisions is often available and should be provided as an input to the DM application.

4) E-banking and personalized services

CMB retain credibility by being able to offer Internet access and defend existing customer base against potential competitors. The e-banking and personalized services are seemed as something that CMB cannot ignore if it wants to fight out a way in banking industries. The Internet is particular well suited to the distribution of financial products. Fortunately there are tangible opportunities to shift manual transactions out of branches and thereby reduce costs the technology will continue to improve.

Now we are going to analysis 2 kinds of the knockout products CMB developed when combining the DW technique.

1) All-in-one credit card

Since July 1995, all-in-one credit card created a new age of personal financial management depending on its advanced technology and fashionable business concept. It has many functions, some of which are also included in credit cards other banks issue, such as arranged transactions, automatic transfers, customer demands, ATM. But the functionalities such as mobile service banking, security, automatic payment, transfers and transactions, montage, pay on net, long distance call, hotel reservation, are characterized with personal financial management services in which other banks are deficient. With the help of the DW technology, CMB is able to provide the services to the customers that tailored to their particular needs. Related card is one of the typical examples. Related card is produced by Nanjing branch and Nanjing Security bureau, which is added with some extra functions especially for the drivers. According to different individual drivers, inquiry of transportation management information and pay traffic fines are accessible in related cards.

2) Mobile banking service (MBS)

CMB cooperated with China mobile corp. and put MBS into marketing. This is a newborn personal banking service in which telecommunication techniques are utilized in order to make personal financial management more efficient than before. MBS contains many personal investment functions, from the common ones like account query, payments, functions to multifunction deposit forms transferring, moreover it also includes advanced personal investment function, as customers can do the daily security information inquiry, entrusting transactions, international currency exchange and inquiry through mobile phone.

4. Models to analysis for CMB

Bank management and government regulators need models that can accurately portray value creation in banking and offer guidelines for strategy and the regulation of strategic behavior by banks. Internet and telephone banking usage per person in the world is increasing rapidly, thereby underlining that banks are intermediaries facilitating direct and indirect financial relations among their customers, rather than creators and distributors of financial products.

4.1 Data Envelopment Analysis (DEA)

DEA is receiving increasing importance as a tool for evaluating and improving the performance of manufacturing and service operations [10][12]. It has been extensively applied in performance evaluation and benchmarking of bank branches. We make an introduction to the DEA and some importance methodological extensions that have improved its effectiveness as a productivity analysis tool for CMB branches. DEA is a multi-factor productivity analysis model for measuring the relative efficiencies of a homogenous set of the decision making units (DMUs). The efficiency score in the presence of multiple input and output factors is defined as

$$\text{Efficiency} = \frac{\text{weighted sum of outputs}}{\text{weighted sum of inputs}} \quad (1)$$

Assuming that there are n DMUs, each with m input and s outputs, the relative efficiency score of a test DMU p is obtained by solving the following model proposed by

Charnes et al.:

$$\begin{aligned} & \max \frac{\sum_{k=1}^s v_k y_{kp}}{\sum_{j=1}^m u_j x_{jp}} \\ & \text{s.t.} \sum_{k=1}^s v_k y_{ki} \leq \sum_{j=1}^m u_j x_{ji}, \quad \forall i = 1 \dots n \\ & \quad v_k, u_j \geq 0, \quad \forall k = 1 \dots s, \quad j = 1 \dots m \end{aligned} \quad (2)$$

x_{ji} = Amount of input j utilized by DMUs i ,

y_{ki} = Amount of output k produced by DMUs i

u_j = Weight given to input j ,

v_k = Weight given to output k

The fractional program shown as (2) can be converted to a linear program as shown in (3).

$$\begin{aligned} & \max \sum_{k=1}^s v_k y_{kp} \\ & \text{s.t.} \sum_{j=1}^m u_j x_{jp} = 1 \\ & \quad \sum_{k=1}^s v_k y_{ki} - \sum_{j=1}^m u_j x_{ji} \leq 0 \quad \forall i = 1 \dots n \\ & \quad v_k, u_j \geq 0 \quad \forall k = 1 \dots s, \quad j = 1 \dots m \end{aligned} \quad (3)$$

The above problem is run n times in identify the relative efficiency scores of all the DMUs. Each DMU selects input and output weights that maximize its efficiency score. In general, a DMU is considered to be efficient if it obtains a score of 1. A score of less than 1 implies that it is inefficient. The primary advantages of this technique are that it considers multiple factors and does not require parametric assumptions of traditional multivariate methods. However there are some critical factors one must consider in the application of DEA models. The discovery scores could be very sensitive to changes in the data and depend heavily on the number and type of input and output factors considered. In general, inputs can include any resources utilities by a DMU, and the output can range from actual products produced to a range of performance and activity measures. The size of the data set is also an important factor when using some of the traditional DEA models.

4.2 Operational efficiency model

Broadly speaking, operational efficiency model adopt either a production approach or an intermediation approach [4]. In the former case the branch is considered as a factory delivering services to its clients in the form of transactions. Benchmarking models examine how well different branches combine their resources to support the largest possible number of transactions. The intermediation approach considers various types of costs as the inputs, and those are combined to support the largest possible number of revenue generating accounts.

1) Model input

The model uses two broad sets of input. One set captures the resources used by the branch. The second set of inputs includes the number of accounts in different account categories. The clientele structure is tightly linked to a specific branch and it changes very slowly with time. Hence, for the purpose of a static analysis this information is part of the operating environment of the branch.

2) Model outputs

The outputs of the model is total amount of work produces by the branch in order to support the given client base. This work is produced in the form of transactions carried out of the various clients and their accounts. A standardizes measure of total work can be obtained by counting the total number of elementary tasks required in order to be executed for these transactions during a working day. Each elementary task requires summing up their standard times in order to be completed. The standard times of each task, for example, filling in a form or getting a supervisor's signature is obtained through a work measured as the total time involved in processing the tasks for all transactions carried out at a branch.

4.3 Profitability efficiency model

We now turn to the final link of the service-profit chain and address the issue of profitability efficiency. Substantial research has been done on this key issue [1][2]. We formulate the model of benchmarking the profitability.

1) Model inputs

The inputs are the resources used by the branch and revenue generating accounts. However that for some

types of accounts is indicative of the demands imposed on the branch's resources for service and maintenance, while the volume of deposits in these accounts is indicative of their contribution to profits. Hence, the accounts of each branch are measured using a different classification and different units than those used in the previous model.

2) Model outputs

The outputs are the profits generated at each branch. Revenue growth could be incorporated as a more appropriate output, but then other inputs should also be included such as service quality, demographics of the region where the branch is located, and competition. The model can be readily extended if such data is available.

4.4 Linking the operational efficiency with profitability

We use operational efficiency model and the profitability efficiency model to analysis the effects of inefficient operations and the costs of offering inappropriate products at each branch. The profitability efficiency model considers both consumable and revenue generating resources as inputs. The consumable resource is operational variables whereas the revenue generating resource is the product of each branch.

5. Retail Banking of CMB and Customers Relationship Management

The industry of universal banking is restructuring, and the customer has never met a richer supply of information and services. The old relationship between bank and customer is changing. Individual consumers are becoming ever more demanding, both on kinds and quality of services. CMB are looking to gain a competitive edge by establishing one-to-one relationships with customers and a higher degree of personalization. For example the profitability of various channels can be notoriously difficult to ascertain accurately, but the profitability of individuals using a particular ATM could be established very easily, aiding decision on whether that equipment was worth retaining or upgrading. Similarly the data might indicate that a particular product is being used by a large number of customers in a very unprofitable way. Also by using DW technology, CMB is able to do customer segmentation:

1) CMB can map the results of customer profitability analyses back to their channels to determined high-value branches, or to specific geographical areas to extrapolate high-value cities or neighborhoods to target. Changes in a customer's profitability over time can also uncover previously unknown customer behavior patterns. Many banks use profitability analysis to the creation of new services, or discarding of old ones. CMB is likely to target particular customer segment, e.g. mass affluent rather than mass market and will try to differentiate itself from existing competitors.

2) Increasing customer lifetime value

Consider, for example, customers of CMB who only use the CMB for a checking account. An analysis reveals that after depositing large annual income bonuses, some customers wait for their funds to clear before moving the money quickly into their stock-brokerage or mutual fund accounts outside the bank. This represents a loss of business for the CMB. To persuade these customers to keep their money in the bank, CMB can use DM tools to immediately identify large deposits and trigger a response. The system might automatically schedule a direct mail or telemarketing promotion as soon as a customer's balance exceeds a predetermined amount. Based on the size of the deposit, the triggered promotion can then provide an appropriate incentive that encourages customers to invest their money in the bank's other products. Finally, by tracking responses and following rules for attributing customer behavior, DM tools can help measure the profitability and ROI of all ongoing campaigns.

6. Personalizations and Customer Oriented Marketing

The Internet is leading marketer to a fundamental paradigm shift from mass marketing to personalized marketing. Databases, cookies and telecommunications technology make it very easy and cost-efficient to mass-market personalized services. Personalization on the Internet refers to the ability of customers to receive personalized information or visit a website with a home page customized for them. Through the use of databases, it is able to store information about its visitors and provide a personalized, free service for them: remaining individuals of important events, such as birthdays,

anniversaries, and graduations. Personalization represents simultaneously the extreme challenge and opportunity present in the form of Internet medium. A fundamental shift is occurring between producer and consumer. Technology-enabled consumers are actively participating in activities, tasks and decisions that were once the sole domain of the marketer. In the past, consumers' decisions were primarily limited to purchase and consumption. Today through the enabling power of technology, consumers are able to design products from their homes, and store and access information at their convenience [7].

7. What Should CMB Improve in Personal Service Area?

1) Financial Advice

One higher level of CMB goes beyond typical to offer more general financial advice, sometimes with a level of interactivity [9]. An important decision that banks will face in the future is how to develop their personalities and how to position themselves in their non-banking capacities. This means understanding customers better and becoming the sort of bank that they would want to do business with.

2) Selling Financial Products

Some banks have gone so far as to sell financial products on the Internet. At this stage it is most common to allow customers to fill in an application form for a credit card on-line and complete the transaction by more mundane methods such as the post, but we can expect that the future will see banks moving to complete sales entirely on-line, and to sell more complex products. Questions are raised such as: what will people be willing to buy on-line? What sort of people will want to make purchases? How secure and confidential can the information generated by a sale be? There are many other questions such as these, which for the time being are difficult to answer, but are likely to emerge as central areas of research not only for banks but for the business world in general.

3) Privacy

In recent years privacy concerns have taken on a more significant role not only in China but also all over the world as merchants, insurance companies, and government agencies amass warehouses containing

personal data. The concerns that people have over the collection of this data will naturally extend to any analytic capabilities applied to the data. Users of DM should start thinking about how their use of this technology will be impacted by legal issues related to privacy. For example, if the primary purpose of the collection of transactional information is to permit a credit card payment, then using the information for other purposes, such as DM, without having identified this purpose before or at the time of the collection, is in violation of the purpose and use limitation principles. The primary purpose of the collection must be clearly understood by the consumer and identified at the time of the collection. Since DM is based on the extraction of unknown patterns from a database, DM does not know, cannot know, at the outset, what personal data will be of value or what relationships will emerge. Therefore, identifying a primary purpose at the beginning of the process, and then restricting one's use of the data to that purpose are the must.

8. Summary

DW empowers banking institutions to provide Internet-based financial solutions to their retail and commercial customers via a cost-effective service. DW offers profit-generating opportunities to its clients through secure, reliable, and scalable products and services. Few business areas are changing so rapidly as the financial services area. Banks have a long history of conservatism in their business practices. However, for the past decade, changes in technology, deregulation and general economic conditions have transformed the industry. The DW technology is rapidly becoming the new medium for financial services. The ramifications of the changes are unpredictable. Many financial services firms outsource their software and hardware development to computer companies. The DW technology makes it possible for large global financial services firms to reach the most remote local markets, but also for small specialized niche banks to reach their customers world wide.

A New Approach to Integrate Heterogeneous Databases: The Mediated Data Integration Architecture

Chaiyaporn Chirathamjaree
School of Computer and Information Science
Edith Cowan University
Australia
c.chirathamjaree@ecu.edu.au

Abstract

Information required for decision making is generally scattered across disparate data sources. To gain competitive advantage, it is extremely important for executives to be able to obtain one unique view of information in an accurate and timely manner. The heterogeneities occur when integrating such data sources which were designed independently. MeDIInt – the Mediated Data Integration architecture is introduced to solve this problem. The mediator and wrappers are employed as the middle layer between application and data sources to homogenise heterogeneous data sources. Both the mediator and wrappers are well supported by the Mediated Data Model (MDM), an object-oriented based data model which can describe or represent heterogeneous data schematically and semantically. The MeDIInt architecture has been tested and evaluated, and the results are promising.

Keywords: Heterogeneous databases, data sources, integration, mediator, wrappers.

1. Introduction

When interoperation between multiple heterogeneous data sources is required, there would be a number of conflicts arising not only from different database designs, but also from different kinds of data models employed within heterogeneous databases. These conflicts generate the difficulties of homogenisation in terms of data model, schema and semantic [2] [3] [4] [5]. The Mediated Data Integration (MeDIInt) architecture for the heterogeneous data integration framework is introduced in an attempt to overcome the above difficulties. It has been developed by focusing on providing a solution to interoperate heterogeneous data sources by transforming both the queries and the data transparently. Furthermore, MeDIInt does not only solve schema and semantic heterogeneities, but also conflicts from different query languages and data models, namely data model heterogeneity.

The integration approach proposed in this research incorporates the advantages of both the mediator systems and metadata repository systems. This means that new

data sources need to be registered when they are added to the integration system. However, the heterogeneities are resolved at the query time making the mediator system more dynamic. The mediated architecture basically adds a third layer between applications and data sources.

2. Architecture Requirements

The following architecture requirements have been formulated as the framework to develop the integration architecture.

- The schema evolution should not affect the integration. This is to cater for dynamic systems where schemas could be changed frequently. When schema modification is made on data sources, it should not cause large-scale modification to the integration system.
- The integration should cover the major kinds of data sources widely used such as legacy, relational model, and object-oriented model systems.
- The approach should increase automation and reduce amount of work required by end-users. Users should not have to deal with conflict resolutions once they issue queries. The different terminologies used in data sources and the different structures of data sources should not affect users when issuing queries.
- The integration architecture should require minimised modifications when a new data source is added or removed.

3. The MeDIInt Architecture

Figure 1 depicts MeDIInt (the Mediated Data Integration Architecture) which is based on mediation and wrapping techniques. The two main components are the mediator and wrappers acting as the intermediate agents between clients and multiple data sources to communicate both request queries from clients to data sources and also query results from data sources to clients.

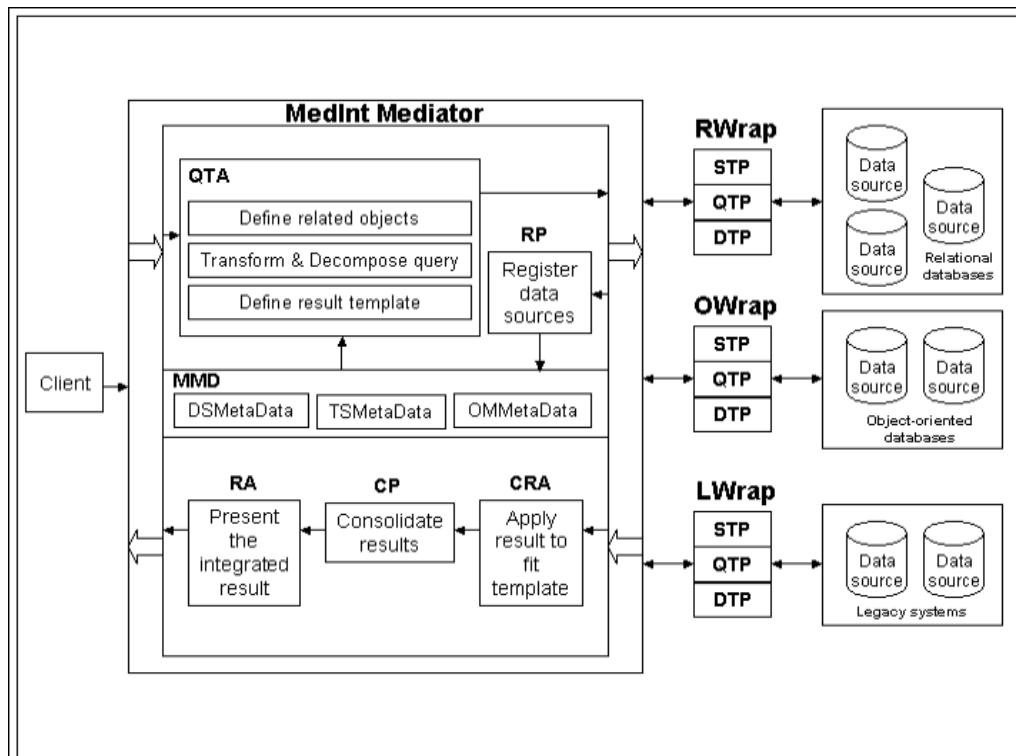

Figure 1: The MeDInt architecture

The MeDInt architecture is represented by four-tiers of components: the application systems which interface to users, the mediator, wrappers and data sources. In addition, the Mediated Data Model (MDM), a data model designed especially for the heterogeneous data integration framework [1], works along with the MeDInt Mediator and wrappers functioning as a central data model and working as the hidden backbone of the integration facilitating the communication between Mediator and wrappers.

3.1 The User Interface

In general, query languages are not capable of utilising and specifying the heterogeneities between heterogeneous systems [6]. Therefore, this approach provides a data model with a query language which captures the heterogeneities on behalf of users so that they can specify their own queries, including semantic contexts.

3.2 The MeDInt Mediator

The MeDInt Mediator provides middle-layer services, as an information integrator does, between the application and wrappers. In general, mediators are responsible for: retrieving information from data sources, transforming received data into a common representation, and integrating homogenised data [7]. In this research, the MeDInt Mediator has been designed to include the following common characteristics of the integration processes:

- registering data sources information,

- defining associate objects and requesting object schemas from wrappers,
- decomposing and transforming a query to subqueries according to data sources,
- generating a result template,
- applying the multiple sets of results to a pre-defined template,
- consolidating the conflict-resolve sets of results, and
- displaying the integrated result to the user.

3.3 Wrappers

Wrappers are in the intermediate layer between the MeDInt Mediator and data sources. A wrapper is invoked when a data source in a difference data model is added to the integration system. Wrappers mainly act as translators providing the MeDInt Mediator with information in the common data model used in the integration system by dealing with the data model heterogeneities of different data sources. The principle objective of wrappers is dealing with data model heterogeneities including the different data definition languages and data manipulation languages by mapping variety data models to the Mediated Data Model. Each MeDInt wrapper is composed of a Schema Translation Processor, a Query Translation Processor and a Data Translation Processor. One novel feature of the architecture is to push unshared characteristics to the wrappers to reduce the amount of middleware modification when a data source is added, removed or modified. In addition, the use of the Mediated Data Model eliminates problems relating to the data model heterogeneity by providing the common data model

acknowledgeable by components in the MeDInt Mediator.

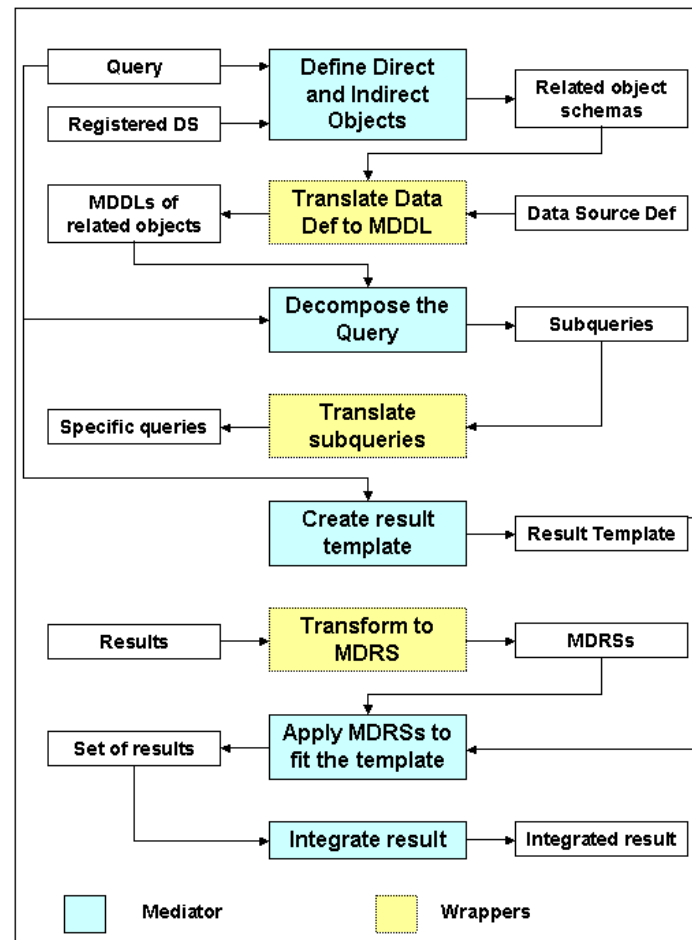

Figure 2: MeDInt Processes

4. MeDInt Processes

Figure 2 illustrates the processes of the MeDInt architecture.

When a new data source is added to the integration system, it is registered to the Mediated MetaData (MMD). Data source information, for example, assigned name, location, type, description, and constraints relating to its structure and semantics are collected into the Data Source Metadata (DSMetadata), a category of MMD. A query from a user to retrieve the information from heterogeneous data sources is sent to the MeDInt Mediator instead of directly to the data sources. The required objects are determined and a request is submitted to the wrapper to get the related object schema definitions. The submitted query from the user is transformed to a specific query language appropriate to the database management system of the data source. A template for the results is created from the results obtained from multiple data sources. This method does not try to resolve conflicts directly which would be more difficult and complicated.

After getting a response data back from data sources, a

component of a wrapper translates the query results into the Mediated Data Representation Structure (MDRS). The conflict resolution is done by applying all MDRSs to fit into the structure of the predefined template. The resultant MDRSs that are structurally equivalent are then integrated and consolidated. Finally the integrated result is sent to the user.

This architecture overcomes the weakness inherent in other approaches that require the physical or logical integration of component schemas. Only the query result from each source, according to the result template, will be integrated instead. The template will be created from the submitted query. The resultant data from each data source will be applied to fit to the template which is the means by which the heterogeneities are resolved.

5. Results and Discussion

A number of example problems of heterogeneities from a number of information systems that require integration have been tested. The objectives are to demonstrate the integration process using the MeDInt architecture and to evaluate its correctness.

Table 1: Summary of the heterogeneities resolved in the MeDInt architecture

Heterogeneities	Conflicts	Test Problem1	Test Problem2	
			Query 1	Query 2
Model		✓	✓	✓
Schema	Naming	✓	✓	✓
	Structural	✓	✓	
	Specialisation		✓	✓
	Relationship		✓	
Semantic	Naming		✓	
	Scaling	✓		✓
	Abstraction			✓
	Representation	✓		

The proposed MeDInt Architecture and MDM have been tested for functionalities and the outcomes look promising. Results (Table 1) indicate that the objectives in resolving conflicts both structurally and semantically have been achieved. From the table above, the following three categories of heterogeneities have been determined: Model, Schema, and Semantic. All of them have been solved as shown by the MeDInt with the support of the MDM which is suitable for homogenising different data models, schemas and semantics of component data sources. Another feature of our proposed model is that it can be implemented in any languages. We have chosen XML as the implementation language in the prototype because it offers a number of advantages. XML is platform independent, provides self-described tags which are easy to understand. It is also suitable for describing schema and semantic of objects in a real world since XML is based on an object-oriented model.

6. Conclusion and Future Works

The research proposes the MeDInt Architecture as the framework based on the mediated approach for the integration of heterogeneous data sources to solve conflicts occurring when interoperability is required. The paper presents a new approach for achieving the interoperability of multiple data sources logically integrated at the time the query is issued. The system is able to describe or represent heterogeneous data both schematically and semantically. No pre-integration is required before users can issue their queries. This avoids the problem of local schema evolution which usually

happens in dynamic systems. Further investigations are planned to cover the query performance issues. Another possible future work is to incorporate the write access through the updating of master data sources and the replication of data sources.

Abstract

Following the evolution of electronic business, collaborative commerce uses information technology to achieve a closer integration and a better management of business relationships among parties including internal personnel, business partners and customers. Recently, market and globalisation competition, customer oriented service strategy and product complexity have pushed enterprises a step further on in collaborative commerce. In brief, collaborative commerce is (1) a collaborative technology – similar to workflow collaboration, (2) a customer-driven technology – similar to a pull-type supply chain, (3) a functionally-integrated technology – similar to concurrent engineering and (4) a business-driven technology – similar to enterprise resource planning, for cross-organisational integration. The paper will illustrate the technologies and the critical success factors of collaborative commerce adoption.

1. Introduction

Many businesses today tie collaborative relationships between partners through the use of digital technologies. The level of collaboration has moved beyond buying-and-selling to planning, designing, developing, communicating, discovering information, researching and providing services among organisations. This new form of collaboration is called collaborative commerce. Following the evolution of electronic business, collaborative commerce is defined as using information technology to achieve a closer integration and a better management of business relationships among parties including internal personnel, business partners and customers [3] [12]. In responding to ever-changing global market demand, business collaboration will bring the whole supply chain to a competitive edge by decreasing product development costs, shortening the time to market and improving product quality.

The survey of over 300 business executives by Deloitte Research in mid-2002 shows that collaborative commerce has led to better business operation and information exchange and has provided a 70 per cent rise in

profitability for those companies who adopted the technology compared with those who did not integrate with their trading partners [6]. Similar results were found in the survey conducted by NerveWire [8]. Companies with a ‘very high’, that is, level 4, external integration level appear to be more competitive in several metrics than those companies with lower integration levels. The average revenue of level 4 companies increases by about 40 per cent, which is about three times of that attained by companies at level 2 or 3. Moreover, cost reductions at level 4 are about two and half times of the average of those at level 2. This are all because the integrated environment can enhance the value chain of suppliers, business partners, customers and employees through flexible business processes, better product quality, rapid order fulfillment, improved reliability, improved capital efficiency and prompt information exchange and knowledge sharing.

The applications of collaborative commerce are various, including promising areas such as collaborative design, collaborative engineering, collaborative decision-making, collaborative forecasting, financial collaboration, sharing knowledge of human resources, collaborative inventory management and consolidating transportation. Moreover, several collaborative models are well known today. For example, collaborative planning, forecasting, and replenishment (CPFR) by the Voluntary Inter-industry Commerce Standards Association uses ERP and demand planning systems for collaborative facilities forecasting and planning. Collaborative forecasting and replenishment (CFAR), jointly initiated by Wal-Mart and P&G, provides no gap between what Wal-Mart plans to sell and what P&G plans to produce [5].

Two points need to be addressed better to understand collaborative commerce:

(1) *Collaborative commerce is the collaborative business.* Just as the terminologies between electronic commerce and electronic business can be used interchangeably, the term ‘collaborative commerce’ can be used interchangeably with ‘collaborative business’. Note that commerce describes the buying-and-selling transactions between parties. However, electronic business has a

broader meaning in which more business operations, such as design, production and transportation, are involved. However, these two terms are sometimes used interchangeably in describing business transactions via the electronic media. Similarly, 'collaborative commerce' is not limited to a collaborative development in buying and selling goods and services. It includes all levels of the activities of business operations.

(2) *Collaborative commerce is an evolutionary technology.* Collaborative commerce evolves from collaboration in the workflow to concurrent engineering and the supply chain and beyond. Three dimensions can be used to describe the movement of these technologies: collaboration, organisational integration and business operations (see Figure 1). Workflow collaboration is an improvement on individual efforts in business activities to stronger co-operation. However, most of these activities belong to the transactional type, which means that a task is assigned to an employee either after another employee has completed his or her task or concurrently with that employee. In contrast, concurrent engineering has a deeper collaborative involvement with the employees.

Concurrent engineering brings employees with different expertise together for product development. These activities involve more functional operations, such as product design, procurement and human resources management. Recent technology in supply chain collaboration, focuses more on inter-organisational integration than on the workflow and concurrent engineering. However, the supply chain linking organisations together to share information is rarely involved at this functional level. Therefore, the trend towards moving workflow collaboration, concurrent engineering and supply chain collaboration to a profound level of functional integration is apparent. This is the origin of collaborative commerce.

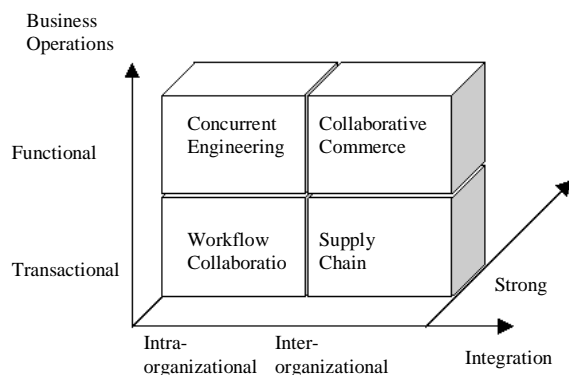

Figure 1. Collaborative Comommerce is an evolutionary technology

While the term 'collaborative commerce', abbreviated as 'c-commerce', was first coined by the Gartner Group in 1999 as the next trend of e-business models and IT investment in B2B world, it was conceptualised as a new form of business model that had been enabled and leveraged by the Internet and integration technologies [3]. Soon after Gartner's coinage of the term, major software vendors including ERP vendors and individual B2B software vendors, such as IBM, i2, SAP, AMR and so on, were competing to provide ways of conceptualising their own way of enterprise collaboration over the Internet.

Although they varied in the way they implemented c-commerce they were all clamouring for the rewards and the competitive edge brought about by the c-commerce business model. In general, collaborative commerce integrates business processes such as demand planning, planning and scheduling, order management, product development, vendor management, sales support and knowledge sharing between partners through sharing information electronically (see Figure 2). Moreover, collaborative commerce is a set of techniques to allow companies to maintain better relationships with their trading partners through automating their cross-enterprise process logic, rules, heuristic and workflow.

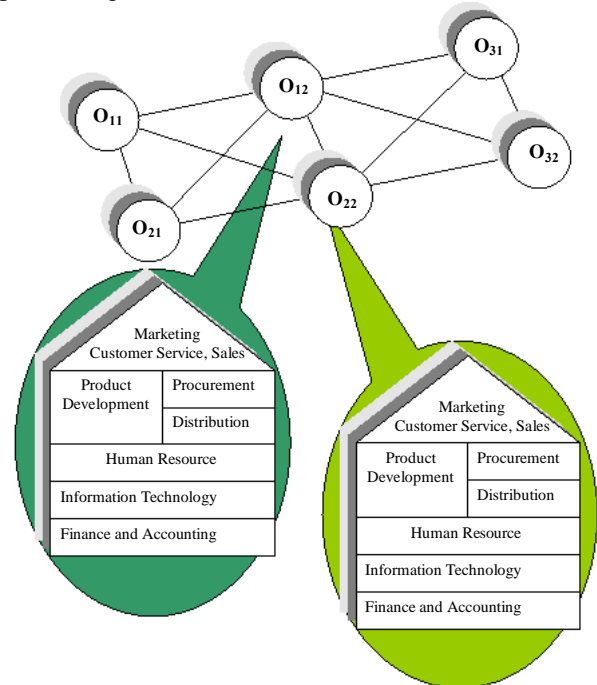

Figure 2. Collaborative commerce integrates business processes across collaborative partners O₁₁, O₁₂, O₂₁, O₂₂, O₃₁, and O₃₂.

The emergence of the collaborative commerce model articulates the succession of continuous improvements in supply chain management. To continue maintaining the competitive edge of an enterprise in the digital economy, several efforts in improving business processes and operations have been made during the past decades. First of all, enterprises adopted enterprise resource planning (ERP) to centralize originally isolated information modules within an organisation. Such efforts result in the increase of information efficiency and integrity. Later, enterprises recognised the benefit of information transparency in the supply chain. Therefore, solutions for the exchange of valuable business information within the supply chain become the focus of efforts to manage supply chain performance. Such efforts reflect the benefit of information synergy on eliminating the bullwhip effect [5].

Recently, market and globalisation competition, customer oriented service strategy and product complexity have pushed enterprises a step further on in business collaboration. To outsource minor business functions effectively and focus on core competitiveness, enterprises need to integrate their information systems with external systems owned by their collaborating partners. In this way the information shared among partners and business processes could flow seamlessly from organisation to organisation. Such system integration brings multiple enterprises to collaborate in shared business opportunities.

In summary, collaborative commerce is (1) a collaborative technology – similar to workflow collaboration, (2) a customer-driven technology – similar to a pull-type supply chain, (3) a functionally-integrated technology – similar to concurrent engineering and (4) a business-driven technology – similar to enterprise resource planning, for cross-organisational integration. The following sections will illustrate the technologies followed by the infrastructure of system integration. Finally the critical success factors of collaborative commerce adoption will be discussed, together with our conclusions.

2. Collaborative Technology

Collaboration is the focal point in collaborative commerce. Traditionally the workflow is created to deal with specific *cases* in an organisation, such as mortgage applications and engineering tests. Each case has a unique identity and a limited lifetime. That is, a case should be completed within certain time limit and will exit the workflow system when the work is completed. That also means that attributes are needed to describe the state and content of the workflow. The work in a workflow can be identified as *tasks*, which represent the indivisible units of works. The tasks are carried out by *processes*. When the

processes are carried out in a workflow they follow a specific sequence, which determines which tasks need to be performed next. There are four different types of sequences: *sequential*, *parallel*, *selective* and *iterative* routings. The sequential routing confines one task to be executed before another task while the parallel routing allows two tasks to be performed without having any result on the other. Similarly, selective routing provides the choice between or among tasks and iteration allows the same task to be performed more than once.

During implementation, the process needs to be enacted to perform a task. The enactment is triggered by *events*, such as external events (a new order having arrived), resources (an employee making a request), or time signals (at eight o'clock every morning) [1]. Note that tasks are assigned to designated *roles* of an organisation following principles such as the separation of duties, least privilege assignment and data abstraction [11]. These principles assure the successful implementation of the workflow. For example, the separation of duties assigns two sensitive tasks to two exclusive roles so that conspired perpetration can be avoided. On the other hand, the least privilege policy, also called the 'need-to-know' policy [4], provides only minimum information for completing the task. In collaborative commerce, a number of organisations, including supply chain partners or even competitors can collaborate in the workflow of an organisation. This implies that better control of access and degrees of collaboration are expected in collaborative commerce.

The workflow management system (WFMS) manages the workflow on a day-to-day basis in various application domains such as office automation, finance, healthcare, telecommunication, manufacturing and production [2]. To allow workflow collaboration across organisations, four elements need to be carefully designed: DBMS, WFMS, administration functions, and applications monitoring. The DBMS manages conventional database tasks, such as data maintenance, data integrity, concurrency control and recovery of current data and historical data. The DBMS needs to manage data sharing among organisations. WFMS deals with the workflow process definition, activities and control. Access to WFMS is across the collaborating organisations. This creates a high degree of complexity.

The applications provide services such as ERP and its corresponding data are normally managed by DBMS. The sharing of applications involves the complexity of both the data level and the functional level. The administration and monitoring element handles administrative tasks which fall outside the scope of the DBMS and WFMS, such as statistical analysis, resource management and operational management. This element also implements some access control mechanisms, especially those

mechanisms related to other organisations. For example, collaborators may be allowed to refer to the statistical data of total sales rather than sales of individual items when designing a product collaboratively.

3. Customer-Driven Technology

Collaborative commerce should be customer-driven, similar to the theme of the pull-type supply chain – pulled by the customer rather than pushed by the manufacturer. Note that the supply chain links organisations together to share information, products, and funds to fulfil their customers' requests efficiently. Supply chain processes can be identified as belonging to four cycles: the customer order cycle, the replenishment cycle, the manufacturing cycle and the procurement cycle [5]. A successful supply chain should be driven by the customer order cycle to the procurement cycle. The shorter the propagation channel, the quicker the response of the supply chain can be. The customer order cycle links customers with retailers to fulfill the customer's orders. The activities in the customer cycle include order entry, order fulfillment and order receiving. The replenishment cycle focuses on replenishing the retailer's inventory by co-ordinating between retailers and distributors.

Activities such as retail order entries, retail ordering, fulfilment of retailer's order and receiving goods are involved. The activities between distributors and manufacturers are considered the manufacturing cycle. In this cycle, the replenishment of the distributor's inventory is the focal point. The activities include the arrival of the order from the distributor, retailer, or customer; the manufacturers' production scheduling, the manufacturing and shipping of the item and receiving it by the distributor, retailer, or customer. The last cycle is the linkage between the manufacturers and suppliers, called the procurement cycle. This cycle ensures that the materials are available for manufacturing by considering orders based on the manufacturer's production schedule or the supplier's stocking needs and the supplier's production scheduling and shipping.

There are many famous implementations of the concept of the supply chain. For example, in the customer order cycle, the online catalogue is a useful implementation for putting products online for customers. This provides significant advantages in giving up-to-date information to customers. Similarly, sales force automation (SFA) automates relations between sellers and buyers by providing product and price information. In the replenishment cycle, vendor-managed inventory (VMI) allows the distributor or manufacturer to manage inventories and the wholesalers or retailers continuous replenishment programmes (CRP) allow suppliers to

replenish the inventories of retailers regularly, based on POS data.

In the manufacturing cycle, advanced planning and scheduling (APS) develops the detailed production schedules about what to make, where to make it, when to make it and how to make it by considering the availability of materials and plant capacity, among other business objectives. The objective of an organisation is to optimize the capacity of manufacturing, distribution and transportation resources based on the data collected from ERP or legacy systems. In the procurement cycle, a content catalogue that focuses on the activities between the manufacturer and its suppliers can simplify the procurement process and allow the manufacturer to keep track of the parts, specifications, prices and order processes of the supplier.

However, to maintain the supply chain relationship, the high degree of trust is needed. In general, trust is nurtured from deterrence-based trust, knowledge-based trust and identification-based trust [12]. Deterrence-based trust uses a variety of formal contracts to ensure co-operation between parties while knowledge-based trust is built on the knowledge of the other trading partner (trustee), which allows the trustor to understand and predict the behavior of the trustee. However, to build a strong relationship, identification-based trust, which allows each party to consider the other party's objective as identical to its own, is beneficial. The same idea is applied to collaborative commerce. Moreover, it should be noted that the partners in collaborative commerce also include competitors, which is not common in the supply chain. Therefore, the degree of trust and the need to do access control are especially important.

4. Functional-Integrated Technology

The degree of collaboration in collaborative commerce should go down to the level of functional integration, similar to that in concurrent engineering (CE) – a systematical approach to integrate product design and manufacturing process support to minimize product development time. Prasad [9] conceptualized the functionalities for CE as two wheels. The first CE wheel represents the integrated product and process organisation while the second concurrent wheel defines the integrated product design and development.

Both wheels have three rings to represent the three essential elements of CE. The inner ring is the hub of the wheel and includes the four Ms: models, methods, metrics and measures. Basically, the four M elements provide the fundamental methodologies for CE implementation. The middle ring focuses on the work groups which drive the wheel forward. The elements in the middle ring for both

wheels are identical: personnel teams, virtual teams, logical teams and technological teams. The centrality of these teams emphasizes the importance of team work. Logical teams are formed to deal with the work process and to ensure that the sub-process interface with one another logically (similar to the tasks in the workflow).

The personnel team is responsible for assigning tasks to roles. The virtual team is formed to assist the personnel team only when conflicts need to be resolved or missions need to be achieved. The technological team manages the quality of products. The outer ring for both wheels functions to implement the CE. In the product and process organisation wheel, the functions are manufacturing competitiveness, life cycle management, process re-engineering, CE definitions, system engineering, information modeling and the whole system product realisation taxonomy. The functions for integrated product development are concurrent function deployment, total value management, development framework and architecture, decision support systems, intelligent information systems, life-cycle mechanisms and CE implementation guidelines.

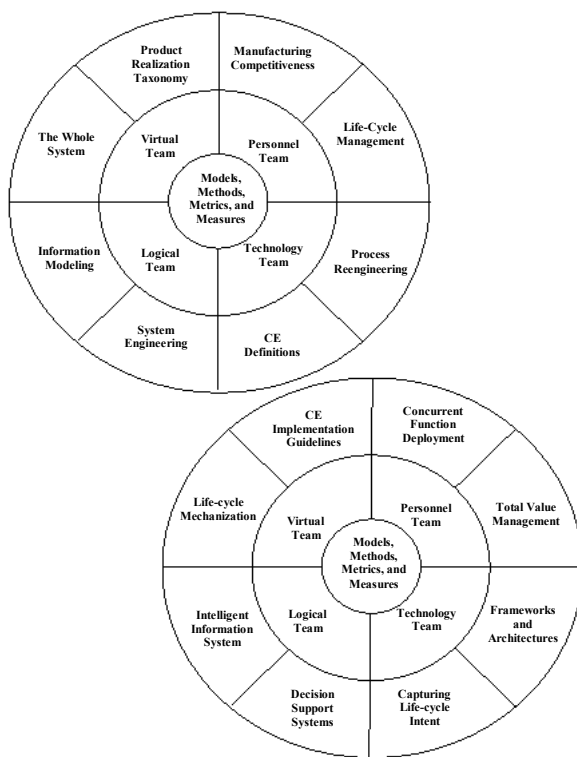

Figure 3. Concurrent engineering wheel [9].

Concurrent engineering tightly links all functions involved in the product development cycle in an organisation. A successful implementing mechanism for

cross-functional integration is therefore very important. Fleischer and Liker modified the five co-ordinating mechanisms proposed by Henry Mintzberg [7] to concurrent engineering to improve cross-functional integration. The mechanisms are (1) direct supervision through the appropriate design of organisation architecture and project management; (2) mutual adjustment through various cross-functional teams, (3) the standardisation of design and performance metrics; (4) the standardisation of work processes, such as operational procedure, planning and scheduling systems, monitoring systems and development process tools and (5) the standardisation of worker skills.

However, the organisation culture which emphasizes collaboration is the most important factor that glues together cross-functional integration. The same idea can be applied to collaborative commerce, which encourages cross-functional and cross-organisational collaboration. Both the 'hard' factors, such as the five mechanisms, and the 'soft' factor, that is, the collaborative culture, are all critical to success.

5. Business-Driven Technology

Business-driven technology creates the possibility of better information technology adoption. Successful information technology adoption can be traced back to the history of the adoption of enterprise resource planning (ERP) against computer-integrated manufacturing (CIM). In the 1960s material requirement planning (MRP) was adopted by most manufacturers to find out 'what are we going to make'. To deliver products to customers, the company needs to examine 'what it takes' to make the products and 'what we have now'. Then, if we do not have sufficient materials to make the products, we must decide 'what we have to get'.

With a little help from computers, these questions were easy to answer in that age since the business operations were simple. However, gradually, the manufacturers wanted to manage both the quality and quantity of the products so that they could deliver them to happy customers on time. This requires an integrated shop-floor control system, which controls the activities of all resources through capacity requirement planning (CRP), scheduling, shop-floor control and other mechanisms. That brings us to a full-scale shop-floor control system, called the manufacturing execution system (MES).

In the 1970s, the focal point of the manufacturers became how to integrate both MRP and MES so that they could manage orders as well as shop-floor production. The new system is called manufacturing resource planning (MRP II). The key to the success of MRP II is in the integration of individual modules and information flow. Fortunately,

a new generation of both the hardware and software was evolved by the growth of information technology. This trend nourished the integration of MRP II. At the same time, parallel to the growth of MRP II, accountants found they needed to handle tasks more than just credit and debit data: they needed methods of internal control. Internal control provides a reasonable way of protecting the business process of an organisation from the misuse of assets. At that time, the accounting information system (AIS) delivered its promise and prevailed in service industries. It is not then surprising that some functionalities of both the MRPII of manufacturing industries and the AIS of the service industries have overlapped in some degree.

In the mid-1980s the new integrated system, called computer-integrated manufacturing (CIM) was proposed by CASA to accomplish functions such as marketing and sales, engineering, R & D, quality assurance, warehousing and distribution, shipping and receiving goods, finance and accounting control, information systems, human resources, customer service and manufacturing material management. The architecture was again represented by SME as an enterprise wheel in 1993 [10]. This architecture integrates both the MRP II and AIS and beyond by introducing inventory management and sales management, financial functions and human resources to MRP II manufacturing and engineering functions to AIS. Enterprise software such as MAPIC/DB from IBM was one of the pioneers in this area.

However, as implied by its name, the core of CIM is in manufacturing; a fact that does not attract enough attention from top executives. This causes some problems, especially when integration obstacles are encountered. Few successful cases in CIM adoption were reported during that period. However, another integration approach blazed the trail in the 1990s. It is called enterprise resources planning (ERP), which compiles similar but fewer functions than CIM. The driving force of ERP is in financial functions, the most interesting function in the enterprise system to top executives. The successful implementation of ERP from companies such as ASP, BAAN, PeopleSoft, Oracle and J.D. Edward has opened a large market for enterprise system.

However, an integrated enterprise resource planning system does not provide enough competitive advantage to companies. Therefore, strategies such as linking the ERP system to electronic commerce to sell products to consumers, to suppliers to provide supply chain partnerships, to customers to provide customer relationship services, to share among employees so as to provide employee management to distribution centres to provide consolidated logistics service have been adopted. The outreach of ERP has created a new phenomenon, a

development from an integrated intra-organisation system into an inter-organisation system, called EERP, or the enhanced ERP.

As will be observed from this history, the successful adoption of collaborative commerce should be business-driven rather than manufacturing-driven. Fortunately, collaborative commerce, as part of its name implies, has built upon the current technologies such as e-commerce, mobile commerce, ERP and the supply chain. This provides the better ground for nourishing its growth.

6. Conclusions

Application platforms have improved in the last decades together with the implementation of enterprise systems. Previously a MRP system sharing information with a department a LAN setting was considered suitable. Then MRP II moved the focus from intra-department integration to inter-department integration. At that time, the single LAN moved to multi-LANs and WAN. The Internet has become the conveyer of information to almost everywhere in the world. At the same time, the system infrastructure also evolves from peer-to-peer linkage to client-server architecture and eventually becomes a three-tier architecture. This evolution supports the growth of enterprises from regional enterprises to global enterprises, which grows collaborative commerce itself.

To provide Internet access, most the commercial enterprise systems moved to the Internet-based ERP in the late 1990s. Nowadays, the new generations of telecommunication technology such as the current 3G technology and the anticipated 4G technologies integrates the wire or wireless Internet with the wireless telecommunication network. This allows the business process to be executed truly anywhere and any time. Will the new generations of telecommunication technology change the implementation of enterprise systems? Or, more precisely, will the high speed wireless transmission change the applications of enterprise system? Collaborative commerce no doubt will be one of the business models if that ever happens. But the types of collaboration may be present in many different formats. To accomplish a collaborative vision of commerce, several factors considered to enable such collaboration.

(1) *Better relationship management.* Since the collaborative commerce business model allows multiple organisations to weave a collaborative network, each collaborator should have the ability to manage the resulting dynamic business relationship. This is especially true when the collaborative community is expanded to a cyberspace marketplace.

(2) *Better business process integration.* Collaborative commerce represents the most efficient way of doing business, where enterprises unwrap their core and competitive business functions to their collaborative partners. The commitment is risky but highly rewarded. The migration to collaborative commerce is equivalent to changing business relationship from independent units to mutually dependent ones. As a result the business process of each collaborator should be understood by every partner. The business process may also need to be decomposed into smaller components so that the integration and collaboration between collaborators become possible. Moreover, the degree of concurrent operations can also be improved if the tasks can be divided into disjoint sub-tasks. The success of seamless collaboration can therefore be achieved by harmonizing all the business process in the network.

(3) *Better knowledge and information sharing.* Since the business processes are contributed to over distributed and heterogeneous networks, it is important to have a superior information infrastructure to allow the information and knowledge to be shared during the processes such as product development. Also, the better sharing of information is rewarded with better access control of the organizational data. Although sharing information is encouraged, it is not difficult to understand that all companies have their own proprietary knowledge, which is not intended to be shared with collaborators, even in the closest relationships. The company may also want to share some general information with specific partners at certain time for certain projects.

(4) *A Better collaborative culture.* Collaborative commerce brings the most talented workers together to develop products to meet consumer demands. Since the workers come from different organizations, they are influenced by different organizational cultures as well as being encouraged by different incentive schemes. Therefore, the successful building of a collaborative atmosphere across organizations determines the success of the collaborative commerce.

In conclusion, an integrated and intelligent system supporting knowledge sharing and collaboration can help companies to distinguish themselves from their competitors. There are many application areas and issues that need to be considered in the collaborative commerce. These topics include areas such as the management of a business infrastructure, capital markets and the virtual economy, improvement of data quality, support of decisions and group systems, enterprise strategies, entrepreneurship and creativity, enterprise process

management, innovation and product development, Internet law and compliance, Internet security and privacy issues and knowledge management business ethics.

Abstract

A powerful online recommendation system in Electronic Commerce (EC) must know its targeted customers well and employ effective marketing strategies. Market research is a very important way to know the customers well. For high-tech products with great variety such as computers, cellular phones, and digital cameras, customers' knowledge level towards products may have a decisive influence on their purchase decision. While many online recommendation systems focus on utilizing data mining techniques in user profile and transaction data, this paper presents a method for recognizing customer knowledge level as a preprocess for more effective online recommendation in EC. The method consists of two Back Propagation Networks (BPN) and predicts based on customer characteristics and online navigation behaviors. A simple simulated digital camera EC store case study was conducted and the good preliminary result implies the good potential of the proposed method.

Key words: Product Knowledge, Web Usage Mining, BPN, EC

1. Introduction

While product recommendation and customization become more and more difficult due to the great and increasing variety of products available on the Internet, e-marketers endeavor to provide effective approaches for product recommendation and personalization. Approaches include: using data mining techniques to conduct market fragmentation and recommend on the basis of the consumer behaviors of each market segment; mining of customers' preference rating for offered products to automatically generate product recommendation through personalized direct marketing; web usage mining of consumer behaviors to provide product recommendation; and the use of segmentation and predictive modeling techniques for database marketing, etc. In the literature, many recommendation systems were built to provide the most appropriate products or services to meet a customer's needs by analyzing his personal preferences based on his profile and purchasing history. However, people with similar profiles may have different preferences, and past purchase patterns may no longer exist. Therefore, it may not be effective to recommend simply according to customer profile and purchase

history.

Of various factors affecting customers and marketing effectiveness, customer knowledge towards products, which consists of familiarity and expertise, has a decisive influence on what categories of products are suitable to be recommended to the customer.

Besides, product description and electronic catalog design are also very important in recommendation. The presentation of products for experts or novices must be different. It is unintelligible to use abstruse wording for the novice, and simple description and specification may not be able to satisfy the customers' professional requirements. Therefore, present and recommend products according to customers' knowledge level in EC may better suit their needs and promote the sales.

This paper proposes a method for recognizing customer knowledge level towards products (Figure 1). The method includes two neural networks; the first neural network learns to classify customers by customer profiles, while the second neural network learns to predict the customer's knowledge level towards products. Both neural networks are BPNs. Since the static user profile only provides basic properties of customers, they alone are insufficient for predicting a customer's knowledge level. A specifically designed questionnaire for customer knowledge level towards the products is combined with the user profile as the inputs for the first BPN. In addition, two sets of navigation patterns, mined from the web logs for experts and non-experts, plus the output of the first BPN (customer profile characteristic) are fed as the inputs to the second BPN. The output of the second BPN indicates the customer's knowledge level.

We begin by reviewing previous works related to our research in Section 2. In Section 3, the proposed method for recognizing a customer's knowledge level towards products is presented. The website implemented for an EC store case study is introduced in Session 4. The experiment results are described in Session 5. Finally, we summarize our contribution and give suggestions for future research in Section 6.

2. Background

2.1 Product knowledge

Customers differ in their prior knowledge about products, which consists of familiarity and expertise as defined by Alba and Hutchinson [1], where familiarity

refers to the acquaintance level towards products and accumulated purchase experiences, and expertise means the professional know-how and understanding. Furthermore, others researchers also defined different categories of product knowledge including subjective knowledge, objective knowledge, and experience-based knowledge. This paper focuses on the recognition of objective knowledge and experience-based knowledge to enhance personalized marketing effectiveness.

Customers in online environment can be roughly divided into two groups, one is expert group and the other is non-expert group. These two groups differ in the criteria for selecting products and in the product searching behaviors. Alba and Hutchinson [1] and Rao [8] both conducted researches on how product knowledge influences customers on information processing. In EC, customers' knowledge level towards products can potentially be recognized by analyzing customers' profile and navigation patterns.

2.2 Web usage mining

In online environment, the website visitors click hyperlinks that are of interest to them and the access patterns to the website may imply some of the customer behaviors. Web usage mining is one of the data mining techniques for the discovery of behavior patterns from web logs. The application of web usage mining is generally divided into two types, personalized recommendation and web site design improvement. Cho et al. [5] have proposed a personalized recommendation methodology based on web usage mining. Their proposed decision tree induction demonstrated good effectiveness and quality of recommendations. Spiliopoulou and Faulstich [13] developed a data mining system for finding the interesting patterns from the web access log. Perkowitz and Etzioni [7] improved a site by creating customized index pages and clustering pages of a site that were frequently visited

together in a single session. Simith and Ng [12] evaluated the feasibility of using a self-organizing map (SOM) to mine web log data and provided a visualization tool to assist user in navigation.

Therefore, mining customers' navigation patterns from web usage log may play a decisive role in recognizing customer knowledge level towards products.

2.3 Back Propagation Networks

Human brains learn via a neural network that consists of neurons, axons, dendrites and synapses. The brain receives inputs, analyzes them and outputs feature or pattern recognition information [9]. There are some researches have gone into creating artificial neural networks that learn in similar ways in recent years.

There are several types of artificial neural networks in use today; one of these types, BPN [11] is widely used in prediction and measurement, such as stock price prediction [2], option market trade [4], fraud detection [10], bankruptcy prediction [6], and medical diagnosis [3].

This paper proposes a method which consists of two BPNs and web usage mining to recognize a customer's product knowledge level as will be introduced next.

3. A Proposed Method for Recognition of Customer Knowledge Level towards Products

3.1 The method for recognizing customer knowledge level

In this paper, we propose a method for recognizing customer knowledge level towards products. Figure 1 shows the recognition mechanism using BPN and web usage mining.

Figure 1. The proposed method of recognizing customer knowledge level using BPN and web usage mining

After consumers sign up, customer profiles and questionnaire results recorded are the inputs of the first neural network which classifies customers. The output value is between 0 and 1, where a value close to 1 means there is a high possibility that the customer has high knowledge level towards products. However, two persons with the same background do not assure that they have the same knowledge level towards a specific type of products. Hence, the output data of the first neural network is only one of the factors considered in recognizing customer knowledge level towards products.

Besides the customer profiles, every time when a customer visits the web site, the system will record all the navigation information in the log file, including the URLs the customer visited, IP addresses, time entering the web page, time leaving the web page, etc. Through sequence pattern mining on the log data, the frequent navigation paths on the web site can be extracted. The frequencies of patterns with lengths 3-6 along with the output of first BPN are the inputs of the second BPN. The output of second BPN indicates the customer's final knowledge level towards products. Once we recognize a customer's knowledge level towards products, the introduction of products, marketing, and recommendation can be personalized according to his knowledge level.

The procedure of recognizing customer knowledge level can be implemented on line in EC. The training data of the BPNs have a critical influence on the performance of recognizing customer knowledge level. The following section explains the procedure of recognizing customer knowledge level with our proposed method.

3.2 The procedure of recognizing a customer's knowledge level

1. Collect training data for the first BPN

Collect the profiles and navigation data of both typical expert and non-expert customers of the web site. The data then are divided into training data and test data sets.

2. Training of the first BPN

The customer profiles and answers to the questionnaires are the inputs of the first BPN for roughly classifying the customers. The only output value is between 0 and 1, where a value close to 1 means the customer may have a high possibility to possess high knowledge level towards products.

3. Classification of the web page contents

EC web sites usually contain dynamic web pages which connect and retrieve data from a database. Web pages retrieving different product details are regarded as different web pages. For example, "pdtl.asp" is a web page to show the details of products, "pdtl.asp?p=A" shows the details of product A, and "pdtl.asp?p=B" presents the details of product B. Although they all belong to the same web page, they should be considered as different web

contents since the URLs are different. Consequently, the more products we have, the more web pages will be created. This will lead to a difficult in finding frequent navigation sequence patterns for experts and non-experts. Product classification may be used here to solve this problem. For instance, products may be classified into fewer categories, such as professional, popular, and novice classes, and so on. This will reduce the total number of various navigation sequence patterns, and thus increase the support count of popular sequence patterns.

4. Web usage mining

Since the sequences of travel paths on web site are important, a sequence mining method is used to extract frequent navigation sequences of various lengths. With sequence pattern mining, sequences can be drawn specifically for experts and non-experts from the log file, and those sequences which are common between experts and non-experts will not be used since they can not be used to differentiate experts from non-experts.

5. Training of the second BPN

The sequence patterns with lengths 3-6 (3-6 consecutive URLs) for both experts and non-experts plus the profile characteristic are the inputs and the knowledge level, ranged between 0 and 1, is the output for the second BPN.

Following the five steps above, once a new customer registers and leaves some navigation sequences at the web site, the developed method can on line recognize the knowledge level of the new customer towards our products, and then the corresponding recommendation can proceed. However, the recommendation based on customer's knowledge level is not attempted in this paper.

4. A Case Study in Digital Camera EC Store

To testify the effectiveness of the proposed method, a case study in a simulated digital camera EC store is conducted.

4.1 The interface of the EC store

In collecting the training data, selected customers are asked to sign up, fill up the profile, answer the questionnaire which is composed of some simple True/False questions about digital camera, and leave some navigation sequences at the web site.

In the experiment, 30 typical experts and non-experts were selected to visit the developed web site and their profiles, answers to the questionnaire, and navigation logs were recorded. Figure 2 is the interface of the developed simulated EC store.

4.2 Training of the first BPN

For the first BPN, 7 different sets of training and test data were randomly generated for both experts and non-experts, where there are 27 and 3 records for training

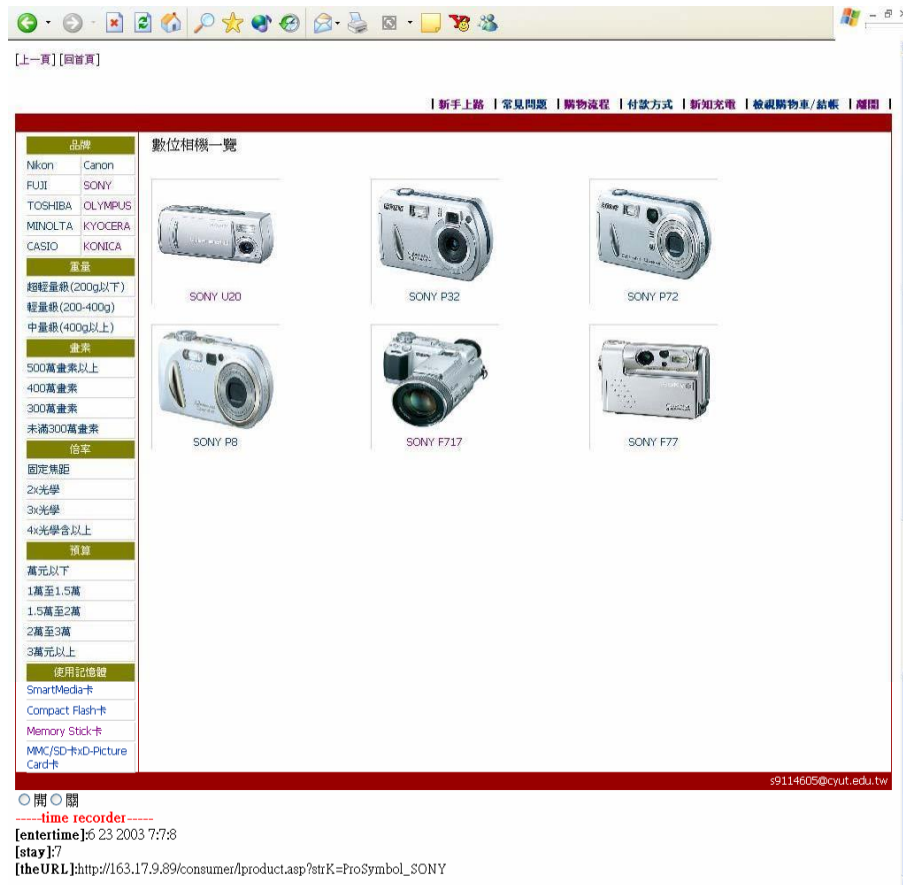

Figure 2. The interface of the simulated EC store

and test purposes for each set of data, respectively. The output of the first BPN denotes the customer profile characteristic, and the more its value is close to 1, the more possibility he has expert knowledge towards the products. The output then becomes one of the input nodes of the second BPN.

4.3 The navigation recorder

To collect customers' navigation data, we developed a navigation recorder which is a plug-in of the web site. While visitors click on the web pages, it records customers' navigation details. The 30 selected experts and non-experts were asked to navigate the EC store, their navigation sequences were recorded for further web usage mining. Table 1 shows some of the navigation details collected. Each record consists of:

1. userID: The user ID.
2. sessionId: While a client connects to the web server, the server will assign a session ID to the client. Though session ID, we can trace the navigation sequences of each session for each customer.
3. theURL: The URLs which a customer has visited.
4. userIP: The IP that each customer used to connect to the web site.
5. TimeIn: The time when the customer enters the web page.

6. TimeOut: The time when the customer leaves the web page.

7. S: Duration of the stay at the web site. Subtract the time entering the web page from the time of leaving the web page and take out the period of time during which the customer's focus is on another URL. By monitoring if a customer's focus is on another application, we can detect if the customer is inattentive while navigating the current URL.

Table 1. Some of the navigation records collected

4	aco	1050883611	http://163.17.9.89/logout.asp	211.74.236.25	03/6/3 pm08:52:33	03/6/3 pm08:52:38	4
5	wice	1050883677	http://163.17.9.89/1product.asp	163.17.9.75	03/6/4 pm05:33:51	03/6/4 pm05:34:11	20
6	wice	1050883677	http://163.17.9.89/1product.asp?strK=P_N	163.17.9.75	03/6/4 pm05:34:11	03/6/4 pm05:34:12	1
7	wice	1050883677	http://163.17.9.89/1product.asp?strK=P_C	163.17.9.75	03/6/4 pm05:34:13	03/6/4 pm05:34:17	4
8	wice	1050883677	http://163.17.9.89/a_new.asp	163.17.9.75	03/6/4 pm05:34:18	03/6/4 pm05:34:25	7

By sequence pattern mining from the customer navigation data which the navigation recorder has recorded, the navigation patterns for both experts and non-experts can be obtained.

4.4 Product classification and sequence pattern coding

Product classification is applied in order to decrease the total number of different navigation sequences. In this case study, we classified products into four groups by product specification. URLs showing the same classified products on the same web page file are assigned with the same web page code. Table 2 shows some of the web page codes according to the product classification and the URL.

Table 2. Web page coding based on product classification and URL

474	Finish pay up	http://163.17.9.89/consumer/lpayOk.asp	74

4.5 Mining the navigation patterns

By mapping the sequence of URLs that a customer visited to the code table (Table 2), a navigation sequence can be converted into a coded sequence such as “2660486400604826525626,” where every two digits denote a URL. With sequence pattern mining, frequent sequence patterns can be drawn specifically from experts and non-experts. Through a sliding window, we can get all the sequence patterns of length 3-6. Table 3 shows the patterns with lengths 3-6 for the specific sequence “2660486400604826525626.”

Table 3. An example of obtaining sequence patterns by sliding window

Navigation	2660486400604826525626
Length 3	266048 604864 486400 640060 006048 604826 482652 265256 525626
Length 4	26604864 60486400 48640060 64006048 00604826 60482652 48265256 26525626
Length 5	2660486400 6048640060 4864006048 6400604826 0060482652 6048265256 4826525626
Length 6	266048640060 604864006048 486400604826 640060482652 006048265256 604826525626

After obtaining the sequence patterns from experts and non-experts, and removing those patterns which are common between experts and non-experts, expert specific and non-expert specific patterns are found.

4.6 Compute the support count for expert and non-expert specific patterns.

Calculate the support counts of all experts and non-experts specific patterns using the collected training data. Then divide the support counts by the value of the maximal support count resulting in the normalized values. Since there are only hundreds of patterns, they are all adopted in the experiment. For a large number of different patterns, only significant patterns with normalized support count values larger than a pre-defined threshold need to be included in the inputs of the second BPN.

4.7 Training of the second BPN

With sequence pattern mining, sequences can be drawn specifically from experts and non-experts, and those sequences which are common between experts and non-experts will not be used for recognition for the second BPN. With the sequence patterns with lengths 3-6 (3-6 consecutive URLs) for both experts and non-experts plus the profile characteristic as the inputs and the knowledge level (0 or 1) as the output value, we can train the second BPN and use it to predict on line if a new customer has high knowledge level soon after he registers and navigates the EC store. All the 27 experts’ or non-experts’ data were fed into the second BPN with the output values of 1 and 0, respectively to train the second BPN. The rest of the 3 experts’ or non-experts’ data were used as the test data for the BPN. The experiment results will be provided in the following section.

5. Experiment results

This case invited some experts who have often posted articles on the digital camera discussion panel and some non-experts who are very unfamiliar with digital cameras.

To avoid bias in separating the data into training and test data sets, this case study divided the data set into two subsets which consists of a training (90%) and a test (10%) data sets. Similarly, totally 7 different ways of dividing the data set were repeated (another 3 inappropriate data sets were disregarded). Table 4 shows the test result of one out

of the 7 data sets.

Table 4 The test results for one set of training and test data

	exp15	exp19	exp23	non11	non14	non25
exp	0.98063	0.041385	0.97488	0.44754	0.44716	0.45059
nonexp	0.043285	0.66249	0.054541	0.73465	0.73492	0.73251
	correct	incorrect	correct	correct	correct	correct

Accuracy: 83.33

In the 7 sets of training and test data for the proposed method, the test results show that the average prediction accuracy is 90.48%. Furthermore, we changed the ratio of training data vs. test data to 6:4, and the average accuracy is 83.33 %.

Although the accuracy is highly dependent on the training and test data sets, the good preliminary results show the high potential of the method to be applied in online customer knowledge level recognition, on which further recommendation can be based.

6. Conclusion and Future Works

This paper proposes a method for recognizing customer knowledge level towards products. The method consists of two BPNs, the first one is trained to differentiate customers based on user profile and specifically designed questionnaire and the second one is designed to predict the knowledge level, by taking into account additional navigation sequences.

In the experimentation, we divided the data set into training data and test data with the ratio of 9:1 repeatedly for 7 different sets, the accuracy is 90.48%. The results show the high potential of the method in recognition of customer knowledge level towards products.

Once a new customer registers and leaves some navigation sequences at the web site, the developed method can on line recognize the knowledge level of the new customer towards our products, and thus further online personalized product recommendation can be generated and offered.

The preliminary result of the case study has shown the high potential of the proposed method in EC. As for the future works, interesting directions to improve include the

questionnaire design, sensitive analysis of how the input data will affect the prediction accuracy, and application of a large real case study to verify the effectiveness of the proposed approach.

Abstract

Singapore's Marine Industry faces strong competition and challenges in the global arena, especially from fast emerging countries such as China and Vietnam where labor costs are much cheaper. Companies of the marine industry are increasingly under pressure in a fast changing business environment to make their operations lean and profitable. Innovativeness in seeking improvements and responsiveness to market changes are essential for gaining sustainable competitive advantage. Information and Communication Technologies (ICT) can play a considerable part in a competitive strategy. E-Commerce could be of a useful tool to achieve competitive advantage, in cost reduction, product differentiation in term of quality service and responsiveness to customer requirements.

Michael Porter's model of five forces of competitive rivalry help firms identify threats to its competitive position and make plans that may include IT and e-Commerce, to protect or enhance that position. E-Commerce offers new ways to manage supply chains, enhancing manufacturing logistics and distribution systems, and linking business partners in a seamless business-operating environment. It also helps to automate business transaction (buy and sell products and services) and flow of information between organizations on the internet. The Singapore Marine Industry would need to seek continuous improvements in all areas of their operations as well as in e-Commerce techniques in order to achieve sustainable competitive advantage.

Background of Singapore Marine Industry

The Singapore Marine Industry is made up of four main sectors: ship repair, shipbuilding, rig building and the marine supporting industries.

Over the last 30 years, Singapore's Marine Industry has undergone various phases of development to emerge as one of the world's premier maritime centers. The ship repair and shipbuilding sectors have achieved world-class status and

contributed significantly to the growth of Singapore as a leading maritime hub.

The marine industry as a whole, being very labor intensive and over the years as the market environment changes, most shipyards are facing difficulties of staying competitive; and more difficulties encountered in the 1990s and beyond. Shipyards were forced to re-consolidate with mergers and acquisitions, and restructuring over the last few years to stay competitive and alive. The marine supporting industries are also facing similar problems and most of the companies in this sector internationalize their business and seek new innovative strategies to stay competitive.

Singapore shipyards face strong competition and many challenges from its counterparts in the global arena. Current over-capacity and strong competition from new ship repair facilities with lower labor costs from China, Vietnam, Indonesia, Thailand and India are expected to compete directly with established yards in Singapore over the near term leading to a downward price pressure.

The uncertain economic climate, keener competition from regional shipyards and the constraints on manpower are old issues that have to be addressed with new perspectives. The innovativeness of the Singapore shipyards in seeking improvements and their responsiveness to market changes are essential to ensure that Singapore remains at the forefront of the global ship repair center.

Competitive Strategy

Companies in the marine industry will only survive if they are competitive; like any other commercial organizations, they prosper if they achieve a competitive advantage. The two generic competitive strategies are price leadership and product differentiation. E-Commerce could be useful tools to achieve price advantage, differentiation and to combat competitive threats. The three basic strategies for competitive advantages are cost leadership, differentiation and focus (Porter, 1980). Cost leadership is simply to be able to sell the goods or provide the service at a price that is lower than that of the competition. Differentiation is where the

goods or services provided have some quality that makes them more attractive than competing products even though the competition may have a somewhat lower price. Focus is concentration on a single aspect of the market, a product niche.

Information and Communication Technologies (ICT) can have a considerable part to play in a competitive strategy. The appropriate use of Information System (IS) and Information Technology (IT) can lower administrative costs of the organization and the use of Information and communication technologies, in the logistics supply chain, can add to that advantage. The use of information and communication technologies, in addition to cost reductions, can also differentiate a product in terms of quality of service and responsiveness to customer requirements. For the niche player, information and communications technologies can be used to target information on the selected segment and to gather customer data from that segment. Eventually quick response supply and just-in-time manufacture, enabled by information and communication technologies, can provide the capability to evolve new products and services and to facilitate customization (Whiteley, 2000).

Michael Porter's model can help firms identify threats to its competitive position and to formulate plans, that may include IT and e-Commerce, to protect or enhance that position. The model shows five forces of competitive rivalry: -

- ◆ Competitive rivalry among existing firms in the trade sector;
- ◆ Threat of potential new entrants to the sector
- ◆ Threat of a substitute product or service to the existing trade
- ◆ The bargaining power of the buyers
- ◆ The bargaining power of the suppliers.

Typically one or two of these five forces dominate in the analysis of the competitive position of an organization in a trade sector. Each of these threats is further examined as below:-

1. Threat of New Entrants

Information Technology can be a barrier to entry into a market. Existing players in the sector may well have a substantial investment in Information System / Technology including the use of Electronic Data Inter-change (EDI) to co-ordinate their supply chain. This experience and investment can be difficult for a new entrant to match. The converse is that developments in IT and e-Commerce may leave existing players with heavy investment in expensive obsolescent technologies giving the new entrant the opportunity to enter the market with fresh ideas and a business plan facilitated by a new generation of IT provision. Internet e-Commerce is a technology that can facilitate new

entrants to existing markets without the need to match the IT and infrastructure investment of the existing players. Recent developments in internet e-Commerce have facilitated the entry of new players into a number of market segments, such as without having much investment in setting up the marketing distribution channel.

2. Threat of Substitution

The IT industry has itself substituted many products previously used in business; one example is the replacement of the typewriter by word processor. Of the e-Commerce technologies, Internet e-Commerce has the potential to make significant inroads into traditional retail sectors such as on-line banking or downloadable information from the web-sites that could substitute distribution channels for conventional retailing and, arguably, constituting substitute products.

3. Bargaining Power of Buyers

The use of IS/IT may help companies achieve efficiencies that enable them to meet the price requirements of the powerful buyer. Another approach is to use information communication technologies to facilitate a level of service that will keep the customer loyal. Short cycle times, quick response supply and reliable services are features that can be enabled by e-Commerce technology. Value added services such as stock control and accountancy facilities available from the suppliers are also features that can lock the customer in.

E-Commerce can also be used to reshape the supply chain. Intermediaries such as wholesalers and agents can become unnecessary when an organization can efficiently deal with small traders and members of the public using e-Commerce systems. Competitive advantage, in all three categories, can be achieved using e-Commerce for direct sales. This process of disintermediarisation can save costs of distribution, allows an organization to differentiate its products and services and/or focus its attention on selected segments of the market.

4. Bargaining power of Suppliers

The strategies of price advantage and differentiation such as branding or quality of service give a stronger competitive position for the suppliers. The ability to trade electronically is a factor in the quality of service and may be a requirement of trade from the buying organization.

5. Competition between Existing Players

E-Commerce is a factor in competition between existing players. The use of e-Commerce can: -

- Reduce the administrative costs of trading (transaction costs);
- Increase the logistic efficiency of the supply chain hence facilitate reduced stockholding and greater reliability of supply ;
- Meet the requirements of trading partners that trade is conducted electronically
- Differentiate the product or service that is offered from that of competitor organizations
- Cut out intermediaries in the supply chain, e.g. replacing sales through an agent with direct sales to the customer;
- Provide a new marketing and servicing channel.

The First Mover Advantage

The ability to gain advantage from the innovative use of IS/IT can owe a lot to timing. The first organization to implement a new type of ICT system will, if the system is successful, gain the price advantage or the differentiation while competitors are still operating with traditional methods and systems (Whiteley, 2000). The shipowners / ship-operators who are customers for the marine industry are located all over the world and the ICT system can provide the advantage for the Singapore Marine Industry.

The first mover can gain advantage but it is a risky business. New technologies and new ways of using them are expensive to develop and are often not successful. There are advantages to being a late mover: the idea has been tried, its effectiveness can be assessed and the later mover can implement an improved version of the system. In terms of technology, the advantages are that it has been tested and will be cheaper and easier to implement the second time round; it may be that standard components have been developed or that packaged solutions are available, advantages that were not available to the first mover. Newcomers to the e-Commerce scene, using EDI or Internet e-Commerce, have the advantages of being able to benefit from the work of the pioneers without the need to contribute to the development effort. The late mover does not, however, have the ability to surprise competitors or the market; it is essentially a catching up operation.

Sustainable Competitive Advantage

Having gained competitive advantage, the problem is then to exploit and sustain it. To gain competitive advantage using IS and IT usually needs an element of surprise; the system needs to be out in the market place before competitors make a start in copying the idea. Sustaining that competitive advantage requires that the technical advantage is converted into brand advantage e.g. amazon.com, or that the technical lead is sustained by continuous product and service development.

Sustainable competitive advantage from EDI systems has been rare. Most EDI systems have been implemented in trade sectors where all competitors have a mature use of IT and IS and hence the use of EDI by one player is readily emulated by the competition.

Sustainable competitive advantage appears to be more common with Internet e-Commerce; probably to be expected with a new technology where the element of surprise can be greater. The notable names in Internet e-Commerce have entered existing markets or created new markets using web technologies at a time when the entry costs to those markets were low and the element of surprise was greatest. In producing technologically sophisticated sites and developing their supply chain logistics, they have considerably raised the entry costs for newcomers.

The possible competitive use of e-Commerce has been illustrated and summarized in the Table below: -

**E-Commerce for Competitive Advantage
(Table 1)**

Force	System	Competitive Advantage
New Entrants/ Substitution	Internet e-Commerce	<ul style="list-style-type: none"> • Reduced entry costs • New sales channel • New service opportunities
Suppliers (&Trade Buyers)	e-Commerce Logistics (EDI/IeC)	<ul style="list-style-type: none"> • Cost reductions • Quick response • Lockin
Buyers (Consumers)	Internet e-Commerce	<ul style="list-style-type: none"> • New sales channel • Dis-intermediarisation • Customer Information
Competitive Rivalry	e-Commerce	<ul style="list-style-type: none"> • Cost leadership • Differentiation • Focus

IeC: Internet e-commerce

What is e-Commerce?

E-Commerce is simply any business transaction that takes place via digital processes over a network. E-Commerce, however, is really much more than just exchanging products or services for money over the Internet. E-Commerce is an enabling technology that allows businesses to increase the accuracy and efficiency of business transaction processing. E-Commerce is also a way for organizations to exchange information with customers and vendors to the benefit of everyone involved. Eventually,

e-Commerce will likely replace the movement of paper within and between organizations, as well as between organizations and consumers (Trepper, 2000).

The Benefits of implementing e-Commerce

E-Commerce is a tool for reducing administrative costs and cycle time, streamlining business processes, and improving relationships with both business partners and customers. By using a public shared infrastructure such as the Internet and digital transmitting and reusing information, e-Commerce systems can lower cost of delivering information to customers. E-commerce systems, being of instantaneous nature, allow a reduction of the cycle time associated with producing and delivering information and services. An effective e-Commerce solution can extend the reach of business by increasing opportunities with customers, suppliers and other business partners. For suppliers, through a direct, information-rich and interactive contact with customers, electronic commerce can enhance the promotion of products (Viehland, 1999).

Organizations that compete effectively in the e-Commerce arena should therefore be able to make better decisions, which should enhance market position, and ultimately profitability.

E-Commerce techniques allow small businesses to have access to the same markets as larger businesses. Small organizations can have instant access to international markets. Customers all over the world can access the web site and buy the products whether the company has one full-time person or one thousand full-time employees. The direct reach to customers and their bi-directional nature in communicating information, e-commerce systems represent a new sales channel for existing products. Small businesses can grow very quickly and can eventually take on larger businesses in their markets. Smaller businesses may also be able to provide a personalized experience for customers who come to their Web site more easily than larger businesses that have to deal with the bureaucracy involved in designing a Web site.

E-Commerce can provide benefits beyond cost reduction. Electronic sign-offs can prevent inappropriate business transactions that can be missed in a paper-based system. Business rules can be implemented electronically so that systems would not accept transactions than have incorrect codes or insufficient electronic authorization. E-commerce will become one of the components of a brand or corporate image, especially while targeting technology-friendly customer segments. The information-based nature of the e-Commerce processes allows for new products to be created or existing products to be customized in innovative ways. Rapid progress in the areas of e-Commerce will force companies to adapt quickly and offer them opportunity to experiment with new products, services and processes (Viehland, 1999.)

Buying patterns can be tracked as well which allows organizations to make better decisions about the product and service delivery. Giving the right information to the right people of the right time can dramatically improve the company's ability to compete in its marketplace. The changing industry structures and the e-commerce systems allow for new business models to enhance competitive advantage, based on the wide availability of information and its direct distribution to end customers.

Organizations that use e-commerce techniques and technology will also attract additional consumers because of a higher level of customer service, through intelligence built into systems and the extended availability of intelligent support systems. It will also allow for more personalized relationships between suppliers and their customers, due to their ability to collect information on customers' needs and behavioral patterns. Organizations that move to the Web will be able to help their customers resolve problems faster, which will eventually lead to better customer relations and more customers. Organizations that customize the interactions of both vendors and customers will appear to be more attractive business partners, which ultimately enhances their market position. Some organizations will find that a majority of their customers prefer to conduct business via the Web rather than traditional methods, which means that the organizations that cannot keep up with the technology will find themselves in trouble.

By simply using e-Commerce techniques will not, however, necessarily lead to success. Organizations that currently suffer from inefficient processes, questionable product quality or poor customer service will find that e-Commerce enables them only to make the same mistakes faster and more frequently. On the other hand, organizations that are truly dedicated to excelling in these and all areas of their operation will benefit from electronic commerce because it will enable them to most efficiently build upon these capabilities.

(Trepper, 2000) states e-commerce, as in a useful way, the benefit of e-Commerce help to define what it is, Electronic Commerce: -

- Offers new ways to manage supply and value chains; to enhance manufacturing, logistics, and distribution systems; and to link business partners together in a seamless business operating environment.
- Provides organizations and individuals with the ability to buy and sell products, services and information on the Internet.
- Automates business transactions and the flow of information between organizations.
- Helps organizations cut customer service costs while improving the quality of service and increasing the ability of the organization to better manage the customer relationship.

Business to Business (B2B) e-Commerce

Business-to-business (B2B) e-Commerce represents an enormous opportunity for organizations both now and in the future. This will certainly also provide opportunities for the marine industry as well. According to Forrester Research, the market for B2B e-Commerce will surpass S\$1.3 trillion in 2003 (Cameron, 2000).

In Singapore alone, 97% of the 1998 S\$1.2 billion e-Commerce market represented B2B e-Commerce, according to the government's Department of Statistics. In addition, Forrester Research's overwhelming worldwide B2B market prediction of S\$1.3 trillion represents only 9.4% of all business sales in 2003 – up from 2% of all business sales in 1998. Clearly, room for growth in this arena extends beyond 2003 and this will include the marine industry.

Although B2B e-Commerce presents far greater opportunity than B2C e-Commerce, implementing it is also considerably more complex. A consumer e-Commerce site requires smooth functioning e-Commerce software, the ability to process credit card transactions, and a solid marketing plan. B2B applications are diverse and vary considerably by industry; the marine industry itself could also vary depending on which sector or areas of specialization the company is in. Furthermore, a single organization often must support a variety of arrangements with its partners – different contracts, discounts, and payment methods, for example. Off-the-shelf software can help implement such applications, but substantial customization is still required.

It is noted that the use of e-Commerce in the Singapore Marine Industry is still in the premature stage, except for the marine supporting sector where companies that are doing more international business especially of foreign owned companies with headquarters abroad and have base in Singapore. However, it has been noted that the major

shipyards in Singapore, such as Keppel and Sembawang groups have recently taken an overall e-initiatives to move from the traditional buying process to become seamlessly integrated as a marine marketplace. The OmixAsia.com is established and will serve as a B2B e-marketplace in the marine and offshore industries. The estimated volume of buying volume within this is said to be about S\$300 million. The use of this e-commerce is through membership and an entrance fee of S\$4,000 with annual subscription fees of S\$4000, and for non-members a two percent (2%) commission is payable for each transaction. This may however act as barriers for smaller companies due to the high fees charged.

Abstract

The Web has become a major repository for financial articles, and the indexing of these articles in an efficient and intelligent manner has become a vital task. This paper describes an intelligent index engine developed to directly log-on to financial Web sites, download financial articles, parse the texts, and index the articles via the use of a semantic network in the domain of corporate economics. The system can be used for retrieving relevant financial information for corporate performance analysis.

1. Introduction

In corporate performance analysis, a successful financial analyst not only observes numbers shown on financial statements, cash flow schedules, or economic index summaries, but also examines related textual information contained in corporate reports, trade journals, government bulletins, and business newspapers that are mainly descriptive and qualitative in nature. Today, the Web has become a major repository of such qualitative information, and the indexing of financial articles from the Web in an efficient and intelligent manner has become a vital task.

This paper describes the design of an intelligent indexing engine for Web financial articles in the domain of corporate performance analysis. The paper first discusses characteristics of the domain, a model that can be used to effectively capture and represent the knowledge in the domain, and semantic networks developed to structure and store the domain knowledge. The paper then presents the design of the Web indexing engine, followed by an illustration of how the system is used. At the end, the paper concludes with recommendations for future research and development.

2. The domain

Similar to evaluating the health of a patient, corporate performance analysis involves a process of diagnosing the state of the health of the underlying company, and the effectiveness of such a diagnosis process relies on support of relevant and timely information. In this domain, the use

of quantitative method such as financial ratio analysis is common. However, financial analysts must open their analyses not only for quantitative constructs in financial statements, but also for many qualitative measures, such as marketing strategies, product development, and so on, contained in corporate reports, trade journals, government bulletins, business newspapers, and so on.

The domain of corporate economics includes tremendous amounts of knowledge with various types of contents and appearances, which makes it essential to find an appropriate representation scheme to structure the knowledge. Valid knowledge representation schemes should be built on common theoretical foundation that can be easily understood by the people in the industry.

Traditional financial reporting system is grounded on the value-driven accounting approach. This approach, however, leads to a very rigid definition for an organization's economics model. The counter-approach to the value-driven approach is the event-driven accounting theories which advocate that an enterprise's approach to corporate information management should focus on managing relevant business events as opposed to managing values shown on the financial reports. The event-driven approach was later applied to develop an entity relationship view of corporate economics called the REA (Resources, Events, and Agents) model [3,4,6]. The model is composed of three classes of economic objects such as resources, events, and agents, and relationships among those objects.

Intelligent information retrieval systems frequently use semantic networks to provide knowledge support for textual information processing for domains with deep knowledge [1]. The concept of the REA modeling technique can serve as the foundation for the development of a semantic network to model knowledge of corporate economics for two reasons. Firstly, the REA model has been proved to be a reliable and consistent knowledge representation scheme for corporate economics. Secondly, because its representation of entity-relationships are exclusively in one-to-one form, the concept of REA model can be used and expanded to develop a semantic network which also uses binary form to represent knowledge.

3. The semantic network

A semantic network is a directed graph in which knowledge objects are the nodes connected by their declared relationships as the links. In the semantic network of corporate economics, the three REA classes of economic objects are the knowledge objects. Defined and identified knowledge objects are related by three sets of binary semantic relationship: generalization, association, and causality. Paired knowledge objects with the semantic relationship are expressed in terms of three semantic predicates: IS_A (generalization), IS_PART_OF (association), and IS_CAUSED_BY (causality). For instance, a "salesman" IS_A "sales representative"; "equipment" IS_PART_OF "asset"; "sales" IS_CAUSED_BY "marketing".

Most semantic networks use the "spreading activation" search algorithm, which navigates the knowledge base by first activating the key objects, followed by objects that are directly related to the objects, followed by objects that are directly related to the objects previously activated, and so on [2]. Psychologists have long recognized that human memory is a system of associated concepts or "chunks" of symbolic information" [5]. The structure of semantic network is analogous to that of the human memory, and the mechanism of spreading activation mimics how human retrieve memory.

Cohen and Kjeldsen [2] also propose three rules that can be used to guide the search. First, the search can cease at a predetermined "distance" (e.g., 3 links or 4 nodes) from the original activation. Secondly, a "fan-out" algorithm can be used to stop the search at objects that have very high connectivity, or fan-out. The third type of constraint uses the idea of likelihood of the relationship between objects. In Cohen and Kjeldsen's [2] GRANT, an intelligent information retrieval system, a minimally constrained spreading activation of a given distance (4 links) is used with satisfactory rates of precision and recall.

4. The system

The intelligent index engine is written in Visual Basic 6 using MS SQL server for data management. The system contains four modules: Request, Index, Retrieve, and Administration.

4.1. The Request module

The Request module uses a COM object to log-on to a financial Web site and downloads a specified HTML page via the HTTP protocol. The module can either download one page at a time or conduct a batch download based on a list of URLs stored in the database.

4.2. The Index module

The Index module parses the downloaded HTML page, analyzes the text, indexes the articles via the use of the semantic network of corporate economics, and saves the

article. The module reads every word of the article, matches the word with the economic objects stored in the semantic network, and build indexes of the article accordingly.

4.3. The Retrieve module

The Retrieve module enables users to retrieve relevant articles based on derived keywords and specified distance for spreading effect. There are two processing elements involved in the derivation of search keys: the semantic network and a search key generator. The semantic network discussed previously is the knowledge base containing the REA objects and their relationships. The search key generator is the inference engine that draws inferences by tracing appropriate links in the semantic network. Using these two elements, the construction of a search key list is accomplished by identifying the primary search key(s) or triggers and constructing a search space (i.e., a contextual base) for the exploration of supplemental search keys by matching semantically related object(s) in the semantic network. In order not to draw the semantic relationships out too far, special rule like "constrained spreading activation" is applied. Using the key list, the search key generator forms text queries to retrieve relevant articles from the article database.

4.4. The Request module

Finally, the Administration module allows users to manage three databases: Web site URLs databases, financial articles database, and the semantic network database. This module, in particular importance, enables the researcher to refine the semantic network over times for better performance.

5. The use of the system

Credit managers and bankers often focus on the liquidity position by looking into a firm's short-term assets and liabilities, or its working capital condition. To analyze a firm's liquidity position, we use the Current Ratio which is calculated by dividing Current Assets value by Current Liabilities value. In order to gain insights into the company's liquidity position, we need to know if there were important activities, such as large bank loans or significant increase in inventory or changes in accounting reporting procedures that might affect its working capital, hence, the current ratio. With the help of the Retrieve module of the system, financial articles related to "liquidity position" in terms of current ratio concept are retrieved as a result of the search for all of the article containing words or terms that are related to the concept of "asset," "liability," and "liquidity". The relevant keywords in the semantic network include "cash," "inventory," "account receivable," "debt," and so on.

7. Recommendations and conclusions

Systems development is a key research methodology that interacts with other methodologies, such as theory building, experimentation, and observation. The advancement of intelligent text processing for Web resources often comes from new systems concepts, but systems must be developed first to test and measure the underlying concepts. The system described in this paper is a result of such a proof-of-concept approach.

Further research work will include substantial testing of the system for precision and recall measurements and the refinement of the semantic network for performance improvement.

Abstract

As the society of knowledge becomes, the most competitive resource for corporations is knowledge. Corporations have to evaluate and improve latent values of 'Intellectual Capital' (IC), which is directly related with the futurity of corporations. Although it has been researched and proposed to evaluate IC values that have been ignored relatively to tangible asset, the indexes of evaluating IC have never been examined and adopted by many corporations. By this reasoning, there have been no systematic models to evaluate IC value and each corporation should re-develop IC valuation model. Economic wastes have been created under this situation. Therefore this study intends to develop a synthetic and systematic model for IC valuation. Consequently the model of this paper is consisted of 3 dimensions, 10 factors, 22 evaluation criteria, and 82 indexes, which was necessary for IC valuation. This model will be practically applied to IC valuation of corporations.

I. Introduction

As a society of knowledge has recently come, corporations become to focus on knowledge management (KM), strictly speaking, 'knowledge-based Management'. Key research fields of KM are approximately divided into four as follows. (1) the research on concept of knowledge management and alignment KM with competitive advantage (Nonaka, 1991; Nonaka & Takeuchi, 1995; Prahalad & Hamel, 1990; Teece, 1998), (2) the research on methodology of KM (Wiig, 1997; Davenport, 1998), (3) the research on knowledge management systems (KMS) (Vian & Johansen, 1983; Kwok & Khalifa, 1998; Zander & Kogut, 1995), finally (4) the research on IC. The fourth field on IC is originally included into financing and accounting area. However, most traditional accounting model based on financial statements focuses on financial performance. In result, differences between market value and book value have not been measured. In order to overcome this defect, some advanced countries

have actively studied with Edvinsson and Malone's Skandia Navigator as the central figure after 1980.

A few researchers studying IC have presented various indexes to value it, but a lot of indexes still are not tested and not verified (Roos & Roos, 1997; Roos, 1998). Therefore our study attempts to integrate various indexes for IC valuation that have been presented in the previous studies, to prepare framework to classify and verify them, and finally to develop organized model. This is an necessary work to reduce enormous time and expenses for developing IC valuation model of each corporation and hereafter can be available as a benchmark tool of many corporations. In sum, our purpose is to overcome some limitations of previous studies (not organized model and not verified indexes) and to develop a model for IC valuation.

II. Intellectual Capital

Until 1980, most attention of competitive advantage was paid on understanding the competitive environment (Porter, 1980; 1985). However this interest is changed to 'resource-based' perspective. In this perspective, the most important resource to sustain competitive advantage is internal resource. This internal resource have been variously named like 'absorptive capacity' (Cohen & Levinthal, 1990), 'core competency' (Prahalad & Hamel, 1992), 'strategic asset' (Amit & Schoemaker, 1993), 'Core Capability' (Zander & Kogut, 1995), 'intangible asset' (Hall, 1992), 'organizational memory' (Walsh & Ungson, 1991). Though terms are varied, all of these mean knowledge (Roos & Roos, 1997). In this sense, IC of an organization is seen as 'the sum of knowledge having latent intangible values, which will create competitive advantage' (Roos & Roos, 1997; Knight, 1999; Teece, 1998; Lev, 2000).

The problem of developing 'IC valuation model' for estimating intangible asset is the remarkable contrast

between expectation and actuality. Skandia reported that 70% of samples on investigation into KM had not related activities for IC valuation with financial performances reporting (Hiebler, 1996). This is because traditional accounting model has focused on past-oriented results rather than future-oriented capabilities. However, as importance of IC has been increased after 1980s, a few studies about IC valuation have been provided.

Edvinsson(1998), the chief architect behind Skandia's initiatives developed a dynamic and holistic IC reporting model called the Navigator. According to Skandia's model, the hidden factors of human and structural capital when added together comprise IC. Edvinsson recommends 112 measurement indexes in the Skandia Navigator and expanded the meaning of IC. Although Navigator reflects the value of innovation, the role of customers and the relationships with customers, there are some limitations as follows. First, each index is given equal weight in the equation process. Second, indexes about qualitative indexes are not included like data quality except physical estimation (Bontis, 1998, 2000). And then Brooking (1997) defines IC as the combined amalgam of these four components: market assets, human-centered assets, intellectual property assets and infrastructure assets. In total, Brooking's model is comprised of 178 indexes. While this approach has been lauded for offering a toolbox for organizations to assign values to IC, her questions are so conceptual that additional measurement process for quantitative analysis is needed. Sveiby (1999) regarded IC as external structure, internal structure, and individual competence. He also saw individual competence as key factor. Bontis (1998) split IC into human capital, customer capital, structural capital, and provided indexes to estimate them. He also presented the relationship each component with organizational performance. However these indexes are too comprehensive to measure concretely. In sum, IC can be classified human capital, structural capital, and customer capital. Though a lot of indexes have been presented in the previous studies, each index is just arrayed based on three capital components. Systematic and organized model has not been offered.

Compared with these studies, the following studies provided criteria to subdivide each capital component. Saint-Onge (1996) suggested that IC is the most concerned factor when strategy is planned in the stirring environment and that structural capital consists of strategy, system, culture, and structural components. Kaplan & Norton (1992, 1998) presented that human resources is the sum of employee satisfaction, employee productivity, employee sustainability, and employee capability. And Knight (1999) defined external capital as customer capital, supplier capital, alliance capital, community capital, regulatory capital, and competitor capital. Especially the boundary of customer is expanded to other external partners in this study. Stewart (1994, 1997) emphasized the importance of intellectual property and explained it as the starting point to develop IC model. And he pointed out main problem of managing intellectual property. Companies didn't know what intellectual property they

had and have no responsibility department. As companies couldn't take advantage of them, investment in intellectual property have not accomplished adequately. Band (1994) presented elements for explaining organizational culture as market-oriented level, strategic position, inter-organizational communication system, attitude to share information, and sharing level of management philosophy. All of above studies offered sub-components of human capital, customer capital, and structural capital. However, compared with Edvinsson and Brooking's studies, they have not presented specific indexes for valuation.

In summary, previous studies are classified two approaches as follows. (1) First, only specific valuation indexes in each capital component are presented without classifying sub-components. (2) Second, only specific sub-component criteria in each capital component are presented without indexes. These two approaches have all some limitations from the view of systematic and organized model for IC valuation. While indexes are presented in the first approach, there are no analytical criteria for classifying each capital component. And these indexes just have been presented according to researchers' literal interpretation without verification. In the second approach, specific indexes have not been offered. But availability is limited because these indexes can be used practically.

III. Model for IC Valuation

Our paper attempts to decide 'dimensions' to be criteria of model and to elicit 'factors' to subdivide dimensions through literature review because systematic model has not been and only indexes have been provided in the previous studies. Indexes for IC valuation then are classified according to elicited factors and factors are continuously classified to evaluation criteria according to similarities of indexes (<Appendix 1>).

3.1 Dimension

Dimensions of IC are classified into human capital, structural capital, and customer capital based on previous research. This paper intends to classify into individual capital concerning individual employees, organizational capital concerning organization processes and asset, and finally expanded customer capital to relational capital including customers and other participants. This classification is based on the boundary of a company.

3.2 Factor

First, **individual capital** is the most basic capital. This consists of 'knowing' (visible knowledge such as scholarship, invisible tacit knowledge), 'emotion of employees' and 'will of employees'. Based on above-mentioned standards, individual capital includes employee capability, employee satisfaction, employee sustainability, employee production mentioned by Kaplan & Norton (1992, 1998). '*Employee capability*' can be conceptualized by idea, creativities, and explicit

qualification. Sveiby (1999) referred this is a key point for organizational growth. ‘*Employee satisfaction*’ is emotional condition of employees and a lot of researchers have emphasized that if organizational system supporting employees and mental expectation of employees are not balanced properly, they may desert their job or overall organization performance may deteriorate (Lester & Kickul, 2001). The meaning of ‘*Employee Sustainability*’ is close to the concept of willingness, motivation. In Evans & Lindsay’s research in 1999, 46% of Human Resource Focus 1000 presented willingness and motivation of employees as one of the most three important issues (Eskildsen & Nussler, 2000; Eskildsen & Dahgaard, 2000). However, indexes of ‘*Employee productivities*’ like sales per employees or individual trading profit are performance after knowledge activities, not individual value as IC. It is not appropriate for valuation indexes for accumulated knowledge of employees. Therefore our paper will evaluate individual capital as employee capability/satisfaction/sustainability.

Second, **organizational capital** consists of culture, IS, organization structure (process) excluding employees in the company and is added intellectual property proposed by Saint-Onge (1996). As ‘*culture*’ is organization philosophy or the way of doing tasks, it is the basis of organizational capital. Elements such as philosophy or employee values must be formed properly for managing tacit knowledge successfully and shared for enhancing values of IC (Leonard & Sylvia, 1998; Roos & Roos, 1997). Next ‘*Information system*’ is very important factor in the information-oriented society. Numerous studies in MIS have found significant positive impacts of IS on firm performance (Barua & Kriebel, 1995). ‘*Process*’ is the same concept as organization structure by Saint-

Onge(1996). It is IC on organization processes where operates practical works. Only when knowledge is connected to actual management process, it contributes to competitive advantage. Knowledge itself has not significant meaning. Finally as ‘*intellectual property*’ is the most explicit IC because of legal protection, it can be perceived as starting point for IC valuation (Stewart, 1994, 1997; Brooking, 1997). However, valuation indexes for culture and process have hardly founded in previous studies. Even Edvinsson’s study has just estimated IS infrastructure for structure valuation (Edvinsson, 1996, 1997, 1998). Furthermore as it has focused on physical sides (for examples, number of PC per 1 employee), IS quality or usage, efficiency of IS have been missed (Bontis, 1998, 2000).

Third, **relational capital** derived from various relationships consists of customers, suppliers and community. Previous researchers have perceived customer as the most important components in relational capital. Nonaka(1991, 1995) pointed out customer is shared knowledge between a company and customers. Most previous studies have restricted external relationship to the relationship with customer. However, as roles of the other participants are more and more important and expanded, our paper attempts to expand the relationship to other participants.

3.3 Evaluation criteria

Indexes for IC valuation presented in previous studies are classified according to above-mentioned ‘dimensions’. And then these indexes are classified into ‘evaluation criteria’ again according to their similarities.

<Table 1> Components of intellectual capital

Dimension	Factor	Definition
Individual Capital	Employee capability	Creative capability or idea of employee which is put to goal accomplishment of organization
	Employee satisfaction	Human relationship or emotion about work of employee in the organization
	Employee sustainability	Will to sustain stable relationship or enthusiasm for work of employee
Organizational Capital	Culture	Founded management philosophy for goal accomplishment of the firm, shared value/creativities between employees
	Process	Efficiency in actual management process in the organization
	Information system	Knowledge level of employees about quality and quantity of information system
	Intellectual property	Capital related with mental output under legal protection
Relational Capital	Customer	Guaranteed customer satisfaction, customer loyalty
	Supplier	Acquired knowledge and suppliers’ satisfaction in the transaction
	Society	Public confidence or trust of the firm in the local community

<Table 2> Dimension & Evaluation Criteria

Dimension & Evaluation Criteria	
Employee capability capital Capability development program Individual capability of employee	Process capital Availability of purchasing Efficiency of order processing of customers Management efficiency

Employee sustainability capital Average length of services Attitude for work of employee Employee satisfaction capital Satisfaction with organizational environment Human relationship satisfaction Culture capital Value sharing level Creativities Information system capital System quality Integration level of systems Knowledge level about IS of employees	Intellectual property capital Management level of intellectual property Customer capital Customer satisfaction Stability of relationship with customers Brand management level Brand value Supplier capital Negotiation power against suppliers Supplier satisfaction Society capital Corporation image

IV. Methodology

Data are collected from middle managements working in 50 corporations in South Korea. It took 9 weeks to finish collecting the surveys. In total, 203 valid questionnaires were returned out of 270 handouts (recording 75% of return ratio). The 95 measurement items were made out based on operational definitions. These definitions were taken and integrated from indexes of Edvinsson(1998), Brooking(1997), Sveiby(1999), Roos'(1997, 1998), Bontis(1998, 2000).

<Table 3> Survey Response Rates

Types of Companies in Sample	Number	%
IT & Network Services	55	27.09
Telecommunication, Computer, Semiconductor, Digital appliances	37	18.23
Finance/Insurance	29	14.29
Consulting	18	8.87
Aerospace industry	14	6.90
Information processing	13	6.40
Film and video industry	8	3.94
Human resource services	7	3.45
Engineering	7	3.45
Mekatronics	6	2.96
Others	9	4.43
Total	203명	100%

V. Test Results

5.1 Assessment of Reliability and Validity

The reliabilities for each scale are shown in <Table 4>. The measure scales used in the study show high levels of reliability - Cronbach's alpha is above 0.60(Nunnally, 1978). However, as reliability of employee sustainability was below 0.60, 3 items of 9 were deleted. Convergent validity is assessed by factor analysis of the scales. The factor loadings are shown in <Table 4>. Through Varimax rotation, the total 92 items (individual capital 22 items, organization capital 47 items, relational capital 23 items) are loaded onto 22 evaluation criteria. As factors above Eigen value 1.0 were loaded, two items in employee capability, three items in employee sustainability, three items in culture, three items in process, three items in process, and two items in community were finally deleted.

And we assess the discriminant validity by testing whether all items load more highly on their associated construct than on any other constructs. The square root of the average variance extracted for each construct was compared to the correlations between each construct and other constructs. All the values of the square root of the average variance (i.e., the diagonals) were greater than the correlations between constructs (i.e., the off-diagonals) in <Table 5>, indicating that all the constructs in the model exhibited the discriminant validity.

<Table 4> Reliability and convergent validity Tests

Evaluation criteria	items	Chronbach's alpha	Factor loadings
Employee capability capital Capability development program Individual capability of employee	8	.7210	0.729; 0.677; 0.782 0.668; 0.788; 0.781
Employee sustainability capital Average length of services Attitude for work of employee	6	.6600	0.771; 0.904; 0.898 0.717; 0.597; 0.827
Employee satisfaction capital Satisfaction with organizational environment Human relationship satisfaction	8	.8042	0.715; 0.815; 0.804; 0.718; 0.596 0.821; 0.743; 0.834

Culture capital Value sharing level Creativities	14	.8804	0.685; 0.689; 0.744; 0.635 0.594; 0.593; 0.629; 0.783; 0.767; 0.792; 0.733
Information system capital System quality Integration level of systems Knowledge level about IS of employees	17	.8654	0.693; 0.650; 0.751; 0.765; 0.808; 0.790; 0.794; 0.733; 0.664; 0.767 0.645; 0.778 0.663; 0.800
Process capital Availability of purchasing Efficiency of order processing of customers Management efficiency	10	.8761	0.492; 0.575 0.683; 0.751; 0.769; 0.564 0.704; 0.675; 0.558
