*Note) Diagonal elements are the square roots of the average variance extracted and off-diagonal elements are correlations between constructs.

5.2 Fit Measures for Proposed our Research Model

SEM (structural equation model) was conducted using AMOS 4.0. The object of this model is to show that the null hypotheses - the assumed research model with all its paths - is insignificant, meaning that the complete set of paths as specified in the model that is being analyzed is plausible, given the sample data. In other words, the object of this covariance-based SEM is to show that operationalization of the theory being examined is corroborated and not disconfirmed by the data (Genfen et al., 2000). And statistically speaking, this research model is the second-order latent variable formed by the first-order latent factors (for examples, in the 'individual capital' case, employee capability, sustainability,

satisfaction are the first-order latent factors). <Figure 1,2,3> depicts the research model of this study.

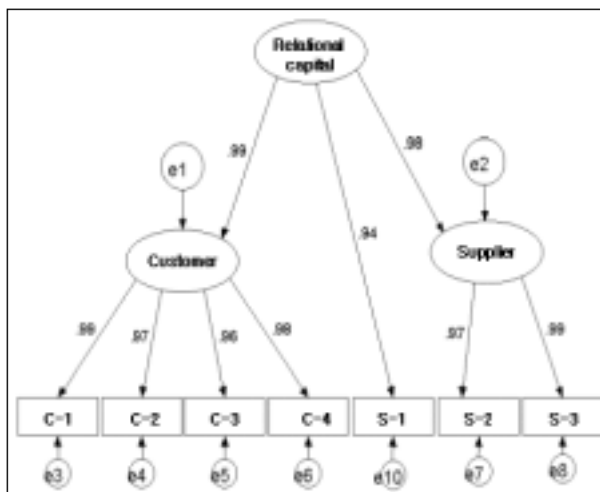

Fit measures for our research model propose in <Table 6>. A chi-square analysis indicates that the model fits the data. However, the chi-square test has been recognized as an inappropriate test for large sample sizes (Marsh, 1994). Showing the <Table 6>, the values of GFI, AGFI, RMR, and NFI are examined for the judgment of the fitness of the model. Therefore, the values of this model are higher than the acceptable level.

<Figure 1> Structural Equation Model of Individual Capital

<Figure 2> Structural Equation Model of Organizational Capital

<Figure 3> Structural Equation Model of Relational Capital

<Table 5> Goodness-of-Fit Indices of Models

	IC	OC	RC
χ^2 statistics	157.341	437.999	410.771
p-value	0.000	0.000	0.000
GFI (>0.9)	0.965	0.941	0.919
AGFI (>0.8)	0.877	0.889	0.810
NFI (>0.9)	0.992	0.986	0.981
RMSR (<0.05)	0.005	0.006	0.010

V. Discussion & Conclusion

In our analysis, we classified dimensions, factors and evaluation criteria of IC for valuation. We found that the model for IC valuation was classified into three dimensions - individual capital, organizational capital and relational capital. Compared with other previous studies, our paper tested unverified indexes of valuation and organized them to systematic model.

Furthermore due to the high demand for KM managers in today's organizations, the results of this study have several implications for practice. First, previous presented indexes arbitrarily by practitioners and researchers were integrated and tested theoretically. Therefore KM managers and CFO can use this model as a tool for IC valuation. Second, other previous studies have only arrayed indexes or presented some factors for classifying. So there has been no systematic model. Our organized model can be used as a foundation to develop and improve the value of IC in strategic respects. For examples, in the auto industry, each company compares its level of IC with others using indexes presented in our model. Analyzing the results of measuring, the company becomes to identify what is underdeveloped and to analyze causes and results in the respect of long-term strategic planning. However, it may be more effective to develop weights of indexes through interviews with domain experts for more precise comparison because of some differences between weights of indexes. In the manufacturing industry where separation of employees leads to great loss, the index of 'separation rate of employees' must be more importantly regarded and can be imposed greater weight. Thus this model should be examined and used on the strategic perspectives.

Like other social studies, we had some limitations. Financial calculating method should be accompanied for a single balance sheet. For this, concrete calculating method should be developed to announce actual \$-values. As our scales of indexes are not unified, new calculating method is needed for conversion to currency value. Though comparisons between companies may be possible through indexes of this model, future research need to develop that method to identify the changes of IC value chronologically or to compare with companies more objectively.

<Appendix 1> Operational and Conceptual Definition of Model for IC Valuation

D: Dimension, F: Factors, EC: Evaluation Criteria

D	F	EC	Conceptual definition	Operational definition
HUMAN CAPITAL	ECC	Capability development program	Education and training program supported by the firm to improve employees' capabilities	y Training time / 1 employee, training expenses / 1 employee y Educational expenses / sales y Average aptitude test frequency y Execution rate of planned training program
		Individual capability of employee	Knowledge and capability level of individual employee	y Number of employees having certifications y Knowledge level of own work y Average educational period y Expert rate / whole employees
	ESC	Average length of services	A length of services of working employees	y Average length of services in the same position y Average length of services in the firm
		Average separation rate	Changing rate of employee to separate or enter a company	y Average separation & entering rate/ 1year, Average separation rate of experts / 1year
		Attitude for work of employee	Employees' enthusiasm level for work	y Commitment level to own work y Rate of absenteeism, lateness, leaving early
	ESAC	Satisfaction with organizational environment	Employees' satisfaction with organizational system or environment etc.	y General satisfaction with the firm y Satisfaction with Evaluation & compensation, work environment y Relative wage level compared other companies
		Human relationship satisfaction	Employees' satisfaction with human relationship (with colleagues, superiors etc.)	y Relationship type with colleagues (officially-friendly), contact frequency y Satisfaction with relationship with superiors
	CULC	organizational openness	Openness level in organizational system or structure	y Empowerment level y Woman manager rate
		Market-oriented propensity	Level to effort to understand and to satisfy customers' needs in the market	y Level to understand target market and customer needs y Customer-oriented effort level
		Value sharing level	Level to share organizational goal and vision	y Recognition level of employees about organizational goal and vision y Cooperation level between members within teams
		Creativities	Level of support for new product and service development of employees	y Expenses for R&D / sales y Number of new products which are in developing
				y Ratio of putting out new products / 1year y Ratio of R&D researchers
				y Level of support for idea development y Ratio of idea execution
IS	IS	System quantity	Volume of information system within organization	y Number of computers / 1 employee y Investment in IS / sales

I T A L	C	System quality	Satisfaction with goal achievement of IS	y	Importance/Relevance/Accuracy/Timeliness/Comparability/Uniqueness/Usefulness/Informativeness
				y	Ease of use
				y	Usefulness of system features and functions
		System integration level	Level of integration of each system around organizations	y	System sophistication integration of systems
				y	ERP, EDI
		Knowledge level about IS of employee	Level of understanding of employees about IS	y	Level of understanding of CEO about IS
				y	Level of understanding of employees about IS
	P C	Availability of purchasing	Efficiency of activities to buy and store inputs which are needed for operation activities	y	Level of operation of subdivided tasks in the order processes
				y	Average response time in order processing
		Availability of production	Efficiency in production activities to produce final products	y	Level of automation in production processes (TQM, PERT, CPM etc.)
				y	Responsibilities for products quality
		Efficiency of order processing of customers	Efficiency in distribution activities to buyers and customers	y	Timeliness of delivery
				y	Average number of channel for delivering products to customers
	I P C	Management efficiency	Efficiency in planning, executing, and evaluating management activities	y	Level of A/S
				y	Whether long-term strategy is formed for a firm's goal or not
				y	Level of strategy achievement
		IP holding rate	Present conditions of intellectual properties under legal protections	y	Whether Systematic performance/compensation system is or not
				y	Number of possessed IP
				y	Average number of year of IP
		IP values	Present values of intellectual properties	y	Market values of IP
				y	Level of usage of IP
		Investment on IP	Investment on IP for its maximum usage	y	Position of responsibility division for IP (or not)
	R E L A T I O N A L C A P I T A L	Customer satisfaction	Customer satisfaction with services and products	y	Strategy formation for IP (or not)
				y	Customer loyalty
		Stability in customer relationship	Level of stability in relationship with present customers	y	Ratio of repetitive buying
				y	Customers' trust for employees
		Level of customer management	Level of support to preserve values of products, services, brand	y	Market share
				y	Average term in relationship with customers
		Brand values	Brand position in market, which acquires customer loyalty and in result makes a profit	y	Ratio of steady customers (above 5 years in relationship)
				y	New customers / loss customers
		Negotiation power against suppliers	Power of a company in transaction and negotiation with suppliers	y	Management system to support brands (or not)
				y	Number of whole responsibility with brand management
	S U C	Supplier satisfaction	Supplier satisfaction with transaction	y	Efficiency in brand management activities
				y	Customer loyalty for brands
	S O C	Corporation image	Corporation image in community	y	Market values of brands
				y	Possession ratio of valuable brands

Asymmetrical Information and Health Care Industry: A Case Study on Indian Drug Stores

Dr.P. GANESAN

Assistant Professor

Department of Management Sciences

Vellore Institute of Technology

Vellore – 632014, TN, India

pgs@vit.ac.in

Abstract

Health care systems are generally recognizing that information is an essential commodity, and the information is a key ingredient to being successful. Any absence of full information can lead to transactions that are ultimately disadvantageous for patients and physician and drugstores. An attempt is made in this study on information asymmetry with patients and drug stores with the principal component analysis of factor analysis and it was extracted 9 interpretable factors from 21 information variables that are possibly attributes the asymmetrical information. From the analysis, it is found that (a) expected role from Drug Store persons and (b) expected details about medicines purchased by the patients are the most important factors. This is because the price and the cost spent for the drugs and medicines are increasing day by day. Another important factor is related to patient “dependency” with drug stores persons and role of drug store persons in building the confidence in the minds of patients. A clear cut legal reforms on health care is required to be streamlined and right to avail the information from the agents of the health care sector viz., physicians and drug stores.

Introduction

Efficient functioning of market depends on the assumption that consumers and producers have full knowledge about product or services characteristics, available prices, and so forth. The absence of full information can lead to transactions that are ultimately disadvantageous [1] [2] [3]. Health care systems are gradually recognizing that information is an essential commodity; and that information is a key ingredient to being successful [4, p.5].

In India, Central and State governments primarily provide medical services. Certain charitable voluntary and private institutions, private individuals also provide medical services to the patients. The hospital firms in Indian economy characterized with perfect market structure, because of its one important feature viz., free flow of information between buyer and seller. In hospital industry, the physician on the one side and drug stores on the other side acts as an agents translating the demand for care by the patient into supply of services from the hospital. It is often observed that the absence of information is prevailing between all the agents of the medical services physician, drug stores and principal (patient). This nature of information asymmetry sometimes adversely affects the health and even resulted in death of the patient. A sudden loss or high cost of medication of a family head or a earning member of a family in a country like India force the family into a poverty pool.

The issue of the role of pharmacists in the greater system of health care provision is central to developing a longer-term outlook on the demand for pharmacists.

Confined to a role of dispensing medication, encroached upon by the availability of improving dispensing technologies and an expanded role of pharmacy technicians, the demand for pharmacists in the future could well decline. Given the growing evidence of drug related complications and the ability of pharmacists to anticipate and forestall many of these problems, however, a more likely scenario is that pharmacists are increasingly valued and demanded for their clinical skills and cost-effective role in the health care system [5].

Against this backdrop this paper made an attempt to study the following objectives: (a) the theoretical perspective on information asymmetry between the ‘triangle’ of the doctor – patient – drugstore; (b) to identify and examine the factor responsible for the information asymmetry and (c) the live cases due to asymmetrical information in the health care industry.

Earlier Views

Very limited analytical research studies are available on the health care and asymmetrical information. Large number of studies have concentrated on concepts and health problems [6] [7] [8] and empirical studies pertaining to health status of the people on the one hand and health care issues between inter and intra States and India on the other hand. Other set of earlier views are mainly concentrated on the customer satisfaction on health care services in general and doctor and nurse services in particular [9] [10] [11]. Only very few studies have discussed about the pharmacies’ role in

medical services and patient satisfaction. Therefore, it is found that most of the earlier Indian studies views are descriptive works and cases [12] [13] [14] rather than analytical one. The analytical studies [15] [16] are related to Western countries and not with that of the developing countries particularly India.

Methodology and tools used

The study based on the primary data. According to the convenience method of non-random sampling procedure, 65 respondents were selected. Each respondent was independently administrated with the questionnaire of 26 relevant informational variables viz., consultation, price, quality of service, drug information, etc [17]. The response are obtained on a 5 point scale ranging from strongly agree, agree, neither agree nor disagree, disagree and strongly disagree. Apart from percentage analysis and mean score, Factor analysis method is used to know which informational factors caused the information asymmetry between patient and drug stores. KMO measures of sampling adequacy test and Cronbach's alpha tests were also performed before proceeding the principal component analysis of factor analysis.

The first section of the article deals with the theoretical 'triangle' asymmetric information between doctor – patient – drugstores. Section II presents the live cases studies and in Section III presents the empirical analysis, its findings and conclusion is given.

Section I - Asymmetry in the 'Triangle'

The following figure indicates the asymmetric information between the various constituents of the 'triangle', that is., between doctor – patient – drugstores.

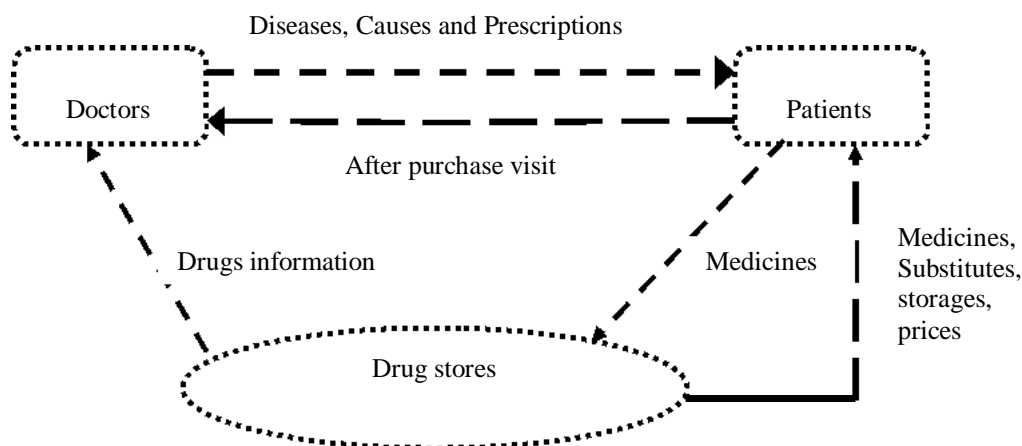

Fig. 1: Asymmetrical information between Doctor, Drugstores and Patients

The nature of information asymmetry process between the doctor – patient – drugstores would witness with regard to the services of the physician and information related to drugs from physician as well as drug stores. The absence of information has influence not only on the economics of the market situation but also the quality of physician services / products, marketing strategies of drug stores, including pricing and long-term effect on the well being of the patients, namely customer care.

Section II: Case studies

Case 1: John Hopkins using Kerala patients as guinea pigs: A major controversy over the alleged trial of a drug on unsuspecting cancer patients at a hospital by the world-famous Johns Hopkins University of the US. The drug, tetramethyl nordihydroguaiaretic acid or NDGA (M4N), was allegedly tested on 24 patients at the Regional Cancer Centre (RCC), soon after it was tested on 36 mice in the US. Reports in the local media said the drug was tried on patients suffering from head and neck tumors during 1999-2000. Several complaints have reached Chief Minister office. Also, some of the RCC doctors were planned to take matters to the court. The trial of another drug, Foscan, at the RCC has raised hackles as the Food and Drug Administration (FDA) of the US and the European committee empowered to give approval for drugs have more than once blocked clearance. A senior RCC doctor said the issue came to light "when one of the doctors in RCC found out that his patients were being used as guinea pigs for this new derivative, without his consent. "When he protested he was sidelined and he has now approached the State Human Rights Commission and the Kerala High Court for justice." "The team led by the RCC director Dr. M. Krishnan Nair instead of removing the tumors on the 24 patients as soon as they were detected, delayed the surgical intervention for varying periods to find out the efficacy of the chemical on cancer cells," he said [18].

Case 2: On Sunday, November 11, 2001, thousands of children throughout India were vaccinated against polio. The effort took a horrific turn in India where 500 children fell ill and at least nine died after a mass polio immunization campaign. Within 24 hours hundreds of children in the Indian state of Assam were taken to local hospitals and health officials report that nine children had died -- all from the same village. The BBC quoted non-governmental agencies as suggesting that the vaccines used in Assam may have been outdated. Regardless, clearly this is likely to be a setback to efforts to eradicate polio [18].

Case 3: The People's Union for Civil Liberties (PUCI) filed a complaint that the authorities in GB Pant Hospital, New Delhi, have been using contaminated, expired and damaged drugs, resulting in an increasing number of patients dying from hospital-acquired infections. The matter has been handed over to the CBI which is also probing another case related to the hospital. PUCI attributes the problem to a cover-up of purchase irregularities worth eighty-six crores of rupees [19].

Results and Discussion

The agreement level on various informational variables that explains the asymmetrical information behaviour is presented in table 1. The more than or equal to 50 per cent of the respondents agreed on the following informational attributes: (a) Pharmacy store sells toiletries, soaps etc. apart from medicines; (b) Shop person always gives me a bill for all the medicines purchased by me; (c) Check the printed prices before paying; (d) The expiry dates before using the medicines; (e) Check the information on how to store medicines; (f) Store the medicines on top of the refrigerator and out of reach to children; (g) All simple diseases like fever, pains I know which medicines to buy and use; (h) Store person always gives me the prescribed medicines and does not offer any substitute; (i) Store always has the medicines which my doctor has prescribed.

On the other hand, in the following variables the respondents expressed their disagreements level: (a) Acceptance of substitute medicines offered by the shop; (b) Does sell small quantities or in loose; (c) Buy my medicines based on the recommendations of the store person; (d) Buy the medicines from the store before going to the doctor; (e) Store person tells me alternative medicines that are available at a lower price than what is prescribed; (f) Pharmacy person always tells me how to store the medicines at home; (g) Store person always tells me the diet details to be observed while taking the medicines; (h) Pharmacy person always tells me the purpose of the medicines which have been prescribed.

The mean score and its standard deviation (Table 2) of the information variables are categorizes the variables

and respondents agreement level. It could be inferred that out of identified 26 variables, higher degree of agreement / disagreement with the mean score above 3.1 is found with 14 variables and with another 12 variables lower degree of agreement / disagreements whose mean score more than 2. The mean scores (greater than 3) of 14 variables categorically supports that the importance attached to these expected information variables by the patients from the drug stores. Though some of the variables scores are less than 3, reverse scores must be taken into account, so that it can be understood in a better way.

The extraction was based upon a varimax rotation; principal component analysis. The Bartlett's Test of Sphericity is extremely sensitive to the hypothesis that correlations within the correlation matrix are zero; even with a relatively small sample size of 65, PCA shows that we are able to reject the null hypothesis of no correlation (Chi-square (325) = 639.34, $p=0.000$). The Kaiser-Meyer-Olkin Measure of Sampling adequacy ($KMO=.512$) is less than the suggested .6 value [21] indicating that the correlation matrix may be difficult to factor. Though there is a low KMO value, 0.512 (Table 3) is within an acceptable range to proceed [22] Cronbach's alpha is an index of reliability [23] associated with the variation accounted for by the true score of the "underlying construct." The higher the score, the more reliable the generated scale is and it has indicated 0.68 to be an acceptable reliability coefficient [24].

The PCA extracted 9 factors, which attributed for the asymmetrical information between the patients and drug stores through the varimax rotation method and the extracted factors accounted 70.36 per cent (Table 4) variance and clearly indicates that above variables (26 items) are important in explaining the asymmetrical information between the drug stores and patients.

The examination of factor analysis through principal component analysis reduced the 26 items into 9 interpretable factors. Cronbach's alpha test was also performed to measure the internal consistency of each factor and it was found that out of 9 factors, 6 factors (Table 5) values are more or less equal to the suggested cutoff value of 0.70, revealing an acceptable level of reliability. The 9 interpretable factors have brought the ideas about the patient expected informational attributes with respect to drug store persons and also reflects the their own responsibility. The theory of asymmetrical information explained that agent knows full information than that of the principal and there would be adverse selection of the commodity. In this study, some of the relevant information between drug stores person and patients is shared, but certain other relevant information are communicated not upto the expected level of the patients.

A conservative criterion loading of .40 was used to determine whether individual scale items were considered for a given factor, all items did meet the criterion cut-off and considered when identifying and naming each factor.

Factor 1: Expected role from Drug Store persons dealt with information sharing on the purpose of the medicines, the diet details to be observed while taking the medicines, buying the medicines from the store before going to the doctor, storage of the medicines at home and the dosage and how to take the medicines. Higher factor scores of the scaled items, grand mean and Cornbach's alpha value signifies the variables and this scaled item explains 10.64 per cent of variance.

The expected information on expiry dates, rates or price of the medicine and interest to know the ingredients of the medicine formed as Factor 2 viz., **Expected details about medicines**. It signifies that the patients or care takers of the patients are keen in knowing the information on expiry dates of the medicines, the prices and wanted to avoid the loose purchase of the medicine. It indicates that the role of drug stores persons in providing the information about the above stated items, so that any adverse effect due to expired drugs or over priced medicines. This factor accounts 9.10 per cent of variance. The internal consistency of the scaled items (0.74) exceeded the suggested level value.

TABLE 1: LEVEL OF AGREEMENTS IN DRUG STORES INFORMATION VARIABLES

Information Variables	Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
Drug store sells toiletries, soaps etc. apart from medicines	2 (3.10)	7 (10.80)	6 (9.20)	23 (35.40)	27 (41.50)
Acceptance of substitute medicines offered by the shop	16 (24.60)	21 (32.30)	17 (26.20)	11 (16.90)	-
Drug store person always gives me a bill for all the medicines purchased by me	4 (6.20)	10 (15.40)	12 (18.50)	25 (38.50)	14 (21.50)
Does not sell small quantities or in loose	15 (23.10)	23 (35.40)	16 (24.60)	8 (12.30)	3 (4.60)
Drug store person never gives me the box, just the cut stripes or open bottles	5 (7.70)	16 (24.60)	18 (27.70)	15 (23.10)	11 (16.90)
Check the printed prices before paying	6 (9.20)	11 (16.90)	14 (21.50)	21 (32.30)	13 (20.00)
The expiry dates before using the medicines	-	5 (7.70)	5 (7.70)	17 (26.20)	38 (58.50)
Expiry date information is always seen clearly	1 (1.50)	9 (13.80)	19 (29.20)	19 (29.20)	17 (26.20)
Do not have to check the expiry dates as the store owner always checks it	17 (26.20)	15 (23.10)	13 (20.00)	10 (15.40)	10 (15.40)
Expiry dates are not clear in many cases	10 (15.40)	11 (16.90)	22 (33.80)	19 (29.20)	3 (4.60)
Rates are not clear in many cases	10 (15.40)	12 (18.50)	18 (27.70)	23 (35.40)	2 (3.10)
No information on how to store the medicines	15 (23.10)	16 (24.60)	17 (26.20)	11 (16.90)	6 (9.20)
Check the information on how to store medicines	6 (9.20)	6 (9.20)	10 (15.40)	24 (36.90)	19 (29.20)
Keep all my medicines in the refrigerator	3 (4.60)	17 (26.20)	24 (36.90)	16 (24.60)	5 (7.70)
Drug store the medicines on top of the refrigerator and out of reach to children	5 (7.70)	5 (7.70)	10 (15.40)	29 (44.60)	16 (24.60)
Buy my medicines based on the recommendations of the store person	13 (20.00)	29 (44.60)	13 (20.00)	6 (9.20)	4 (6.20)
Buy the medicines from the store before going to the doctor	24 (36.90)	17 (26.20)	13 (20.00)	8 (12.30)	3 (4.60)
All simple diseases like fever, pains I know which medicines to buy and use	3 (4.60)	14 (21.50)	12 (18.50)	18 (27.70)	18 (27.70)

(Table Contd.,)

Drug store person tells me alternative medicines that are available at a lower price than what is prescribed	13 (20.00)	24 (36.90)	9 (13.80)	16 (24.60)	3 (4.60)
Drug store person always gives me the prescribed medicines and does not offer any substitute	3 (4.60)	8 (12.30)	19 (29.20)	17 (26.20)	18 (27.70)
Drug store person always tells me the dosage and how to take the medicines	9 (13.80)	10 (15.40)	17 (26.20)	23 (35.40)	6 (9.20)
Drug store person always tells me how to store the medicines at home	13 (20.00)	22 (33.80)	20 (30.80)	5 (7.70)	5 (7.70)
Drug store person always tells me the diet details to be observed while taking the medicines	10 (15.40)	20 (30.80)	20 (30.80)	11 (16.90)	4 (6.20)
Drug store person always tells me the purpose of the medicines which have been prescribed	10 (15.40)	23 (35.40)	13 (20.00)	15 (23.10)	4 (6.20)
Drug store person always makes note of the doctor who prescribed the medicines from the prescription	10 (15.40)	10 (15.40)	18 (27.70)	21 (32.30)	6 (9.20)
Drug store always has the medicines which my doctor has prescribed	2 (3.10)	13 (20.00)	15 (23.10)	22 (33.80)	13 (20.00)

TABLE 5: FACTORS DETERMINES ASYMMETRICAL INFORMATION BETWEEN DRUG STORES AND PATIENTS

Factor	Factor Score	Grand Mean	Alpha
Factor 1: Expected role from Drug Store persons			
Drug store person always tells me the purpose of the medicines which have been prescribed	0.80	2.64	0.75
Drug store person always tells me the diet details to be observed while taking the medicines	0.68		
Buy the medicines from the store before going to the doctor	0.67		
Drug store person always tells me how to store the medicines at home	0.67		
Drug store person always tells me the dosage and how to take the medicines	0.46		
Factor 2: Expected details about medicines		2.74	0.74
Expiry dates are not clear in many cases	0.92		
Rates are not clear in many cases	0.88		
Does not sell small quantities or in loose	0.50		
Factor 3: Patients' believability		2.48	0.66
Acceptance of substitute medicines offered by the shop	0.77		
Do not have to check the expiry dates as the store owner always checks it	0.71		
Buy medicines based on the recommendations of the store person	0.65		
Factor 4: Drug persons versus company and doctor		3.05	0.54
Keep all necessary medicines in the refrigerator	0.76		
Drug store person always makes note of the doctor who prescribed the medicines from the prescription	0.59		
Factor 5: Accepting one's own responsibility		3.62	0.48
Check the information on how to store medicines	0.73		
Expiry date information is always seen clearly	0.73		
All simple diseases like fever, pains I know which medicines to buy and use	0.45		
Factor 6: Information sought and verification		3.60	0.04
Pharmacy store sells toiletries, soaps etc. apart from medicines	0.66		
Check the printed prices before paying	0.64		
No information on how to store the medicines	-0.62		
The expiry dates before using the medicines	0.51		

(Table Contd.,)

Factor 7: Right Medicine		3.54	0.62
Drug store person always gives me the prescribed medicines and does not offer any substitute	0.86		
Drug store always has the medicines which my doctor has prescribed	0.71		
Factor 8: Low priced medicine and billing		3.05	-0.81
Drug store person tells me alternative medicines that are available at a lower price than what is prescribed	-0.76		
Drug store person always gives me a bill for all the medicines purchased by me	0.73		
Factor 9: Accepting loose sales and instruction on the storage		3.44	0.37
Drug store person never gives me the box, just the cut stripes or open bottles	-0.67		
Store medicines on top of the refrigerator and out of reach to children	0.49		

Factor 1: Expected role from Drug Store persons dealt with information sharing on the purpose of the medicines, the diet details to be observed while taking the medicines, buying the medicines from the store before going to the doctor, storage of the medicines at home and the dosage and how to take the medicines. Higher factor scores of the scaled items, grand mean and Cornbach's alpha value signifies the variables and this scaled item explains 10.64 per cent of variance.

The expected information on expiry dates, rates or price of the medicine and interest to know the ingredients of the medicine formed as Factor 2 viz., **Expected details about medicines**. It signifies that the patients or care takers of the patients are keen in knowing the information on expiry dates of the medicines, the prices and wanted to avoid the loose purchase of the medicine. It indicates that the role of drug stores persons in providing the information about the above stated items, so that any adverse effect due to expired drugs or over priced medicines. This factor accounts 9.10 per cent of variance. The internal consistency of the scaled items (0.74) exceeded the suggested level value.

Factor 3: Patients' believability dealt with the patients' dependency on the drug store persons. The factor included the items like acceptance of substitute medicines offered by the shop, do not have to check the expiry dates as the store owner always checks it and buy medicines based on the recommendations of the store person.

The factor 4 reflects the drug store persons and their relationship with doctor and company. The items included under this factor are: keep all necessary medicines in the refrigerator and Store person always makes note of the doctor who prescribed the medicines from the prescription and the factor is labeled as **Drug persons versus company and doctor**. This factor attributed the variance to the level of 8 per cent.

Factor 7: Right Medicine reveals the level of confidence of the patients on the drug store persons. The scaled items viz., store person always gives me the prescribed medicines and does not offer any substitute and store always has the medicines which doctor has

prescribed categorically supports that the above mentioned factor 3. This factor reflects that the drug store persons always does his duty to the patients and not act as a self-centered person or a business motive person to achieve his goal.

The drug store person sometimes suggests the alternative medicines that are available at a lower price than what was suggested by the doctor and giving the bill for the medicines purchased is included in the factor **8: Low priced medicine and billing**.

The factor **5 (Accepting one's own responsibility)**, **6 (Information sought and verification)** and factor **9 (Accepting loose sales and instruction on the storage)** are considered as less important informational items, because of the less reliability of the data (Cornbach's alpha values are less than the suggested value).

Conclusion

From the empirical investigation it is found that the 9 interpretable factors are attributed for the asymmetry information between drug stores (agent) and patients (principal), the important factors are: (a) expected role from Drug Store persons and (b) expected details about medicines purchased by the patients. This is because the price and the cost spent for the drugs and medicines are increasing day by day. It is often noticed that the price difference between 'Generic' name of medicine and 'Brand' name is very high. Physicians have a greater role and create awareness to the patients to buy the 'Generic' form of medicines.

Another important factor is related to patient "dependency" with drug stores persons and role of drug store persons in building the confidence in the minds of patients.

The listed live cases categorically supported the factors of the asymmetrical information and its impact on the patients through contaminated drugs, ignorance, etc in the health care sector. Not only these case studies, there are many live cases which emphasizes the selling of

fake drugs through the Over the Counter sales, using contaminated drugs and injections to the patients, etc. the another common cases witnessed in Indian hospital industry especially in large hospital, superspeciality and multispeciality are that the physicians or consultants and the hospital administration are forced the patients and / or care takers to buy the medicines with their own drug stores.

The most common features is that for the top 10 diseases like head ache, fever, dry cough, body pain, the patients who affected just walk into the drug stores and purchase the medicine from the drug stores without doctor prescriptions. The other occasions, the chronic diseased people normally purchase the medicine based on used medicine strips, not even with the prescription sheet of the physicians.

Under the above circumstances, the role of drug store persons is vital. It was stated in Canadian Newswire Services [25] that Pharmacists, as the most accessible of the primary health care providers, have a wealth of information and expertise to share. Pharmacists also offer solutions to some of the challenges facing the health care system Through one-on-one consultation with their patients, pharmacists can change these staggering numbers. Thus, this literature supports the study's importance in a developing countries in general and India in particular.

A clear cut legal reforms on health care is required to be streamlined and right to avail the information from the agents of the health care sector viz., physicians and drug stores.

Limitations and Future Research

The major limitation of the present study is related to the sample size. It is also evident from the analysis and the test statistics like Kaiser-Meyer-Olkin Measure of Sampling Adequacy and Cronbach's alpha. The application Structural Equation Modelling (SEM) would give much better understand of the variables under study and that could be the second limitation of the study. However, this study provides an empirical and theoretical idea related to the principal – agent communication gap or information asymmetry and adverse effect in the health care industry.

The author suggested the following areas for further research: first investigation on price of the generic and branded medicines, use of expired and spurious drugs or medicines and its adverse effect on family. Secondly, an indepth study with respect to doctor and drug stores and their communication process with patient by taking into consideration of all relevant information attributes is need of the hour.

Abstract

Budget allocation to competing projects is an age-old problem in any organisation. Due to funding cuts and other socio-economic priorities budget allocation in public sectors is even more difficult where the norm now a days seems to be doing more for less. Traditional approaches to budget allocation are therefore inadequate to address the myriads of problems. This paper presents a new computer based group decision support system (GDSS) and process for budget allocation. The system called ALLOCATE and the group decision support process called Decision Conferencing for budget allocation are described in details. Their application in the Horticulture program of the Department of Agriculture WA is then presented. The results indicate that the process and system of budget allocation is integrated nicely and new insights are thus generated which lead to effective budget allocation.

Keywords: Group decision support, decision conferencing, budget allocation, resource allocation.

1. Introduction

In recent years, as budgets tighten in all levels of government, the Department of Agriculture Western Australia (DAWA) has had to face the challenge of achieving its goal under increasingly tight budget conditions. Moreover, as there is now increased emphasis on accountability and transparency and the application of competition principles in public sector business activities the agency is in fact under pressure to do more with less. Given its vital role as a leader in agricultural research, development and extension activities for the benefit of all Western Australians, it is important therefore for the

agency to identify those R&D and extension projects which should receive funding priorities for efficient allocation of its limited budget. To identify such projects it is essential to develop and apply a methodological framework consistent with the mission and objectives of the agency by analysing and providing a maximum possible information to the decision makers.

At present the process and criteria applied in the allocation of budget in DAWA are as follows (Agriculture Western Australia, 1997). The agency's budget working group rely on several assessment criteria. Industry program managers (PM) are informed about these criteria and judgments about desirable funds allocation. In formulating such judgments the PMs are provided with some key questions to justify their budget bid. The questions are mainly related to the issues of market failure, competitive advantage, government's commitments, agency's objectives, contribution to the State's economy, and productivity gains.

Based on responses to these questions and on several discussions with the PMs two broad principles are used by the working group in recommending budget allocation. The principles are *precedence* and *strategic merits*.

In the principle of precedence, the previous year's budget allocation is used as a guide for the current allocation. In the principle of strategic merit the PMs' budget bids are assessed to ensure that they are consistent with the strategic plan of each program and are consistent with the agency's broad strategic directions. However, wherever necessary strategic merit is supported or restricted by the consideration of: (a) legislative, contractual, and tied obligations; (b) community services obligations; (c) ministerial imperatives; and (d) equity issues.

Although rigorous in process, the current practice does not consider the competitive budget bids in an objective manner with respect to multiple criteria and multiple stakeholders in a participative environment. This paper presents a budget allocation process which addresses this gap. Our process considers multiple conflicting criteria of agency and program in an explicit way via an interactive computer based system called ALLOCATE. It also allocates the budget with respect to various wants and demands of the multiple stakeholders following a structured group decision process called Decision Conferencing (Quaddus *et al.* 1992; Quaddus and Siddique, 2001). We apply this process of budget allocation in the Horticulture Program of the Department of Agriculture Western Australia.

In the next several sections we first describe the ALLOCATE model. The group decision process called Decision Conferencing for the Horticulture program is then described which uses the ALLOCATE system as the backbone. The results of budget allocation in the Horticulture program are presented next. Finally, conclusions are presented.

2. The ALLOCATE Model

The ALLOCATE model is essentially a Multiple Attribute Decision Modelling (MADM) type benefit-cost model (Hwang and Yoon, 1981). It emphasizes a widely known process, called Decision Conferencing (Quaddus *et al.* 1992; Quaddus and Siddique, 2001) to develop the model structure. ALLOCATE uses a hierarchical structure to develop the model by interacting with the DMs. Although hierarchical structure is most popular in MADM, there is a general lack of agreement on the exact form of hierarchical representation in the MADM literature (Belton, 1985, 1990). Figure 1 shows the hierarchical structure used in the ALLOCATE model.

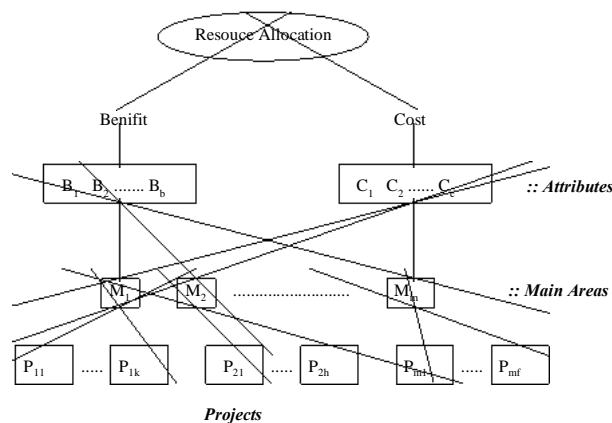

Figure 1. Hierarchical Structure of the ALLOCATE Model.

It is observed from Figure 1 that the global attributes of the ALLOCATE model are benefit and cost, which are then sub-categorised into specific benefit and cost type attributes. The projects are grouped into various main areas. Depending on the problem domain these main areas could be manufacturing, human resources etc. ALLOCATE uses a simple value elicitation approach. It also uses a simple additive model of MADM. Mathematical model of the above hierarchical structure is as follows:

$$\text{Maximise}[\text{Satisfaction}\{V_i(\bar{B}), V_i(\bar{C})\}]$$

$$i \in p$$

$$\text{Subject to } V_i(\bar{B}) = \sum_B W_{MB} W_{B^j}^P P_{iM}^B$$

$$V_i(\bar{C}) = \sum_C W_{MC} W_{C^j}^P P_{iM}^C$$

Where, p = number of projects
 $B \subset \bar{B}$ = set of benefits attributes

$C \subset \bar{C}$ = set of costs attributes (one of which is the \$cost)

$M \subset \bar{M}$ = set of main areas

$V_i(\cdot)$ = additive value function for project i

W_j = normalised swing weight of attribute j (benefit or cost)

W_{Mj} = normalised swing weight of the main area M with respect to the attribute j (benefit or cost); and

P_{iM}^j = preference score for project i w. r. t. attribute j within the main area M

It is observed from the above model that Decision Maker's (DM's) "satisfaction" with respect to the benefit and cost values is maximized over all the projects. This is done by displaying the efficient frontier and extensively interacting with the participating DMs. It is also noted that the value functions are additive in nature. Stepwise procedure of the ALLOCATE system of resource allocation is as follows:

Step 1. Problem structuring:

The ALLOCATE tree is developed.

Step 2. Project preference scoring:

P_{iM}^j scores are obtained by interacting with the stakeholders.

Step 3. Determining the weights W_{Mj} :

These are called "within" weights, i.e. within each of the benefit or cost criterion j . Found by interacting with the stakeholders.

Step 4. Determining the weights W_j :

These are called "between" weights, i.e. between the criteria j (benefit or cost). Found by interacting with the stakeholders.

Step 5. Finding the satisfactory solution:

The efficient frontier is explored in an interactive way. Both graphical and text displays are used as required.

2.1 The Decision Conference for Budget Allocation

Decision Conferencing (DC) is characterised by a problem solving environment which recognises that it is always a top level *group* in the organisation that makes decisions based on judgment – in particular uncertainty, preference, and trade-off (Phillips, 1989; Quaddus *et al.* 1992). As budget allocation must deal with uncertainty, preferences of the stakeholders and trade-off, DC is an appropriate process in this domain. In DC, the owners of the budget allocation problem participate in a single day problem-solving session that features on the spot computer modelling, aided by a facilitator and an analyst. The analyst uses a computer and appropriate software to build models and capture information. In the budget allocation process for the Horticulture program the ALLOCATE software is used. The facilitator works directly with the group to help it to structure and focus discussions, to think creatively about the problem, and to address the full range of issues involved. Information technology supports the activities of the DC by enhancing the efficiency of information flow and transfer.

Although every decision conference is different, the process consists of some common broad stages. These are: (i) structuring the problem; (ii) assessing the parameter; (iii) running the sensitivity analyses; and (iv) planning the implementation (Phillips, 1989). The decision conference for the budget allocation process was carried out as detailed below. It is noted that another software called EXPERT CHOICE was used primarily for benefit assessment (Expert Choice Inc., 1995).

Pre-conference Stage

- (i) Identify the stakeholder group from the Horticulture program.
- (ii) Identify the projects for budget allocation.
- (iii) Collect data via survey to assess project benefit; and

- (iv) Assess the project benefits by EXPERT CHOICE software, for each individual stakeholder and also for the group.

Decision Conference

- (i) Revisit the group benefit assessment by survey and fine tune the pairwise comparison data in a face-to-face environment.
- (ii) Recalculate the project benefit for the group and perform a range of sensitivity analyses.
- (iii) Find the final benefit ranking for the projects to be used in the ALLOCATE model.
- (iv) Populate the ALLOCATE system with cost and benefit data as obtained from above; and
- (v) Allocate budget as suggested by the system and as chosen by the group. Perform sensitivity analyses to achieve the final budget allocation.

3. Results of Budget Allocation

This section presents results of budget allocation exercise for projects in the Horticulture program of the Department of Agriculture WA. Both the pre-conference and the decision conference stages are described in details. It is noted that the pre-conference stage was dominated by the questionnaire-based survey to collect relevant data to assess the project benefits. The decision conference stage then fine tuned this data and dealt with the actual budget allocation in a group environment.

3.1 Assessment of Benefit

To assess the project benefits, a hierarchy of objectives has been developed from various Horticulture documents. Figure 2 shows this hierarchy. Level 1 of the hierarchy contains the program goal, which is: “A profitable, sustainable and growing industry supplying safe quality products to domestic and world markets”. To attain this goal the Horticulture Program has to achieve a number of specific objectives, which are shown in level 2.

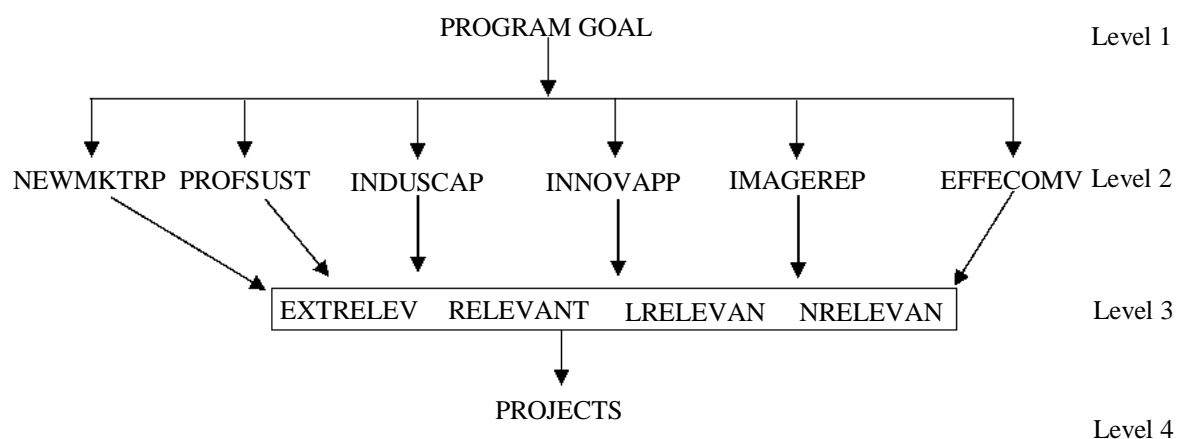

Figure 2. The horticulture program hierarchy of objectives.

Level 3 of the hierarchy provides the intensities (in terms of *extremely relevant*, *relevant*, etc.) that have been used to evaluate the degree of relevance of the various projects in achieving the program objectives. Level 4 shows the actual projects (25 of them).

Two questionnaires were developed based on the above hierarchy: (i) to **assess the importance or priority weights** of the objectives at level 2 and the intensities at level 3 of the hierarchy; and (ii) to **rank the projects** based on the degree of relevance of each project with respect to the objectives of level 2. The questionnaires were distributed to all the relevant stakeholders of the Horticulture program with detailed instructions to fill them up. Five responses were received by the deadline.

Table 1 presents comparative results of the **relative priority** of the objectives based on the survey, which have been obtained by using the software EXPERT CHOICE. All these values are in between zero and one (0 – 1). The first five columns present the individual responses. The second last column presents the average of the five responses. It is observed that the individual responses vary widely, which is expected. Last row of Table 1 shows the inconsistency ratio of assessment. This ratio indicates the degree of inconsistencies of each respondent in the pairwise assessment of the objectives. In general, if an object A is preferred to B, and B is preferred to C, then one should prefer A to C. Any violation of this indicates inconsistency. EXPERT CHOICE provides a measure of the level of inconsistency in the assessment. One should always expect some level of inconsistency in his/her assessments. But this must be less than 0.1. It is observed from Table 1 that all the inconsistency ratios are less than 0.1. However, respondent 3 has an inconsistency ratio of 0, which is unusual! The relative priority of this respondent is also doubtful! The last column, called Group, will be addressed later.

Table 2 presents the ratings of the projects as obtained from the survey. All the values in this table are in between zero and one (0–1). Note that these ratings indicate the relevance of the projects with respect to the objectives of Table 1 (see also at level 2 in Figure 2 above). As before the ratings by different individuals vary

widely. The second last column also shows the average of the five respondents.

3.2 Re-assessment in Decision Conference

The entire assessment process of the hierarchy of Figure 2 was revisited during the decision conference. A group of seven stakeholders participated in the decision conference. Since the group had already gone through the assessment via survey they were more focussed in revising/fine-tuning the assessments. Considerable time was devoted in this part of the decision conference. The group debated various issues, which primarily dominated by the meaning of various objectives of Figure 2. Sometimes the group struggled for meaning and assessment of some objectives. After much discussion the group came up with the required assessment. The last column in Table 1 shows the group consensus assessment for the objectives. Note that the group decided to give a very low priority for the EFFECINV (i.e. to maximise effectiveness of program investment) objective. The group rating of projects is shown in the last column of Table 2. Note that the group ratings are quite different from any other ratings. In fact, the group moved up the ratings of many projects during the assessment process.

The group rating of Table 2 (last column) was used as the assessment of benefits of the projects in the next phase of the decision conference, ie budget allocation. However, before moving on to the next phase some sensitivity analysis of the projects ratings were done. In order to do that the top eight projects from Table 2 (group column) were chosen. Figure 3 shows one such sensitivity graph. It shows the sensitivity of PROFSUST objective (highest group priority) with respect to the eight projects. With its current priority of 0.301 the HAS project (Develop low input wine...) is rated first. If this priority is decreased, there is no change in the rating, unless it becomes less than 0.15 (approximately). However, if it is increased beyond 0.375 a new project (HGD Developing the Cotton Ind ...) is rated first. Therefore, for PROFSUST objective there is a range of 0.15 to 0.375 between which the ratings of the projects do not change. This is a very valuable information. Sensitivity analysis, like this, can be done for all the objectives.

Table 1. Relative priority of the objectives

Objectives	1	2	3	4	5	Ave 1-5	Group
NEWMKTRP	0.238	0.277	0.200	0.086	0.117	0.180	0.194
PROFSUST	0.179	0.266	0.200	0.430	0.233	0.272	0.301

3.3 Budget Allocation

The budget allocation process began during the second half of the decision conference. The ALLOCATE software was used for budget allocation. Budget allocation model needs the dollar value of cost and benefit of each project. The group rating of the projects (last column of Table 2) was taken as the benefits of the projects and actual value of cost was taken from the Horticulture program log frame summaries. The ALLOCATE system was populated with these costs and benefits data. Various displays were then presented to the group for discussions, comments and changes, if necessary.

The group was specially alerted of the fact that for some projects the cost is extremely high compared to the benefit. The group was then presented with the “order of buy” display from the ALLOCATE software, which is shown in Figure 4.

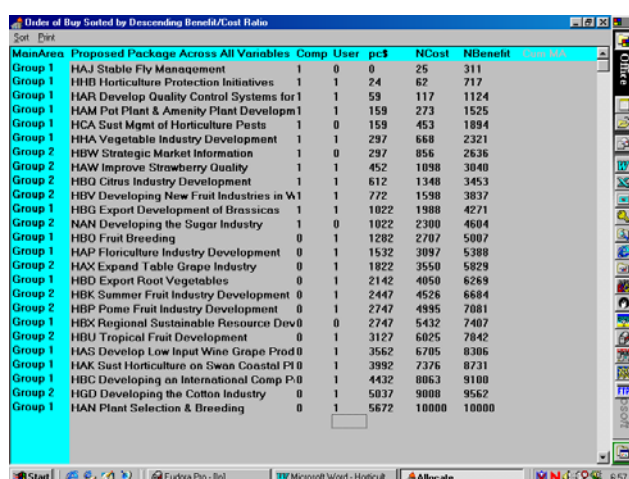

Figure 4. The order of buy.

Figure 4 is an important display. The first column shows two groups of projects, which were arbitrarily created to keep the list of projects manageable within each group. The column “Comp” presents the computer

chosen projects, where the relative benefit is more than the relative cost. The next column “User” presents an opportunity for the group to select any project they like. In this case, the group chose to select the top 20 highest benefit projects. Next column shows the total \$cost for these 20 projects, which is \$5.672 million. Note that total cost to do all the projects is \$6.403 million. The last two columns show the normalised total cost and total benefit (normalised to sum to 10000). Normalisation is done by converting both costs and benefits into a common unit of measurement. These normalised values are needed for equitable comparisons. Using this “order of buy” table the group can make the ultimate decision for project selection and budget allocation. The group can use the model prescribed projects as guide for ultimate selection of projects due to other political and non-quantifiable reasons.

After selecting the 20 top projects from Figure 4 the group was provided with the efficient graph as shown in Figure 5. This graph shows how good is the user chosen package of projects. Each dot in the figure represents a package of projects which can be displayed by clicking the corresponding dot. The dotted line running from the bottom left hand corner to the top right hand corner represents the efficient line. Any dot below this line represents an inefficient package of projects. For example, the group-selected package of projects in Figure 4 is shown by the 3rd top dot in Figure 5, which is below the dotted line. This package is inefficient as we can move up towards the dotted line and choose a package which costs the same but gives more benefit (e.g. second dot from top). Or we can move left and choose a package which will give the same benefit but will cost less (e.g. 5th dot from top).

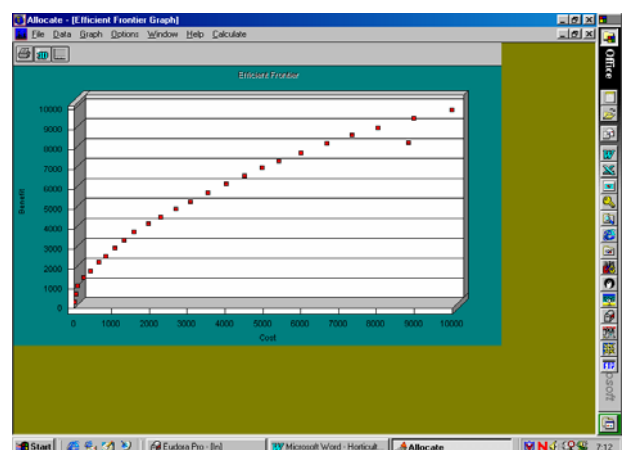

Figure 5. The efficient graph of projects.

The group can move between Figures 4 and 5 a number of times until they are completely satisfied.

In this decision conference the group investigated a number of project packages including the top five projects (fell in the efficient line), the bottom five projects (fell in the inefficient region), and the middle

five projects (fell in the inefficient region). This was an eye opener for the group. The group then wanted to populate the ALLOCATE software with the average 1-5 benefits from Table 2. This was done and results similar to above were obtained, although the project packages were different.

The decision conference was concluded with further discussions on how the EXPERT CHOICE and LLOCATE system can be used effectively for future budget allocation in the horticulture program.

4. Conclusions

This paper presents a process of budget allocation in the Horticulture program of the Department of Agriculture WA. Based on the notion of Decision Conference the process uses an ALLOCATE model for the budget allocation. The ALLOCATE model and the Decision Conference process for budget allocation is described in details.

The Decision Conferencing approach to budget allocation offers a number of benefits to the Horticulture Program. The ALLOCATE model prescribes an efficient allocation of the budget. The budget allocation will thus provide an insight into the Horticulture projects and can be used as a vehicle for any future negotiation with the Government for funding. The ALLOCATION model offers different scenarios of efficient projects and the corresponding budget, which can be used for forward planning and negotiation with the external agencies.

Abstract

As the issue of information security becomes increasingly important, high-level management security awareness on operation of organizational information security activities is a significant factor in success. Hence, the aim of this research is to explore how the organizational information security activities are being influenced by high-level management security awareness, and to use information security standard BS7799 to evaluate the execution phase of organizational information security. Combining literature research, case study and the main security codes of BS7799, this paper proposes a conceptual model of high-level management security awareness, organizational information security activities and organizational information security standard in relation to each other. In our conclusion, we discovered that the higher the high-level management security awareness cognizance about industry risks, the implementation of security measures and the threats to organizational security not only facilitate the four information security activities of deterrence, prevention, detection and recovery, they also enhance the standard of organizational information security. In practice, the conclusion of this paper hopes to remind high-level management to be aware of the threats of human factors and also to strengthen risk evaluation and deterrence activity.

Keywords : Information security, safety awareness, BS7799, case study.

(I) Introduction

The trend in the introduction of information security is reaching the mature stage overseas, but it is just at the starting stage within the country. In recent years, the rapid change in computer virus variety, the invasions by unavoidable hackers, the event of the 9/11 terrorist attack and the inferno at the Eastern Science-based Park altogether induced domestic security awareness. Nonetheless, Baskerville & Stage (1996) mentioned that information security management was an important but often ignored issue, and it was often restricted by the discussion of the information technology development

viewpoint and was rarely discussed through the management viewpoint.

BS7799 stated that one of the significant success factors in information security introduction was the support by high-level management, but there are not many high-level managers in Taiwan corporations who really understand information security, and people within the industry are biased toward sales and not on resolving projects; these are the obstacles to the information security environment. High-level managers usually do not have sufficient cognizance about information security, although they do spend a lot of money and manpower to purchase related security products like fire-prevention walls, invasion detection, computer virus protection, but they do not effectively resolve a variety of security loopholes and threats of hacker invasion. Consequently, high-level management's security awareness can influence the implementation of information security activities within the whole organization.

The full name for 「BS7799」 is 「BS7799 Code of Practice for Information Security」. It was proposed by a U.K. standard institution called BSI in 1995 and is currently the most well known security standard internationally. BS7799 is a set of fairly complex information security application and provides a complete set of policies, procedures, implementations and organizational structures as a reasonable safeguard to corporations in order to reach their corporation goals as well as to avoid, detect or correct the aftermath of unanticipated events. To combine all above mentioned points, the main aims of this research are as follows :

1. To understand what is the current security awareness of high-level management in high technology industry and how high-level management's security awareness influences the implementation of the four types of information security activities, deterrence, prevention, detection and recovery.

2. Through the use of BS7799-2 : 1999 to proceed with analysis of differences in the execution phase of information security and to understand the deficiencies in information security activities within the current high technology industry.

3. To propose a set of conceptual models to assist high technology industry in conducting information security activities.

(II) Literature Research

(i) High-management security awareness

Atreyi et al. [1] stated that although information security was becoming an important management issue, the industry did not attach importance to this in practice. Management's concern in information security was always lower than other issues (Brancheau, Janz & Wetherbe, 1996; Olnes, 1994). Verton (2002) did survey 459 CIO's and IT managers of medium and large corporations comprehensively about information security and discovered that less than 50% of their employees had IT security education and training within the company, indicating that high-level management in medium and large corporations attached low importance to information security. In addition, Zviran & Haga (1999) pointed out that high-level management did not give sufficient concern to information security, which could lead to serious invasion of information systems. The lack of concern by high-level management to information security might even influence the establishment of a corporation.

Goodhue & Straub [2] were the first researchers to apply the satisfaction level theory to cognizance of information security and proposed that the organizational environment, information system environment and individual characteristics could influence users to pay attention to the importance of security. Straub & Welke [3] improved Goodhue & Straub's Security Concern Model to become industry risk, risk reduction in security control measures and individual factors, which could influence high-level management's cognizance regarding information security.

Drawing 1 : High-level management Security Concern Model

(ii) Organizational Information Security Activity

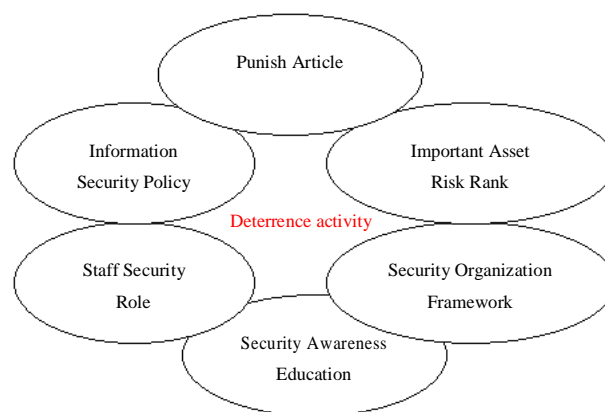

Based on the General Deterrence Theory, scholars (Forcht 1994; Martin 1973; Parker 1981) proposed four different types of sequential security activities, which

could reduce information systemic risk. These four activities are : deterrence, prevention, detection and recovery.

Blumstein et al. (1978) wrote that the deterrence theory provided disincentives or restricted the occurrence of abnormal behaviors and also provided restrictions by deterring potential perpetrators. Furthermore, Straub and his research partners successfully applied deterrence theory to informational system environment. Straub (1998) mentioned that information security activities could deter potential computer hackers who stealthily or overtly violate organizational policies.

Respective explanations of these four activities are as follows :

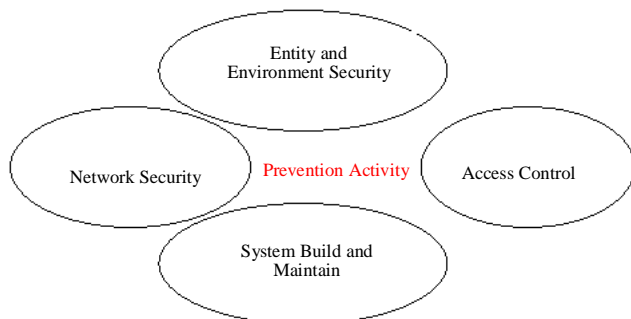

1. Deterrence activity : Blumstein et al. (1978) wrote that deterrence activity might cause potential hackers to understand the risk of penalty. Parker (1981, 1983) pointed out that deterrence activity should include : security policy and clauses to reduce the invasion by white-collar people. Dunn (1982) also mentioned that deterrence activity should clearly explain how to use information system legally and to reduce potential hackers' perpetration motives. Straub (1990) stated that deterrence activity in practice should include : input of security man-power and time, reasonable system usage guidelines and clauses for system usage. Straub (1988) also wrote that security awareness education was a type of deterrence activity. The following drawing partially summarizes the above-mentioned details:

Drawing 2 : Deterrence Activity (sorted by this research)

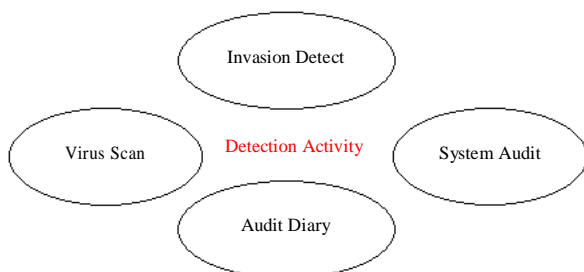

2. Prevention Activity : Gopal & Sander (1992, 1997) wrote that prevention activity was mainly a proactive security control measure, including implementation of information security policy and prevention of invasion or intentional abusive usage by unauthorized people. Hsaio et al. (1979) stated that prevention activity should include : physical security and security software (e.g. password protection). Straub (1998) also mentioned that implementing door control system and password saving

and extraction control system for the computer room was also considered as prevention activity. Atreyi et al. [1] believed that operating system and database management including security functions and even the use of special security software could all prevent the risk information system from being invaded. The prevention activity can be categorized into the following parts :

Drawing 3 : Prevention Activity (sorted by this research)

3. Detection Activity : Detection activity is mainly for collection of invasion records and also to identify potential perpetrators. Straub & Nance (1987) wrote that only few invasion events were discovered by a pre-emptive type of detection activity because detection activity was more like fishing expeditions and could not successfully lock in on a target. However, Nance & Straub [10] also stated that relying only on two activities of deterrence and prevention could not totally avoid the occurrence of invasion events, organization also required detection activity to detect invasion before its occurrence. Straub (1998) indicated that detection activity could include two types : a pre-emptive type of security response and a reactive type of security response. The pre-emptive type of security response is to detect potential problems (risks) preemptively prior to their occurrences, examples of pre-emptive detection are invasion detection reports, system auditing, virus scan reports. Reactive type of security response is to proceed with detection through security invasion records after the event. The following is a brief summary of detection activity :

Drawing 4 : Detection Activity (sorted by this research)

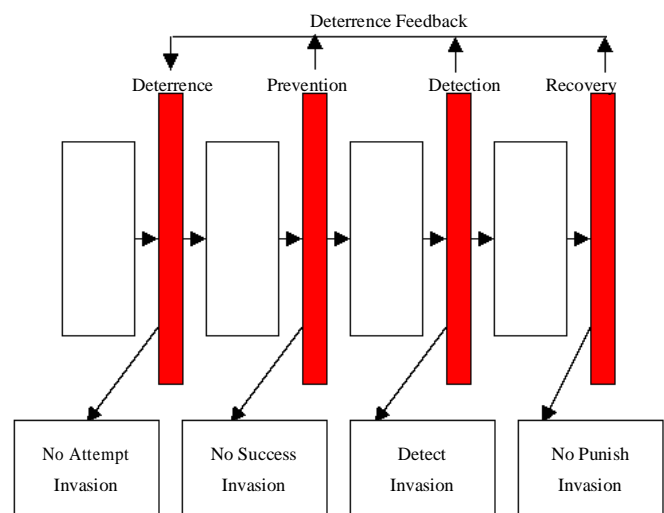

4. Recovery Activity : Straub (1998) stated that the majority of top-managers were rarely concerned about how to recover after security was invaded and the system

was damaged leading to unsalvageable corporation loss. In fact, other than deterrence, prevention and detection, effective security procedures needs to include recovery activity to reduce damages caused by invasion activity so that corporations can recover their operations at the shortest time period and also to punish perpetrators. Recovery activity is summarized below :

Drawing 5 : Recovery activity (sorted by this research)

According to deterrence theory, Straub (1998) stated that the combination of these four security activities could have continuous future deterrence effects. The integration of these four activities is as follows :

Drawing 6 : The process of four security activities (sorted by this research)

(iii) Evaluation of Information Security Execution

NIST in the U.S. announced the self-evaluation guide on the information security management system in 2001 and requested using the Risk Based Decision Mode as a basis for secrecy, wholeness, undeniability, regularity and usability of the information industry for self-evaluation. In our country, "the Electronic Information Management

Center within the Directorate General of Budget Accounting and Statistic Executive Yuan, R.O.C.” also announced “self-evaluation form for external auditing on information security” to assist corporations in understanding the facts in executing information security management system and can be used as a reference for improvement.

BS7799 includes two parts, Part 1 : Practical criteria for information security management and Part 2 : Standard for information security management system. Because BS7799 Part 2 explained in detail the requirement for establishment, implementation and maintenance of information security system, pointed out that organizations need to follow one type of risk evaluation for the most appropriate control items, and also used the appropriate control items for their own needs, we will use BS 7799-2 to analyze the differences in the execution phase of information security in order to understand an individual company's current information security execution level.

Drawing 7 : 10 main points and goals of BS7799
(sorted by this research)

(III) Conceptual Model and Research Method

(i) Conceptual model

Similar to the literature research discussed previously, Straub (1998) stated that if organizations implemented those four security activities, they could effectively deter potential hackers and reduce invasion risks for organizations. In addition, Straub (1998) also mentioned that if high-level management executed these four security activities, this would effectively reduce systemic risk. Hence, the level of high-level management cognizance and security awareness about industry risk, security control measures and threats to an organizational can influence the execution of information security activities and can even influence organizational information security standard. R.Von Solms et al. [6] also wrote that through BS7799, high-level management could evaluate the information security execution phase to adjust the deficiencies in organizational information security activities in order to meet legal standards,

industry standards, customer requirements, supplier requirements and the requirements of anyone who is related to corporation profits. Through literature research, we proposed a conceptual model to evaluate high-level management security awareness, organizational information security activities and organizational information security execution.

Drawing 8 : This research paper's conceptual model

As indicated in drawing 8, Straub (1998) mentioned that high-level management's security awareness and cognizance about industry risk, implementation of security measures and threats to organizational security could lead to differences in organizational activities of deterrence, prevention, detection and recovery. Consequently, we believe that high-level management security awareness affects organizational information security activities. Solms & Haar (1994) wrote that organizational information security control measures could use international security evaluation standards to understand the execution level of organizational information security. Because BS7799 is an internationally well known security standard, we believe that BS7799-2 : 1999 can be used on organizations' deterrence, prevention, detection and recovery activities to proceed with the differential analysis on information security execution phase and to understand the differences between an organizations' four information security activities and the basic standard.

(ii) Creation of Assumptions

Through the modification of variables in the conceptual model, various assumptions were made in this research. Assumptions are categorized into two main parts : The first part is assumption between the relation of high-level management's security awareness and organizational information security activities. The second part is assumption between the relation of organizational information security activities and evaluation of information security execution phase.

Assumption 1 : When high-level management's understanding is higher with respect to the cognizance on industry risk, implementation of security measures and threats to organizational security, organizations can do better on the four information security activities of deterrence, prevention, detection and recovery.

Assumption 2 : When high-level management is being influenced by other external factors, they cannot do as well for those four information security activities.

Assumption 3 : Organizations pay more attention to prevention activities than other activities of deterrence, detection and recovery.

Assumption 4 : As organizations' information security activities of deterrence, prevention, detection and recovery are being actually executed, they can better conform to the information security standard of BS7799-2 : 1999.

(iii) Research Method

This research paper uses various case studies to solve research problems, mainly directed to : factors that influence high-level management security awareness(Why), how high-level management security awareness affect the c of organizational information security activities(How) and investigation about what is used to evaluate organizational information security execution phase(What). Further analysis through interviews and other literature are conducted to investigate the execution phase of information security in the current high technology industry.

Case study is a form of empirical inquiry for investigation, Yin (1994) wrote that when research objects and actual situations were not very distinctive, using case study to solve "How" and "Why" types of research problems and through multi-varied evidence sources could emphasize the object events for research purposes. Because case study conforms to our research aim, we will use case study to solve research problems.

(IV) Analysis Individual Cases

I Individual case findings

Our method to choose cases is as follows : 1.Choose higher information density within high technology industries; 2. Industry members who agree to accommodate us by having interview visits. Data collected conforms to points raised by Yin(1994) : (1) Using multi-varied evidence sources with two or more sources to obtain evidence; (2) Establish a database for individual cases to formally assemble together all the collected data from interview visits; (3) Connect all relevant evidences and connect research problems, data from interview visits and verified conclusions together.

Table 1 : Basic data for individual cases

Individual Case Name	Industry	capitalis_ation	Overseas Subsidiary Location	Staffs population	Execution IS Initial Time	co-opera tive enterprise
X Company	Informat_ion	700 million	USA .	1300 .	1979/8	Trend Symantec Sysware
Y Company	Photoele_ctic Tec_ hnology	680 million	China .	1100 .	1999	Trend An Yi Accounting Services Company

This research paper analyzed the interview results of system development engineers from Company X and the MIS departmental head of c Y as well as these two companies' information, together with other information security management literature were analyzed. The conclusions of analysis are discussed below.

(i)The Security Awareness of High-level Management

Comparison was conducted based on "cognizance of industry risk", "security measured implemented" and "threats to organizational security" (shown in Table 2), it was discovered that high-level management's security awareness performance from Company X is not only affected by security events within the same industry, this company also pays attention to the importance of human factor threats; although the organization does not conduct risk evaluation, this company has an IT background, so it believes that it is more likely to be influenced by mainframe computer loopholes and copyright issues, hence the security measures are biased toward the technological side. The security awareness of high-level management within Company Y is not influenced by events within the same industry, it would strengthen security phase only through client requests. Because high-level managers do not have IT backgrounds, they need to be informed by employees from lower levels to know basically that the organization is affected by copyright issues, hacker invasions and other human and non-human factors. When faced with security problems, they should authorize lower level employees to solve problems, hence this company is also biased toward the technological side. In comparison, the security awareness of high-level management from Company X is higher than those from Company Y; furthermore, security awareness is higher if high-level management have IT backgrounds.

Table 2 : Comparison of security awareness between high-level management in individual cases

High-Level Management awareness		X Company	Y Company
	Industry Risk	affected within the same industry, enhance deterrence activity	affected without the same industry, within the customer
	Security Control Measures	biased toward the technological side	biased toward the technological side
	Organizational Security Menace	mainframe computer loopholes and copyright issues, and no risk estimate	copyright issues and hacker invasion, and no risk estimate

In addition, other factors of organizational information security goals, security behavior, serious information security events, security event reports and high-level management's managing methods can be used to understand high-level management's level of security awareness (shown in table 3). For example, high-level management in Company X believes that security is mainly for maintenance of normal organizational operation system, when security events occur managers not only are management involved in managing the event, they also proactively teach employees about the importance of security so they adjust information security

activities based on their experience of previous serious security events. In contrast, although high-level managers in Company Y also believe that the goal of the company's information security is to maintain normal operation of the system and procedures, they normally authorize lower level employees to manage serious security events when they occur, so their support for information security is more passive and their security activities will also be influenced by previous serious security events that occurred. Hence, the other factors listed in the table below can further strengthen the support that high-level management's security awareness in Company X to be higher than that of Company Y.

Table 3 : Comparison of other security awareness factors in individual cases.

	X Company	Y Company
security goals	maintenance of normal operation system	maintain operation of the system and procedures
security behavior	positive attitude	passive attitude
serious IS events	hacker invasion	virus invasion
after events action	prevention and detection	enhance prevention
security event reports and managing methods	management involve	management authorize

(ii) Organizational Information Security Activities

X and Y Companies' information security activities are shown in table 4. Although Company X's deterrence activity does not have a uniform information security policy, its policy does include some provisions about information security and employees understand their own responsibilities in security. Even though there are no information security experts to assist the drive of information security activities, high-level management actively participate in the policy formulation on information security and also regularly educate and train employees on information security. This induces the organization to conduct deterrence activity, indicating that this company pays attention to the importance of information security and can deter intentional or unintentional hackers. In contrast, although there is a uniform information security policy in Company Y, high-level managers only orally support this issue and do not personally drive the matter; the information security education is conducted irregularly depending on the volume of sales. In addition, there is no clear strict penalties in penalty clauses, so their overall performance in deterrence activity is passable.

With respect to prevention activity, although Company X does not have suitable documentation, because high-level managers have IT experience and there are more information technology personnel in the organization, this company tends to apply self-management of information security protection, maintenance or correct versioned security software purchase in the areas of physical security, internet security, saving and extraction control, virus protection

and system development, so its prevention level is very good. In contrast, Company Y has suitable documentation, but because high-level managers do not have IT experience and there are few information technology personnel in the organization, the physical security, Internet security, saving and extraction control and system development tend to be outsourced. The IT personnel only need to conduct simple information security maintenance and management. Hence, the overall performance of Company Y is passable.

Table 4 : Comparison of information security activities between individual cases.

	X Company	Y Company
Deterrence Activity	achieve expect security experts, risk analysis ,policy formulation ,management actively participate	achieve expect security experts, risk analysis, irregularly depending management passively participate
Prevention Activity	have quite level except suitable documentation	although have suitable documentation, but not have quite level
Detection Activity	no detection unit each team member to detect, have inner and outer auditors full use daily	no detection unit have inner and outer auditors few use daily
Recovery Activity	security limit is lower : strict penalties continuous procedures	no security limit no strict penalties procedures irregularly

Regarding the detection activity, although Company X does not have a security detection unit, each team member within the organization does his/her best to detect the existence of any undiscovered security invasion and even uses abnormalities reported in auditing diary to find relevant security events. Company auditors will regularly audit to find out whether the company complies with security environment and security measures; and clients will come unannounced to audit the use of working capital by the company. Hence, the overall performance of detection activity in Company X is clearly better. There is no security detection unit in Company Y as well, but invasions are often discovered only after the event. Although there is a security diary to report abnormal security events, it is rarely inspected and reviewed to determine whether any abnormal events are occurring. Because the internal and external auditors in this company are not very familiar with IT, complete and effective audits cannot be achieved. Consequently, the overall performance of detection activity is very poor for Company Y.

Regarding the last activity of recovery, the specified information security limit is lower for Company X; damage recovery is to proceed when that reached is lower than the specified limit . There are rules for strict penalties, but no record of cases about actual penalties being applied. There are regular meetings to review the continuous operation procedures in the organization as well as regular important data about assistance from other sources in case of a serious events occurring, so the overall performance of recovery activity for Company X is fairly good. In Company Y, there is no clear

information security limit, no active execution of strict penalties and only modifications of continuous operation procedures irregularly, so the recovery activity for Company Y is passable.

(iii) Evaluation of Execution phase on Information Security

This research paper used the ten main control points in BS7799-2 : 1999 to evaluate whether company X and Y's execution phase of information security conforms to the standard. We used conform, partially conform, currently establishing, under consideration and not implemented to evaluate information security execution phase for both company X and Y, and categorized them into three results : good performance, passable performance and poor performance. These three results are relative concepts and are not absolute.

Drawing 9 : Evaluation of information security execution phase for company X.

It can be seen from drawing 9 that based on the ten controls in BS7799-2 : 1999, company X nearly conforms to all controls, except the security policy and few parts are either currently establishing, under consideration or not implemented. This result supports the performance of those four information security activities mentioned previously. Hence, the information security execution phase for company X is judged to be of good performance.

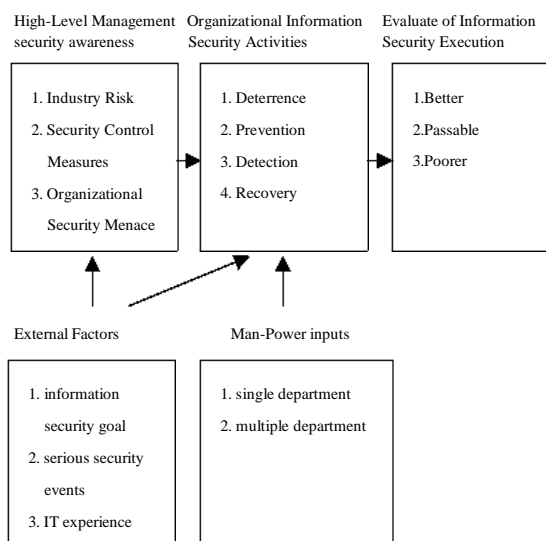

Drawing 10 : Evaluation of information security execution phase for company Y.

It can be seen from drawing 10 that based on the ten controls in BS7799-2 : 1999, company Y conforms to the standard for the following controls : communication and operation management, saving and extraction control, system development and maintenance and compliance.

The rest, for example : security organization, personnel security, physical security, physical and environmental security, saving and extraction control, system development and maintenance and continuous operation management of the corporation, are mainly categorized into the partially conform type.

It appears that the majority of security organizations, physical and environmental security and system maintenance and development are in the not implemented category. Therefore, the overall result of company Y supports the performance of those four information security activities mentioned previously. Hence, the information security execution phase for company Y is judged to be of passable performance.

Based on the above analysis, the former conceptual model is modified (as shown in drawing 11) to understand that the security awareness of high-level management not only influences organizational information security activities, external factors also influence organization information security activities of deterrence, prevention, detection and recovery. Furthermore, adding the man-power input through high-level management information security activities also influence the execution phase of organizational information security.

Drawing 11 : Modified conceptual model .

The following table lists the variables in individual cases :

Table 5 : A list of variables in individual cases

	X Company	Y Company
Industry Risk	Yes	No
Security Control Measures	Widely Understand	Narrowly Understand
Security Menace	Understand	Not Understand
information security goal	fit organization goals	fit organization goals
serious security events	Yes	Yes
IT experience	Yes	No
Security Activities	Deterrence passable others better	Detection passable other poorer
Man-Power inputs	Multiple department	Single department
Evaluate Security Execution	better	passable

II Verification of Assumptions

Our verification result for this research is contained in table 6.

Table 6 : This research's verification result for both company X and Y.

hypothesis	X Company	Y Company
Assumption 1	fit	partial fit
Assumption 2	fit	high-level managers do not have IT backgrounds
Assumption 3	fit	fit
Assumption 4	partial fit	partial fit

(V) Conclusions and Recommendations

This research is mainly to investigate how high-level management security awareness affect the drive for organizational security activities, and ten control points from BS7799-2 : 1999 are used to evaluate the performance in the execution of other information security. Our conclusions are as follows :

1. Through analysis of individual cases for the understanding of organizational information security goal, serious information security events previous occurred and IT experience can influence the bias of organizations for particular information security activities.

2. High-level management with higher security awareness can do better on the four information security activities of deterrence, prevention, detection and recovery with better performance in the execution of information security.

3. Through individual cases to understand slight deficiencies in the performance of deterrence activity in organizations, which appears in corporations with weak information security management.

4. Through individual cases to understand that corporations have a tendency to ignore threats from

human factors. This can be a hidden worry worthy of consideration.

5. Through individual cases to understand that corporations need to strengthen risk evaluation to effectively distinguish sources of threat and severity level in order to assist in the choice of effective security control measures.

Our research follow-up recommendations are listed below :

1. Outsourcing of information security can be investigated to determine how it influences information security management between corporations.

2. We recommend that follow-up research can be directed to discover how organizational information security activities can be improved through humans, technology, policies and procedures and to propose effective improvement methods.

Abstract

Spatial association rule mining is a kind of spatial data mining to carry some interesting and implicit knowledge about spatial associations from spatial databases. Moreover, many excellent studies on Remote Sensed Image (RSI) have been conducted for potential relationships of crop yield. Lee and Chen [13] proposed a two-phase algorithm by creating Histogram Generators for fast generating coarse-grained spatial association rules, and further mining the fine-grained spatial association rules w.r.t the coarse-grained frequently patterns obtained in the first phase. However during the image processing, partitioning the image into parts can improve its efficiency; to this point, the concept of image blocking is incorporated onto the coarse-grained two-phase data mining of spatial association rules. Therefore, an adaptive two-phase spatial association rules mining method is proposed in this paper to improve two-phase method in terms of efficiency. The proposed adaptive method conducts the idea of partition on an image for efficiently quantizing out non-frequent patterns and thus facilitate two-phase process. Such adaptive two-phase approach saves much computations and will be shown by lots of experimental results in the

paper.

Keywords: Spatial Database, Data Mining, Spatial Association Rules, Remote Sensed Image

1. Introduction

Those spatial data, from satellite photos or automated data gathering tool, such as remotely sensed images, local population, and what not have many widely-used sides of application, in many of today's research fields. When storing large amount of either spatial or non-spatial data in the spatial database, the past data gathering tool always emphasizes on how to improve on searching spatial data as well as storage system. However, there is very likely some knowledge or expertise potentially resided in this large amount of acquired data that is not discovered. In this case, it's very important at this moment to find an effective method to acquire this undiscovered knowledge or expertise from such large amount of spatial data and to further analyze for it to be applied on decisions of spatial applications. With the help of spatial data mining, more interesting and useful information are discovered [2][3][4][5][6][7][8] [9][11][12] [13][14][15]. This has, in turn, brought up a new,

very popular field for research today.

The methods in [3][4][5][13][15] for data mining on Remotely Sensed Images (RSI). In [3], the method is to take advantage of the association between reflectance intensities on RSI and crop yield through association rule. But if applying data mining simply on discovering this knowledge from large amount of remotely sensed images, it does not sound very economical considering the time spent and efforts put in. So, designing an effective data mining method is very worthwhile for in-depth research.

More details on methods will be discussed in Section 2. Section 3 presents a method for adaptive two-phase spatial association rules mining. Section 4 verifies the validity of our proposed method through experimentation and discussion. Last section is our conclusion.

2. Literature Reviews

2.1 Association Rules

An association rule [1] is “ $X \rightarrow Y, (s, c)$ ” where X and Y are itemsets with X being the antecedent and Y being the consequent of association rules. In example of the association between population and crop yield, s denotes the degree of support in which it represents the probability that X and Y occurs simultaneously, and c denotes the degree of confidence in which it represents the probability of Y occurrence when X occurs. Therefore, $c = \frac{\text{support}(X \cup Y)}{\text{support}(X)}$. In some

reference, support count = $s \times |D|$, where $|D|$

is the count in data table. Throughout our paper, the support count (*count*) will be taken as the

count of frequent itemsets. Decision makers can pre-define a minimum support count and minimum confidence in order for the elimination of infrequent itemsets and the creation of association rules through frequent itemsets.

2.2 Spatial Data Mining on RSI

Images on RSI can be parted into a couple of different types such as TM, SPOT, AVHRR, and TIFF. Take TM image on RSI as example, TM consists of seven bands which are B for Blue, G for Green, R for Red, RIR for Reflective-Infrared, MIR for Mid -Infrared, TIR for Thermal-Infrared, and MIR2 for Mid-Infrared2 [3][4][5][13][15]. Each band contains a relative reflectance intensity value in the range 0 to 255 for each pixel. One remotely sensed image is associated with yield, in the way which that one yield image is a map that defines agricultural yield standards. It is often shown in color or gray-scaled image. Shown in Figure 1 (a) is a remotely sensed image and Figure 1 (b) is a yield image. Incorporating the association between remotely sensed image and yield, data mining is to excavate the useful expertise that may help the experts or agribusiness people to improve crop cultivation.

Figure 1: Remotely sensed image and Yield map

2.3 Two-Phase Spatial Association Rules Mining Method

Two-phase association rule architecture for RSI data mining is proposed by Lee and Chen [13]. First, an image from RSI database is acquired. Do a color count and analysis of variance on this image. According to the analysis of image from RSI database, the Histogram Generator (HG) from the user-predefined intervals is generated. HG looks for the most representative characteristic value in an image to quickly find the coarse-grained association rules. From these coarse-grained association rules, fine-grained association rules are found. This method is primarily divided into four steps. First step is color count and analysis of variance on remotely sensed images. Second step is to generate Histogram Generator according to user-predefined intervals. Third step is to mine out the coarse-grained association rules according the user generated HG through algorithm of association rules. Fourth step is to mine out the fine-grained association rules according to the coarse-grained association rules.

3. Adaptive Two-Phase Spatial Association Rules Mining Method

The two-phase data mining of spatial association rules in Section 2.2 can improve the Apriori method in terms of its efficiency. However during the image processing, partitioning the image into parts can improve its efficiency; to this point, the concept of image blocking is incorporated onto the coarse-grained

two-phase data mining of spatial association rules. Image blocking performs the mining on each of the disjoining blocks partitioned from an image. The motive of taking on the image blocking is due to the inter-pixel redundancy in image data [16]. That means, the occurrences of neighboring image points redundancy is quite high; in other words, there is a higher possibility of more frequent itemsets. Therefore, the adaptive two-phase data mining of spatial association rules is to eliminate the blocks which do not produce frequent itemsets to improve its efficiency through image blocking.

3.1. Flowchart of the Adaptive Two-phase Data Mining of Spatial Association Rules

Figure 2 is the flowchart of adaptive two-phase spatial association rules for RSI data mining. Exploration of the frequent itemsets in coarse-grained association rules is made in four main steps. First step is to partition an image. Second step is to produce local frequent itemsets and record local non-frequent itemsets at the same time. Third step is to group each local frequent itemsets into global candidate itemsets. Fourth step is to add together the support count in global candidate itemsets as well as in non-frequent itemsets to be the final support count in global candidate itemsets. When bigger than the minimum support count, a global frequent itemsets is produced. Next sub-section will put more emphasis on each of the four steps.

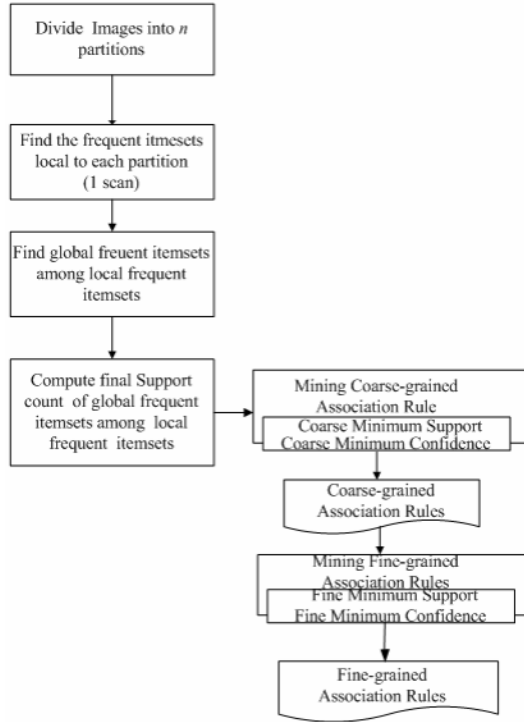

Figure 2. Adaptive two-phase association rule flowchart for RSI data mining

3.2 Procedures of the adaptive two-phase data mining of spatial association rules

Step 1: Partition the image

According to the mined coarse-grained association rules by Histogram Generator proposed by Lee and Chen [5], T^{HG} is the data table through HGs quantization of T^{origin} , which incorporates the RSI and yield images into one data table based on their positions of coordinates. Perform data mining on T^{HG} to explore the coarse-grained association rules. First is to partition into n number of disjoining blocks $\{P^1, P^2, \dots, P^n\}$. Divide the minimum support count by the count in data table T^{HG} . Multiply what's left in the previous calculation by the count in P^i to obtain the minimum support

count in each block ($s_p^c = \frac{s^c}{|T^{HG}|} \times |P^i|$), where

s_p^c is the minimum support count in the block,

$|T^{HG}|$ is the count of data table T^{HG} , s^c is the

minimum support count and $|P^i|$ is the count in the block.

Example 3.1: Table 1 is an image of 8×2 pixels, after which the data table T^{HG} is made from quantization by four HGs on bands R, G, B and Yield, respectively. The image is partitioned into four small blocks ($n=4$) in which block P^1 consists of $\{1, 2, 3, 4\}$, block P^2 of $\{5, 6, 7, 8\}$, block P^3 of $\{9, 10, 11, 12\}$, and block P^4 of $\{13, 14, 15, 16\}$. Whereas minimum support count (s^c) is 10, the minimum support count in

$$\text{each block is } s_p^c = \frac{s^c}{|T^{HG}|} \times |P^1| =$$

$$\frac{s^c}{|T^{HG}|} \times |P^2| = \frac{s^c}{|T^{HG}|} \times |P^3| = \frac{s^c}{|T^{HG}|} \times |P^4| =$$

$$\frac{10}{16} \times 4 = 2.5.$$

Table 1. Four partitioned blocks 8×2 image

data table						
Partition	Id	coordinate	R	G	B	Yield
P^1	1	0,0	3	3	3	3
	2	0,1	0	0	0	3
	3	1,0	3	3	3	3
	4	1,1	3	3	3	3
P^2	5	2,0	3	3	3	3
	6	2,1	0	0	0	3
	7	3,0	0	0	0	3
	8	3,1	1	1	1	3
P^3	9	4,0	3	3	3	3

	10	4,1	3	3	3	3
	11	5,0	3	3	3	3
	12	5,1	3	3	3	3
P^4	13	6,0	3	3	3	3
	14	6,1	3	3	3	3
	15	7,0	3	3	3	3
	16	7,1	3	3	3	3

Step 2: Exploration of local frequent itemsets in each block

Step2.1: Calculate local frequent 1-itemsets

(F_1^i) for each P^i . And each item in local frequent 1-itemsets is represented as $I(band_j^{S_a}, Yield^{S_a'}, count)$ because the itemsets in F_1^i can be represented as an association rule that consists of a antecedent and a consequent. For the association rule by the itemsets I , its antecedent is represented as $I. band_j^{S_a}$ and consequent as $I. Yield^{S_a'}$. $I.count$ is the support count of the itemset. For example, $I(R^0, Yield^1, 5)$ represents the color value of R as 0, the color value of Yield as 1 and the support count equals to 5.

On the other hand, record all the local non-frequent 1-itemsets that are smaller than the minimum support count in the block onto NF_1^i . Similarly, the format of local non-frequent 1-itemsets is $I(band_j^{S_a}, Yield^{S_a'}, count)$, where $I. band_j^{S_a}$ is represented as the antecedent, $I. Yield^{S_a'}$ as the consequent and $I.count$ as the support count of the itemsets.

Step2.2: Assume $\theta_1 \hat{I} F_{i-1}^i$ and $\theta_2 \hat{I} F_{i-1}^i$ where

q_1, q_2 . To produce local frequent 1-itemsets (F_1^i), first step has to consider whether or not $\theta_1.Yield^{S_a'}$ equals to $\theta_2.Yield^{S_a'}$. And if they equal to each other, they are joined together to produce local candidate 1-itemsets (C_1^i). In local candidate 1-itemsets, each format of the itemsets is $I(band_1^{S_{a1}}, band_2^{S_{a2}}, \dots, band_{i-2}^{S_{a_{i-2}}}, band_{i-1}^{S_b}, band_i^{S_g}, Yield^{S_a'}, count)$, of which $I(band_1^{S_{a1}}, band_2^{S_{a2}}, \dots, band_{i-2}^{S_{a_{i-2}}}, band_{i-1}^{S_b}, band_i^{S_g}, Yield^{S_a'}, count)$ is the antecedent, $I. Yield^{S_a'}$ is the consequent and $count$ is the support count. The support count is defined as $\min(q_1.count, q_2.count)$ of these established association rules in the local candidate itemsets. When the support count is larger than the minimum support count in the block, local frequent 1-itemsets (F_1^i) will be produced. local frequent 1-itemsets are formatted as $I(band_1^{S_a}, band_2^{S_a}, \dots, band_i^{S_a}, Yield^{S_a'}, count)$. Similarly, $I. band_1^{S_a}, I. band_2^{S_a}, \dots, I. band_i^{S_a}$ is represented as the antecedent, $I. Yield^{S_a'}$ as the consequent and $I.count$ as the support count of the itemsets. For example, $q_1=(R^0, G^0, Yield^1, 4) \in F_2^i$, $q_2=(R^0, B^0, Yield^1, 3) \in F_2^i$. When $q_1.Yield^1 = q_2.Yield^1$, $I(R^0, G^0, B^0, Yield^1, 3)$ will be produced and support count = $\min(4, 3)$; again when the support count is larger than the

minimum support count in the block, the global frequent itemsets of $I(R^0, G^0, B^0, Yield^1, 3)$ will be produced. The color value of R is 0, of G is 0, of B is 0, of Yield is 1, and the support count is equal to 3.

On the other hand, record all the local non-frequent l-itemsets that are smaller than the minimum support count in the block onto NF_l^i . Similarly, the format of local non-frequent l-itemsets is $I(band_1^{S_a}, band_2^{S_a}, \dots, band_l^{S_a}, Yield^{S_a}, count)$, where $I(band_1^{S_a}, band_2^{S_a}, \dots, band_l^{S_a})$ is represented as the antecedent, $I.Yield^{S_a}$ as the consequent and $I.count$ as the support count of the itemsets.

Example3.2: Take Table 1 for example, the block P^3 in which local frequent 1-itemsets are produced, $(R^3, Yield^3, 4)$, $(G^3, Yield^3, 4)$ and $(B^3, Yield^3, 4)$ are also produced. Furthermore, the local frequent 2-itemsets are $(R^3, G^3, Yield^3, 4)$ where $count=4$ obtained from $\min(4, 4)$.

On the other hand, no local frequent itemsets are produced in the block P^2 because the support count of the itemsets is smaller than the minimum support count in the block. Our method records the itemsets onto the local non-frequent itemsets so as to produce the local non-frequent itemsets such as $(R^3, Yield^3, 1)$, $(G^3, Yield^3, 1)$, and $(R^3, G^3, Yield^3, 1)$.

Step 3: Composition of a global candidate itemsets from each local frequent itemsets

First step is to incorporate the local frequent l-itemsets F_l^1, F_l^2, K, F_l^n in each block into

a global candidate l-itemsets (C_l). Second is to calculate the support count in C_l ; that is,

$$C_l.count = F_l^1.count + F_l^2.count + \dots + F_l^n.count.$$

Example 3.3: In Table 1, the local frequent 3-itemsets in P^1 are $(R^3, G^3, B^3, Yield^3, 3)$, and the local frequent 3-itemsets in P^3 and P^4 are $(R^3, G^3, B^3, Yield^3, 4)$. Incorporation of both comes the global candidate 3-itemsets which are $(R^3, G^3, B^3, Yield^3, 11)$, where $count=(3+4+4)=11$.

Step 4: Calculation of the final support counts in global candidate itemsets for establishing the global frequent itemsets

Adding together the established global candidate itemsets C_1, C_2, K, C_l in Step 3 and the support count in each local non-frequent itemsets (NF_l^i) yields

$$C_l.count = C_l.count + NF_l^i.count, \text{ and the final}$$

support count in the global candidate itemsets can be produced. If the support count is larger than the minimum support count (s^c), then they are the global frequent itemsets.

Example 3.4: Again take Table 1 as an example, the global candidate itemsets $(R^3, G^3, B^3, Yield^3, 11)$ are produced in Step 3. There are local non-frequent itemsets such as $(R^3, G^3, B^3, Yield^3, 1)$ in the P^2 . Thus the final global candidate itemsets that are produced are $(R^3, G^3, B^3, Yield^3,$

12), where $\text{count}=(11+1)=12$ that is larger than the minimum support count 10. So the global frequent itemsets (R^3 , G^3 , B^3 , Yield^3 , 12) are produced.

4. Experimental results of adaptive two-phase data mining of spatial association rules

The experiments conduct on the time-related ratio between the adaptive two-phase data mining, the two-phase data mining of spatial association rules and the Apriori.

Figure 3 shows the time-related ratio between the adaptive two-phase data mining which incorporates the Histogram Generator count that is 128 as well as blocking and the Apriori on five 50,000 pixels images under different color counts. Figure 3 also shows the time ratio between the two-phase data mining which incorporates the Histogram Generator count that is 128 but excludes the blocking and the Apriori. When the time ratio is less than 1, it

implies that both the two-phase data mining and the adaptive two-phase data mining are effective. From the Figure 3, the adaptive two-phase data mining yields the time ratio that is significantly less than the two-phase data mining; in other words, the adaptive two-phase data mining can improve the two-phase data mining of spatial association rules on its effectiveness.

Figure 4 is the time-related ratio between the adaptive two-phase data mining which incorporates the Histogram Generator count that is 128 as well as blocking and the Apriori. It also shows the time ratio between the two-phase data mining which incorporates the Histogram Generator count that is 128 but excludes the blocking and the Apriori. When the time ratio is less than 1, it implies that the adaptive two-phase data mining is very effective. From the Figure 4, the adaptive two-phase data mining requires significantly less amount of time; in other words, image blocking in the first and coarse-grained association rules in the later are able to enhance the two-phase data mining in its effectiveness

Figure 3. Execution time comparison between 128 HGs w.r.t. Partition (adaptive two-phase data mining) and 128 HGs (two-phase data mining) for some color count

Figure 4. Execution time comparison between 128 HGs w.r.t. Partition (adaptive two-phase data mining) and 128 HGs (two-phase data mining) for some variation

5. Conclusions

Our proposed two-phase data mining method in this paper is essentially effective for the applications of data mining on remotely sensed images. Adaptive two-phase spatial association rules mining method conducts the idea of partition on an image for efficiently quantizing out non-frequent patterns and thus facilitate two-phase process.

Abstract

There is massive potential in the higher education space spread across the Asian continent especially in countries like India and China. Global players operating in this space are eyeing these markets. This throws opportunities as well as challenges. There are many players, local as well as global, who have experimented or are experimenting online (pure play) or blended models in education. There have been failures and mistakes, which have thrown lot of learning. As a result players have improvised their offers. Online education is now working. Though the progression is slow, it is expected to grow exponential in the coming years.

E-learning is network enabled learning. There is a race to get into e-learning space in India given the scope and size of this market in India. But many organizations and academic institutions trying to foray into E-learning are getting imbalanced due to the lack of proper understanding of the market place and internal/external requirements. IT assimilation throws unimaginable challenges. What should be the operating strategy, deliverable value, approach, processes and technology assimilation strategies so that the entire organization moves towards successful implementation of the E-learning project without compromising on its existing competencies is a serious matter for researchers to ponder. This paper tries to answer some of the above issues with the help of the experiences gained from one of the largest online education project launched and running quite successfully in India. The suggested framework evolves around discovery of a collaboration model with software and connectivity service providers and criteria of collaboration to be drawn from the learner needs and requirement. The collaboration should balance to achieve necessary value proposition for the intended learner segment by careful crafting of the Learner Centric Value Chain.

1.0 Introduction:

Campus-based education has an important place in building knowledge strength of economies though it has its limitations, especially with respect to reach and capacity. With growing population and ever increasing need of quality education for all, there is an enormous potential to tap the education market, especially in the

developing countries. The role of distance and open learning has become very important in recent times to address the educational needs of the society. Advances in information and communication technologies have provided a much needed medium in the form of internet for distance education to flourish. The new technologies are not just improving existing forms and structures of higher education through better in-campus information infrastructure but are also transforming learning from focus on the institutions and instructors to focus on the learners. There are mainly two types of delivery method adopted by educational institutions in India - in campus and distance learning model. Both these models could operate in their zones in non-information and communication technology (ICT) based environment. With the use of ICT in content creation and delivery mechanism, the approach and the target segments are getting overlapped - the in-campus model extending reach and the distance model enhancing interaction quality and quantity. In such situation, it has become a daunting task for institutions to figure out synergies between their legacy and the evolved approach.

E-learning is network enabled learning. Many organizations and academic institutions trying to foray into E-learning are getting imbalanced due to the lack of proper understanding of the market place and internal/external requirements. IT assimilation throws unimaginable challenges [1]. There is a race to get into e-learning space in India given the scope and size of education market. Given the population base of around one billion and a huge working class in India, the opportunity for a cost effective open learning model to tap the potential is definitely quite tempting. With a huge demand and limited supply in the distance learning space, e-learning models have made only little ground and there is continuous search for a more viable model.

What should be the operating strategy, deliverable value, approach, processes and technology assimilation strategies so that the entire organization moves towards successful implementation of the E-learning project without compromising on its existing competencies is a serious matter for researchers to ponder. This paper examines the e-learning potential in the perspective of sector structure and size. The e-learning throws opportunities as well as challenges and there are many local as well as global players experimenting online (pure

play) or blended models in education. There have been failures and mistakes, which have thrown lots of learning. As a result players have improvised their offers. Though the progression is slow, it is expected to grow exponential in the coming years. This paper focuses on higher education and highlights issues in the e-learning based on a case study. Thus an attempt has been made to provide a framework for e-learning.

2.0 Evolution of E-Learning:

E-learning has evolved in the last couple of decades from a simplistic computer based supportive system to a highly advanced model used as a core strategic application by players in this space. Like any other service, concerned organizations need to respond to challenges like advancements in technology, changes in stakeholder demands and the challenges and opportunities arising due to globalization. Institutions and corporates across the globe have been experimenting with different models of learning throughout, alongside the advances in technology to add value in the learning process to address the challenges.

The e-learning germinated as a concept when in mid 70's research scientists who were also involved in academics interacted with students through computer networks. It was used by academia for information exchange and then as a support to university level courses. The universities started tapping the digital networking capabilities from the early 80s aggressively and started testing newer applications for feasibility. In 80's various experiments were done at the secondary level education which were national as well as global initiatives, linking school children and teachers across schools of some western countries. The results indicated knowledge enhancement and exposure to a global perspective for learners [2]. However, the first fully online Executive Education program in 1982 by the Western Behavioral Sciences Institute (WBSI) did not produce very encouraging results. This provided some important lessons for the domain experts like un-workability of long textual presentations by the instructors in online systems. Also the experience suggested that group learning applications yield better results than standalone applications. The Open University of UK rolled out first application of computer conferencing in 1989 on large-scale in a distance education course which was quite successful [3].

The Internet-based education became focus of study in distance as well as campus base educational institutions in the 90s and still continues to hold attention for some potent reasons. The advent of email system as a means of communication has been a big boost to online education projects as it provided a medium for easy online two way interactivity [4]. Internet is becoming the primary delivery mechanism because of its reach, cost efficiency and relatively easy availability. It provides flexibility not only

to the learner to learn at his/her pace from anywhere/anytime but also to the instructor to operate at his convenience. A web-based course enables opportunity of creating newer learning models.

The developments in the online learning have led to initiatives among interested groups in different parts of the world to assess the differentials vis-à-vis offline distance learning. Efforts to assess the effectiveness of online education system and there by developing a comprehensive model have remained inconclusive. One such case study concluded that the quality of distance education was inconclusive and, thus, much is still unknown regarding how and in what ways, technology can enhance the teaching learning process [5].

The on-line education models have been developed across a continuum from physical to digital version taking all necessary elements to make them student centric learning models. Some examples of such efforts include European Campus 2000 initiative [5] and BESTnet and AFRINet initiative which linked universities and related entities in the learning space in US, Canada, Latin America and Africa [6].

In the late 90s, the thrust shifted to benchmarking and developing standards of e-learning. The example of such endeavor includes the initiative by the Institute for Higher Education Policy, US which established benchmarks and ranked institutions in e-learning space. The benchmarks were based on institutional support, course development, teaching/learning, course structure, student support, faculty support and assessment methodology [7].

3.0 The E-learning Sector in India:

3.1 Structure:

A quick recap of the market place is essential to have the perspective in place. The structure can be understood with the help of figure 1 given at the end. At the core of the process are service providers and the customers, whereas the government, infrastructure developers, content providers, technology vendors, and strategy consultants etc make up the external but essential entities in the game. The service providers could be academic institutions, both hybrid as well as pure online institutions, NGOs, individuals or corporates imparting education to the employees. Similarly the customers could be individual learners, academic institutions or employees. The corporate-employee interaction is gaining quite a bit of significance of late along with the academic institution-student interaction. For example 37 per cent of the 130 corporates surveyed in India by Federation of Indian Chamber of Commerce said that they use e-learning for skill upgradation and training of employees [8]. The government support is essential in educational services and may come in the form of fixed grants and development of the basic telecommunication

infrastructure. The other external players also have a very important role in the entire structure in terms of developing the required technologies, support materials, infrastructure as well as providing trained man power to handle various specialized tasks related to online delivery. These different players have played varied roles in different countries. In some countries the initiatives are divided across private and government institutions whereas in others like India the initiatives have mainly come from the Government or the government owned institutions, primarily because of no prior experience and the capital and risks associated with such large projects.

3.2 Size:

The size of the market can be mainly categorized across students segment and corporate segment. Whereas there are no authentic figures to indicate the domestic education market of India in value terms that can be tapped through e-learning but one can take clues from the information about market subsets or the rough projections of players in the field.

The market size for e-learning has close linkages with distance education market because the players in this space are targeting the same segments. Therefore, understanding of distance learner segment is essential to get some understanding of e-learning market. One can get an idea about the distance education market in India by looking at table 1. The table gives the increase in enrollments at Distance Education (DE) institutions for the period 1975-2001. The share of distance mode has gone up to 20 % in 2001 from 2.6 % in 1975-76 as percentage of total student registered for higher education (HE). Thus every fifth student at tertiary level is enrolled with the DE system. The growth in this segment is expected to be 30-40%. According to government reports, presently there are 10 Open Universities in India, with some having more than 0.1 million students. There are about 90 dual mode universities and a few privately owned professional institutions offering courses through distance mode. Thus the potential of distance education is enormous in India. The ten open universities in the country have around 0.6 million students across 3,200 study centers with around 36,000 councilors. The study centers are normally controlled by the regional centers. The learner/councilor ratio is around 16 whereas the study centre/ regional centre ratio is around 30 which depicts gaps in required mentoring and management of study centers and service levels. [9][10][11][12].

It has been estimated that in early 1990s, over 1.5 million Indian students in the higher education level were studying abroad. The US is the leading exporter of higher education in Asia followed by France, Germany and the U.K. India is fourth major importing country of educational services after China, Japan and Korea [13][14]. According to an estimate by Global Alliance for Transnational Education, about US\$ 27 billion worth of

higher education is exported to Asia and Pacific by three countries namely USA, UK and Australia. Roughly 50,000 students are enrolled for studies abroad from India and the number is leaping every year.

The VSAT service providers who are presently very active in education space peg the market for VSATs at around 4800-7200 units in next 3 years and 8000-12000 units in next 5 years. At present there are hardly 25-30 units functioning, disseminating education services to around 500 institution centers across the country [15].

The corporate market is very huge and companies have started using e-learning model [16]. For example LG Electronics in India decided in 2001 to impart 70% of training to its employees online [17]. There is push in corporate across private and public to using cost effective methods of training.

4.0 E-Learning Models in India:

There are mainly three types of models adopted by educational institutions in India with the advent of World Wide Web platform:

1. In-campus
2. Distance learning
3. Blended

4.1 In-campus:

Various academic institutions are enabling their existing processes with the information technology support for better administration, course management and value interaction. They normally use basic Learning Management Systems (LMS) from off the shelf or a customized package developed by the software solution providers locally. Various premium management and technology institutes of India fall into this category where instructors are using applications like Web-CT, Blackboard etc. to support instructor-learner interaction and course management.

4.2 Distance learning:

Many institutes of repute like Indian Institute of Management, Calcutta, Management Development Institute, Gurgaon, Indian Institute of Technology, Delhi and National Institute of Design, Ahmedabad, are collaborating with academic publishing houses to offer short term executive development programmes mainly targeted at corporates. These programmes are totally web-based without any face-to-face component of any sort. The numbers are growing gradually and there are different experiences of learners across these various programmes.

4.3 Blended:

In this category, academic institutions with strong brand equity are trying to offer educational services with the aim of providing face to face experiences. There is face-to face faculty interaction in the beginning of the program followed by one way video and two way audio conferencing. The institutions in this category, typically have the content and brand to capture the market place but do not have the facilities and technical know how of offering online courses. This obstacle is being taken care of by collaboration with V-SAT service providers.

This model has the limitation with regard to number of learners that can be serviced at a particular receiving center as well as instructor capacity to handle queries in real time interaction mode across number of receiving centers.

4.4 Issues:

With the growing use of ICT in content creation and delivery mechanism, the approach and the target segments are getting overlapped – the in-campus model extending reach and the distance model enhancing interaction quality and quantity. In such situation, it has become a daunting task for institutions to figure out synergies between their legacy and the evolved approach. One can figure out critical areas of competency that apply in different models that can service learner requirements across learner styles, infrastructure and needs. The areas are mainly content, interaction and platform. The institutions are positioned at different slots across three dimensions of Platform, Interactivity and Readable content between physical and digital modes of these dimensions (Fig.2).

The institutions in India have tried alternatives across delivery and content dimensions but have yet not touched the third dimension. The Institutions, who had their courseware organized, were comfortable to digitize the content and got on to the e-learning mode by using web base delivery methods. The learners, however, have not been able to find enough value due issues mainly related to compatibility of the new interface with the legacy procedures, systems and mindset. The learner's preference is still for a hardcopy of the material or physical book as compared to digital content. The hyper linked quality has not been able to offset the comfort of using a physical book. Most of the learners in distance mode are working people who normally find time while traveling in a common passenger vehicle or their homes after office/ working hours. They normally do not have internet access in such places and if at all it is there, the costs are well beyond the perceived utility by the learners.

It is now only that in last couple of years, the third dimension is being looked at seriously by some institutions. This has been a result of continuous effort

across academia, content players in software sector and corporate learning chiefs. This is, however, just the beginning and there are still lots of apprehensions by the teaching community and learners which need to be analyzed and taken care of.

5.0 Case Study: Indira Gandhi National Open University

The Indira Gandhi National Open University (IGNOU) enrolls more than 1.3 million students in 235 academic programs leading to certificates, diplomas and degrees at under graduate and post-graduate levels [18]. It started first time in the country in 1998-99 using computer networks to support distance learning in two disciplines – the degree programs in Computer Application and Management. The project called 'Management Education through Interactive Delivery Systems' (MEIDS) was initiated in late nineties to offer degree and short capsule programs to distance learners through a blend of technology and offline support. Students were provided with online application facilities, continuous assessment, online query handling and online access to digital library with the help of an external software developer. The software developer also provided the hosting facility. The content delivery plan included a hard copy of the reading material along with the web support for most of the content. The content was primarily developed in-house or by leading experts of the field on contractual basis. The mentoring included sessions by local faculty at 20 partner institutions and weekend teleconferencing sessions from IGNOU head office. The partner centres were required to have the facility of receiving teleconferencing, internet connectivity, online continuous assessment supervision and administrative liaison between students and IGNOU. The first Masters Degree program in management was launched in 1999 along with 20 other short capsule programs. The prospective learners for degree program were required to go through a comprehensive written test. Around 275 students were enrolled from all parts of the country for all the programs on offer. The revelation of experiences by the learners provided lot of substance to figure out challenges and opportunity of e-learning in this country. The authors conducted a survey of the first batch of learners through this system. Out of 275, a sample of 150 was chosen by clustering from different programs. 35 of the learners responded. The methodology of the study was based on critical incidence technique which has already proved effective in assessing perceptions about use of computer base self-service facilities. The respondents were asked to list the most satisfying and dissatisfying experiences during the last six months of the program. The responses were clustered and factored to find the priority list of critical processes for action.

From the learners perceptions, following experiences were recognized as the top of mind satisfiers:

1. Quicker online registration and assignment assessment completion without a breakdown of the network possibly in allotted minutes (67%).
2. An immediate response through e-mail or telephone within 1-2 hours by the responsible service provider to provide process tracking facility for learners (62%).
3. Modular, comprehensive and updated course material to be received by the learners in the scheduled time and should be properly backed by web support without frequent failure of web support (62%).
4. There should be multiple channels of communication (56%).

The top dissatisfiers were as follows:

1. The connectivity fails during registration process or assessment test submission (77%).
2. The partner institution doesn't care to attend their grievances (69%).
3. The IGNOU coordinator is not available at critical times on phone or is not responding e-mails same day (66%).
4. The resource person on teleconferencing is not fully prepared on the topic (62%).

From the above results, following conclusions can be drawn about the processes considered to be the most critical for the value delivery by the learner segment catered by open universities like IGNOU:

1. Quicker Response.
2. Friendly software application and performance.
3. Modular design of courses within the program and comprehensive instructional material delivered in time.
4. Multi-channel delivery approach and flexible pedagogical structure.

6.0 Suggested Framework:

In the light of the issues discussed, it seems likely that the partnership trend among the different players which includes education service providers, software solution provider and connectivity service providers is going to increase in the future. Each provider will focus on its competence area. The collaboration criteria and the enrichment of Learner centric Value Chain (LCVC) need to be centered on the requirements of the learners. The frame work has been presented in figure 3. Although the learner is interacting only with the service provider, the feedback need to go to all the players involved and all the

players need to model their activities keeping the end customer, i.e. the learner at the center. Experiences learned so far suggest that the learner requirement vary and therefore, the value proposition has to be mapped accordingly. The efforts should focus at finding a collaborative model, centered on the right segment of learners, which will be decided based on the offering and competencies. The academic institutions should focus more on content and expert interaction, the software solution providers should focus on learner centric web ready content and other requisite interfaces and the connectivity providers should provide satisfactory links across the users.

7.0 Conclusion:

Given the massive potential and stiff competition in the e-learning space in India, the players need to work on a proper model in order to maximally exploit the opportunities and create win-win solutions for all the players involved. Whatever be the e-learning model, the service provider needs to pay utmost attention to learner needs of flexibility and tolerance by way of providing modular based programs through multiple channels of communication and with high performance, friendly application support. The core idea should be to create a learner centric value chain which can eliminate any scope of dissatisfaction and enhance satisfaction of the remote learner.

Abstract

Progresses in the field of information and communication technologies in last one decade or so have transformed our lives in many ways. One of the strongest impacts of these breakthrough discoveries can be seen in the way businesses are run. Organizations today are faced with a fundamental challenge of finding competitive advantage in a world in which many of the old sources of competitive advantage are no longer enough. In such dynamic environment leaders have the challenge of developing new skills and competencies to cope up with the competition and uncertainties of the environment. This study is an attempt to find these changing dimensions of leadership. The study has special significance for practitioners. It gives the dimensions of leadership, which the leaders of future need to develop. Leaders willing to win and organizations willing to succeed in the new business environment need to compare their actual strengths with the ones they would need to be successful and develop the required competencies accordingly.

1. Introduction

We live in an era of rapid changes in every sphere of life, be it individual life styles, organizations or societies [1] [2]. These changes are primarily driven by the technological revolution of last one decade or so, especially in the field of information and communication technologies. The business environment though trying to reach a stable state, is still in a state of great flux. Gary Hamel, in his famous work “Leading the Revolution” says [3, p 4]:

“...We now stand on the threshold of a new age – the age of revolution”.

It is this ‘age of revolution’ which has been given various names like ‘new economy’, ‘digital economy’, ‘information age’, ‘knowledge age’, post-industrial economy’ etc by the scholars [3] [4] [5] [6]. Organizations today are faced with a fundamental challenge of finding competitive advantage in a world in which many of the old sources of competitive advantage are no longer enough. This has implications for leadership too. There is increasing acknowledgement by scholars that the requirement of leadership competencies for success in new economy will be different from that for the old economy [7] [8] [9]. Identification of these dimensions is

important for leaders as well as organizations in order to be successful as well as to implement organization wise strategies for leadership development to face the challenges of the new economy.

2.0 Research Question and Literature Review

The study attempts to answer the question whether there is any change in the requirements of leadership for successfully operating in the new economy and if indeed there is change in leadership requirements, what are the leadership dimensions which are more important than others for the new economy.

The study looks at leadership from competency perspective. The review of literature suggests that in recent times more and more importance is being given to leadership competencies under various leadership approaches. The existing competency literature on leadership includes many studies of current leadership competencies and surveys of leaders inquiring about their views on future leadership competencies [10] [11] [12] [13]. However literature is lacking to assess how leadership competencies will be different in the new economy as compared to the traditional old economy. The studies done in India on business leadership primarily focus on past and current successful leadership examples and the issues related to leadership development [14] [15] [16] [17]. Although these studies are certainly informative and lessons learned continue to be applicable, these cannot be sufficient guides for the changing business environment. What is more important today is not to analyze how one achieved success in the past but to identify how to be successful in the future. There is huge gap in available literature when it comes to leadership issues for the future in Indian context. This study is an attempt to bridge this literature gap.

On review of extant literature, following competencies were identified for the study:

Vision, problem solving, integrity, team Building and team work, human resource management, innovative and creative thinking, initiative, customer orientation, teaching (coaching, mentoring), interpersonal skills, communication, self-awareness, financial management/quantitative ability, technical competence,

technology adoption and management, negotiation, influencing others, flexibility, speed in decision-making, ability to take risk, ability and willingness to learn, conflict management, external awareness, and stamina (physical and mental).

3.0 Methodology

A survey of Indian corporate leaders, both from old economy as well as digital economy organizations was conducted with the help of a self administered questionnaire. The subjects belonged to top and senior level executives of Indian corporations as well as Indian subsidiaries of multi national corporations. Though most of the competencies used in the study have been used by researchers in earlier studies, a pre-test was employed to refine the questionnaire. A sample of 40 leaders was selected by convenience sampling for pre testing and reliability analysis was carried out via item to total correlation and Cronbach coefficient alpha using SPSS-11.0. All the competencies were found to be above the cut off point of 0.3 and the values of Cronbach coefficient alpha for old economy as well as digital economy was found to exceed 0.7.

An informal face validity test was conducted and the questionnaire was shown to academicians and industry experts. After satisfactory responses from the experts, the questionnaire was subjected to factor analysis using SPSS 11.0. All the competencies were factor analyzed together to test the convergent validity for old economy and digital economy separately. A minimum value of 0.40 was used to indicate the loading of any factor. It was found that the competencies for both, old economy as well as new economy were convergent.

The main study was carried out during April 2002 to August 2002. The sample was chosen by stratified random sampling from ET 500 (March, 2002) and Global 500 (July 22, 2002) [18] [19]. The companies were stratified into new economy and old economy organizations to have equal representations of the view points of both sets of leaders.

The questionnaires collected for the pre-test were also included for final analysis. A total of 249 correctly completed questionnaires were received, of which 109 belonged to leaders from new economy organizations and 140 belonged to old economy organizations. The reliability of the scale for old economy and digital economy was assessed again via item to total correlation and Cronbach coefficient alpha using SPSS-11.0. All the competencies used in this study exceeded the cut off point of 0.3 on item to total correlation. The Cronbach coefficient alpha was 0.938 for old economy competencies and 0.931 for new economy competencies.

4.0 Analysis and Findings

Dependent samples t-tests were used to see if leaders perceived certain competencies to be more important for new economy as compared to old economy. Based on the average rankings of individual competencies for new economy, a set of competencies was identified to be critical for successful e-Leadership.

The results of dependent sample t-test reveal that the importance of most of the competencies has changed significantly from old economy to new economy in the perception of Indian leaders. The p-value of 0.05 was used for testing the null hypothesis that there is no significant difference in the importance ratings for a particular competency for digital economy as compared to traditional old economy. The competencies for which the test does not support a significant difference (p-value greater than 0.05) are listed in the table 1.

Table 1: Leadership Competencies, which are not significantly different in new economy from old economy

Perception of old economy leaders	Perception of digital economy leaders	Perception of old economy & digital economy leaders taken together
Integrity Interpersonal Skills Communication Skills Self Awareness Conflict-Management Stamina	Problem Solving (p=0.053) Communication Skills Negotiation (p=0.060)	Communication Skills Negotiation Influencing Others (p=0.064)

Communication skill is common for all three and we can conclude that requirement of communication skills, as leadership competency has not changed in digital economy from traditional old economy. Other skills, requirement of which have not changed in the perception of old economy leaders are integrity, interpersonal skills, self-awareness, conflict management and stamina. In the perception of digital economy leaders, communication is the only skill whose requirement has not changed significantly since p-value for problem solving and negotiation is very close to 0.050. If we take the perceptions of both, digital economy and traditional old economy leaders together, we can see that requirements of 'negotiation' and 'influencing others' besides 'communication' have not changed, though the test results are very weak for 'influencing others' competency.

Table 2 lists the competencies which have changed most in importance for new economy from old economy in the descending order.

Looking at the rankings, only for the new economy, the top five competencies which can be said to be critical for success in the new economy are Vision, Customer

Orientation, Technology Adoption & Management, Speed in Decision-making and Innovative & Creative Thinking.

Table 2: Leadership Competencies that have changed most for new economy

	Competency
1	Technology Adoption & Management
2	External Awareness
3	Speed in decision making
4	Teaching (Coaching, Mentoring)
5	Ability and willingness to learn
6	Innovative & Creative Thinking
7	Customer Orientation
8	Human Resource Management
9	Flexibility
10	Ability to take risk
11	Team Building & Team work
12	Technical Competence
13	Vision
14	Financial/Quantitative Ability
15	Initiative
16	Conflict Management
17	Stamina (physical and mental)
18	Self Awareness
19	Interpersonal Skills
20	Problem Solving
21	Integrity
22	Influencing others
23	Communication Skills
24	Negotiation

5.0 Conclusion

The study supports the view that the requirements of leadership are changing. It specifically brings forth the competencies whose importance has changed most and also how a different set of competencies has emerged to be critical for success in digital economy.

This study will be significant to both academicians and practitioners. It fills a big gap in leadership literature when it comes to assessing the changing requirements of leadership competencies for digital economy. From a practitioner's perspective, this study gives the dimensions of leadership, which the leaders of future need to develop. Leaders willing to win and organizations willing to succeed in the new business environment need to compare their actual strengths with the ones they would need to be successful. The leadership competencies identified in this

study to be important, will help the managers in developing right kind of competencies to become successful leaders. The findings of the study could be useful for the human resource managers in making right selections for leadership roles. The study should also be useful for the old economy organizations, trying to adapt to the new business environment.

Abstract

The balance scorecard [6] is a performance measurement system that supplements traditional financial measures with the criteria that measures performance from three additional perspectives: customer perspective, internal business perspective, and innovation and learning perspective. In recent years, the balanced scorecard has been applied to information technology in order to ensure that IT is fairly evaluated. The same methodology has also been applied to E-business. Since some of the parameters in the measurement are somewhat inexact, the idea of fuzzy logic can be applied to allow manipulation of both exact and inexact (fuzzy) inputs from the e-business to the balanced scorecard. This fuzzy model works with a grade of membership and portrays inexact information represented by fuzzy statements, and explains both fuzzy conditional statements and the inference mechanism. This paper tries to develop a frame-work for Fuzzy-based Balanced Scorecard for E-business.

Introduction

Internet technology is creating a universal technology platform for buying and selling goods and for driving important business processes inside the firm. It has inspired new ways of organizing and managing that are transforming businesses and the use of information systems in everyday life. Along with bringing many new benefits and opportunities, electronic business (E-business) has created a new set of management challenges. An organization must understand the management, organization, and technology issues that must be addressed to benefit from E-business. The successful organization requires the high level information integration, and companies increasingly are depending on such infrastructure to remain efficient and competitive. The Internet has shrunk the information asymmetry. Now the businesses are not required to make trade-offs between the richness and reach of their information.

E-Business

E-business can be described as the process of buying and selling or exchanging of products, services, and information; generating demand for them through marketing and advertising; servicing customers; collaborating with business partners; and conducting electronic transactions within an organization via computer networks, including the internet. E-business will improve business performance through low cost and open connectivity by introduction of new technologies in the value chain and connecting value chains across businesses in order to improve service, reduce costs, open new channels and transform the competitive advantage. [15]

Companies are becoming increasingly aware of the many potential benefits provided by E-business. [15],[2]. Some of the E-business potential benefits are: support of Business Reengineering efforts, expansion of the market reach that goes beyond any border, strengthening of relationships with customers and suppliers, cost reductions through the deployment of electronic internal and external business processes, and lower telecommunications costs as a result of the inexpensive Internet infrastructure. E-business projects often are deployed on the basis of a step-by-step approach. A well-known Gartner-model describes four levels of E-business: (1) the publishing level focusing on showing information of the company on a web site, (2) the prospecting level with customer oriented information, (3) the business integration level which is transaction centric and can be defined as E-commerce, and (4) the business transformation level which is the mature level of E-business that includes supplier and customer integration. *Completion of steps of the E-business project plan* will represent this evaluation item. An E-business project represents a capital investment that entails expenses as well as revenues. The start of an E-business project is also the initiation of a permanent commitment to resource demands because of ongoing expenses that often difficult to predict.

Because of the intangible nature of some of these benefits, it is difficult to measure the contribution of E-business initiatives to business performance and to manage these projects to ensure that real profits are realized. In practice, E-

business projects are often managed too technically and little attention is paid to the business case.

Uncertain Future

The new world of business imposes the need for variety and complexity of interpretations of information outputs generated by computer and information systems. Such variety is necessary for deciphering the multiple worldviews of the uncertain and unpredictable future. With increasing computerization in organizations, organizational routines originally embedded in standard operating procedures and policies become embedded in the firm's dominant logic embedded in programs and databases in the form of 'best practices'. Such formalized information systems tend to be inflexible and are often based upon designers' belief that they have already identified the organizational and environmental properties. However, with increasingly rapid, dynamic and non-linear changes in the business environment, static assumptions embedded in such systems become vulnerable. Growing realization of such vulnerabilities is behind increasing interest in designing information systems that can take dynamic and diverse interpretations of changing information into account.

Performance Measurement

For years, firms valued financial performance or market share as the most important success measures. The large firms fostered competition among their brand groups or retail outlets and measured success by the bottom line (profits). Many still do. During the mid- to late-1990's, the dot-com firms ignored financial measures and focused on growth, much to their dismay. These approaches are narrowly focused and place more weight on short-term results rather than addressing the firm's long-term sustainability [1].

These weaknesses paved the way for enterprise performance management systems that measure many aspects of a firm's achievements. The **Balanced Scorecard**, developed by two Harvard Business School professors in 1990 [6], is one such system. Fifty percent of organizations worldwide have adopted the Balanced Scorecard with excellent results ("The E-Commerce Balancing Act" 2000). The scorecard approach links strategy to measurement by asking firms to consider their vision, critical success factors for accomplishing it, and subsequent performance metrics in four areas: customer, internal, innovation and learning, and financial. In the following sections typical goals and metrics in each perspective are described.. However, it is important to remember that each firm defines the specific measures for each box—the system is very flexible.

Customer Perspective		Internal Business Perspective		Innovation and Learning Perspective		Financial Perspective	
Goals	Measures	Goals	Measures	Goals	Measures	Goals	Measures

Four Perspectives

The *customer perspective* uses measures of the value delivered to customers. These metrics tend to fall into four areas: time, quality, performance and service, and cost. They can include measures such as time from order to delivery, customer satisfaction levels with product performance, amount of sales from new products, and industry-specific metrics such as equipment up-time percentage or number of service calls.

The *internal perspective* evaluates company success at meeting customer expectations through its internal processes. The items with greatest impact in this area include cycle time (how long to make the product), manufacturing quality, and employee skills and productivity. Information systems are a critical component of the internal perspective for e-business firms.

The *innovation and learning perspective*, sometimes called the *growth perspective*, is one of the Balanced Scorecard's unique contributions. Here, companies place value on continuous improvement to existing products and services as well as on innovation in new products. These activities take employees away from their daily work of selling products, asking them to pay attention to factors critical to the firm's long-term sustainability—especially important for e-business firms. Measures in this area include number of new products and the percentage of sales attributable to each; penetration of new markets; and the improvement of processes such as CRM or SCM initiatives.

If the projected outcomes result from the previous perspectives and performance metrics, the financial perspective will be on target too. Financial measures include income and expense metrics as well as return on investment, sales, and market share growth. Companies must be careful to relate measurements from the first three perspectives to the financial area whenever possible.

Each firm will select metrics for the four perspectives based on its objectives, business model, strategies, industry, and so forth. The point is to understand what the company wants to accomplish and devise performance metrics to monitor the progress and see that the goals are reached.

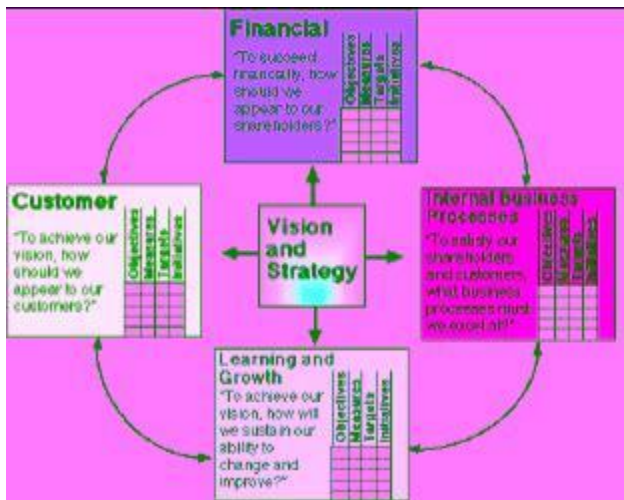

Figure 1

Scorecard Benefits

The Balanced Scorecard system helps a firm obtain timely information to update its strategy. Its four perspectives balance long-term and short-term measures and evaluate every part of the firm and how each contributes toward accomplishing selected goals. It also helps firms leverage their relationships with partners and supply chain members. The scorecard can be used by all types of organizations, both profit and not-for-profit, and in all industries, if they select appropriate metrics.

The Balanced Scorecard has many other specific benefits. First, it provides a way to go beyond financial metrics in measuring many different aspects that lead to effective and efficient performance. Second, it creates a long-term perspective for company sustainability. Third, it forces companies to decide what is important and translate those decisions into measurable outcomes that all employees can understand. Next, it is a great communication tool because employees can use the scorecard as a guide to coordinate their efforts. In addition, it supports employee evaluation in that individual performance can be tied to successful outcomes on the metrics. Also, it provides a way to measure intangible as well as tangible assets. This is especially important for firms using e-business models because knowledge, information, and innovation are critical to their success. Finally, the Balanced Scorecard

is valuable because of its flexibility in allowing firms to select appropriate metrics for their goals, strategies, industry, and specific vision.

The general BSC-framework can be translated to the more specific needs of the monitoring and evaluation of the IT function and recently the IT BSC has emerged in practice [5],[18],[16],[17]. Many firms have successfully implemented the Balanced Scorecard. Hilton Hotels attributes its number-one ranking in customer satisfaction during 2000 and highest industry profits to this approach (Jackson and Baskey 2000). In another example, Wells Fargo Bank created Online Financial Services in the early Internet days to capitalize on new technologies. Its goal was to migrate current customers and draw new customers to the online channel. Using the scorecard as a roadmap to provide value to customers and to be sure internal processes and the technology could handle the anticipated volume, Wells Fargo beat its goal of 1 million customers within a short time ("The E-Commerce Balancing Act" 2000).

Balance Scorecard in E-Business Application

The Scorecard can use a Business-Centred model and structured sets of questions to enable you to assess where and how effectively you currently use e-business, and to explore and identify areas where e-business can be extended and improved [10], [3]. It is not a rigid 'e-specification' for every business but an independent and balanced source of innovation and challenge across key business processes [11], [12]. It can be designed to cover the impact of e-business on commercial strategy and operations and also reviews technical strategy in areas such as infrastructure and security.

The Scorecard can provide a comprehensive real-world framework coupled with a business process focused diagnostic tool to help the organization, irrespective of its size or nature of business, to identify 'where its main e-business opportunities are' and 'what it needs to do to enhance its e-business'. Larger, more complex, organizations can leverage key recommendations from the Scorecard assessment process across the business. Smaller organizations can benefit from the 'knowledge investment' made by medium and larger sized companies in e-business and are able to implement solutions more quickly. Appendix shows the generic measurement parameters [18], [12], [4].

Measurement

You can't improve what you can't measure. So metrics must be developed based on the priorities of the strategic plan, which provides the key business drivers and criteria for metrics managers most desire to watch. Processes are then designed to collect information relevant to these metrics and reduce it to numerical form for storage, display, and analysis.

Decision makers examine the outcomes of various measured processes and strategies and track the results to guide the company and provide feedback. Leading organizations agree on the need for a structured methodology for using performance measurement information to help set agreed-upon performance goals, allocate and prioritize resources, inform managers to either confirm or change current policy or program direction to meet those goals, and report on the success in meeting those goals. Also it is essential to know the data flow correctly so that it can be measured accurately.

Data Flow in BSC

There are two sets of more-or-less continuous data flows required in the BSC system:

1. Downward information flow

Line managers at the Directorate, Department, and Branch levels define goals, desired outcomes, initiatives, metrics, targets, and schedules. The goals, metrics, targets and schedules are aligned with those specified in the top-level strategic plan and balanced scorecard performance plan. Some of these parameters may have to be translated from general to more mission-specific to apply to the work being performed at each organizational level. Specific desired outcomes and initiatives to attain them are developed by these managers, and the metrics, targets and schedules are then developed. This results in a hierarchical set of balanced scorecards that are pertinent at each organizational level. It also has the effect of giving the organizational stakeholders a meaningful role in performance evaluation and strategic management.

2. Upward information flow

Define collection methods for each of the BSC metrics. This is the most expensive, labor-intensive, aspect of the BSC system, and has the most impact on the rank-and-file employees. I therefore recommend that for survey-based measurements, surveys should be carefully and professionally designed to minimize complexity and impact on the employees' time. Aggregate metrics data by organizational code. Create reports at each line management layer. These will provide feedback to the managers on metrics that are pertinent to their own strategic interests. Aggregate at each level (without filtering or loss of data). At the senior management layer, combine the metrics data into the 'vital few' needed to give an overall picture of the agency's balanced scorecard, on a continuous basis. These two information flows are illustrated in the Figure 2, using a notional organization chart:

PERFORMANCE EVALUATION DATA FLOWS

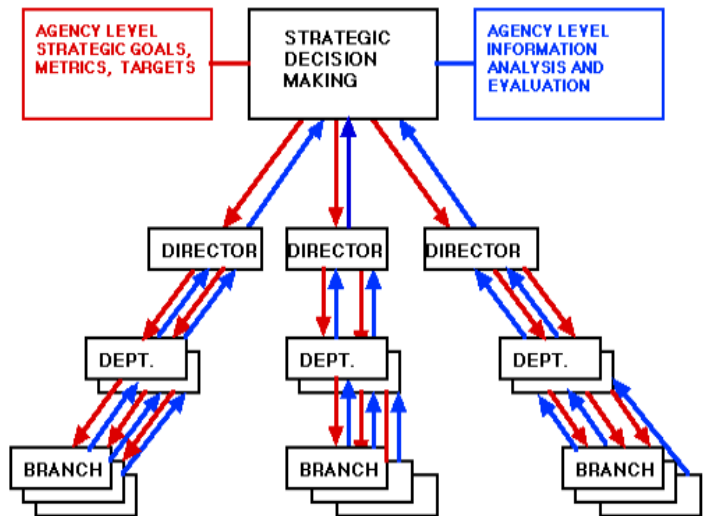

Figure 2 : Performance Evaluation Data Flows

In this figure, the top-level strategic goals, metrics and targets are in red, and they flow downward from the headquarters strategic planning office. The balanced scorecard measurements, in blue, are collected starting at the bottom (branch level) and flow upward. (This is analogous to the circulation of blood from arteries to veins.)

At each level of the organizational hierarchy, the data are aggregated across the lower levels. Aggregation serves to reduce information overload. Periodically, measurements can be collected, aggregated and analyzed at each management level. These data provide the managers with knowledge of strategic performance within their own part of the organization. In other words, the performance evaluations are not only for the top-level managers. Each manager, at each level, benefits by seeing the same metrics as they apply to his or her own area of responsibility. This is an incentive to support the balanced scorecard: *we are measuring ourselves - and we get to use the data we collect for our own purposes.*

As it is clearly evident from the discussion above, there are a number of parameters in the performance measurement as far as the E-business balance scorecard is concerned. Out of all these parameters, some are exact (like financial data) and some are inexact (like customer satisfaction, etc.). As far as the inexact parameters are concerned, most of the items depend on some information flow and communication. The communication may be in the form of analog (human-based) or digital (computer-based). The analog communication may be ambiguous, vague or unclear. Since the measurement in these cases are, somewhat, inexact, the idea of fuzzy logic can be applied to allow manipulation of both exact and inexact (fuzzy) inputs from the e-business to the balanced scorecard.

This fuzzy model works with a grades of membership and portrays inexact information represented by fuzzy statements, and explains both fuzzy conditional statements and the inference mechanism.

The Notion of Fuzzy Sets

The characteristic function of a crisp set assigns a value of either 1 or 0 to each individual in the universal set, thereby discriminating between members and nonmembers of the crisp set under consideration. This function can be generated such that the values assigned to the elements of the universal set fall within a specified range and indicate the membership grade of these elements in the set in question. Larger values denote higher degrees of set membership. Such a function is called *membership function* and the set defined by it a *fuzzy set* [20].

Let X denote a universal set. Then, the membership function μ_A by which a fuzzy set A is usually defined has the form

$$\mu_A: X \rightarrow [0,1] \quad (1)$$

where $[0,1]$ denotes the interval of real numbers from 0 to 1, inclusive.

The fuzzy set provides us with an intuitively pleasing method of representing one form of uncertainty. Obviously, the usefulness of a fuzzy set for modeling a conceptual class or a linguistic label depends on the appropriateness of its membership function. Therefore, the practical determination of an accurate and justifiable function for any particular situation is of major concern. The methods proposed for accomplishing this have been largely empirical and usually involve the design of experiments on a test population to measure subjective perceptions of membership degrees for some particular conceptual class. There are various means for implementing such measurements. Subjects may assign actual membership grades, the statistical response pattern for the true or false question of set membership may be sampled, or the tie of response to this question may be measured, where shorter response times are taken to indicate higher subjective degrees of membership. Once these data are collected, there are several ways in which a membership function reflecting the results can be derived.

Fuzzy-based Measurement

The process of human-based communication consists of a vast array of different types of simultaneously communicated signals, many of which conflict with each

other. It is, therefore, difficult to determine the precise intention and meaning of the communication, because of both distortion from environmental noise and ambivalence on the part of the sender. Nevertheless, the receiver must respond appropriately in the face of this fuzzy or vague information [21].

Suppose that X constitutes the universal set of all possible signals x that may be communicated by the sender. Because of the distorting factors mentioned above, a clear, unique signal may not be available. Instead, the message received is a fuzzy subset of M of X , in which $M(x)$ denotes the degree of certainty of the receipt of the specific signal x . In order to determine whether an appropriate response can be chosen based on the message received or whether some error was involved in the communication, an assessment of the quality of the transmission must be made. Let the maximum value of membership that any $x \in X$ attains in the set M correspond to the *strength* of the transmission. If the set M is large, no unique maximum, then the message is called *ambiguous*. If the support of M is large, then M is considered to be *general*. The clarity of the message can be measured by the distance between the maximum membership grade attained in M and the next largest grade of any signal x in M . When the message received is strong, unambiguous, and clear, then the signal attaining the maximum membership grade in M can easily be selected as the most obvious intended communication. Difficulty occurs, however, when the message is weak, ambiguous, or unclear. In this case, the receiver must determine whether the problem in the communication lies in some environmental distortion (in which case a repetition of the signal may be requested) or in the sender of the message (in which case a response must be made that is, as far as possible, appropriate).

Usually, the receiver of the communication possesses some background information in the form of probabilities or possibilities of the signals that can be expected. If $p(x_1), p(x_2), \dots, p(x_n)$ represent the probabilities associated with each of the signals $x_1, x_2, \dots, x_n \in X$, then the probability of the fuzzy event of the receipt of message M is given by

$$p(M) = \sum_{x \in X} M(x) p(x) \quad (2)$$

The receiver can use this information to assess the consistency of the received message with his/her expectations. If the probability of the received message is high, then it can be assumed that little distortion was introduced by the environment. On the other hand, if the message is very clear and unambiguous, then as appropriate response can be made even if the probability of the signal was low.

Instead of the expectation or background information being given in probabilistic form, this information may be given in

the form of a possibility distribution r on X . In this case, $r(x) \in [0,1]$ indicates the receiver's belief in the possibility of signal x being sent. The total possibility of the fuzzy message M is calculated as

$$r(M) = \max_{x \in X} [\min(M(x), r(x))] \quad (3)$$

As in the case of probabilistic expectation, if the received message conflicts with the expected possibility of communication, then the receiver may attempt clarification by requesting a repetition of the transmission. Before this new transmission is sent, the receiver will probably have already modified his/her expectations based on the previous message. If r_0 indicates the initial expectations of the receiver, and r_1 is the modified expectations subsequent to the receipt of message M , then

$$r_1(x) = \min [r_0^a(x), M(x)] \quad (4)$$

for each $x \in X$, where a indicates the degree to which past messages are considered relevant in the modification of expectations. The procedure for signal detection now consists of the following: a test of the consistency of M against the expectations and a test of the message M for strength and clarity. If both of these values are high, the signal attaining the maximum value in M be comfortably assumed to be the intended signal. If both tests yield low values, the expectations are modified and a repetition is requested. If only one of these tests yields a satisfactory value, then either a new signal is requested or a response is made despite the presence of doubt.

An additional complication is introduced when we consider that the receiver may also introduce distortion in the message because of inconsistency with the expectations. Let

$$s(M, r) = \max_{x \in X} [\min(M(x), r(x))] \quad (5)$$

correspond to the consistency of the received message with the possibilities expectations. Then, let M^s denote the message that the receiver actually gets, where

$$M^s(x) = M^s(x) \quad (6)$$

for each $x \in X$ where $s = s(M, r)$. The less consistent M is with the expectations, the less M^s resembles M . Since the receiver will be modifying his or her expectations based on the message thought to have been received, the new possibility expectation structure is given by

$$r_1(x) = \min[r_0^{1-s}(x), M^s(x)] \quad (7)$$

for each $x \in X$.

Finally, once a determination has been made of the signal $x \in X$ that was sent, an appropriate response must be chosen. Let Y be the universal set of all responses, and let R , the subset of $Y \times X$ be a fuzzy binary relation in which $R(y, x)$ indicates the degree of appropriateness of response y given signal x . A fuzzy response set $A \in Y$ can be generated by composing the appropriateness relation R with the fuzzy message M ,

$$A = R \circ M \quad (8)$$

or

$$A(y) = \max_{x \in X} [\min(R(y, x), M(x))] \quad (9)$$

for each $y \in Y$. The membership grade of each possible message y in fuzzy set A thus corresponds to the degree to which it is an appropriate response to the message M . A more interesting case occurs when the elements $y \in Y$ are not actual messages, but instead indicate characteristics or attributes that the appropriate message should possess. This allows for creativity in formulating the actual response.

Conclusion

In this paper, the balanced scorecard concepts are applied to E-business projects. The fuzzy logic framework has been applied to a generic E-business balanced scorecard and presented as a measuring and management instrument. The proposed fuzzy logic framework can be applied to the inexact parameters of three perspectives (out of four): the customer perspective, internal perspective, and Innovation and Learning perspective. These fuzzy-based monitoring instruments are a must when building, implementing and maintaining an E-business balance scorecard.

Appendix

Measurement Parameters

Customer Perspective	
Goals	Possible Measures
Build awareness of a new Web site service	Survey target awareness of service Number of visitors to the site
Position firm as high tech	Survey target attitudes
Increase number of software downloads from the Web site	Number from Web site log
High customer satisfaction with Web site	Survey of target at Web site Number of visits and activity at site
High customer satisfaction with value of online purchasing	Number of complaints (e-mail, phone) Number of abandoned shopping carts Sales of online versus offline for same products
Increase the amount or frequency of online sales from current customers	Mine the database for change in frequency of purchases over time
Build customer relationships	Number of purchases per customer over time (using cookie data) Customer retention percentage
Appropriate target markets	Data mining to find purchase patterns by targeting criteria
Buy-to-delivery time faster than competition	Number of days from order to delivery Competition delivery times
Increased coupon use from Web coupons	Number who redeem
Build communities on the site	Number of registrations to community Number of posts to community bulletin board
Value for Business Partners	
Increase number of affiliates in program	Number of affiliates over time
Cross-sell to partner sites	Number of visitors to partner site from our site

Innovation and Learning Perspective	
Goals	Possible Measures
Online service innovation	Number of new service products to market in a year Number of new service features not offered by competitive offerings Percent of sales from new services
Continuous improvement in CRM system	Number of employee suggestions Number/type of improvements over time
High Internet lead to sales conversion	Revenue per sales employee from Internet leads Number of conversions from online leads
Increased value in knowledge management system	Number of accesses by employees Number of knowledge contributions by employees
Successful penetration of new markets	Percentage of the firm's sales in each new market

Internal Perspective	
Goals	Possible Measures
Improve the quality of online service	Target market survey Number of customers who use the service Time to run the service software from Web site
Quality online technical help	Amount of time to answer customer e-mail Number of contacts to solve a problem Number of problems covered by Web site FAQ Customer follow-up survey
Quick product cycle time	Number of days to make the product
High product quality for online service	Product test statistics on specific performance measures

Web server size adequate and operational 24/7	Number of actual simultaneous Web page requests ? maximum possible Percentage of up-time for server Number of mirrored or backup sites
Optimized number of customer service reps responding to online help	Number of inquiries to customer service rep ratio
Superior Web site content management	Number of updates per week Web site log traffic pattern statistics
Optimized inventory levels	Average number of items in warehouse Inventory turnover Supplier speed to deliver product
Supply Chain Value to firm	
High supplier satisfaction	Supplier profits from our firm's orders
Partner value	Number of visitors from partner site to ours and number that purchase Partner contribution to product design

Financial Perspective	
Goals	Possible Measures
Increase market share for online products	Market share percentage (firm's sales as percentage of industry sales)
Double digit sales growth	Dollar volume of sales from one time period to the next
Target 10% ROI within one year for each new product	ROI
Lower customer acquisition costs (CAC) in online channel	CAC (costs for advertising, etc. divided by number of customers)
Increase conversion rates at Web site	Number of orders divided by number of visitors to site
Increase individual customer profit	Average order value Profit contribution over time less CAC
Achieve at least a 10% Net profit in first year of new product	Net profit as percentage of sales

Abstract

Although E-Commerce has marketability as well as usefulness, there are few empirical studies on consumer acceptance using the transaction cost theory. This paper suggests that consumer product acceptance is determined by the difference of transaction cost. And the uncertainty and asset specificity which determine the transaction cost can affect the consumer acceptance of products. In addition, we focus on the different characteristics of digital and physical products in electronic markets.

We found that transaction cost, uncertainty, and asset specificity have a significant effect on consumer product acceptance of digital products, while only transaction costs and uncertainty have a significant effect on consumer product acceptance of physical products. In consequence we provide companies to some guidelines of strategic planning for the development of products in electronic markets.

1. Introduction

Recently electronic markets have reduced time and costs, and provided opportunities by creating new values, such as a cyber marketing channel. Physical products were the only goods available for marketing in the early stage of electronic markets. However, the importance of marketing for digital products has been increasing in that demands on digital products have been increasing dramatically in information-oriented society.

The main reason to take notice of digital products is that the purchasing process of digital products differs from that of physical products. And digital products have different economical characteristics from physical products; Reproduction cost and distribution cost are almost zero, and then the price of digital products can continue to fall. Furthermore, the price of digital products may be set high according to the value that customers feel as the products could be customized and personalized to meet the desire of customers [24][32]. That suggests that customer acceptance of products could be different according to the characteristics of products.

Previous studies said that consumers preferred a purchase in the market where transaction costs were low. And the asset specificity and uncertainty of products and a process affected transaction costs [23] [25] [30] [38]. However, since the advent of the Internet, those studies were not enough to explain consumer's purchase with economic terms in electronic markets. Some researchers have studied the purchase of physical products with a viewpoint of transaction cost in electronic markets [4] [5] [10] [23] [25] [29] [30]. But studies on adoption of digital products in electronic markets have hardly been performed. Therefore, this study aims to find that the influence of asset specificity and uncertainty of physical products is different from that of digital products in electronic markets based on the transaction cost theory. Furthermore, it is going to verify whether consumers' product acceptance is distinguishable regarding the different characteristics of physical and digital products.

This study contributes for firms to realize economic incentives and different characteristics of physical and digital products in electronic markets. It causes firms to be able to cut down costs, not just seeking low price strategies but overall cost reduction strategies. Thus, the study also contributes to suggest some guidelines of differentiation strategies for firms to develop new products for meeting consumers' needs.

This paper is structured as follows. The next section shows the transaction cost theory. In the third section, we develop hypotheses through reviewing previous studies on consumer purchase process regarding each products group; physical products group and digital products group. Section four describes the measurement and methodology, followed by empirical results in Section five. Section six discusses main findings, and Section seven concludes this study.

2. Transaction Cost Theory

The transaction cost theory has been developed as a useful framework to explain business administration such as management strategy, marketing, and organizational theory [1] [7] [12] [19] [20] [28] [37]. The transaction

cost means the cost of negotiating, monitoring, and enforcing accompanied by an exchange between two parts. Williamson[38] said that the transaction cost has been formed, because opportunism occurs by the limited rationality that human beings have. Moreover, the transaction cost is produced according to properties of assets such as products and services as the object of exchange, and it is caused by conditions such as uncertainty, information impactedness, and atmosphere of transactions.

Particularly, the asset specificity is an important concept among some factors to affect transaction cost. If assets are specific, the possibility to be exposed to opportunism is high. The transaction of the assets is hard, and then a high transaction cost is produced. Whether non-specific or specific assets are decided by the impossibility of relocating the assets without sacrificing their value. The asset specificity refers to the degree to which durable investments, that are undertaken in support of particular transactions, the transaction-specific skills and assets that are utilized in the production processes and provision of services for particular customers, such as human (e.g., people who have specific technology or knowledge), physical (e.g., specific facilities), site (e.g., geographical proximity), and temporal asset specificity (e.g., specific time) [23] [25] [38].

Uncertainty, presented with the second property by affecting transaction costs, means that the impossibility of forecasting problems and accidents occurred in the middle of transactions. It causes transaction costs, since decision-making is difficult because people cannot forecast future problems. It can be divided into two, the uncertainty of a transactions itself occurred in the transactions process and the uncertainty of a product itself. Researchers insisted that the more complicated the transactions and the product explanations are, the more the uncertainty and transaction costs have increased [23] [25] [38].

3. Hypotheses

3.1 Physical Products, Transaction Cost, and Consumer Acceptance

Studies on the transaction cost theory have been performed in both electronic markets and traditional markets. Most studies showed that the transaction cost of physical products in electronic markets became lower compared to traditional markets [4] [5] [10] [25] [39].

Williamson [39] insisted that electronic markets have a low transaction cost, but high risks in the process of transactions. That is, a price and search costs of products become lower in electronic markets, whereas the process of decision-making has been complicated because of the risk of the fall of product's value in the middle of transactions, and the cost related to a physical transfer from a seller to a buyer and the cost for participating markets.

Malone et al. [25] suggested that electronic markets have been more efficient since as information technology

is improved, it simplifies a complicated product explanation and decreases asset specificity in electronic markets.

Clemons et al. [10] showed firms make decisions on minimizing the risks and costs of producing products. That is, improved information technology causes the firms to reduce costs of exchanging and processing information by the reduction of coordination costs. And it makes the possibility of information usage and processing capability increase.

Bakos [4] [5] proposed the hypothesis on reduced price in electronic markets. He suggested that the Internet have attracted thousands of buyers and customers to electronic markets and then electronic marketplaces have been generated. And the search cost of the electronic marketplaces has been getting lower and lower.

Liang & Huang [23] studied that consumer acceptance based on the transaction cost theory applied for electronic markets. They suggested that consumers move to the electronic markets which have a low transaction cost. Because consumers' product acceptance is influenced by transaction cost consisted of the uncertainty and the asset specificity. This study also showed that some products, such as books and flowers are more suitable for marketing on the web than any other physical products.

As discussed above, in electronic markets, the problems or risks occurred in the process of the transactions have decreased and the properties of products have been explained as enough as buyers can select the product because of improved the availability of information technologies. And then the uncertainty of the transaction and the product becomes lower. Besides, asset specificity has become lower since it is not necessary for customers to stick to the specific time or the specific site. As a result, the transaction cost decreases [26] [40]. Therefore, consumer acceptance of physical products in electronic markets will increase. Accordingly, this discussion leads to the following hypotheses.

Hypothesis 1: The consumer acceptance of physical products increases in electronic markets. Because the transaction cost of the products becomes low as uncertainty and asset specificity have decreased.

Hypothesis 1-1: The transaction cost of physical products becomes low as uncertainty and asset specificity of them have decreased in electronic markets.

Hypothesis 1-2: The consumer acceptance of physical products increases as the transaction cost of the products becomes low in electronic markets.

Hypothesis 1-3: The consumer acceptance of physical products increases as uncertainty and asset specificity of the products becomes low in electronic markets.

3.2 Digital Products, Transaction Cost, and Consumer Acceptance

As discussed the chapter 3.1, transaction costs has decreased gradually in electronic markets. However, these results maybe just applying for physical products. Could the same result be expected for digital products? Because

they have different characteristics from physical products [31].

Products mean the things firms are going to sell, that is, physical things in narrow meaning. In a broad sense, however, products mean the tangible and intangible things satisfying human desire and providing functional, social, and psychological benefits and utilities. Therefore, products are all things including products, services, and ideas that can be acquired through exchange [24]. Physical products are music CDs, shavers, groceries, the clothing which exist in the traditional store and are able to touch directly, whereas digital products have not physical forms such as software, traveling information, an electronic books, information of stocks, and MP3 files [6] [21] [31].

Digital products can satisfy consumer demands by providing customized products and services quickly, and can become the source of inventing values by making knowledge as products through information technology [3] [11] [13] [14] [15]. Bakos & Brynjolfsson [6] insisted that digital products can create new opportunities through contents re-package strategies such as licensing, rental, a differentiated prices and using cost per unit. Thus, the asset specificity of digital products will be increased by providing specific products to a customer because of the characteristics of digital products that can be customized and personalized in electronic markets. For example, customized and personalized digital products are software by version, traveling information, education information, and stocks information for an each customer.

For digital products, software offers enough product information and gives an opportunity of using a trial version [6]. Therefore, the uncertainty of digital products is considered to be low in terms of the characteristics of these digital products. That is, the uncertainty of digital products becomes lower by providing enough product information and also transactions are simple in electronic markets, and the transaction costs are decreasing.

Digital products have the following advantages. Firstly, the products are not extinguished (indestructibility). Secondly, the products are very likely to be changeable easily (transmutability). And thirdly, the products are reproduced easily (reproductibility) [31]. It costs very much to produce the first digital product. But it does not cost much to reproduce it because marginal cost is almost zero. The transactions of digital products are expanded to various fields such as online newspaper, digital image, music, software, all kinds of information services and games through the Internet. Some studies suggested that transactions of digital products in Internet business is getting more and more active, even though the market size of digital products is far small comparing to that of a physical product at the moment [6] [21] [31].

It was presented that a price of digital products was low in study of Strader & Shaw [29] which studied a cost difference between traditional markets and electronic markets. Some physical products have advantages in a product price, search cost and a sales tax section on the buyer side and in advertising cost and indirect cost on the seller side, whereas digital products have advantages in

almost all fields such as marketing cost, overhead cost, inventory cost, product cost and distribution cost in electronic markets. Strader & Shaw [29] suggested consistent results that the price of digital products and search cost in electronic markets is lower than that in traditional markets.

As discussed above, the asset specificity of digital products will increase by offering customized products and services quickly and expanding benefits and values that an each customer feels. And then consumer acceptance of digital products increases. The uncertainty of digital products will be low in that customers can easily get all the information of products and even experience them in advance through the Internet. However, the transaction cost of digital products will hardly increase because added costs to expand benefits and values are lower than that of physical products and firms are able to apply various price strategies to the transaction of digital products [3] [6] [11] [13] [14] [15]. Accordingly, consumer acceptance of digital products will still increase. The following hypothesis summarizes the above discussion.

Hypothesis 2: The consumer acceptance of digital products increases in electronic markets. Because the transaction cost of them becomes low even though uncertainty has decreased but asset specificity has increased.

Hypothesis 2-1: The transaction cost of digital products becomes low even though uncertainty has decreased but asset specificity has increased in electronic markets

Hypothesis 2-2: The consumer acceptance of digital products increases as transaction cost of them becomes low in electronic markets.

Hypothesis 2-3: The consumer acceptance of digital products increases as uncertainty has decreased but asset specificity has increased in electronic markets.

4. Research Methodology

4.1 Sample and Data Collection

The subjects were individuals (male and female) who have purchasing power in an electronic market and have experience that they have ever used the Internet. The sample was consisted of 238 undergraduate students who were taking Internet business course, 72 graduate students (business persons are 44 among them), and 77 businessmen including I firm and S firm. The data collection was performed during two months from May to June in 2000. Eventually, 340 responses were obtained.

Out of the 340 responses, 57 had to be excluded because 47 of them had incomplete data and 10 of them reported that they had never experience in purchasing in electronic markets. As a consequence, 287 questionnaires remained as the samples for this study.

4.2 Physical Products and Digital Products

According to Kim [21], for physical products, books

and cards were ranked at the highest, and then PC and computer parts and software were ranked high in electronic markets. For digital products, Kim [21] also suggested several widely used products such as traveling information services, reservation of hotels or performances, information services on stocks, education services, electronic books that could be read through the Internet, games and MP3 files in electronic markets. Therefore, this study selected ten physical and digital products considering the study of Kim [21] and the characteristics of the products. The physical products selected in this study were books, music CDs, household electric appliances, life goods, shoes and clothes, and gift goods and the digital products were software, traveling and reservation information services, educational information services, and information services on stocks.

4.3. Measurement of Variables

Consumer acceptance was measured by one item on a five-point scale. This item was developed by relying on the measure of Liang & Huang [23]. Transaction cost was measured by seven items on a five-point scale. These measures were adopted from the work of Williamson [37] [38] and Malone et al [25]. Uncertainty was measured by two items on a five-point scale. These items were developed by relying on the measures of Williamson [38], Malone et al [25], and Liang & Huang [23]. Asset specificity was measured by five items on a five-point scale. These measures were adopted from the work of Williamson [37] [38], Malone et al [25] and Liang & Huang [23].

<Table 1> Measurement of variables

Construct	Items	Operationalization
Consumer Acceptance	Decision on purchasing products	(Liang & Huang, 1998)
Transaction Cost	Search Cost	(Williamson, 1975), (Williamson, 1981), (Malone <i>et al.</i> , 1987)
	Comparison Cost	
	Examination Cost	
	Negotiation Cost	
	Order/Pay Cost	
	Transportation Cost	
	Post-Service Cost	
Uncertainty	Product Uncertainty	(Williamson, 1981), (Malone <i>et al.</i> , 1987), (Liang & Huang, 1998)
	Process Uncertainty	
Asset Specificity	Site Asset Specificity	(Williamson, 1981), (Malone <i>et al.</i> , 1987), (Liang & Huang, 1998)
	Physical Asset Specificity	
	Human Asset Specificity	
	Brand Asset Specificity	
	Time Asset Specificity	

The reliability of these items was confirmed, since the Cronbach's alpha of transaction cost, uncertainty, and asset specificity were estimated as 0.82, 0.78, and 0.84 respectively. Further, the validity of these items was confirmed by factor analysis.

4.4 Method of Analysis

Data analysis was conducted using a structural equation modeling to evaluate research model and understand the relationship of four variables such as consumer product acceptance, transaction cost, uncertainty, and asset specificity. Structural equation modeling has many advantages over path analysis or regression analysis especially when the observed

variables contain measurement errors and the interesting relationship is among the latent (unobservable) variables [7].

To analyze the difference of the relationships of four variables according to the characteristics of products, this study divided products into two product groups, such as a physical product group and a digital product group and evaluated the research model with each products group.

5. Results

5.1 Hypothesis 1 Test

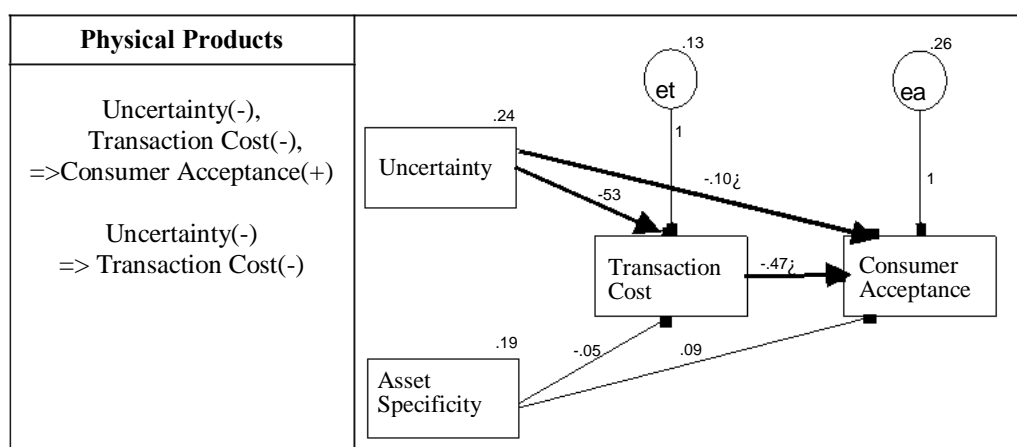

Consumer acceptance of physical products in electronic markets was evaluated. Table 2 showed coefficients of variables and Figure 1 suggested the result

of consumer acceptance of physical products.

<Table 2> Coefficient matrix of consumer acceptance of physical products

	Transaction Cost	Uncertainty	Asset Specificity	Squared Multiple Correlations
Consumer Acceptance	-.470*	-.102*	.092	18%
Transaction Cost		-.529*	-.051	29%

*p<0.05; **p<0.01.

*p<0.05; **p<0.01.

<Figure 1> Consumer Acceptance Model of Physical Products

Structural equation modeling was conducted using AMOS to test the fit between research models (Figure 1) and data set. There is no single recommended measure of model fitness. Therefore, a variety of measures are suggested [8] [16] [18]. Since chi-square statistics is very sensitive to both sample size and distribution of observed variables, several fit measures must be considered simultaneously.

In general, the goodness-of-fit is satisfactory when chi-square is not significant, the Goodness of Fit Index (GFI) is greater than 0.9, the Adjusted Goodness of Fit Index (AGFI) is greater than 0.8, and the Root Mean Square Residual (RMSR) is lower than 0.1 [18]. Overall, the various goodness-of-fit statistics indicate that the model shows a good fit with the data. In our dataset, the value of GFI is 0.996, the AGFI is 0.96 and the RMSR is 0.007 respectively.

As for the physical products, uncertainty (-0.529) significantly influences transaction cost indirectly but

asset specificity insignificantly leads to transaction cost. Transaction cost (-0.470) and uncertainty (-0.102) significantly influence consumer acceptance of physical products directly, whereas the direct influence of asset specificity on consumer product acceptance is not significant. That is, transaction cost and uncertainty are significant variables for consumer to accept physical products. Therefore, Hypothesis 1-2 is supported and Hypothesis 1-1 and Hypothesis 1-3 are partially supported.

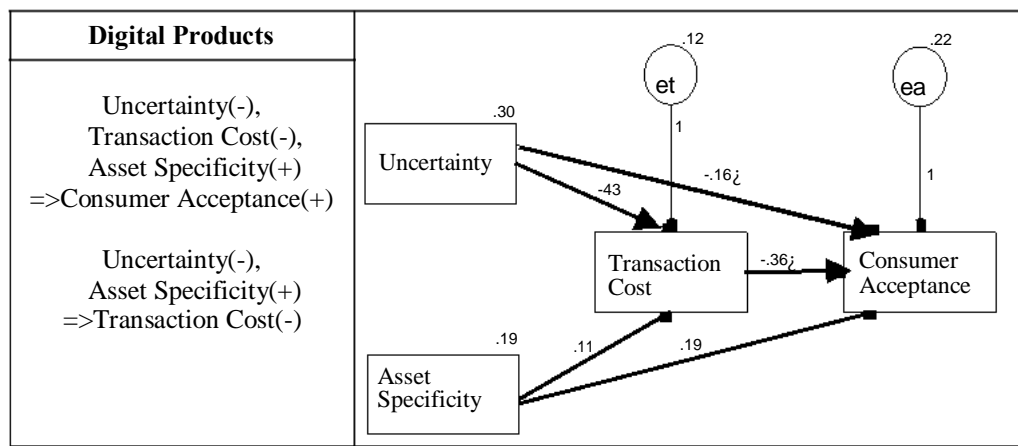

5.2 Hypothesis 2 Test

Consumer acceptance of digital products in an electronic market was evaluated. Table 3 showed coefficients of variables and Figure 2 suggested the result of consumer acceptance of digital products.

<Table 3> Coefficient matrix of consumer acceptance model for digital products

	Transaction Cost	Uncertainty	Asset Specificity	Squared Multiple Correlations
Consumer Acceptance	-.364*	-.163*	.194*	19%
Transaction Cost		-.433*	.107*	32%

*p<0.05; **p<0.01.

*p<0.05; **p<0.01.

<Figure 2> Consumer Acceptance Model of Digital Products

Overall, the various goodness-of-fit statistics indicate that the model shows a good fit with the data. In our dataset, the value of GFI is 0.997, the AGFI is 0.974 and the RMSR is 0.006 respectively.

As for the digital products, uncertainty (-0.433) significantly influences transaction cost but asset specificity (0.107) significantly leads to transaction cost indirectly though the strength is marginal. Transaction cost (-0.364), uncertainty (-0.163) and asset specificity (0.194) significantly influence consumer acceptance of digital products directly. Therefore, all Hypothesis 2-1 to 2-3 are supported.

6. Discussion

The verification of the hypotheses about digital products showed that uncertainty, asset specificity, and transaction cost are critical variables to cause consumers to accept them. The uncertainty and asset specificity have indirect influence on transaction cost, and this accords with transaction cost theory of Williamson [39]. For digital products, the indirect effect of asset specificity on transaction cost decreases the strength that transaction cost has effect on consumer products acceptance, whereas

the consumer acceptance of digital products was higher than that of physical products because of the direct influence of asset specificity on consumer products acceptance.

However, the verification of the hypotheses about physical products showed that the influence of asset specificity on consumer products acceptance is not significant. It could be interpreted that asset specificity is relatively small, and the physical products were not able to affect consumer acceptance because of standardization and simplification of products in an electronic market.

7. Conclusions

Based on the transaction cost theory, this study suggested a consumer acceptance model of physical and digital products in electronic markets and verified the relationship of transaction cost, uncertainty, asset specificity, and consumer acceptance. The study showed that transaction cost is a critical factor for consumers to accept products even in electronic markets.

The consumer acceptance was different according to two products groups. For digital products, there were negative(-) effect of transaction cost, negative(-) effect of

uncertainty and positive(+) effect of asset specificity on consumer acceptance. However, for physical products, transaction cost and uncertainty had negative(-) effect on consumer acceptance. That is, the study showed that the transaction cost of digital products is different in a degree of asset specificity and uncertainty. The uncertainty of digital products could decrease as providing product information more; for example order and delivery information or payment information in electronic markets. Transaction costs have become low since uncertainty is decreased. Eventually, the consumer acceptance of digital products goes up. Furthermore, the asset specificity of digital products could increase by personalization and customization in electronic markets. That means that consumers are willing to accept customized own products because digital products can give high value toward specific users.

Therefore, companies should develop new product lines considering the characteristics of digital products. In order to sell digital products efficiently in electronic markets, it will be necessary to establish strategies that manage uncertainty and asset specificity related to products.

This paper suggests that firms could recognize digital products newly considering the characteristics of the products. That is, the paper suggests that the asset specificity of digital products is a critical factor and a way that increases consumer acceptance of digital products in electronic markets. Secondly, the consumer acceptance model contributes to provide some guidelines of product development and strategic planning for digital products.

Abstract

There are two main sources of knowledge about customers: customer profile and customer participation. The companies use information technologies to analyze the customer profiles and extract tacit knowledge about customer via customer participation. The result of this experiment demonstrates that the use of customer profile improves customers' perception on goods quality and increase the effectiveness of Customer Relationship Management (CRM). In addition, customer participation can improve customers' perception on goods quality and enhance performance of CRM through perceived participation. The result indicates that the customer profiles and customer participation are two crucial factors for companies to maintain customer relationship.

1. Introduction

Companies are now focusing on high customer retention and maintaining long term customer relationship [2][28]. Customer relationship management (CRM) is a high customer retention strategy. It is very important to know more about customers' needs and offer customize products and services in order to improve customer satisfaction and loyalty [6]. To collect customers' profiles and to get customer participate are two main strategies to know more about customers' needs. CRM research highlighted the knowledge about customer are critical but the tacit knowledge of customer are not much

emphasized which the company need to make CRM efforts effectively [19]. Therefore, corporations should seek new interaction mechanisms to achieve complete communications and building partnership with customers and get more non-structured information of customers that is leveraged to drive CRM activities. In the context of urgent demand of tacit information about customers, customer participation in the service research should be considered as one important source of knowledge about customers besides customer profiles acquired by database technologies. Also, user participation is able to directly increase users' perception about the services provided by the companies.

The main objectives of this paper are to (1) discuss and integrate the CRM, customer knowledge management, customer participation relative researches to infer the conceptual model include customer profile and customer participation and measures of CRM performance; (2) to investigate the relationship between the degree of using customer profile and customer's perception on goods quality; and (3) to investigate the relationship between the degree of customer participation and customer's perception on goods quality and CRM performance.

To draw the impact of customer profile and customer participation on the CRM performances, this study examines the theories of CRM, customer participation and customer knowledge management.

2. Customer relationship management

The new marketing paradigm is based on knowledge and experience [21]. The knowledge-based marketing paradigm indicates corporations need to know more about customer and the experience-based marketing paradigm suggests that bring more interactions into customer related activities. From the 90s, there are lots of similar terms: customer management, customer information systems, customer value management, customer care and sometimes customer centricity or customer-centric management, but now clearly, the term Customer Relationship Management has overtaken the market [4].

CRM is an interactive process that turns customer information into customer relationships through active use of and learning from the information. It is a cycle for encompassing major group of actions: knowledge discovery, market planning, customer interaction, and analysis refinement [28].

Ryals and Knox [25] address the philosophical bases of CRM are: a relationship orientation, customer retention and superior customer value created through process management and successful implementation of CRM requires cross-functional reorganization, especially marketing and IT, to work closely together to maximize the return on customer information. The impact of use of IT on marketing reflecting the database marketing grew in significance in the late 1980s [21]. In summary, CRM integrated practices of database marketing to support short-term market tactics and conceptual frame to relationship marketing to develop long-term customer relationship strategy.

3. Customer knowledge management

There are some characteristics about the companies perform well on customer relationship management: excellent product, excellent management, and the use of knowledge about customer [7]. Customer knowledge management is going to be a research stream in Taiwan

recently [14]. There is similar concept: knowledge-enabled customer relationship management (KCRM) addressed by Tiwana in 2001. KCRM is a business model/strategy to manage customer knowledge to generate value-creating lock-ins and channel knowledge to strengthen relationships and collaborative effectiveness. It's more than a technology-focused solution [30].

Customer knowledge management is integrating with IT and business processes turns the customer information to knowledge which used to support marketing, sale and service decisions and build up good and strong relationships with customer base on knowing customer's need and create value to customer [14]. Knowing customer more, the corporation can precisely invest on valuable customers and reduce the cost on valueless customers [31]. In summary, CKM is the management technique turns the information from customer to the strategic-support knowledge to reinforce the value of goods which company offer for customer.

4. Customer participation

Insufficient knowledge base of customer limits the value which company can offer to the customers [7][39]. The basic component of customer knowledge comes from customer profile that obtained by use of database technologies in organizations. The customer profile is a more structured part of customer knowledge and a more non-structured part could come from customer participation.

In the service research area, customers contribute information or efforts in the service encounter process with the service provider fulfill the process together while the service produced and consumed at the same time [5][13][23][29]. For example, the patients describe their own symptom to doctors. It makes the process of diagnosis more smoothly. These services performance is heavily influence by the information and efforts of customers [13][17].

There are different dimensions of participation including personal interaction, information sharing, and responsible behavior. It suggests that participation has a positive impact on customer's perceived product/service quality and customer satisfaction and a mixed impact on retention. Different aspects of participation do not contribute equally in these models; specifically personal interaction was found to have more significant effects while the information sharing were thought to be of particular significance from a conceptual perspective [13]. There is a similar result in the new product development research area. It indicates that through close contact with customers, designers can accurately identify market requirements, quickly refine product specification and reduce time to market to remain competition [10].

Not much CRM research did specific effort on getting and using the non-structure information about customers [19]. And customer participation could fulfill the shortage of applications gaining tacit customer knowledge. Customer participation in the delivery of service process highly related the perceive quality of service, customer satisfaction and new product's performance [13][17]. Customer would contribute his own information in the process of participation and also get information about the corporation. This is a two-way communication between buyer and seller which would create impacts on the CRM's performance.

There are some similar discussions on participation in numbers of different research areas. In the service research, customer participation refers to the contribution of customer information and effort spent in the process of service encounter [5][13][23][29]. Customer participation influence the quality of service [13][17]. In the information system development research, user participation would influence user perceived system success and user satisfaction [34]. In the advertisement research, scholars concern about the impacts of customer involvement of advertisement and products on the

purchase decisions [37].

5. The research framework and hypothesis

Figure 1 presented this study's conceptual model derived from preceding discussion.

There are two main kinds of knowledge sources in the CKM construct, Customer profile and Customer Participation, the former represent use of IT to acquire and create information about customer in the organization and the another shows there are two-way communication and interaction between corporation and customers. In the CRM performance construct includes three measurements: Customer Satisfaction, Customer Loyalty, Customer Retention, this conclusion drew from the literature [8][16][33].

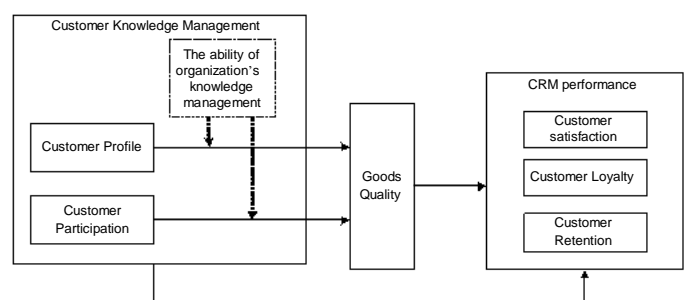

Figure 1. Conceptual model

5.1 The effect of customer profile on perceived goods quality

Goods mean the service or product which company offers to customers. Although there are many measurements to examine the quality of products, customers usually determine the quality of product base on their own subjective points of view [35]. From this viewpoint, the main factor of product's quality would base on the degree of conformation to customer demand. And it's harder to measure the quality of service when the goods is intangible [23]. The output of service is the process itself. The judgment of service quality would base on customer experiences and perceptions on the process [35]. The above discussion shows that it is crucial to measure customers' perception on goods quality.

Customer profile is a base form of customer knowledge. By obtaining and analyzing customer profiles, corporation can develop products and services to fit the customer's needs. Showing customers that the company is using their profiles to provide customized goods will also lead users to raise their perception on good. To examine this proposition, we propose the first null hypothesis of this research:

H1: Company obtained and used of customer profile could not influence its good's quality offer to customer.

5.2 The effect of customer participation on perceived goods quality and CRM performance

Besides getting customer profile to find out customer's needs, corporations also need to seek solution to gain more tacit information from customer to know customer better [19]. This situation indicates corporation should build some channels and launch activities to enable the transform of tacit information with customer. Based on preceding discussion on customer participation, it is possible for corporation to interact and get insights of customer needs through customer participation. Getting customers to participate in value delivery processes helps customers to know corporation ability better and raises the customers' perception on goods. The customer participation has also positive effects on customer satisfaction, customer loyalty and customer retention [10][13][17]. To examine this proposition, here propose the second and third null hypothesis of this research:

H2: Customer participation could not influence the goods' quality that companies offer to customer.

H3: Customer participation could not influence the performance of CRM.

H3a: Customer participation could not influence the customer satisfaction.

H3b: Customer participation could not influence the customer loyalty.

H3c: Customer participation could not influence the customer retention.

5.3 The effect of ability of organization's knowledge management

The building design research pointed out that there are several reasons that buildings do not meet the needs of their users, such as clients' need are not studied and documented and hard to trace and management these requirement and it also proposed a project focuses on the development of methods and tools to capture customers needs and interpret them into requirement and to manage the conformity of technical solutions [15]. It shows that organization don't know where their best knowledge is and how to use it well. The front end of company capture customer input continually while the limited ability of company's knowledge management might cause difficulties transferring the customer's requirements into new product characteristics and also to build meaningful and strong customer relationship with customer [7]. In order to discover main effects of customer profile and customer participation on the goods quality and performance of CRM, this research control the ability of organization's knowledge management as a constant construct which represents the organization use 100% of customer knowledge well and not examine this construct's effect in this framework.

5.4 The effect of goods quality on CRM performance

Service quality the company provide to customer positive affect the customer relationship quality, customer satisfaction and loyalty [20][32]. The quality of goods would influence the customer's buying decision-making. When quality of goods is higher than customer's expectation, customers are motivated to buy the goods. The goods quality depends on customers' subjective perceptions on how these high quality goods will bring them benefits [35]. High perception of goods quality leads to high customer satisfaction, loyalty and retention. To examine this proposition, here propose the third null hypothesis of this research:

H4: The quality of goods could not influence performance of CRM.

H4a: The quality of goods could not influence customer satisfaction.

H4b: The quality of goods could not influence customer loyalty.

H4c: The quality of goods could not influence customer retention.

6. Research Design

To test the relationships of customer profile and customer participation on perceived goods quality and performance of CRM, this research employ an experiment with scenarios of services encountered and the recall-base questionnaire. The primary advantage of using scenarios is that they eliminate difficulties of observation on the use of customer profile and the practice of customer participation in organization's everyday working. And also the use of scenarios reduces biases from memory lapses, rationalization tendencies, and consistency factors, which are common in results based on retrospective self-reports [26].

Recently, the on-line bank has prompted their on-line services and this would be a focal development in the future of the banking industry. This is the reason that this research used on-line bank service as scenarios and focus on five on-line services: credit card's bonus and gift exchange service, high amount transaction confirmation, payment reminder service, comments, and new service development conference, to narrow down the complexity and more precise reappearance of variable manipulation.

The subjects for this experiment were composed of students from four departments of EMBA in the Fu-Jen University. There were 119 EMBA students involved in the experiment and data collected using individually completed questionnaires after the last step of experiment. Of the 119 subjects, 96 subjects' questionnaires were valid. Among these 96 subjects, 68 were male, 28 were female.

7. Experimental Design

The experiment employed a 2X2 between-subjects design, in which customer profile and customer participation were manipulated. Each treatment is a scenario that was combination of one of two customer profile scenarios (high or low) with one of two customer participation scenarios (high or low).

This study deemed these three conditions would affect the perception of subject on the process. After separating subjects based on these conditions, assign subjects based on questionnaire filling time would reach random sampling. Subjects were asked to fill out the questionnaire and set their own account and password which be used to login the experiment system as realized scenarios of on-line bank. Subjects then read the explanation of specific terms and notice. The program drew data from the personal-data questionnaire to assign subject into one treatment of experiment. Subjects used their own account and password to login the on-line bank of the experiment. The first page subjects read was subject's account data which was default value represented the scenarios of on-line bank. Subjects were asked to transfer money for credit card payment used the on-bank interface which was a practice for subjects to familiar the operation of experiment on-line bank system and also a cue that the subject was one of on-bank customer. Subjects will then proceed to credit card bonus and gift exchange service. This step was the beginning of experiment's manipulation. The different semantics and operation on the page of on-line bank represented each manipulation of the experiment. Subjects then updated the setting of payment inform service, high amount transaction confirmation service. The different semantics and operation on the page of on-line bank represented each manipulation of the experiment. Only subjects in high participation treatment then asked to provide their comments. The last step is to ask subjects to participate in a new service development conference.

After the manipulations, subjects fill out the questionnaires based on the experience of previously operations of the on-line bank system.

8. Manipulation of factors and Measurement of Variables

Customer profile and customer participation are two independent variables of this study respectively. Each of them were manipulated as high and low degree based on the previous researches discussed above and represented as on-line banking system. The detail of manipulation and definition of independent variables are discussed below.

8.1 Customer Profile

Customer profile variable indicated that organization has had acquired the customer's information by different kinds of channels or systems to transform this information into practical instruments to provide customized goods. This study manipulated low and high degree of customer profile by the different semantic descriptions on the webpage such as "these gift are prepared for you based on your past transactions via our on-line banking service" as the cue and let subjects believed this on-line banking system provided customized service base on their own profiles and this would be the highly customer profile degree.

8.2 Customer participation

Customer participation means customer has to contribute some effort or information in the process of products or service fulfillment for customer. And this variable indicated that organization had built mechanisms and also invites customers to participate actively. This study manipulated this variable by supply different flexibilities of services for customers in the low and high customer participation treatments. In the high customer participation treatment, the subjects have more than one options base on their own demand and there was only one choice for subjects in the low participation treatment. For example, subjects in high participation can decide mean

and time to get informed on the due date of payment and the subjects can not decide in the low participation treatment.

8.3 Questionnaire

After going through all of the experiment steps, subjects were asked to fill out the questionnaires. The questionnaire is divided to two sections: first section contains four questions to check whether the subject perceived the proper scenarios in the right manipulation treatment. And the second section contains 20 questions of the intermediary and dependent variables included perceived goods quality, customer satisfaction, customer loyalty, and customer retention. All the questions are 7 points likert scales used number 7-1 presented very strong agree to very strong disagree and positive semantic statement.

9. Result

9.1 Data Validation

To measure the internal consistency of the collected date, this study assessed the instrument's reliability by the Cronbach Alpha coefficient. The result presented in the table 1. All Cronbach alpha values reach the level of generally considered acceptable reliability.

Table 1. Cronbach Alpha coefficient value

Constructs	Number of items	α
Perceived customer profile using	2	0.78
Perceived participation	2	0.66
Goods quality	5	0.86
Customer Satisfaction	4	0.89
Customer Loyalty	6	0.80
Customer Retention	1	1.00

The questions were adapted from relative researches and examined by two experts. Questions were modified to reflect problems encountered by the pretest subjects. The content validity and face validity would be acceptable.

To ensure the subjects had perceived the scenarios

in the right aspect, this doubt was tested using the two-tailed t-test. The results presented in table 2, 3, 4, and 5.

Table 2. Mean and St. Dev. of high and low customer profile

	Treatment	n	Mean	s.d.
Customer profile	H	49	5.73	1.24
	L	47	4.75	1.63

Table 3. t-test result of high and low customer profile

	t-value	d.f.	p-value
Customer profile	3.328	94	0.001*

*p<0.05

Table 4. Mean and St. Dev. of high and low customer participation

	Treatment	n	Mean	s.d.
Participation	H	45	5.46	1.17
	L	51	4.89	1.52

Table 5. t-test result of high and low customer participation

	t-value	d.f.	p-value
Participation	2.016	94	0.047*

*p<0.05

The results show that most of subjects perceived the right scenario and the high and low degree of manipulation also made significant difference.

9.2 The effect of customer profile

Table 6 shows the result of main effect of two independence variables on all dependence variables.

Table 6. Results of MANOVA

		F-value	p-value
Customer Profile	Goods quality	5.033	0.027*
	Customer satisfaction	1.303	0.257
	Customer loyalty	2.002	0.160
	Customer retention	0.140	0.709
Customer	Goods quality	1.064	0.305

Participation	Customer satisfaction	1.440	0.233
	Customer loyalty	0.333	0.565
	Customer retention	0.303	0.583

*p<0.05

The result shows that the use of customer profile would reflect on customers' perception of goods quality (p=0.027). Thus null hypothesis H1 is rejected. That is, the degree of using customer profile by company is positively related to customers' perception of goods quality. This means subjects have perceived the service was designed based on their historic transaction and are more satisfied for their needs thus raised their perception on the goods quality.

9.3 The effect of customer participation

The result indicated customer participation is not significantly related to the subjects' perception on goods quality, customer satisfaction, loyalty and retention (see table 6). Thus there is no significant evidence to reject the null hypothesis 2 and 4. Wu [34] suggests that perceived participation should be an intermediary between participation and user satisfaction in the information system development research area. It would be discussed later of this paper to see if the perceived participation makes different.

9.4 The effect of goods quality

The effect of perceived goods quality on the CRM performance is presented in the table 7. It shows that goods quality makes significant effect on the customer satisfaction, loyalty, and retention thus the hypothesis 3 is rejected.

Table 7. The effect of goods quality

		F-value	p-value
Goods Quality	Customer satisfaction	9.313	0.000*
	Customer loyalty	4.698	0.000*
	Customer retention	3.013	0.000*

*p<0.05

10. Discussion

According to Wu [34], perceived participation is an intermediary between user participation and user perceived success and satisfaction on the information system development. Thus here to see if the same result comes out in this study. Table 8 and 9 shows the effect of perceived participation.

Table 8. The effect of Customer participation to Perceived participation

		F-value	p-value
Customer participation	Perceived participation	4.063	0.047*

*p<0.05

Table 9. The effect of Perceived participation

		F-value	p-value
Perceived participation	Goods quality	7.78	0.000*
	Customer Satisfaction	9.55	0.000*
	Customer Loyalty	4.861	0.000*
	Customer Retention	3.845	0.000*

*p<0.05

The results shows that perceived participation indeed intermediate between customer participation and customer perception of goods quality, customer satisfaction, loyalty, and retention.

11. Conclusion

Based on the finding of this study, it's necessary to modify the research framework to suit the results of test. Figure 2 shows the final model.

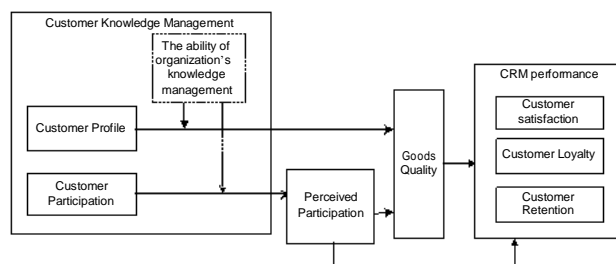

Figure 2. Modified model

This study investigated the effect of customer profile and customer participation on the goods quality. The finding suggests that the organization apply customer profiles into practical characteristics of products or service will raise the customer perceived goods quality and further affects the CRM performance. In this study, since the condition is simulated, it can be argued that the effect would be greater when the customers see their real profiles were used. Base on this study's findings, the impact of customer participation on goods quality and CRM performance is mediated by the perceived participation. In this study, users did not actually interact with representatives from the company. It can be argued that the effect would be greater when the customers interact with real person. This process changes customer's attitude toward this organization and reflect on customer satisfaction, loyalty and retention.

Although every effort was made to accomplish the scenarios of experiment toward be a near-real environment, limitations do exist because the subjects knew it is experiment and have different levels of perception as customers of an on-line bank. These would cause the inaccuracy of results between scenarios environment and the real-world cases.

Overall, this study explores the different dimensions of CRM theoretical development drawn from service research area in the context of service industry as main trend business world. These findings can be considered as the elements of building strong customer relationship that ultimately is needed in order to survive in today's competitive environment.

Abstract

Internet Banking is one of the channels for providing banking services. It is a delivery means that banks employ to expand their services in addition to traditional services provided through a branch's counters and ATMs. This paper aims at investigation, design, and development of an Internet-based retail banking prototype for Thai customers. The data were gathered from three major sources which were; (i) a survey on existing Internet banking services both overseas and in Thailand, (ii) questionnaires distributed to Internet users, and (iii) interviews with the executives of the major Thai banks. It was found that more than half of the sample Internet users in Thailand are very interested in using Internet banking services. The main features needed are balance inquiry, bill payment, fund transfer, business information, and payment for goods purchased. The prototype was then developed and validated.

1. Introduction

For a long time, banking has been one of the most important business sectors. It deals with almost all other businesses ranging from small activities to very large ones. Banks serve as financial intermediaries for individuals, companies, corporations and institutions both in public and private sectors.

In the banking business, providing good services to customers is an essential element of which every bank is conscious. In Thailand, most Thai banks have expanded their operations by setting up more branches to gain access to more customers. Having more branches enables banks to provide services covering larger areas although it requires large amounts of money for construction and equipment, as well as the high cost of hiring more staff.

Due to technological breakthroughs, banks have brought automatic teller machines (ATMs) to provide services to the customers. With these machines, the customers can make deposits, withdraw money, and check an account balance almost any time they want, in addition to the bank-working hours. Nevertheless, numbers of ATMs are limited, i.e., they cannot be available everywhere and there are several transactions that require customers to go to the bank by themselves.

Such transactions include opening a new account, borrowing money, etc. At the same time, banks have limited working hours, thereby bringing inconvenience to the customers. Owing to exorbitant costs, banks are obviously unable to open more branches, install ATMs everywhere, or extend working hours to facilitate and respond to the demand of every customer.

Contributed by substantial growth in information technology, especially with the advent of the Internet, both public and private sectors have modernized their operations in favor of providing services to their customers. In terms of banking business, many banking activities can be done through the Internet that will make banking services available any time and anywhere, covering the customers' offices, or even customers' homes. This will eliminate the necessity of setting up more branches and install ATMs everywhere. The customers can perform several banking transactions through their personal computers with modems, and their Internet account numbers. Such a process is called "Internet Banking".

Like traditional banking, Internet banking can be divided into two main categories, i.e., personal banking or retail banking and business banking or corporate banking. For retail customers, although they have small amount of money compared to corporate ones, they all comprise a large customer base and their banking activities do occur more often and regularly. Therefore, Internet banking can be another efficient channel of delivering services to such customers.

Although Internet banking, originated in western countries, is a good alternative that helps to get rid of exorbitant costs incurred from establishing new branches and ATMs, it may lead to some important problems in Thailand. In the case of Thai banks, there may exist some questions of what is the suitable strategy in delivering the service, what are the most appropriate features to be included or what are the actual customers' requirements, as well as which way Thai Internet banking will move to in the future. Therefore, this study aims to; (i) investigate retail banking services on the Internet, (ii) conduct a series of interview and a questionnaire survey in order to study the needs for Internet banking services for Thai customers, and (iii) develop a prototype of a retail banking service on the Internet for Thai customers. The proposed prototype is focused on the front office

system. It also simulates the host of the bank system by building a three-tier architecture including a front office system, database system and some processes in the back office system that support the front office.

2. Review of Literature

2.1 Internet Banking

In general, there are three ways banking services can be offered electronically to the home market [1]. The first is when banks supply their customers with bank-branded software to load onto their computers at home. Then, by using a modem and dialing the bank's main computers, customers can query their balances, review their account activity, transfer funds between accounts, and pay bills. This client-based service, for which bank software is loaded directly onto the client, is offered by banks such as Citicorp and Bank of America. The limitation of this kind of service is that the customer must dial the bank directly from his or her computer. This type of connection might prove a hardship when traveling overseas.

The second kind of delivery mechanism available to banks is to use an on-line service provider. By giving their customers access to their accounts by one of these avenues, the banks are taking advantage of an existing global network infrastructure to deliver their services. In doing so, they are, in effect, outsourcing many of the security issues and responsibilities as well. Institutions such as First Chicago Bank and Bank of America are using this method, and, through various online service providers, they are providing customers with home banking.

The third method of delivering home banking services is by owning and maintaining a dedicated Web server. This mechanism provides the capability of offering customers a fuller range of services, but increases the risk for the Web owner. Financial institutions such as, Security First Network Bank and Wells Fargo have gone down this route. These banks have developed their own Web servers, and offer services directly on the Internet. Examples of Banks that offer Internet Banking are reviewed as follows;

2.1.1 Foreign Banks

- Security First Network Bank

In mid-1995, the U.S. government's Office of Thrift Supervision gave approval to Security First Network Bank (SFNB) to provide Internet-based banking services. SFNB, formed by three banking companies (Huntington Bancshares, Inc., Wachovia Corp., and Area Bancshares Corp.), is an FDIC-insured bank that basically exists only on the Internet. In October 1995, SFNB opened its government-insured checking accounts to its customers via the Internet, and as of that date it was the only bank to have received approval to

conduct online operations between accounts, update balances in real time, open accounts, and reconcile bank statements. Services also include an on-line check register that functions similarly to personal finance software, and customers can view digital images of their cleared checks. (At present, SFNB is under RBC Group).

- Citibank

Citibankonline.com, the online banking component of Citigroup, continues to enhance its already broad online banking offering. With a single login, Citibank online banking customers can view all of their accounts held at Citibank. Credit card customers can link their account to view it alongside other deposit and loan products. Furthermore, customers have the ability to link or unlink their accounts together, at their discretion. Online banking customers can also make internal transfers from their deposit accounts to their loan accounts, including their Citibank credit cards [2].

Other Internet banks are shown in Table 1.

TABLE 1
Examples of Internet Banking Services

Bank	Online Services
NetBank [4]	Account summary, tax information, fund transfer among accounts, bill payment, check copy request, check & deposit slip reorder request, bank mail, and financial calculator.
Nbank [5]	Account summary, transfer among accounts, bill payment, pending transaction, custom reports, notification system, password and personal information.
Wells Fargo [6]	Account information, foreign currency, travelers cheques, cashier's / official bank check, check copy reorder, statement request, user preferences, transfer funds, online bill payment, financial planning.
ANZ [7]	Balances and transaction history, credit card statements, fund transfer and bill payment, business accounts, share trading and investment management.
USABancShares [8]	Interactive customer service, account balance, ask questions through web site, account summary, fund transfer, loan advance, loan payment, bill payment, and message center.
Bank of America [9]	Account balances, accounts summary, fund transfer, self-service feature (reorder check, order a copy of a check or statement), download transaction information to financial management software, send and receive secure customer online mail, bill payment and bill presentment.
BankOne [10]	Account summary, download account activity, funds transfer, bill payment, bill presentment, customer service (read messages, send a message, update profile, reorder check), and financial management software.
Fleet [11]	Online Banking with HomeLink (check balance, check recent transactions, confirm cleared deposit, confirm check cashed, bill payment, personal financial software, customized PIN, online investment).

2.1.2 Thai Banks

- Siam Commercial Bank

Sceasy.com was a new service, initiated in September 1999, by the Siam Commercial Bank (SCB). SCB is the first bank in Thailand to introduce this kind of service under the name "www.scbpark.com" later changed to "www.sceasy.com". The present version of the service allows customers to use the following online services: sign-up, balance inquiry, fund transfer, fund transfer to the third party, current and past statement inquiry, check withholding, bill payment, loan application, and online shopping [3].

- Bank of Asia

Bank of Asia was the second bank in Thailand to provide an Internet banking service called "AsiaCyberbanking". Its system was tested in January 2000, and became available around September 2000. Bank of Asia does not provide application services on the Internet banking for the following reasons:

1. Before giving approval to each Internet banking applicant, the bank requires signed documents for identification purposes, despite the application screen being available in its web site. The bank considers the Thai postal service as unreliable: documents sent to customers and returned to the bank may be delayed or undelivered. Therefore, customers have to apply in person at the bank.

2. There are more likely to be junk files submitted by those who do not really want to apply for the service. Nevertheless, the bank does create mandatory information management to eliminate these junk files [12].

So far, customers in AsiaCyberbanking service include both individual and corporate customers. Online account summary, account inquiry, inter-account fund transfer, bill payment, etc. are available to individual customers, while online import-export and remittance services are provided to corporate ones [13].

- Thai Farmers Bank

Thai Farmers Bank's Internet service formally commenced operation on December 2000 under the website name "www.gototfb.com". The range of services includes application for services (such as opening a new account, applying for TFB Internet banking), balance inquiry, viewing all transactions occurred, inter-account fund transfer, fund transfer to a third party, inter-bank fund transfer, salary payment (juristic person users only), bill payment transactions, and personal information changes [14, 15]. (Thai Farmers Bank is now Kasikorn Bank. -- www.kasikornbank.com).

Other Thai banks that offer Internet banking include Bank of Ayudhya (www.krungsrionline.com), Krung Thai Bank (www.ktb.co.th), and Bangkok Bank (www.bbl.co.th).

2.2 Features Comparison between Foreign and Thai Internet Banking

A survey on Internet banking services offered by foreign banks, particularly those in the U.S., and Thai banks reveals a noticeable difference. The former are largely non-branch banks, i.e., each bank simply establishes its own head office and delivers services through electronic channels such as ATMs, the Internet, phone, etc., whereas the latter mainly provide services through their own branches and subsequently introduce Internet banking as another means of delivering services.

With regard to pattern of services, both foreign and Thai banks generally provide the same basic services including account summary, statement inquiry, bill payment, and fund transfer. Differences exist only in the detail of each service, and other supplement services in each bank. Some features of these services are summarized below.

2.2.1 Fund Transfer

Currently, features in fund transfer service provided by foreign and Thai banks are similar. That is, they offer inter-account fund transfer and fund transfer to a third party whose pre-authorization is registered. Nevertheless, they differ in that foreign banks permit their customers to transfer funds across banks for inter-account fund transfer and/or fund transfer to a third party, depending on the policy of a particular bank. First Internet Bank of Indiana (www.firsttib.com), for instant, offers inter-account fund transfer both within the bank and across banks, while fund transfer to a third party is not allowed at all. Through "Live Chat" inquiry, the expert from the bank clarifies authenticity for security reasons, and if customers wish to transfer funds to a third party, they can use a cheque instead [16]. Several foreign banks also perform the same service.

2.2.2 Bill Payment

In general, functions in bill payment services offered by both foreign and Thai banks are similar for single payments for the current day or the future. After transactions have been done, customers can check both history and pending transactions, which can be cancelled prior to due date. Some Thai banks, however, do not provide all of these functions but only offer immediate bill payment. Almost all foreign banks prefer to have multiple payment (customers can pay bills to many payees in one process) and recurring payment (customers can set up scheduled future payments covering long period) options.

One obvious difference in this service as provided by foreign and Thai banks lies in the fact that foreign banks generally offer an "add payee" function, customers simply fill out payee's name, address,

account number, and then select payee types available in a combo box such as electric, gas, credit card, etc. Generally Thai banks, on the other hand, do not provide this "add payee" feature. Their customers are permitted to make payments only to payees specified by the banks. Other Thai banks though provide an "add payee" feature, but payees must be in the banks' list, i.e., they are required to make contact with the banks before being in the payee list.

Finally, although the Internet banking services provided by banks around the world have some different features, they have one thing in common, that is, almost every bank requires their customers to be local residents only. For this reason, it might be inferred that Internet banking is a service designed under the concept of "Think Global, but Do Local," even though the Internet contains technology that can link people worldwide.

2.3 Important Factors for Internet Banking Services

From the preliminary survey, it can be concluded that the first thing that should be emphasized when developing Internet banking is customers' need. Focus should be given to new systems seeking to supply new services. Banks should introduce advanced services that attract a large number of customers.

Secondly, banks should study consumer behaviors. Even if excellently developed, Internet banking will be futile unless customers like it. Consumers, for example, may be concerned or unsure about the system, and prefer traditional services. Banks should, therefore, try to inform and convince them.

The third factor is security. In order to make customers feel safe, special attention should be paid to the security system. The fourth factor is the user interface. Banks should simplify system usage procedure and provide response time at an acceptable level.

Finally, functions should be able to off-load work from branches, so that users are aware that services provided through Internet banking are the same as those at branches, but the former is far more convenient. All of these are major points to which an Internet banking developer should pay careful attention. Nevertheless, the structures of Internet banking and timing to implement it depend critically on which particular policy the banks' executives concentrate. Nowadays, technology stands ready to serve the decision.

3. Vision of Thai Bank's Executives

The following section derives from the interview with four Thai bank's executives, one from the Bank of Asia, Thai Farmers Bank, Krung Thai Bank, and Siam Commercial Bank. The results of the interview are summarized as follows; [17, 18, 19, 20]

3.1 Policy of Internet Banking and the Whole Picture

Normally, the core banking system is made up of two parts: a deposit system and a credit system. The services are provided as either "services at the branch", where customers take their passbook to the counter for any transaction or "self-services", where transactions are performed via automatic machines such as ATMs. Self-service also include non-cash services such as telephone banking, and Internet banking that does not involve cash but is concerned with such transactions as statement inquiry, inter-account fund transfer, payment for purchased goods and services, etc. A non-cash service is one of the channels that enable banks to offer more services to their customers; however, this is rather new for the Thai banking system.

The core banking system in Thailand remains unchanged. Deposit and credit systems are still the dominant part of retail banking. In view of Internet banking, a major concern that plagues one of the executives is the question whether Thai banks are "following a craze." In Thailand, so far, there are approximately 600,000 to 800,000 Internet users, mostly (around 500,000 to 600,000) consisting of students, and the remaining of 200,000 are workers in private companies. When compared to the whole Thai population of 66 million, this figure is substantially small. Although the ratio in some countries is higher, Thai banks are less likely to compete with banks in those countries. Nowadays there are a large number of virtual banks offering in several countries, and most of them do not establish an office or branch, i.e., they are virtual banks in a real sense. The only investment required is to open web sites that impose a very low cost. Comparatively, Thai banks incur substantial costs, due to their established offices and branches.

If, in fact, the Thai banks are "following a craze", the immediate question is "do we need Internet banking now?" The answer is "yes", because unless banks do it now, they are more likely to lose their customers sooner or later. New customers, mostly of a young generation, will replace the old ones. These new customers, by nature, are eager to learn new things, and hence more likely to enjoy new technology. It is, consequently, reasonable for banks to provide Internet banking to serve this group of customers.

3.2 Security Concern on Internet Banking

The security system is another crucial issue for Internet banking to which banks pay careful attention. Bank of Asia, for example, has set up preventive measures; standardized by ABN-AMRO Bank (Bank of Asia is a member of ABN-AMRO Bank). Security systems initiated by the measures include a firewall and data encryption. In addition, the bank inserts its own

add-on module into the security system. At present, the bank follows a 128 Bit SSL standard. Similarly, Thai Farmers Bank also employs the same security system, i.e., firewall, and it is in the process of obtaining a SSL-128 Bit standard.

With respect to digital signature, the opinions are different. Since digital signature is quite new for Thailand and a law has not created to support it, some banks are currently studying on how to apply it to their Internet banking services. Thai Farmers Bank insisted that digital signature is unlikely to be used in Thailand because of the lack of CA, which is very difficult to obtain, inconvenient, and costly. The Siam Commercial Bank's Executive viewed this issue on a different point, he clearly suggested that SSL is sufficient, and digital signature is not necessary, as evidenced by the boom in e-commerce in the U.S., where identification verified through credit card number is sufficient. The application of digital signature imposes more expense and complex procedures to the users, and may have a negative affect on the use of Internet banking.

3.3 Customer Database

To the question whether the "Internet-banking customer database should be integrated with, or segregated from, the existing customer database", a senior director of Bank of Asia supported the concept that the customer database should be integrated because transactions generated from the Internet service have to be incorporated with normal transactions. On the other hand, the Thai Farmers Bank Executive suggested that there should be no integration (i.e., Internet-banking database and normal database). The two cannot be fully integrated, when considering terms of design. The reason is that once customers register on the Internet, the bank must have a database that keeps such data. In short, some data must be segregated, whereas others must be shared.

The Executive Vice President of Krung Thai Bank indicated that the customer database should depend on implementation methods as well as the computer system of a particular bank, and the segregated system might be more beneficial. The Vice President of Siam Commercial Bank expressed his view that the two databases should be segregated, because information on Internet-based customers is different from those of normal customers. The database may be shared, but detail may be different because the marketing concepts for Internet-banking customers are very much different from those of normal customers. At present, the customer database of Siam Commercial Bank is still integrated, but this may not be so in the future, depending on the policy. In conclusion, Thai banks should integrate databases, that is, allowing customers to have accounts that can be used either through Internet banking or branches' counters. Later, these accounts may be separated.

3.4 Feasibility of Internet Banking in Thailand

From the point of view of banks' executives, they all believe that Internet banking is likely to grow significantly in the near future. The major reason contributing to such growth is the steadily increasing number of Internet users and most of them are well educated and middle-class people in society. They, therefore, tend to rapidly accept new technology. Seemingly, the likely growth is independent of e-commerce law, and most banks are now in the process of Internet banking development. Although the law will serve to assure users legally, it may introduce more difficulties to the application of the system. However, banks' major concern lies in the competition; if some banks develop Internet banking whereas another bank does not do, this bank is more likely to lose customers, particularly prospective customers. Generally, targeted customers of these banks are the new generation people with a relatively high education.

Growth of Internet banking in Thailand depends crucially on an appropriate timing and number of Internet users. Obviously, the greater the number of Internet users, the higher the chance of success will be.

The Critical Success Factor (CSF) for Internet banking implementation in Thailand can be summarized into 5 areas;

- Customers' confidence in the security system: the extent to which the system is reliable for the customers.
- Convenience and simplicity that the system provides.
- Banks' policy on timing and priority of implementation.
- Banks' marketing strategies to enhance customers' demand.
- High system flexibility in response to market demand.

3.5 Strengths and Weaknesses of System Development

Bank of Asia's executive stated that the strength of the Internet banking system of the bank is that its database is characterized by a CIS (Customer Information System) which enables the bank to see the whole picture of their customers. Once Internet-customer logs in to the system, all information on that customer will be shown on only one screen, thereby bringing about convenience to the customer. He or she does not have to know whether the account is current or saving or time deposit, and does not have to key-in an account number, because it will be shown by the system. This system, as a consequence, allows the bank to add on several functions easily. The bank pays great attention to its security system, which several parties can be concerned about. Presently, the security system is quite reliable.

Thai Farmers Bank's executive indicated that convenience is the strength of their system, whereas the small number of users or a very low demand is the weakness of the bank's Internet services. It is estimated that there are approximately 800,000 Internet users, which is smaller than the number of mobile-phone users, over half of these Internet users are students.

Krung Thai Bank's executive said that easy access to the system and availability to the customers is an important strength and security might be the major weaknesses of their system at the moment. Siam Commercial Bank's executive said that since the bank is the first to launch Internet banking, its brand name should, therefore, be its strength. Another strength is that the bank uses its own staff to write software, thus leading the bank to achieve a higher degree of flexibility than those that cannot write their own software.

All the executives agree that the budget for system development is a major concern. Internet banking requires a large amount of investment. The approximate figures for implementing internet banking for the four banks are: 20 million baht (500,000 USD) for Bank of Asia, 20 – 30 million baht (500,000 – 750,000 USD) for Thai Farmers Banks, 10 million baht (250,000 USD) for Krung Thai Bank, and 30-40 million baht (750,000 – 1 million USD) for Siam Commercial Bank.

3.6 Obstacles to System Development

It can be summarized from the interviews that the problems and obstacles of developing internet banking in Thailand are as follows;

- 1) Highly changing requirements cause the bank to consistently monitor the market and adjust the system accordingly.
- 2) Most customers perceive Internet banking as a 24-hour service, but in fact, most of the other systems of the bank do not run 24 hours a day, since they are run with a batch system at night.
- 3) Since Internet banking has to utilize resources from several departments, the supports from managerial level as well as the cooperation from operational level are very crucial.
- 4) Owing to rapid change in technology, human resource development keeping up with the change poses a certain problem.

4. Prototype Development

The methodology used for prototype development was substantially based on a Software Development Life Cycle (SDLC) comprising eight different steps, i.e. preliminary planning, study of relevant theories and researches, data collection, analysis, design, development of system prototype, verification test and

improvement, and conclusion and documentation.

4.1 User Requirement Analysis

User requirement was obtained from the analysis of banks' customer requirements for Internet banking services. The analysis is entirely based on questionnaires surveyed, covering 318 participants. Of this, 245 are Internet users, whereas 73 have never used the Internet. Most of the latter are relatively ill educated, rather aged, and Internet-illiterate. On the grounds of data analysis, it is found that those who are Internet-illiterate provide no relevant information for this research, and thus are ruled out from the analysis.

The questionnaire analysis reveals the five most popular services as, in order, balance inquiry, bill payment, fund transfer, business information, and payment for the purchased goods or services. It should be noted that although the business information service provides customers with banking and other economic information is one of the first services offered via banks' web sites, it is still of interest for all customers. In regard to payment service for goods or services purchased via the Internet, customers want to make payments from their own accounts, in addition to credit cards, which are widely used in e-commerce.

Also demonstrated by questionnaire analysis, highly secure service is what Thai Internet users require first. The other crucial elements are reliability, confidentiality, facilities, fast process, good user interface, and variability. Furthermore, the most important influences in attracting Internet users to Internet banking services are time saving and fast processing. The other reasons center around facilities, elimination of the need to travel to banks, a new alternative, 24-hour service, modernity, and cost saving. On the other hand, factors that dissuade Internet users from using Internet banking services are uncertainty in security system, no need to use, lack of support by law, unwillingness to pay more fee, and non-ISP member.

The figures from questionnaire analysis show that those who are willing to use the service at the level of "very interested" and "interested" account for up to 64.5%, while the level of "moderate" comprises 20.8%, and "not interested" and "indifferent" are made up of only 14.7%. Of this number, those who are most likely to use the service account for 12.7%. Based on an estimated number of Internet users in 2005, prospective users of Internet banking service will approximately vary between 353,943 and 408,238 throughout Thailand.

4.2 Proposed Prototype (CNet Bank)

The prototype developed in this paper is called "CNetBank", shown in Figure 1., and is divided into six main parts: banking information, system sign-in,

banking transactions, customer information management, system administrator, and customer help services. The first part includes banking information, help for general customers, and application for CNetBank online member. The second part covers not only the verification of a customer's authority, but also the identification of whether the customer signing in is either a CNetBank customer or CNetBank system administrator. CNetBank customers can access both the third and fourth part of the system. In the third part, a customer can do several banking transactions involving account summary, statement, bill payment and funds transfer, while in the fourth part, a customer can manage his or her information such as changing personal information, editing a personal account, and changing user name and password. In the CNetBank system, an administrator can access the fifth part to simulate the back-office system. The final part, customer help service, is divided into two sections – help for general customers, and help for Internet banking members. Both types of help perform similar function, except that the latter provides member information for the relevant members only.

Figure 1. CNet Internet banking startup page

From the system point of view, the prototype consists of two main parts: front-office functions and user interface. In this prototype, it is focused solely on the presentation of a front-office system, whereas the back-office system is partly presented in the administrator center page in order to simulate the back-end operation of pending transaction and recurring fund transfer processes.

The front-office system of this prototype, called CNetBank Personal Online, contains the major service features developed on the basis of user requirements derived from the customer survey using questionnaires. Furthermore, it was developed under the guidelines obtained from the visions and conceptions on Internet Banking derived from four Thai bank executives' interviews. Service functions mentioned above can be represented in the structural chart, a top-down chart showing each level of a design, its relationship to other

levels, and its place in the overall design structure shown in Figure 2.

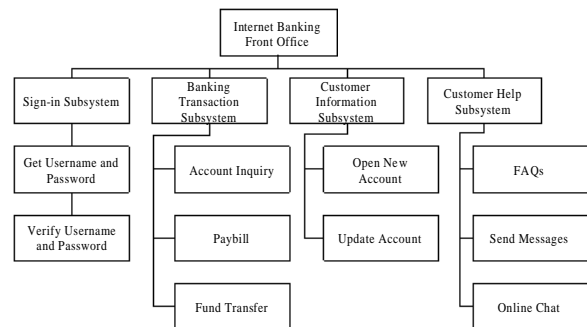

Figure2. Structural Chart for Front Office System

4.3 Features

The advantages of the CNetBank are summarized as follows;

1) Customers who open at least one savings account or current account with the bank can apply for the Internet Banking service online by filling out only one account number. Right after being given approval, a customer is allowed to increase or decrease number of his or her account and third party account all of which are used in Internet Banking service without asking for permission to the bank. This is because the system is designed to link with all account information and personal information of customers. As such, the system can instantly check the number of customers' accounts during online time. Furthermore, if the customer opens another account after applying for an Internet Banking service, information on this new account will appear in the "account management" screen of that customer, and a customer can select this new account to be used in Internet Banking. On the other hand, a customer can withdraw any account from Internet Banking, and then all information on that account will no longer exist. This "account management" feature, therefore, provides customers with high flexibility in managing his or her accounts used in Internet Banking.

2) Customers can conduct bill payment and fund transfer by specifying "today transaction" and/or "future transaction". This service allows customers to be well prepared for their bill payment and fund transfer. For example, if customers know that they will be busy at any given date in the future, they are, by this service, assured that their bill payment and fund transfer will be conducted.

3) Transaction checking is another key feature that enables customers to check both history and pending transactions that occurred in either payee account, payer account or both for up to 12 months. For pending transactions, customers can cancel them prior to the due date.

4) In fund transfer, customers can set a period of

recurring fund transfer for up to 12 periods, thereby saving their time and expenses in traveling to the bank.

5) Every fund transfer transaction provides a memo for customers to take note. When a transaction is viewed, the memo will appear behind it. For bill payment, customers do not have to write a memo, because it will be automatically managed by the system.

6) In this prototype, customers are permitted to deal with their own security information at any time. That is, they can change user name and password themselves. They can also change their address and personal information themselves.

7) The customer help center offers four service channels including frequently asked questions (FAQs), message sending, online chat, and a call center. The key feature lies in the online chat that provides real time conversation between customers and bank staff through the Internet. When online chat is in use, the bank will instantly know whom the bank is talking to and his or her personal information. This enables the bank specialist to respond to customers' questions more effectively, and to offer products and services more suited with the customers' interest.

4.4 Experts' Validation

From interviewing Internet banking experts, the following comment and suggestions on the CNetBank prototype were provided.

1) In reference to the security system, modern systems typically require customers to use their e-mail address as a user ID instead of an arbitrary name when they apply for the service.

2) In online application forms, they should require customers to fill out only necessary information such as personal information and bank account number both for verification, and current address for contact with the bank. Here, an e-mail address is very important. Any other unnecessary information should not be required because it may cause customers to be tired and must be kept in the database that, in practice, should not be bulky.

3) For web design in Internet Banking services that mainly involve money, they should be simple, easy to use and understandable.

4) An "Account summary" describing information on all accounts customers have with the bank is a good idea. However, it should be available for customers to choose which accounts do appear or do not appear in the "account summary". This is because some customers do not want account information to be shown in Internet Banking.

5) With respect to the system configuration of actual Internet Banking used nowadays, when customers are applying for Internet Banking services, they will access a web application server with several web servers working together. Networks are linked as an Ethernet

with load balance working as an operator. Before ODBC linking to the host transaction server where the customers' information is kept in the database server and transaction information are kept in the transaction server, there will be a firewall dealing with enhanced security. Transaction server processes occur through a watch table, a file used for time checking in updating transactions. Upon the information being updated, the system will link it to be processed in the bank's host, which is usually a mainframe system.

4.5 Comparison between the proposed prototype and the actual system

1) The survey on Thai banks reveals that, in light of bill payment, any payee whose name and account number is available in the payee list typically contacts banks before hand. If a payee is not in the bank's contact list, an Internet Banking member of that bank will not be able to use the bill payment service to make payments to that payee, and will not be able to add the payee to the bill payment service. In order to use bill payment service, the payee and payer are also required to be customers of counterpart banks. These are two limitations imposed by both Thai banks and this prototype. Some eminent foreign banks, on the other hand, allow their customers to add a payee at will, by simply filling out the payee's information.

2) In light of fund transfer, the system in this prototype permits customers to conduct inter-account fund transfer and fund transfer to a third party with the condition that both sending and receiving accounts must be opened with CNetBank. Fund transfer to foreign banks is not allowed, however. In any case, the survey on fund transfer transactions in Internet Banking services of Thai banks shows that Siam Commercial Bank and Thai Farmers Bank provide fund transfer to a third party. The former requires that both accounts be in the same bank (intra-bank only), while the latter allows inter-bank fund transfer through the Internet. For the foreign banks, some of them such as Netbank, allow customers to make inter-bank fund transfer to a third party via the Internet, whereas some banks impose conditions that a counterpart bank be a nominated company only.

3) Customer information linked to Internet Banking may cause some customers (who are not confident in doing Internet Banking transactions) to be uncertain whether their information will be available if hackers attack the system. In a real banking system, an extremely reliable security system is established. It is required that there be a firewall and other necessary check points in the back end system. Moreover, transaction information in the Internet must be encrypted through secure socket layer (SSL) for at least 40 bits (from a standard of 128 bits) so that it is difficult for a hacker to access the system. In this system, on the

other hand, is not necessary to implement SSL, because the developed system is only a prototype.

4) In light of service fees for all types of fund transfers and bill payments offered in the CNetBank, there is no function designed for charging the fees from customers, because the business rule of the CNetBank allows them to use its services free of charge. This is applied to any transactions at any time (not just during the promotion period). However, this is not the case in the real world where banks can gain substantial income from charging service fees for every transaction occurring in their Internet banking services.

5) Regarding security in fund transfer to the third party, banks pose a limit on the amount of the transfer. Some banks, for instant, set a limit amount of 500,000 Baht (USD 125,000) per day for each username. CNetBank, allows customers to transfer up to 50,000 Baht (USD 1,250) per transaction. This means that, in a single day, customers can transfer funds to a third party several times. However, it might be unsecured for the bank to do so.

6) In order to facilitate customers, CNetBank permits its customers to immediately add the account number of other persons into the system for the purpose of fund transfer. Customers are not required to submit requests to the bank for permission, in view of security; this might be unsecured as well. In practice, banks have to pre-approve customers' requests prior to giving approval. For example, Siam Commercial Bank sends a letter of agreement to their customers to sign and return to the bank. Thai Farmers Bank requires their customers to submit a copy of an identification card and census record after adding an account number of other persons. Upon verifying these documents, the bank allows the other account number to be used in its system.

7) The online chat service provided in this system is viewed in terms of technology development that supports the bank's customers. It can be said that real banks can afford to provide this service or even voice chat, ICQ, and Internet phone to support their customers in addition to a traditional call center. There may be an issue whether these services are worthwhile in the long run, because banks have to allocate people for delivering the services. This point should be left to economist to further investigate, and if it turns out that the services are not worth investing in, online chat provided in this prototype may become a weak point.

8) CNetBank is merely a prototype and efficiency of hardware resources obtainable limit development tools used in the development. For example, Microsoft Access, which cannot be used in the real banking business, is employed as a database management system, but it can be used in CNetBank prototype because the information on customers used in this system is imaginary and small.

5. Concluding Remarks

As long as businesses are in a highly dynamic and competitive environment, the search for modern technology is unavoidable. Internet banking is another channel to provide value added services to either existing or new bank customers. The survey from the executives of four Thai banks reveals that there is a potential growth for retail Internet banking in Thailand. Therefore, this paper proposes the prototype of a retail Internet banking system that meets the requirements of Thai customers. The data from the interview and the questionnaire are used to develop such a prototype, called CNetBank.

CNetBank prototype is divided into six parts – banking information, system sign-in, banking transactions, customer information management, system administrator, and customer help services. The first part includes banking information, help for general customers, and application for CNetBank online member. The second part covers not only the verification of a customer's authority, but also identification as to whether the customer signing in is either a CNetBank customer or CNetBank system administrator. CNetBank customer can access both the third and fourth part of the system. In the third part, a customer can do banking transactions including account summary, statement, bill payment and funds transfer, while in the fourth part, a customer can manage his or her information such as changing personal information, editing a personal account, and changing user name and password. In the CNetBank system, an administrator can access the fifth part to simulate the back-office system. The final part, customer help service, is divided into two sections –help for general customer, and help for Internet banking members. Both types of help perform similar function, except that the latter provides member information for the relevant members only.

After prototype development was initially carried out, it was evaluated, reviewed, and commented on by experts. The prototype was then improved and adjusted in accordance with these comments. Ultimately, the prototype was completed with several prominent advantages contained in the service features derived from the survey on user requirements that identify customer needs. In addition, the prototype provides flexibility in account management, time scheduling in transactions, checking for both history and current transactions, and scheduling of recurring fund transfers for up to 12 periods, etc.

The Impacts of Establishing Enterprise Information Portals on e-Business Performance

Shu-Min Yang, Ming-Hsien Yang, Ji-Tsung Ben Wu

Department of Information Management, College of Management

Fu-Jen Catholic University

Taiwan

yang@im.fju.edu.tw

Abstract

The Enterprise Information Portal (EIP) provides access - a single point of personalized, on-line access - to business information and knowledge sources, and real-time access to core application and processes. EIP is defined as an ultimate window that presents e-business fruitful results. Our research focuses on investigating the relationship between organizational characteristics and whether EIP is adopted in the business operations and the relationship among the function application degree, implementation type, integration ability, and users of EIP and e-Business performances. The result of our study shows that: (1) Between those organizations have and those have not adopted EIP, there are significant differences in the maturity and familiarity of information technologies, and organizational size; (2) In the way of implementation EIP, the relationship among function application degree, implementation type, integration ability, and e-Business performance are also significantly influence; (3) The impact between function application degree of EIP and e-Business performance will be enhanced by high e-business degree; (4) The impact between implementation type of EIP and e-Business performance will be intervened by e-business degree; (5) The implementation time of EIP has no significant impact on the relationship between implementation EIP and e-Business performance.

1. Introduction

The rapid developments of Internet and information technology not only provide great growth opportunities, but also change the way that enterprise operates and shaped the era of digital economy. The U.S. Census Bureau's e-Business Steering Committee divides the "electronic economy" into three layers: e-Business infrastructure, e-Business ("any process that a business organization conducts over computer-mediated network channels"), and e-commerce ("any transaction completed over a computer-mediated network that involves the transfer of ownership or rights to use goods or services") (Mesenbourg, 2000). As Gerstner (2000) indicated, "Today, e-Business is just Business – real business." Thus it can be seen e-Business will play an important role in digital economy to enhance competitive advantages.

Due to technology advances and the wide dissemination of information, many institutions suffer from information overload and need to apply information

management to deal with this information chaos in this digital world. Furthermore, organizations increase the requirements of experience and knowledge sharing, system integration ability, and personalized. The Enterprise Information Portal (EIP) provides access - a single point of personalized, on-line access - to business information and knowledge sources, and real-time access to core application and processes. According to Shilakes & Tylman (1998), Enterprise Information Portal is considered an emerging market opportunity, an amalgamation of software applications that consolidate, manage, analyze and distribute information across and outside of an enterprise (including business intelligence, content management, data warehouse/mart, and data management applications.)

Recently, industry trend-watchers have forecasted the rise of portal development in corporations. For instance, Gartner Group predicts with 80% probability that more than half of all major companies by the end of the year 2001 will implement corporate portals as the primary method for organizing and discovering corporate resources (Detler, 2000). Likewise, the Enterprise information Portal adoption rate based on a Delphi Group survey of Fortune 500 companies in 1999. About 35% of these companies have implemented a corporate portal and another 30% are in the pilot/experimental stage of development (Aneja et al., 2000). Further, Shilakes & Tylman (1999) estimate that the market for portal tools and services will be worth upwards of \$14.8 billion by the year 2002. Consequently, the Enterprise Information Portal is the most important business information management project of the next decade (Collins, 1999).

Our research focuses on investigating the relationship between organizational characteristics and whether EIP is adopted in the business operations and the relationship among the function application degree, implementation type, integration ability, and users of EIP and e-Business performances. Then, we address the e-Business degree and implementation time in intervening the influence of the impact of establishing EIP and e-Business performance.

2. Related Research

2.1 Enterprise Information Portal

Reynolds & Koulopoulos (1999) identify four phases of web portal development: boolean search, categorized

navigation, personalization and, finally, integration of additional features providing direct access to other specialized information and commercial worlds. This web portal evolution impressed the corporate community, which viewed the possibility to use the same technology to manage structure and facilitate the task of accessing the companies' internal information.

There has been a great interest during the past two years in the emergence of Enterprise Information Portal. In sum, an enterprise portal can be defined as a single point of access (SPOA) for the pooling, organizing, interacting, and distributing of organizational knowledge (Aneja et al., 2000; Schroeder, 2000).

Since newly developed, the terminology related to the Enterprise Information Portal has not been settled yet. The terms "corporate portal", "corporate information portal", "business portal", and "enterprise information portal" are used, some times, interchangeably as synonyms (Dias, 2000). Cutter Consortium also indicated Enterprise Information Portal is a "fuzzy word" (Chen, 2002).

Shilakes & Tylman (1998) identified Enterprise Information Portal as an amalgamation of software applications consolidate, manage, analyze and distribute information across and outside of an enterprise and enable companies to unlock internally and externally stored to make informed business decisions. Eckerson (1999) uses another term "business portal" and defines it as an application that provides business users one-stop shopping for any information object they need inside or outside the corporation. Dias (2001) uses a term "corporate portal", closely related to EIP, and use technical point of view to identify corporate portal uses metadata and eXtensible Markup Language (XML) to integrate unstructured data to structured data from operational databases, supplying access to corporate information through a personalized interface, available over the internal hypertext network-The Intranet. On the other hand, Murray (1999) stated that portals that focus only on content are inadequate for the corporate market and that "corporate portals must connect us not only with everything we need, but with everyone we need, and provide all the tools we need to work together" (Murray, 1999).

Portals have fairly complex structures and features. According to survey results for Intelligent Enterprise readers, once deployed, EIP resources will be divided among these functions: B2B e-commerce(38%), B2E e-commerce(37%), B2C e-commerce(25%) (Willen, 2000). However, their functions and elements are relatively easy to define (Roal et al., 2002). First, from an operational perspective, the strength of corporate portals lies in its ability to provide Web-based access to enterprise information, applications and processes. Second, from a functional perspective, they leverage existing information systems, data stores, networks, workstations, servers, and applications as well as other knowledge bases to give each employee in every corporate site immediate access to an invaluable set of corporate data anytime, anywhere (Kendler, 2000; White, 2000).

Functions and features are fairly difficult to define separately because they may have inter-related macro and micro level components. In most corporate portals, features and functions co-exist at the same level because they are still in the maturing process. Typically, the more common functions are the components that provide access to the range of disparate enterprise databases and information resources and the ease with which users can set up personalized access to enterprise and external information resources (White, 2000). In most enterprise portals, these functions may include, but are not limited to security, network, administrative tools, search, content management, collaboration personalization, extensibility, easy to use, and scalability (Eckerson, 2000).

2.2 E-Business

E-business is more than just an Internet presence or e-commerce transactions. It is a new business design "that emphasizes a finely tuned integration of customer needs, technology and processes" (Kalakota & Robinson, 1999).

Kalakota & Robinson (1999) define e-business as the complex fusion of business processes, enterprise applications, and organizational structure necessary to create a high-performance business model. e-Business includes e-commerce, as well as both front- and back-office applications that form the engine of modern business (Kalakota & Robinson, 1999).

e-Business is an enterprise with the capability to exchange value (goods, services, money, and knowledge) digitally. It has properly designed business processes for this new way of conducting business. Further, it understands the human performance challenges not only within its organizational boundaries but also for other people in its enterprise network: customers, partners, and suppliers. e-Business is a new way of doing business that involves connectivity, transparency, sharing, and integration. It connects the expanded enterprise through a universal digital medium to partners, suppliers, and customers. It requires the integration and alignment of business processes, technology, and people with a continuously evolving e-business strategy (Hackbarth & Kettinger 2000).

2.3 Organizational Characteristics

The organizational characteristics have significant impacts on quality and effectiveness of the planning process of information systems. The planning method of information systems must match the organizational characteristics (Premkumar & King, 1994). The relationship between organizational characteristics and whether Information Technology is adopted has been emphasized in both empirical and prescriptive studies (Yap, 1990; Grover et al., 1993; Yap & Thong, 1995; Premkumar & King, 1994).

Thong & Yap (1995) found that business size is the most significant discriminator in determining the use of information technology. Because here are some limitations for the small companies to adopt IT, such as

poor resources, financial constraints, lack of specialists, and high sensibility to outside pressures. They also demonstrated that competitiveness in the environment and information intensity does not significantly influence the adoption of information technology by small businesses. Grover et al. (1995) found that organizational structure and centralization influence organizations to adopt telecommunication technology.

According to prior research, this paper conduct seven organization characteristics from related research, including business size, information intensity, formalization, centralization, the maturity and familiarity of information technologies, industry type, and competitiveness of environment.

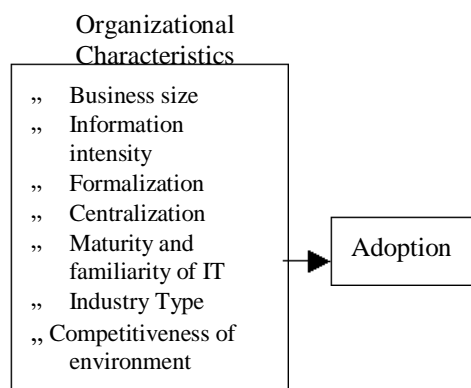

Fig. 1 Research Modal 2

In research model 1, we want to investigate the correlation between organization characteristics and the strategic decision to implement the Enterprise Information Portal. In independent variables, we induced seven organization characteristics from related research, including business size, information intensity, formalization, centralization, the maturity and familiarity of information technologies, industry type, and competitiveness of environment. The dependent variable, adoption, can be divided into two groups, adoption and non-adoption.

In research model 2, we would like to investigate the relationship among the implement of EIP and e-Business performances. Then, we address the e-Business degree and implementation time in intervening the influence of the impact of establishing EIP and e-Business performance. There are 4 directions to probe into the implement of EIP including application function degree, implementation type, integration ability, and users of EIP. In aspect of e-Business performance, we induced three different indicators from related literatures to measure, included operation performance, marketing performance, and adaptability performance. In intervening variable, the implementation time of EIP is different from each corporation, the time period my influence the e-Business performance. In addition, EIP is an important part of e-Business. Therefore, e-Business degree may influence the e-Business performance.

3. Research Method

3.1 Research Model

The objectives of this study were to understand the relationship between organizational characteristics and whether Enterprise Information Portal is adopted in the business operations and the impact of e-Business performances when implementing Enterprise Information Portal. According to the research objectives and related researches and literatures, there are two phases of research model were shown in Fig. 1 and Fig. 2.

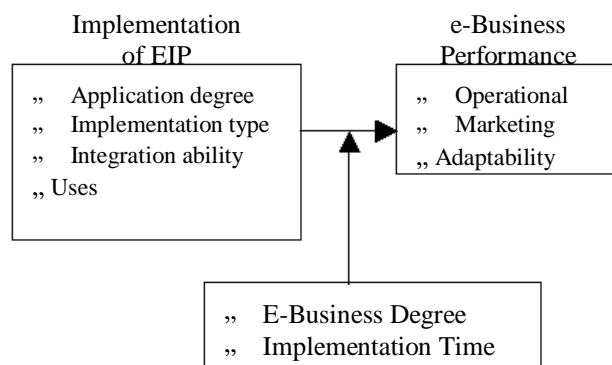

Fig. 2 Research model 1

3.2 Hypotheses

The relationship between organizational characteristics and whether information technology is adopted has been emphasized in both empirical and prescriptive studies (Yap, 1990; Grover et al., 1993; Yap & Thong, 1995; Premkumar & King, 1994). According to the results of prior researches, organizational characteristics do significantly influence the adoption of information technology. The organizational characteristics have significant impacts on quality and effectiveness of the planning process of information systems. The planning method of information systems must match the organizational characteristics (Premkumar & King, 1994). This leads to Hypothesis 1 (all hypotheses will be stated as null hypotheses):

H1: Organizational characteristics do not significantly influence the adoption of enterprise information portal.

We induced seven organization characteristics from related research, including business size, information intensity, formalization, centralization, the maturity and familiarity of information technologies, industry type, and competitiveness of environment. This leads to the following additional hypotheses:

- H1a: Business size does not significantly influence the adoption of EIP.
- H1b: Information intensity does not significantly influence the adoption of EIP.
- H1c: Formalize does not significantly influence the adoption of EIP.
- H1d: Centralize does not significantly influence the adoption of EIP.
- H1e: The maturity and familiarity of information technologies does not significantly influence the adoption of EIP.
- H1f: Industry type does not significantly influence the adoption of EIP.
- H1g: Competitiveness of environment does not significantly influence the adoption of EIP.

According to survey results by Chen (2002), applications functions of EIP do significantly influence on business performance. Consequently the stronger application function ability the corporations have, the corporation can more easily to achieve the requirements of increase ROI, enhance competitive advantages that the corporate needs. So, the stronger application function ability of EIP, the more brilliant e-Business performance. This leads to Hypothesis 2:

H2: The application ability of EIP does not significantly influence the e-Business performance.

- H2a: The application ability of EIP does not significantly influence the operation performance.
- H2b: The application ability of EIP does not significantly influence the marketing performance.
- H2c: The application ability of EIP does not significantly influence the adaptability performance.

The EIP product market is relatively young because it only started in early 1998 (Raol et al, 2002). The market is very immature and it is crowded with vendors offering different capabilities. Each product available on the EIP product market, when compared to its competitors has its own characteristics, distinct structure or additional components, presented as competitive (Dias, 2002).

White (1999) point out the two functions of EIP, decision-making support and collaborative processing, classifying EIP into four main categories: "Intranet Portal", "Collaborative Portal", "Decision Processing Portal", "e-Business Portal". It's the phases of EIP evolution. An EIP begins to add real business value to an organization when it supports access to information managed by decision-processing systems. In Other word, in the phase of decision process portal, EIP start to add real business value to corporate and in the phase of e-Business portal, EIP can contribute the hugest business value to corporate. For the reason, different implement

type of EIP may influence the business performance. This leads the Hypothesis 3:

H3: The implementation type of EIP does not significantly influence the e-Business performance.

- H3a: The implementation type of EIP does not significantly influence the operation performance
- H3b: The implementation type of EIP does not significantly influence the marketing performance
- H3c: The implementation type of EIP does not significantly influence the adaptability performance

Application integration services enable EIP to provide users with a centralized, unified, and consistent environment for interactions with all applications (Hummingbird, 2000). As described by Shilakes & Tylman (1998), central to the concept of Enterprise Information Portals is the assumption that disparate applications (content management, business intelligence, data warehouses/marts and data management) will :1) access other internal and external sources of information and data , 2) exchange information (bi-directional) and 3) use that information within the application for processing and analysis. In other words, these applications must be integrated with each other and to other external systems. The biggest selling point of EIP is their ability to present information from diverse sources through a common interface. Consequently, the most visible integration requirement for EIP is to provide an integrated web interface-based view of all (whether data store, content, or application server-based) of the information resources of the enterprise and external information resources that are the target of the EIP application (Joseph, 2001). This leads Hypothesis 4:

H4: The integration ability of EIP does not significantly influence the e-Business performance.

- H4a: The integration ability of EIP does not significantly influence the operation performance.
- H4b: The integration ability of EIP does not significantly influence the marketing performance
- H4c: The integration ability of EIP does not significantly influence the adaptability performance

Besides employee, the user of EIP includes suppliers or partners and customers. EIP can Diver business advantages through real time collaboration among employee, customers, suppliers and partners. EIP users can be external users, such as suppliers, partners, and customers. It will promote business volume and operational performance. Therefore, the different users of

EIP may influence the e-Business performance. This leads Hypothesis 5:

H5: The users of EIP do not significantly influence the e-Business performance.

H5a: The users of EIP do not significantly influence the operation performance.

H5b: The users of EIP do not significantly influence the marketing performance.

H5c: The users of EIP do not significantly influence the adaptability performance.

e-Business degree of organization is also the one of the factors may affect the e-Business performance. The successful implementation of the EIP is not only based on the business strategies that are tailored for the company, the corporation itself has also implemented e-Business in a satisfactory level. If the corporation still relies on traditional paper work culture, the competitiveness of the corporation will be decreased because of lack of informatics and digital technology. Furthermore, it will also create a barrier for the industry to launch and be one of the users of the prosperous internet, and it will not be able to gain all the benefits that the EIP can bring as a result. We therefore propose the following hypotheses:

H6: The impact between the implementation of EIP and e-Business performance will not be intervened by e-business degree.

H6a: The impact between application degree of EIP and e-Business performance will not be intervened by e-business degree.

H6b: The impact between the implementation type of EIP and e-Business performance will not be intervened by e-business degree.

H6c: The impact between the integration ability of EIP and e-Business performance will not be intervened by e-business degree.

H6d: The impact between the user of EIP and e-Business performance will not be intervened by e-business degree.

Furthermore, the implementation time of EIP is different from each organization, and the length of time will affect the performance. Base on the result of prior research, Chen (2000) mentioned the implementation time of IS has a significant impact on business performance. In other words, the longer time of the implement of system, the better business performance have. We therefore propose the following hypotheses:

H7: The impact between the implementation of EIP and e-Business performance will not be intervened by implementation time or EIP.

H7a: The impact between application degree of EIP and e-Business performance will not be

intervened by implementation time or EIP.

H7b: The impact between the implementation type of EIP and e-Business performance will not be intervened by implementation time or EIP.

H7c: The impact between the integration ability of EIP and e-Business performance will not be intervened by implementation time or EIP.

H7d: The impact between the user of EIP and e-Business performance will not be intervened by implementation time or EIP.

3.3 Sample and Data Collection

The sample frame for this survey was constructed using stratified disproportionate random sampling from the list of Taiwan Top 1000 companies was furnished by Common Wealth Magazine. The survey includes data from finance, service and manufacture industry sampling 100, 300, 600 firms respectively as the sample for this study. The key informants were the IT senior managers.

4. Analysis and Results

4.1 Data Collection

1000 surveys were mailed to IT senior managers on Dec, 2002. A month after the first round mailing, reminders and follow-up questionnaires were mailed out to 883 non-responding firms. 192 surveys were returned and 181 had complete data usable for analysis, yielding an effective response rate of 18.1%.

Among 181 respondents, 52 respondents indicated that they had completed an EIP deployment and 35 respondents were developing. They all start to implement EIP, so we classify 87 (48%) respondents into adoption group. Another 50 respondents were still in the conceptual stage of EIP project, and 44 respondents have yet to plan and establish. We classify 94 (52%) respondents into non-adoption group.

4.2 Stability Test

The non-response bias was tested in two ways. First, early and late respondents were compared upon four descriptive variables (e.g., industry type, turnover, total assets and employee numbers). The results of Chi-square test indicated that no significant differences in these four variables between early and late respondents (p-value are 0.102, 0.205, 0.586, 0.468). Thus, there was no evidence of obvious response bias in the sample.

Second, population and sample was compared upon three descriptive variables (e.g., industry type, total assets and employee numbers). The Chi-square test results also provides evidence that there was no non-response bias problem in the sample (p-values are 0.1845, 0.429, 0.072).

4.3 Validity & Reliability Test

Content validity is the determination whether the scale items used in the survey cover sufficient contents of the

underlying constructs. Firstly, it was established through a careful assessment of the literature. Secondly, the pre-test is done by 3 EMBA students, and some refinements are done according to their suggestions. Finally, at each stage, the questionnaire is iteratively revised by experts in the MIS field.

Those items to represent a construct as a one-phase measurement model or a dimension as a two-phase measurement model must have the unidimensionality to make sure the total score is valid to measure a single concept. The items without the convergent validity should be eliminated, according to factor loadings.

In this study, we used Exploratory Factor Analysis (EFA) to test the construct validity of the measures and evaluate the factor loading. Principal component analysis with a Varimax rotation technique was conducted on all items and no restrictions were placed on the number of components to be extracted. The principal components

were extracted on the basis of the “eigenvalues greater than 1” heuristic

In determining the appropriate minimum loadings required, loadings greater than .30 are considered significant; loadings of .40 are considered more significant; and loadings of .50 or greater are considered to be very significant. Thus, items were eliminated if the factor loading was below .50.

Both the Bartlett Test of Sphericity, a statistical test for the presence of correlation, and Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy are to determine the appropriateness of the factor analyses. Table 1 shows that KMO measures of sampling adequacy are higher than 0.725, with accepted level above 0.5, and the Bartlett test of Sphericity indicated significant differences in each construct, with p-value less than 0.05, the model is statistically significant and further analysis could be conducted.

Table 1 KMO & Bartlett test of sphericity

Construct	KMO Measure of Sampling adequacy	Bartlett Test of Sphericity	
		Approx. Chi-Square	p-value
Organizational characteristic	0.725	1488.760	0.000*
Application ability	0.875	401.999	0.000*
Implementation feature	0.900	1691.983	0.000*
Integration degree	0.861	592.938	0.000*
e-Business degree	0.891	2088.584	0.000*
Operation performance	0.884	661.550	0.000*
Marketing performance	0.725	336.933	0.000*
Adaptability performance	0.844	591.508	0.000*

Cronbach’s coefficient alpha is a widely used measure of scale reliability. Typically, a scale is reliable if α value is 0.7 or higher. Reliability tests were performed through the calculation of Cronbach’s α for each construct. Besides one construct named information sharing which alpha value is 0.6933 slightly less than 0.7. Others’ alpha value ranged from 0.7067 to 0.9468. Consequently, the result indicates internal consistency of the scales.

study, due to industry type is belongs to nominal data, used Chi-square test to proof the hypothesis. Others are used one way ANOVA.

ANOVA requires the test for homogeneity of variance first. To compute the Levene test for homogeneity of variance, as show in Table 2, the results are not significant in all variables of organizational characteristic. This is evidence that the assumption of homogeneity of variance has not been violated.

4.4 Hypothesis Testing

4.4.1 The Relationship between Adoption EIP and Organizational Characteristic

In the variables of organizational characteristic of the

Table 2 The relationship between organizational characteristic & the adoption of EIP

Organizational Characteristic	Levene (p-value)	Method	Adoption EIP		Result
			F (χ^2)	p-value	
Business size	2.470(0.118)	ANOVA	7.295	0.008*	rejected
Information intensity	1.409(0.237)	ANOVA	0.000	0.983	not rejected
Formalization	0.481(0.489)	ANOVA	0.411	0.522	not rejected
Centralization	0.485(0.457)	ANOVA	0.019	0.892	not rejected
Maturity and familiarity of IT	2.655(0.105)	ANOVA	21.061	0.000*	rejected
Competitiveness of environment	0.045(0.832)	ANOVA	0.496	0.482	not rejected
Industry type	-	Chi-square	(2.781)	0.245	not rejected

The result of the one-way ANOVA and Chi-square test indicates that between those organizations have and those have not adopted EIP, there are significant differences in the “business size” and “maturity and familiarity of information technologies” ($p < 0.05$). Thus, H1a and H1e are rejected. In addition, as show in Table 2, the correlation between other organizational characteristics included “information intensity”, “formalization”, “centralization”, “industry type”, and “competitiveness of environment” and adoption of EIP was not significant.

Therefore, H1b, H1c, H1d, H1f, H1g aren’t rejected.

Moreover, in order to find the organizational characteristic which can totally explain the reason why corporate adopted the EIP technology, we used stepwise discriminate analysis to test. Table 3 shows, in sequence, the variable of organization characteristic in explaining why corporate adopted EIP is related to “maturity and familiarity of information technologies” and “business size”.

Table 3 Stepwise discrimination analysis of organizational characteristic

Order	Organizational Characteristic	F	Wilk’s Lambda	Standardized canonical discriminat function coefficient
1	Maturity and familiarity of IT	21.061*	0.895	0.853
2	Business size	12.389*	0.878	0.399

4.4.2 The Relationship between Implementation of EIP & e-Business performance

This study grouped application degree into high, medium, and low three categories based on the average score of the items, then analysis with e-Business, operational, marketing, and adaptability performance by ANOVA. It can be seen from the Table 4 that the hypothesis H2 is rejected for all performance indices.

Because we force to divide application degree into three group, its may reduce or enlarge the variability of application degree. This study tests the hypothesis again to ensure the result by stepwise regression analysis. As show in Table 5, the result is the same as ANOVA. Application degree of EIP does significantly influence the e-Business performance as well as three sub-construct of e-Business performance included operational, marketing, and adaptability performance.

Table 4 The result of application degree and e-Business performance

Variables	Sum of Squares	df	Mean Square	F	p-value
E-Business performance	12.971	2	6.486	14.800	0.000*
Operation performance	13.690	2	6.845	14.832	0.000*
Marketing performance	9.959	2	4.979	6.540	0.002*
Adaptability performance	15.715	2	7.858	15.956	0.000*

Table 5 Regression analysis of application degree and e-Business performance

Variables	Samples	R ²	β	t	p-value
E-Business performance	181	0.156	0.395	5.752	0.000*
Operation performance	181	0.154	0.393	5.713	0.000*
Marketing performance	181	0.082	0.286	3.995	0.000*
Adaptability performance	181	0.155	0.394	5.737	0.000*

In order to classify EIP into several types, this study employed the factory analysis according to its feature. Responses to the 17-items scales analyze by using a principal component analysis with a Varimax rotation through Exploratory Factor Analysis. The result extracted three factors solution of implementation features and named as follow: information application, information presentation and information sharing In all, the factor loading is greater than 0.5 level and accumulated percentage of variance is equal to 62.198%.

To test H3, we grouped the respondents by conducting the cluster analysis on the score data of the feature factors, and then used the ANOVA to check if the average scores of the implementation features of different group of respondents are significantly different. We used the Ward’s method, one of the hierarchical cluster methods,

for the cluster analysis. The respondents were divided into three groups were 33 (18.7%) low gradation EIP, 126 (70%) developing EIP, and 21 (11.5%) omnibearing EIP; they were so called because of the difference in their perceptions of the implementation feature factors.

Table 6 shows the results of the ANOVA of the scores of performance indices of the three groups of respondents. It can be seen from the table that H3 is rejected for the e-Business, operational, marketing, and adaptability performance. Therefore, the relationship between implementation type of EIP and e-Business performance has significantly influence. Omnibearing EIP type has high e-Business performance than other two types of EIP in evidence.

Table 6 The result of implementation type and e-Business performance

Variables	Sum of Squares	df	Mean Square	F	p-value	Scheffe
E-Business performance	14.628	2	7.814	14.628	0.000*	A3>A2,A1
Operation performance	14.625	2	7.312	14.625	0.000*	A3>A2,A1
Marketing performance	18.480	2	9.240	18.480	0.000*	A3>A2,A1
Adaptability performance	14.569	2	7.284	14.589	0.000*	A3>A2,A1

Ps. A1: low gradation EIP; A2: developing EIP; A3: omnibearing EIP.

As well as application degree, this study grouped integration ability into high, medium, and low three categories based on the average score of the items, then analysis with e-Business, operational, marketing, and adaptability performance by ANOVA. It can be seen from the Table 7 that the hypothesis H4 is rejected for all performance indices.

Because we forced to divide grouped integration ability into three groups, it may reduce or enlarge the variability of grouped integration ability. This study tested the hypothesis again to ensure the result by stepwise regression analysis. Through Table 8, the result of the correlation of integration ability and e-Business performance is significant as well.

Table 7 The result of integration ability and e-Business performance

Variables	Sum of Squares	df	Mean Square	F	p-value
E-Business performance	16.702	2	8.351	20.014	0.000*
Operation performance	16.460	2	8.230	18.456	0.000*
Marketing performance	14.783	2	7.391	10.066	0.000*
Adaptability performance	19.011	2	9.505	20.056	0.000*

Table 8 Regression analysis of application degree and e-Business performance

Variables	Samples	R ²	β	t	p-value
E-Business performance	181	0.251	0.501	7.739	0.000*
Operation performance	181	0.243	0.493	7.589	0.000*
Marketing performance	181	0.131	0.361	5.185	0.000*
Adaptability performance	181	0.247	0.497	7.665	0.000*

On the based of 52 respondents had completed an EIP deployment. The users of EIP were divided into employee, partners/suppliers, and customers. As show in Table 9, H5

is not rejected. Hence, whatever the user type, the Impacts of Establishing Enterprise Information Portal on e-Business Performance do not significantly influence.

Table 9 The result of user of EIP and e-Business performance

Variables	Sum of Squares	df	Mean Square	F	p-value
E-Business performance	1.480	2	0.627	1.229	0.235
Operation performance	1.928	2	0.803	1.232	0.226
Marketing performance	1.918	2	0.757	0.876	0.325
Adaptability performance	1.501	2	0.794	1.530	0.238

4.4.3 The Intervening Variable of e-Business Degree

To test the impact between the implementation of EIP and e-Business performance if be intervened by e-business degree, this study grouped e-Business degree into high, medium, and low three categories based on the average score of the items. We verify the hypothesis by two-way ANOVA. If the result is significant, we go a step further to confirm the intervention is to enhance or weaken the impact by the graph of curve.

Table 10 demonstrates the impact between the implementation of EIP and e-Business performance is intervened by e-business degree. H6a is rejected. Fig.3

illustrates the interaction of application degree and e-Business degree. Whether the level of application degree is, high e-business degree has higher e-business performance than others. For this reason, we can infer the intervention is enhancing the impact between the implementation of EIP and e-Business performance. Furthermore, the curve line of low e-Business degree is not in common with others, especially in medium application degree. This is because in the group of medium application degree and low e-Business degree, among total 8 respondents, only one corporation was developing EIP. 3 corporations were still in the conceptual stage of EIP project, and other 4 respondents have yet to plan and establish. They all completely accomplish the

implementation of EIP to lead to the bias of the result.

Table 10 The interaction between application degree and e-Business degree

Source of Variance	Variables	Sum of Squares	df	Mean Square	F
Application degree * e-Business degree	E-Business performance	7.169	1.792	5.113	0.001*
	Operation performance	8.909	2.227	5.722	0.000*
	Marketing performance	7.218	1.805	2.737	0.030*
	Adaptability performance	6.508	1.642	4.061	0.004*

Fig. 3 Application degree and e-Business degree interact on e-Business performance

For the sake of accuracy of the result, we test the hypothesis again based on 52 samples had completed an EIP deployment. It can be seen from the Table 11 that the hypothesis H6a is rejected as well. As show in Fig. 4, high e-business degree has higher e-business performance than others consistently. The curve of line of low e-Business

degree is also different. The bias is formed on account of the low application degree only has three samples and high application degree just has one sample, in low e-business degree group.

Table 11 The interaction between application degree and e-Business degree (n=52)

Source of Variance	Variables	Sum of Squares	df	Mean Square	F
Application degree * e-Business degree	E-Business performance	2.424	0.808	2.942	0.043*
	Operation performance	5.295	1.765	5.299	0.003*
	Marketing performance	4.307	1.436	2.636	0.061
	Adaptability performance	0.332	0.111	0.279	0.840

Fig. 4 Application degree and e-Business degree interact on e-Business performance (n=52)

By two-way ANOVA, the impact between implementation type of EIP and e-Business performance will be intervened by e-business degree ($F=2.549$, $p<0.05$), as show in Table 12. Therefore, H6b is rejected.

According to the graph illustrates the interaction of implementation type and e-business degree on e-Business performance, with the exception of omnibearing type of EIP, high e-Business degree has higher e-Business

performance approximately. On omnibearing type of EIP, lower e-Business degree corporations have highest e-Business performance than higher e-Business degree corporations instead because of this group is only has one

sample. It raised the result of e-Business performance.

Table 12 The interaction between implementation type and e-Business degree

Source of Variance	Variables	Sum of Squares	df	Mean Square	F
Implementation type * e-Business degree	E-Business performance	3.469	0.867	2.549	0.041*
	Operation performance	3.908	0.977	2.446	0.048*
	Marketing performance	5.078	1.269	2.099	0.083
	Adaptability performance	2.973	0.743	1.812	0.129

Fig. 5 Implementation type and e-Business degree interaction on e-Business performance

5. Conclusion

The result of our study shows that: (1) Between those organizations have and those have not adopted EIP, there are significant differences in the maturity and familiarity of information technologies, and organizational size; (2) In the way of implementation EIP, the relationship among function application degree, implementation type, integration ability, and e-Business performance are also significantly influence; (3) The impact between function application degree of EIP and e-Business performance will be enhanced by high e-business degree; (4) The impact between implementation type of EIP and e-Business performance will be intervened by e-business degree; (5) The implementation time of EIP has no significant impact on the relationship between implementation EIP and e-Business performance.

The most important reason corporations adopt EIP is "the maturity and familiarity of IT". Thus it can be seen EIP is a new concept of information management, the more IT implementation experiences, and the easier accept the new application system. Secondly, "business size" is another factor influence corporations adopt EIP. In general, the larger size of corporation, the requirement of information is more complex. Moreover, the cost of adopting new information

technology must be expansive. The larger corporation may be more possible to implementation or prepare to start EIP project.

According to the result, more than half corporations implement EIPs since last two years. 52 respondents indicated that they had completed an EIP deployment and 35 respondents were developing. They all start to implement EIP, so we classify 87 (48%) respondents into adoption group. Another 50 respondents were still in the conceptual stage of EIP project, and 44 respondents have yet to plan and establish. More than three fourth corporations had implemented EIP or started to plan EIP project. Thus it can be seen that EIP is available concept and the current trend of information management and e-Business project.

We divided EIP into three types: "low gradation EIP", "developing EIP", "omnibearing EIP". Only 10% corporations belong to omnibearing EIP, 70% corporations belong to developing EIP. It shows the implementation of EIP is immature.

The most important feature of EIP is easy to use and the users increase the familiar of internet environment. For users, EIP has more usability than other e-Business project. For corporations, the difficulty to train users to use EIP is lower the other e-Business performance.

Abstract

The technology of PKI can satisfy most of the needs of security in e_Business. But it is restricted to use the PKI technology adequately because applications can not know the PKI System very well without an uniform architecture standard of PKI system. Now, XKMS gives the standard of key management, so applications can use the underlying PKI system transparently by using the standard interfaces. In this paper, we introduce the XKMS Web Services and the client software development kit (brief as CSDK) developed by ourselves. The web services and the CSDK are all in accord with the XKMS specification.. We also have developed an application system about e_Business to see how to call the web services by using the CSDK.

Key Words: XKMS; PKI; Web Services

1. Introduction

Information security has become the very hot topic, especially the rising of electronic commerce make it more important. The Public Key Infrastructure (PKI) can satisfy most of the needs of information security. The using of PKI is restricted because it needs that applications can know the architecture of PKI very well. XKMS^[1] can solve the problem well. In this paper, the research state of XKMS is introduced firstly. Secondly, we introduce the XKMS web

services^[2] and the client software development kit developed by ourselves in detail. At last, we introduce an application of e_Business briefly which is used to demonstrate that the XKMS web service and CSDK can solve the security problem in e_Business or not.

2. Overview of XKMS

2.1 Research Background of XKMS

Information security has become the very hot topic, especially the rising of electronic commerce make it more important. The Public Key Infrastructure (PKI) can satisfy most of the needs of information security. The using of PKI is restricted because it needs that applications can know the architecture of PKI very well, but most of applications, such as database and deal processing software, could know it very poor.

World Wide Web Consortium (W3C) has issued XML Key Management Specification(XKMS) which is proposed by Microsoft, VeriSign and WebMethods. The specification could simplify the integration of PKI and digital certificate by using XML applications. PKI is made to be transparent to any application. So programmer can add the function about XML signature and XML encryption easily in the application of e_Business.

As XML is an extensible language, the information expressed by XML can be known by different systems. It is good at sharing data

between different systems. Furthermore, it will promote the application of PKI widely in internet.

2.2 Present Research Condition of XKMS

W3C had issued XML Key Management Specification(XKMS) which was proposed by Microsoft, VeriSign and WebMethods in November 27,2000. It denotes that the research of XKMS has been a rudiment. W3C issued XKMS version 1.0 in March 30,2001. It includes XML Key Information Service Specification(X_KISS)^[1] and XML Key Registration Service Specification(X_KRSS)^[1]. X_KISS includes “locate service” and “authentication service”. X_KRSS includes “registration service”, “revocation service”, “key recovery service”. In XKMS it gives not only the format of request message of client and response message of server, but also the description of element and compute formula. W3C issued XKMS version 2.0 in August 1,2002 and “reissue service” was added in X_KRSS. W3C is to modify XKMS continually in order to make it more well. The latest working draft is the one modified in April 21,2003. In the meanwhile, W3C issued other specifications, such as XML Signature Specification (XML_SIG)^[3], XML Encryption Specification (XML_ENC)^[4] and XML Query Specification (XML_Query)^[5]. These specifications can provide valid security service for e_Business application.

With developing of XKMS, many large corporations has developed a lot of products to support XKMS. VeriSign corp. gives a XKMS Java SDK which can be used to develop XKMS client rapidly. Entrust corp. has accomplished the function of X_KRSS now. The function of X_KISS will be provided in the near time. Microsoft also supports XKMS in ASP.NET. Evisable corp. has embedded XKMS in their product named as Evisable INK which can link to Trust Web Service transparently.

2.3 Inclusion of XKMS

There are two part of contents in XKMS. One is X-KISS (XML Key Information Service Specification), the other is X-KRSS (XML Key Registration Service Specification). The former includes “locate service” and “authentication service”. The later includes “registration service”, “reissue service”, “revocation service” and “key recovery service”. There are request message and response message in every service. Request message is made by client and analyze by server. Response message is on the contrary.

2.3.1 X_KISS

A protocol to support the delegation by an application to a service of the processing of Key Information associated with an XML signature, XML encryption, or other public key. Its functions include the location of required public keys and describing the binding of such keys to identification information

X-KISS allows a client to delegate part or all of the tasks required to process XML Signature <ds:KeyInfo> elements to a Trust service. A key objective of the protocol design is to minimize the complexity of applications using XML Signature. By becoming a client of the trust service, the application is relieved of the complexity and syntax of the underlying PKI used to establish trust relationships, which may be based upon a different specification such as X.509/PKIX, SPKI or PGP.X-KISS.

By design, the XML Signature Specification does not mandate use of a particular trust policy. The signer of a document is not required to include any key information but may include a <ds:KeyInfo> element that specifies the key itself, a key name, X.509 certificate, a PGP Key Identifier etc. Alternatively, a link may be provided to a location where the full <ds:KeyInfo>

information may be found.

2.3.2 X_KRSS

A protocol to support the registration of a key pair by a key pair holder, with the intent that the key pair subsequently be usable in conjunction with the XML Key Information Service Specification or higher level trust assertion service such as XML Trust Assertion Service Specification [XTASS].

The XML Key Registration Service Specification permits management of information that is bound to a public key pair. The XKRSS service specification supports the following operations:

- z Register

Information is bound to a public key pair through a key binding

- z Reissue

A previously registered key binding is reissued.

- z Revoke

A previously registered key binding is revoked.

- z Recover

The private key associated with a key binding is recovered.

The Register operation does not in itself place any requirement on the Registration Service to communicate that information to any other party. In most applications, however, a Registration Service will provide key information to other trust services such as those described in the XKMS specification or a separate underlying PKI such as PKIX.

3. Main Working

In this section, we will introduce our main working, including the XKMS web services, CSDK and the application of e_Business. All of them are developed by our lab.

3.1 Former Working Flow of our PKI System

Our lab has developed a PKI system. Figure3-1 shows the working flow.

Figure 3-1 former working flow

Without a unified standard of PKI system, so user can visit it only by explorer. The function of PKI system can not be embedded in an application.

3.2 What To Do

In order to make user to use PKI system conveniently, we accomplished the functions of X_KISS and X_KRSS and deployed them as web services. In the meanwhile, we also developed the CSDK which is provided to user. We call the PKI System developed by ourselves as underlying PKI system. The CSDK gives the interfaces to call the web services. The details of underlying PKI system have been hidden and it is fully transparent to applications. Applications can only use the interface functions provided by the CSDK to operate the underlying PKI system by sending XKMS request message and receiving XKMS response message. Applications is not concerned with the architecture of the underlying PKI system .

We deploy the web services into XKMS server. XKMS server receives the request message from client and transmits it to the underlying PKI system. After processing the request message, the underlying PKI system sends the result to XKMS server. At last, XKMS server send the result to client.

In the meanwhile, we developd an application named as Fund Project Appraisal System By Experts Through Internet. We hope that we can solve the security problem of the application by calling the XKMS web services with the CSDK. It is the fact that the application can do it without knowing any detail of the underlying PKI system.

3.3 How To Do

We have developed server software module and client module module. The server software module accomplishes the functions of X_KISS and X_KRSS. All the functions of XKMS are deployed as web services in the server named as XKMS server which is supported by Apache tomcat^[8] server. CSDK gives interface functions to user.

SOAP^[6] protocol is used to correspond between in XKMS server and client. Client uses RPC (Remote Procedure Call) to call the XKMS web services deployed in the XKMS server. Sender packs up XKMS message to SOAP message and sends it to receiver. Receiver gets the valid information form the SOAP message received from sender. In order to make the underlying PKI system not to modify more, XKMS server corresponds to the underlying PKI system with HTTP protocol which can be known by it. So XKMS server should know the architecture and details of underlying PKI system. On the one hand, XKMS server would convert the request message received from client to the one which can be known by the underlying PKI system. On the other hand, it would get the valid information from the processing message returned from the underlying PKI system. After that, it would convert them to XKMS response message and send it to client. The correspondance between them is fully transparent to an user. The user should only know the functions of the XKMS web services in XKMS server. It enlarges the

area to use a traditional PKI system . Figure 3-2 shows the working flow.

Figure 3-2 working flow

3.3.1 Accomplish X_KISS

X_KISS includes “locate service” and “authentication service”.

(1) Locate Service

“Locate service” includes “locate public key” and “locate certificate”. When an user received a signature document and the corresponding certificate, he would want to know that the signature is valid or not. As client couldn’t analyze the X.509 certificate, he need to send the request message of “locate public key” to XKMS server.. The certificate contains the public key should be included in the request message. Since XKMS server is able to analyze a X.509 certificate, it would analyze the certificate by itself after receiving the request message of “locate public key” from client. There is no any request to be sent to the underlying PKI system. XKMS server sends response message which includes the public key got from the certificate.

When client sends “locate certificate” request message, we add some function to XKMS because there are more than one certificate in the locate result. We divide “locate certificate” into “locate certificate list” and “locate specified certificate”. When client sends “locate certificate” request message, we will

locate certificate list firstly. XKMS server sends a locate certificate request message to the underlying PKI system and the certificate list according with locate condition will be returned to XKMS server. There are certificate serial number, DN, issue date, invalid date, key length, revocation date, certificate status, Email algorithm and certificate type in the certificate list. As HTTP protocol is used in the corresponding between XKMS server and the underlying PKI system, XKMS server should process the response message from the underlying PKI system and find the data demanded by the certificate list. After finished it, XKMS server would send a response message containing these information with SOAP protocol to client.

The user selects one certificate from the certificate list and sends a “locate specified certificate” request message containing the serial number of the certificate to XKMS server. After receiving it, XKMS server sends a locate certificate request message containing the certificate serial number received from client to the underlying PKI system. The underlying PKI system will locate the certificate with the serial number and locate the CA certificate. After that, two certificates will be sent to XKMS server. As the same reason, XKMS server also needs to process the return message and get the two certificates. A response message contains the two certificate will be sent to client from XKMS server.

The method to process the HTTP message received from the underlying PKI system in XKMS server is to look the HTTP message as a string and analyze its structure. The method in other service is the same when XKMS server communicates with the underlying PKI system.

(2) Authentication Service

When client receives some signature Email and corresponding certificate, client need to

authenticate the certificate is valid or not, is revocatory or not, is the sender’s one or not etc. Since client has not the authentication function, it needs to send “authentication certificate” request message to XKMS server. The request message contains the certificate which would be authenticated and its certificate chain. After receiving the request message, XKMS server gets the serial number of the certificate and locates the certificate using the serial number from the underlying PKI system. The underlying PKI system returns a certificate list which contains the certificate. In this certificate list there are a lot of information about the certificate. XKMS server finds the certificate status and the public key of the certificate after processing the return message. The certificate status and the public key are all sent to client.

3.3.2 Accomplish X_KRSS

X- KRSS includes “registration service”, “reissue service”, “revocation service” and “key recovery service.”

(1) Registration Service

The Register request is used to assert a binding of information to a public key pair.. Generation of the public key pair MAY be performed by either the client or the Registration service. Registration service can registry not only a personal certificate but also a server certificate.

The information used to registry a personal certificate are as follows.

Name: CN

Department: OU

Unit: O

City: L

Province: SP

Country: C

Email : E

All the information are binding to the

certificate. Moreover, key length, authentication code and revocation code are all necessary.

Certificate request encoding (refer to the standard of PKCS#10^[7]) is the only required to registry a server certificate. Registration service can get the necessary information from the encoding. Authentication code and revocation code are also necessary

Before registration, client needs to get an authentication code with offline mode from XKMS server. The authentication code is used to authenticate his request. Client selects a revocation code to authenticate itself should be necessary to revoke the registration at a later date. If the key pair is generated by client, client should make a signature of a string with the private key to demonstrate that it owns the private key. If the key pair is generated by server, server should encrypt the private key and send it to client after finishing the registration. In this case, the private key can only be an encryption key. To be a signature key is denied.

After finishing the registration, client will receive a message to show the registration is successful or not. If success, client will save the private key generated by client or received from server to a temporary file. After the RA and CA all pass the registration, the private key stored in the temporary will be stored into a keystore file. In the keystore file the serial number of corresponding certificate will be the alias name of the private key.

XKMS server will authenticate the request is been authorized or not after received a registration request. If the authorization is passed, XKMS server still need to distinguish which type of certificate is registried. The certificate request encoding will be sent to the underlying PKI system directly when it is to registry a server certificate. If it is to registry a personal certificate XKMS server should distinguish how to generate a key pair.. If the key pair is generated by client XKMS server should authenticate that the user own the private key or

not. If the authentication is also passed, XKMS server will get public key, DN and other information from the request message. If the key pair is generated by server, XKMS server will get DN and other information form the request message. XKMS server sends to the underlying PKI system a request message which contains public key, DN and other information. The underlying PKI system will registry a certificate with these information and return a response message to XKMS server to denote the registration is successful or not. XKMS server convert this message to a XKMS message and send it to client.

(2) Reissue Service

The registration service may permit clients to reissue previously issued assertions. The reissue request is made in the same manner as the initial registration of a key. The principal reason a client would make a reissue request is to cause the registration service to generate new credentials in the underlying PKI system, e.g. X.509 Certificates. The key and DN will not vary in the new certificate.

(3) Revocation Service

The revocation service may permit clients to revoke previously issued assertions. Clients should give the revocation code contained in the registration request message to authenticate its identity.

The working flow is as follows.

Client send a revocation request message contains the certificate to be revoked and the revocation code to XKMS server. XKMS server gets the revocation code and the serial number of the certificate form the request message and send them to the underlying PKI system. XKMS server will return to client a response message contains the information about revocation is successful or not after receiving the return

message from the underlying PKI system.

(4) Key Recovery Service

The key recovery service may permit clients to request to recover the backup private key in the XKMS server. The backup private key may be the one generated by server. It also may be the one generate by client. If the key is generated by client, it should be encrypted with the public key of server certificate and sent to XKMS server. Only encryption key can be backup and recovered. XKMS server will revoke the private key whenever key recovery is performed. Client also needs to get an authentication code with offline mode from XKMS server. The authentication code is used to authenticate his request is authorized by XKMS server or not.

The working flow is as follows.

Client computes the digest of the authentication code and makes the signature of the digest with signature private key. The digest, signature and signature public key will be sent to XKMS server. After receiving the request message, XKMS server will validate the signature. If the validation is right, XKMS server will send a request message to the underlying PKI system to request key recovery. XKMS server encrypts the private key returned by the underlying PKI system with the user's signature public key. And sends it to client. Client will decrypt the encrypted private key with its signature private key after receiving the response message from XKMS server. At last, the private key will be stored into the keystore file.

3.3.3 Explanation ff Correlative Computation

(1) Computation of Authentication Code

Computation :

Number "0X1" is as the seed to generate a random key. Algorithm HMAC-SHA1 is used

to compute the digest of authentication code.

The formula is as follows.

$\text{digest} = \text{HMAC-SHA1}(\text{authentication code}, 0X1) \dots \dots \dots (1)$

For example, if the authentication code is "024837". The formula is as follows.

$\text{digest} = \text{HMAC-SHA1}("024837", 0X1) \dots \dots (2)$

Then we will make the signature of the digest with the private key K_{pri} generated by client. The formula is as follows.

$\text{signature} = K_{\text{pri}}(\text{digest}) \dots \dots \dots (3)$

Authentication:

XKMS server decrypts the signature with the public key K_{pub} received from client to get the original digest'. The formula is as follows.

$\text{digest}' = K_{\text{pub}}(\text{signature}) = K_{\text{pub}}(K_{\text{pri}}(\text{digest})) \dots \dots \dots (4)$

Compare digest' with digest firstly. It demonstrates that the signature is right if they are equation. Or else the signature is wrong. Secondly, XKMS server computes the digest'' with authentication code "024837" at the same method. The formula is as follows.

$\text{digest}'' = \text{HMAC-SHA1}("024837", 0X1) \dots \dots (5)$

Compare digest'' with digest . If they are equation, the request is passed. Or else it is not passed.

(2) Computation of Revocation Code

The compute method of revocation code resembles as the compute method of authentication code. But the digest should be computed twice. when XKMS server authenticates the request it is the only step to validate the signature.

Computation:

Firstly, Number "0X1" is as the seed to generate a random key. Algorithm HMAC-SHA1 is used to compute the digest of authentication code. The formula is as follows.

$\text{digetst1} = \text{HMAC-SHA1}(\text{revocation code}, 0X1) \dots \dots \dots (6)$

Secondly, number "0X1" is as the seed to

generate a random key. Algorithm HMAC-SHA1 is used to compute the digest of digestst1. The formula is as follows.

$$\text{digest} = \text{HMAC-SHA1}(\text{digestst1}, 0X2) \\ = \text{HMAC-SHA1}(\text{HMAC-SHA1}(\text{revocation code}, 0X1), 0X2) \dots\dots\dots(7)$$

The digest is the result.

For example, if the revocation code is “I Will Reveal My Key”. The formula is as follows.

$$\text{digest} = \text{HMAC-SHA1}((\text{HMAC-SHA1}(\text{“I Will Reveal My Key”}, 0X1), 0X2) \dots\dots\dots(8)$$

Then we will make the signature of the digest with the private key K_{pri} generated by client. The formula is as follows.

$$\text{signature} = K_{\text{pri}}(\text{digest}) \dots\dots\dots(9)$$

Authentication:

XKMS server decrypts the signature with the public key K_{pub} received from client to get the original digest'. The formula is as follows.

$$\text{digest}' = K_{\text{pub}}(\text{signature}) = K_{\text{pub}}(K_{\text{pri}}(\text{digest})) \dots\dots\dots(10)$$

Compare digest' with digest firstly. It demonstrates that the signature is right if they are equation. It shows that the client owns the private key. Or else the signature is wrong and the client doesn't own the private key.

3.3.4 develop an application

Furthermore, we have developed an e_Business system named as Fund Project Appraisal System By Experts Through Internet. The system includes five main steps. The first step is researcher applys a project. The second step is to authorize by college and technology department. The three step is the subject director selects some experts to appraise this project. The four step is the experts give their appraisal opinion. The last step is the subject director confirms the project is passed or not. All of these operations are doing through internet. It demands that the system can not only encrypt the data transmitted in the internet but also

validate the identity of all kinds of users.

We have embedded our CSDK into the system. The system calls the XKMS web services by CSDK to satisfy the need of security. The fact is the CSDK can solve the security problem easily in e_Business.

4. Further Working

We have accomplished the six kinds of service functions of XKMS. But we should make them more sophisticated in order to adapt new needing because XKMS is developing constantly.

The main working we have done is only adapted for the PKI system developed by ourselves. Our next plan is to make the web services and CSDK adapting for more different PKI system to enhance their commonality. So we will provide a group of standard interfaces for underlying PKI system for the use of sending data to it or receiving data from it. After accomplishing these working, the format of input data or output data of all kinds of PKI system with different architecture is unified and a standard user interface of PKI system is provided for users through our XKMS web services.

5. Conclusion

With the using of PKI in e_Business becoming more and more widely, XKMS would be more important. XKMS could not only develop following the development of PKI, but also promote the development and using of PKI technology.

Abstract

The collaboration issues on research and development (R&D) projects are getting critical. Shorten time-to-market (TTM) of new product is crucial competency of high-tech industries. However, lacks of post-project review, real-time communication and information sharing make barriers to reduce TTM. This would lead to downcast competition in the globalization. In this research, a concurrent knowledge learning (CKL) model is proposed to enhance R&D project collaboration. With the CKL model, R&D collaboration could be improved via the concurrent knowledge reusability and the collaboration mechanism among partners.

1. Introduction

Shorten the time to market (TTM) is the central of R&D projects management. While R&D projects generate artifacts in various forms of knowledge, there should be an efficient knowledge management mechanism so that the R&D projects could be executed efficiently and the TTM could be improved. This knowledge management mechanism should be encouraged by integrating with project management. Through the knowledge learning process, organization can keep continuous improving in the efficiency of R&D projects and shortening TTM [9]. However, most organizations lack post-project review processes. And projects are closed before reviewing the causes of their failures and successes [10]. This can discontinue the organization learning process and restrain the improving of R&D efficiency. The lack of post-project review results in learning discontinuity, knowledge disintegration, and makes barriers to shorten the TTM. Concurrent Engineering (CE) is one of the remedy to shorten TTM. CE was introduced in the late of 1980s to improve collaboration efficiency with team, which highlighted the synchronism of relevant sequential activities of new product development [14]. Also, CE was discussed to be consolidated with process modeling and analyzing. Process modeling made the new R&D projects process to be easily analyzed, and synchronized with the concurrent engineering [1]. With such a concurrent development process, the TTM of R&D projects could be improved for the enhancement of collaboration and concurrent capability.

2. Barriers of R&D Collaboration

R&D projects always have more complexity, difficulties and dynamics [12]. All of them make a higher risk to R&D projects. Nowadays, many companies try to utilize collaboration in R&D projects to share information. However, collaboration itself raises some issues. After literature review, the barriers of R&D collaboration are categorized into two main categories: the information sharing and the organization learning. The barriers of R&D collaboration are summarized in figure 1.

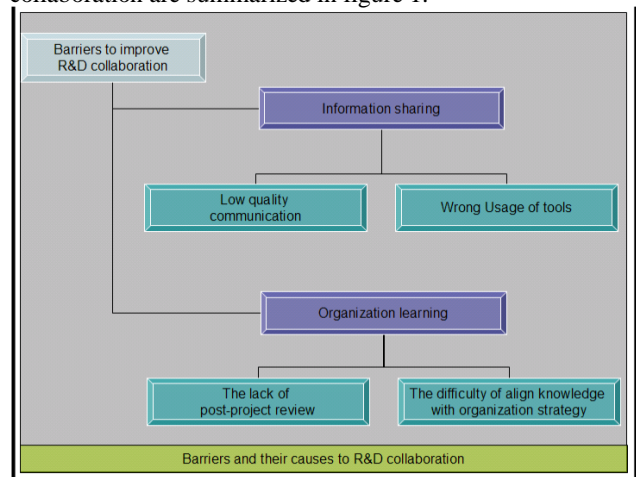

Figure 1: Barriers of R&D collaboration

With the difficulty of establishing and maintaining the communications, R&D project teams are encountering low quality communication. Most communication problem arises from cultural differences as well as roles and responsibility problems. Such problems could lead to downcast efficiency, even mistrust or suspicion [11]. However, information sharing and communication between partners are critical with globalization and collaboration [4]. Wrong usage of groupware or information sharing tools can also limit the learning and innovation in R&D teamwork [3].

Besides, knowledge management has been emphasized for its importance of knowledge reusing and diffusing. Organizations gain knowledge to improve developing process and reduce TTM from the implementation of post-project review [5] [7] [9] [13]. But this is difficult because of the differences in resource,

information, specification among projects and the fragmentation of the team by profession or know-how of team members [10]. An "aging work force" and rapid advance in technology even makes it critical for organization to filter knowledge into its core strategy [6].

Collaboration makes it easy for each R&D team unit (an individual or a subgroup) to focus on its core ability. This could lead to the maximized synergy if the quality of collaboration is made certain. In next section the CKL model will be described, by which above barriers could be overcome by the employing of CE and Knowledge Management.

3. Concurrent Knowledge Learning Model

The Concurrent Knowledge Learning (CKL) model integrates two levels of organization learning, with a central concept of concurrent engineering (Figure 2). The infrastructural level, which is shown in the center of Figure 2, contains one kernel and two shells, the Concurrent Knowledge Engine (CKE) as the kernel, with the Virtual Value Chain (VVC) shell and Knowledge Network shell. R&D project collaboration forms the application level which is based on the infrastructural level and shown as the skirt of the infrastructural level. The CKL model

proposes a framework for R&D collaboration to extract and imbibe knowledge through each activity among R&D projects. By this circulating model, artifacts of variety of knowledge are fed back and diffused concurrently to improve the quality and help decision making of each R&D project. Future more, for the R&D project collaboration, the barriers of information sharing and organization learning could be overcome with its abilities of concurrent information sharing and concurrent knowledge learning. Four major components of CKL model are described as follow.

3.1 Concurrent Knowledge Engine

The central concept of CKL model is the Concurrent Knowledge Engine (CKE), which is shown as the kernel of model in Figure 2. CKE stress the parallelism of the two levels. With the CKE, the valuable artifacts which generated from activities among R&D projects can be shared to each others concurrently, rather than the traditionally sequential ways. In other words, in a CKE based environment, the diffusion of knowledge within an organization is no longer passed one by one, but concurrently radiate to every department, every member, even every stage among different R&D projects. This

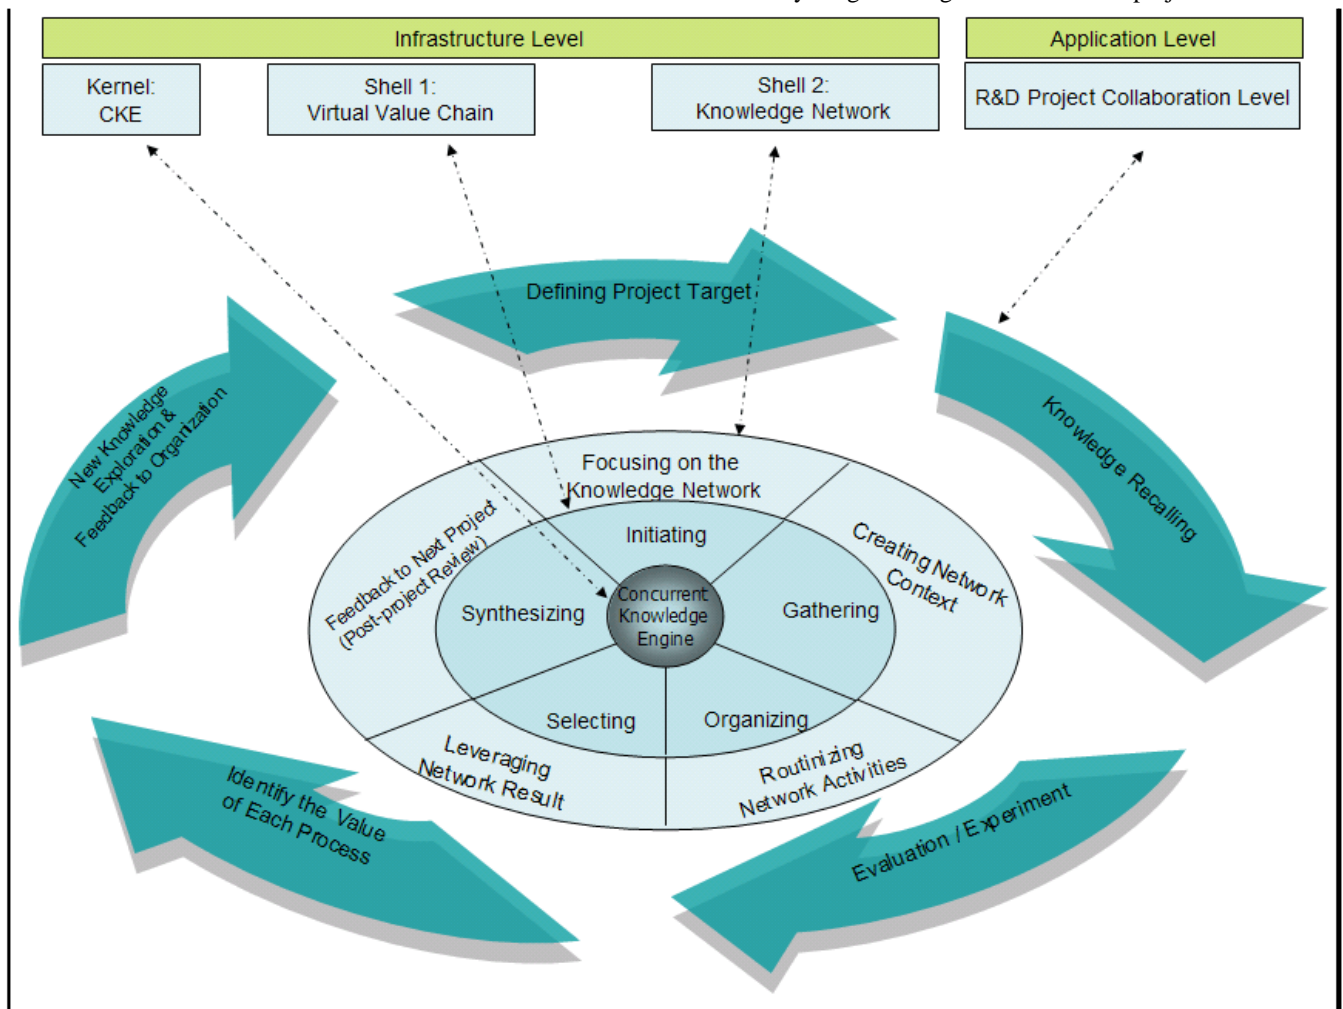

Figure 2: CKL model

could be performed by a centralized knowledge base, which contains knowledge of R&D artifacts and relative value of R&D activities.

3.2 Virtual Value Chain Shell

Virtual value chain was first introduced by Jeffrey F. Rayport and John J. Sviokla in 1994 and described much more specifically in 1995. Five value-adding steps - gathering, organizing, selecting, synthesizing, and distributing - are performed in the virtual value chain (VVC). The value-adding process is fundamentally different from sequential physical value chains. Virtual value chain creates value from extracting information from physical process, organizing the information, selecting and synthesizing valuable ones, finally distributing them into proper destination [8]. The CKL emphasize the concurrent operation of the virtual value adding activities. While each activity adds value to R&D artifacts, the value of new explored knowledge is distributed and shared concurrently to each others.

In CKL model, an initiating stage is added into the VVC shell in order to correspond with the knowledge network shell and R&D collaboration level. In the initiating stage, a new R&D project is getting started and the knowledge network is getting focused. Organization begins to identify related resources and information, including human resource, project specification, even the knowledge fed back by other R&D projects and other tangible and intangible ones. In this stage, value is added onto those information or resources. For example, the configuration of human resource and the project specification are modeled into standard form, making them easier to access and becoming more valuable information during the entire R&D project process. The gathering stage gathers knowledge from organization knowledge base. The knowledge is extracted from activity of every previous R&D projects. By gathering and reusing the knowledge, the value of knowledge is utilized by the on going R&D projects. The organizing stage then organizes the information and the knowledge extracted from organization knowledge base to fit current R&D project. Turning and modifying the knowledge rules are performed in this stage in order to make them more adapted to the situation. Also, knowledge rules are organized and integrated within this stage. In CKL model, the organized knowledge rules are applied to current R&D project, used to select most important and most valuable experiments to be performed. These knowledge rules help R&D team making decision and technology selection and to avoid unnecessary cost, both tangible and intangible, by the support of selecting what activity is need and what is not. In the selection stage, new valuable knowledge rules are selected to be synthesized.

At last stage, the synthesizing, original knowledge and new explored knowledge are compounded and new value is extracted again. These knowledge and value are concurrently fed back to the CKE and diffused through the

concurrent environment to other on going R&D project. For example, at the synthesizing stage of project A, the R&D team might find a better way to allocate limited human resource and fed it back to the CKE. And this value-adding knowledge is extracted through the CKE by the team of project B which is just at the initiating stage. So the project manager of project B now can do a better configuration of human resource with the help of the valuable knowledge and experience from project A, as “concurrently” as possible. This is the concurrent collaboration among R&D projects.

The first four stage of VVC shell in CKL model all attempt to extract new knowledge, which adds value to the organization. At the synthesizing stage, original knowledge and new explored knowledge are compounded to extract new value. The knowledge is then concurrently fed back to the CKE and diffused to other R&D project concurrently.

The reason why the distribution stage of VVC is not shown in CKL model is that the distributing of information and knowledge has been implied within the CKE

3.3 Knowledge Network Shell

Four stages for building a knowledge-creating value network are defined in [2]. In CKL model, one new stage is added in order to utilize the knowledge created through the network and to link all others. That is to feedback the new extracted knowledge to next project or is called post-project review [10]. While knowledge rules diffuse to each R&D projects concurrently, the organization is learning from previous R&D project and related knowledge expands. Therefore, the knowledge network shell becomes a spiral expending loop that the knowledge expends and is shared concurrently with each R&D project. Knowledge network shell can be seen as a more practically expended view of the virtual value chain shell in CKL model. Each stage of the knowledge network shell and the relationship with the virtual value chain shell in CKL model are described as follow.

First stage is focusing on the knowledge network. The knowledge network is initiated in this stage and need to be focused to be aligned to the core strategies of the organization. In R&D project case, the network should be highly supported by the organization and be ensured to organization learning level but not only individual level. And the strategy is to shorten TTM. In the second stage, to create the network context, the activity of “gathering” in the virtual value chain shell plays an important role in this stage. Reliable experts are selected to ensure the accuracy and rank the effectiveness of each knowledge rule, so that R&D team can then trust in what their decision making are supported by. After creating knowledge network context from gathered information and knowledge, the network should be organized for routinizing network activities, in the third stage in knowledge network shell. In CKL model, establishing a “network heartbeat” [2] would be the most

important part in this stage. Network heartbeat decides the frequency of R&D project activities routine. The routine activities of R&D project in CKL model are the reusing of knowledge to shorten the TTM and decrease development cost. In one hand, the frequency that the team recalls the knowledge should be dynamic change with the situation of the project going on. On the other hand, new available knowledge generated from each R&D team should be positively passed to each other via the concurrent knowledge engine. The fourth stage in this shell is leveraging network result. In this stage, the value of each R&D process are considered and ranked in order to perform the selecting stage in virtual value chain shell to extract the knowledge of identifying what are most important process and what might reduce the R&D TTM or so on. The fifth stage of knowledge network shell, feeding knowledge back to next project or called post-project review, is added in order to utilize the knowledge that created through the network and to link all other stages into a spiral expending loop. The knowledge extracted from each R&D project must be fed back to organization through the post-project review process to synthesis its value [10]. While valuable knowledge rules diffuse to other ongoing R&D projects through CKE as soon as the knowledge is extracted, the organization is learning from previous R&D project and the R&D related knowledge expands. Therefore, the knowledge network shell becomes a spiral expending loop that the knowledge expands concurrently with each single R&D project and shared among every R&D projects.

3.4 R&D Collaboration Level

In this level, R&D activities are happening practically. Specifications are defined. evolution and experiments are performed. The most important part, knowledge from previous R&D projects is reused to help current project reducing TTM or avoiding similar mistakes.

In the initiation of a R&D project, the target and specification of the project is defined. The specification defining process could be referred to previous similar R&D project for the allocation of resource, the configuration of schedule and so on. After specification is defined, in the traditional way the project should be start. But in CKL model, the project must be start after the process of knowledge recalling. In this stage, knowledge rules are reused by their ranking of helping shorten TTM. With the help of these rules, the evaluating process would be shorten and optimized. This could lead to shorten TTM and decrease development cost.

After the evaluating process, each used knowledge rule is re-scored and re-ranking. A correct rule would be rewarded, but an inaccurate one would be punished. So the ranking of rules might be changed. Finally, a post-project review process reviews the project for the reason of failure and success. These experiences could be then shared as knowledge to other R&D teams via the CKE concurrently. For example, knowledge about how to avoid failure or how

to approach success is recalled. Or some knowledge rules might indicate the most important experiments among all while some others are not so important and might be skipped to reduce unnecessary cost. In the post-project review process, new knowledge rules would be found and synthesized concurrently with the old ones.

3.5 Summary of CKL Model

Table 1 summarizes the CKL model. With CKL model, the two major identified barriers faced by R&D collaboration – information sharing and organization learning – could be overcome by the employment of CE and knowledge management. CE plays a role of concurrent sharing of information and knowledge. Base on CE, the concept of VVC and knowledge network could provide a concurrent environment to extract, organize and refine experience and knowledge. The R&D collaboration could be then enhanced with the concurrent information sharing and organization learning. This could lead to shorten R&D TTM and further more, to increase competency of high-tech industries in the globalization.

4. Conclusion & Future Work

The CKL model integrates various artifacts and enhances the concurrent knowledge refining and diffusing, so that the R&D project collaboration could be improved continuously with the concurrent knowledge learning environment. In other words, the CKL model is itself an experts system with dynamic and grow-able knowledge base. The knowledge of CKL model will expand with new artifacts generated from every R&D project, and are refined through knowledge selection during every R&D projects. This is the key to shorten TTM.

The future work of this research is to implement CKL model as a web-based environment and validate it in the industry. The CKL methodology and the implemented environment would be introduced to the world-class high-tech industries in Taiwan. The semiconductor or optoelectronics industries are the first priority. Through the cooperation of industry and academics, the expected benefits are as follows:

- 1) The TTM of R&D projects could be shortened by the capability of knowledge and experience recalling in CKL.
- 2) The quality of real time information / knowledge sharing could be improved through the employment of CKL.
- 3) The efficiency of R&D project collaboration could be continuously improved by CKL model for the improvement in concurrent knowledge reusing and information sharing.

In addition, CKL model delivers the reference model for the R&D projects and knowledge management to shorten the TTM. Besides, this research proposes a suggestion for the refinement of the virtual value chain [8] and the knowledge network [2] by integrating them with the

concept of concurrent engineering [14]. These could contribute to the field of new technology innovation and

knowledge management.

Table 1: Summary of the CKL model

Component		Description	Major Function
Kernel	Concurrent Knowledge Engine (CKE)	CKE is the kernel of the CKL model, served as a knowledge base which collects and diffuses knowledge concurrently.	<ul style="list-style-type: none"> A centralized knowledge base Diffusing knowledge and information Enabling a real-time knowledge sharing environment
Infrastructure Level	Shell 1: Virtual Value Chain (VVC)	VVC is the basic concept of extracting value-adding knowledge from physical process.	<ul style="list-style-type: none"> Defining the five value-adding stages Extracting “virtual value” from “physical process”
	Shell 2: Knowledge Network	Knowledge Network forms a method to extract, utilize, and refine knowledge which extracted from physical process.	<ul style="list-style-type: none"> Linking the virtual value chain concept and physical R&D processes Defining the standards for knowledge formation, reusing, ranking, and refining.
Application Level	R&D Collaboration	This level defines a looping process for R&D collaboration, which is not as the traditional sequential way. Concurrent knowledge reusing and post-project review are the major method to enhance R&D collaboration.	<ul style="list-style-type: none"> Collaborating different R&D projects by mutual knowledge reusing Recalling knowledge to shorten TTM and decrease cost Refining knowledge as an organizational learning process through the post-project review

Optimal Scope and Length of Software Patents

A Simulative Approach

Abstract

Traditionally, only technical inventions such as light bulbs or pharmaceuticals were protected by patents. Nowadays software patents are a widely discussed topic in the U.S. and in Europe because of their proposed impact on national innovation rates. Based on an analysis of the determinants of successfully developing software, we use a bipartite probability model to compare a deregulated market without patents to a market using a patent system. Applying computer-based simulations, we analyze different scenarios to test the impact of different patent duration and width on the innovation behavior of the software market. We can show that strong patent protection is globally efficient only in markets with a relatively low profit potential.

1. Introduction

Traditionally, patent protection was awarded only to technical inventions, such as light bulbs, shavers, or pharmaceuticals. After computer programming became viable, and protection of computer programs became desirable most countries decided that software was too abstract or intangible to be patentable, and copyright became the dominant form of protection. In the last years firms were going to demand patents on software-related inventions, which drove an intense public and academic discussion regarding the use of patent systems to protect software.

Software consists of functional as well as expressive attributes. Functional attributes describe special instructions and expressive attributes their representation [7]. This hybrid structure made it difficult for patent officials to assess the technical character of inventions, which is a prerequisite for patenting inventions. Another problem is the lack of qualified patent inspectors and the associated difficulty to assess the novelty. This has resulted in quite a number of patents being granted for inventions considered to be obvious by experts in the field.

The goal of this paper is to answer these questions:

1. How do scenarios with and without patent system differ in terms of the endemic propensity to monopolize?
2. In which scenario can we expect a higher level of innovation?

After an overview of specific characteristics of the software market (section 2.1) a survey of economic and

legal patent issues (section 2.2) is given. Based on this, an economic simulation model incorporating individual patent incentives and their implications on (aggregate) system behavior is recapitulated from an earlier paper (section 3). Section 4 presents the simulation results as well as the arising conclusions. Section 5 gives a short summarization of the paper and proposes future research.

2. Literature Review

2.1 Special Issues of the Software Market

Market topology: The market for software products is embedded into the IT market, which is part of the Information and Communication Technology (ICT) market shown in Figure 1.

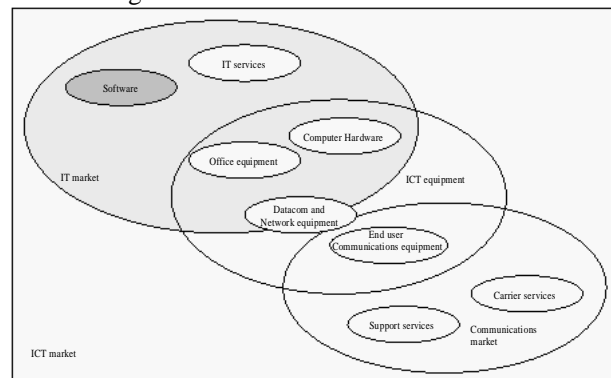

Figure 1: Complexity and different submarkets of the ICT market

Beside a high momentum in technical innovations and strong competitiveness in the ICT market, leading to constantly shorter product cycles and even higher pressure towards innovativeness, one can also identify paradigm shifts that lead to fundamental changes of business rules in general [5]. The wide application of ICT has led to a rapid decline in prices and costs in the computing and telecommunications sector with positive repercussions for a variety of other products, like aircrafts, automobiles and scientific instruments. Table 1 shows the forecasted revenues in different regional software markets [12].

Cost structure: It is relatively costly to produce the first copy of a software product while the costs of additional copies are very low (e.g. CD-ROM) or even negligible (e.g. if distributed via download from the Internet). From an economic perspective this means high fixed costs and very low marginal costs leading to substantial

economies of scale [29]. Compared to the chemical market with fixed costs for developing one product amounting to € 300 million [6], the fixed costs are low. Since software is immaterial, the distribution costs also are significantly lower than for physical goods.

Instant scalability: Closely related to the cost structure is the phenomenon of instant scalability in software markets. Since it is very easy to reproduce and distribute copies of software, suppliers can respond very quickly to an increase in demand. Therefore, once a software product is recognized as superior, the particular vendor might be able to gain a significant market share in a short period of time [25].

Pricing: Cost structure and instant scalability influence pricing strategies in software markets. Of course it does not make sense to apply marginal-cost-based pricing if the costs of reproduction are close to zero. Pricing is more likely to be determined by consumer value, leading to differential pricing [29]. Because of the importance of the installed base due to positive network effects, dy-

namic pricing (and in particular penetration pricing) is one of the most important strategies in modern software markets.

Positive network effects: It is common in many markets that a consumer's buying decision influences the others' decisions. Interdependencies such as the bandwagon, snob, and Veblen effect are broadly discussed in the economic literature (e.g. [8]). Beside these general effects, which apply to all consumer decisions, software markets are determined by positive network effects, the so-called demand-sided economies of scale, deriving from the need for product compatibility. This means that the willingness to adopt a product innovation correlates positively with the number of existing adopters. These effects mainly originate from two different areas, the need for compatible products to exchange data or information (direct network effects) and the need for complementary products and services (indirect network effects) [11] [14] [23].

Table 1: Total Revenue of the ICT market (Million €) [12]

2003	Western Europe	Eastern Europe	USA	Japan	Rest of World	World
ICT equipment	211,544	12,236	208,721	119,759	216,815	769,077
Software	81,856	1,845	135,606	22,813	45,070	287,189
IT services	158,773	2,876	262,536	73,276	85,203	582,664
Carrier services	278,381	19,244	293,541	111,801	338,207	1,041,173
Total	730,554	36,201	900,404	327,649	685,295	2,068,103

Tippiness: Supply-sided economies of scale, instant scalability, and positive network effects can result in a specific dynamic structural change in software markets referred to as tippiness. If the diffusion of a certain software product gains sufficient momentum the market might tip meaning that a particular product takes over the entire market in a short time. The phenomenon is analyzed analytically in [2] and empirically in [25].

Start-up problem and critical mass: Due to the existence of network effects, early technology adopters bear the risk of buying a product which might not succeed in gaining the expected market share. This can lead to excess inertia even if the product is seen as superior [2]. Related to the start-up problem is the critical mass, being the threshold number of users needed to overcome the start-up problem. Reaching this point in the diffusion process might then again result in rapid acceleration and in tipping of the market.

Propensity to monopolize: Network effect literature states that multiple, incompatible technologies can only rarely coexist in markets with network effects, and that instant scalability results in an additional tendency to monopolize. Empirical observations show monopolistic structures in some of the modern software markets like the market for office suites, word processors, or spreadsheets [25].

Utilization and availability of open code: Open code is one of the most important external factors for software development (up to 20%) [15]. The strongest usage ema-

nates from independent developers, but recently the reuse of open source software by medium-size and large companies has increased as well [15]. Open source has a generic character, i.e. in many cases it is functional input which makes software development more effective. There is no significant argument for utilizing open source, but a relatively well balanced set of motives (e.g. adaptability, state-of-the-art, costs and quality). Disclosure of code is used mostly as strategy to diffuse information about one's own performance.

2.2 Special Issues of Patents

2.2.1 Legal Perspective

Until the US Supreme Court's decision *Diamond vs. Diehr* in 1981, patent protection for software was almost non-existent. In this instance, the Court ruled that a computerized process for curing rubber was patentable even though the process involved an algorithm which by itself was not patentable [27]. The distinction was that the algorithm was applied to a process, as opposed to attempting to patent the algorithm [27]. Computer programs are patentable in the USA today. It is even possible to patent business methods. Basically, the requirements for patentable items (inventions) are ruled in part II, chapter 10 of the U.S. Patent Act [31]: "Whoever invents or discovers any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof, may obtain a patent therefore, subject

to the conditions and requirements of this title” [31, § 101]. The criteria for granting a patent are:

The person is the inventor [31, § 102], the invention is the proper subject matter for a patent: machines, articles of manufacture, compositions of matter, and processes [31, § 101], and the invention is "useful", "new", [31, § 102] and "unobvious" [31, § 103].

For most types of inventions, the first two requirements usually present little difficulty. Generally speaking, an invention is useful if the invention has an utilitarian or commercial value; an invention is new if it is the first embodiment of the idea in a useful thing or process; and an invention is unobvious if it would not have been obvious to a person reasonably skilled in the pertinent art, given what already existed in the particular field. This last requirement often is the most difficult barrier for patenting a new invention since often it is very subjective to determine whether the differences between the new invention and the prior state of the art are obvious solutions to known problems. The four mentioned categories (process, machine, manufacture, or composition of matter) have - together with the requirements of utility and novelty - the function to restrict the set of patentable inventions; explicit prohibitions do not exist. The process for obtaining a patent on an invention typically starts with a patent attorney preparing and filing a patent application for the inventor and owner of the invention with the United States Patent and Trademark Office (USPTO). The first inventor is entitled to the patent over any subsequent inventors - even if the subsequent inventor applies first - as long as the first inventor can prove the earlier date of the invention.

Table 2: Patents granted by class in the years 1997-2001 [32]

Class	1997	1998	1999	2000	2001	Amount
700	349	660	536	465	660	2670
701	329	510	684	824	1253	3600
702	350	517	512	517	574	2470
703	224	297	301	285	275	1382
704	365	611	627	534	610	2747
706	202	305	128	130	157	922
707	580	1189	1283	1131	1256	5439
716	191	269	246	236	404	1346
717	128	306	406	370	467	1677
Amount	2369	4004	4187	4027	4996	Total: 22253

The application must be filed not later than one year after: public use of the invention, the placing on the market of the invention for sale in the U.S., or the publication of a description of the invention anywhere in the world. Table 2 clarifies granted patents in the field of „Data Processing“¹ in the U.S. between 1997-2001 [32]. A detailed

overview of positive and negative patenting decisions involving software is given in [27].

2.2.2 Economic Perspective

Patents and the incentive problem: The standard economic rationale for patents is to protect potential innovators from others' imitation, thereby providing incentives to incur the cost of innovation. The innovator receives a temporary monopolistic position [3]. The usage of the patent system therefore has two essential advantages:

- The patent owner (monopolist) is able to claim higher prices and larger market shares.
- The time frame for skimming the market will be artificially extended.

The patent owner has the possibility to offer licenses and the chance to participate in the development or improvement of future innovations by licensees [28]. Since the patenting process is expensive (one application in Europe can cost up to € 50.000 [1]), small and medium-size enterprises (SMEs) in particular are discriminated. As a consequence, scarce financial resources constitute substantial barriers to patenting among SMEs. Hence, nondisclosure can be an optimal strategy [15].

Jaffe suggests that patents inhibit other innovation activities, for example by preventing access to licenses needed for improvements. This is characterized as negative after deductions effect [22]. Furthermore Kortum & Lerner point out that despite decreasing R&D expenditure, the number of patents in the U.S. is increasing quickly. They substantiate these correlations with company-wide advanced innovation management [24]. The same perception is represented by Bessen & Maskin. Moreover they discuss about trivial patents which conduct knowledge that is considered common knowledge and therefore not patentable [4].

Patent race and cross licensing: Because each innovation can only be assigned once, innovators often find themselves in a patent race. Although the losers face R&D and patent application costs, they attain no revenue. In this context Dasgupta & Stieglitz speak of a socially unwanted situation [10]. At the same time, the licensing process offers a possibility for reducing future innovation costs of other innovators [26] [28]. The winner normally is not engaged in offering licenses. Licensing implies competition and endangers the patent owner's monopoly position. This leads to the inhibition of R&D by other inventors with concepts for improvements on a patented product [4].

If, for example, another actor has invested in developing an improvement to a product, the firm holding the original patent may use its monopoly position to appropriate some of the value created by the complementary innovation. This can occur even if a second firm ob-

¹ Class 700: Generic Control Systems or Specific Applications, Class 701: Vehicles, Navigation, and Relative Location, Class 702: Measuring, Calibrating, or Testing, Class 703: Structural Design, Modeling, Simulation, and Emulation, Class 704: Speech Signal Processing, Linguistics, Language Translation, and Audio Com-

pression/Decompression, Class 706: Artificial Intelligence, Class 707: Database and File Management, Data Structures, Or Document Processing, Class 716: Design and Analysis of Circuit or Semiconductor Mask, Class 717: Software Development, Installation, and Management.

tains a patent on the improvement. If the second firm can market its innovation with the consent of the first firm, the first firm can increase its profits on the second's account by bargaining to license the complementary technology at less than full value. This holdup problem reduces R&D in complementary technologies through inventors reducing the expected return on their investment [9]. Although it appears as though licenses will never be as-

signed in such situations, it still happens. Nowadays patents offer the function of currencies. If a company needs another firm's license for its own activities, it tries to exchange its own license with that of the other license holder. This operation is referred to as cross licensing. Patents are used as weapon in competition and play a decisive role second to negotiations [20].

Table 3: Positive and negative aspects of patents

Positive aspects	Negative aspects
Microeconomic perspective	
Imitators are discouraged through the consequences of infringement. Patents also hamper piracy. An extended time frame for skimming the market is given.	Substantial costs: Costs of patent description and of patent agents, patent application and the costs of assignation of patents, costs of the extension of a patent.
Patents enforce the first mover advantage and therefore the de-facto-standardization (positive feedback loops).	Patent infringement is difficult to control, especially in embedded systems. Moreover discovery of infringement is very expensive.
Patents represent assets strengthening the relative competitive position.	The liability of disclosure (6 months) opens the ideas for others and gives them the chance to market the ideas earlier.
The liability of disclosure (6 months) opens the ideas of others for own developments.	Development costs increase, because of licenses or bypass of patented developments. Improvements are only possible on a complementary way (low rate of code re-using). Risk of market exclusion.
Expending of development costs through the chance of being monopolist and claiming higher prices.	Patents can hamper interoperability.
Licensing and cross licensing are possible.	
Macroeconomic perspective	
Patents are an important incentive for spending capital in R&D.	Decrease of development efforts (holdup problem), cannibalizing the own network.
	Decrease of product variety.
	Inhibition of technical progress through the denial of licenses.

Patents, sequentiality, and complementarity: Sequentiality describes each successive invention being built on the preceding one. The rate of re-using code is very high [4] [3]. Complementarity means that each potential innovator takes a somewhat different research line, thereby enhancing the overall probability that a particular innovation goal will be reached within a given time [4]. The sequential and complementary nature of innovations is widely recognized, especially in high tech industries [17] [18] [9]. Analyses of many innovations found that most of the productivity gains are achieved via improvements to the original innovation (e.g. [13]). Empirical evidence for innovative complementarities is provided by [30] [19].

Table 3 summarizes positive and negative aspects of patenting software. We distinguished between the view of an individual actor (microeconomic perspective) and the macroeconomic perspective.

3. The Model

In the following our model for investigating the economic impact of patents will be introduced. The main difference to existing work in this research field is the approach of a simulation model to augment the small analytical models, proposed by Bessen/Maskin 2000, Green/Scotchmer 1995, Chang 1995 etc. about the impact of additional key factors like different levels of complementarity, cost structures, and multiple periods. The increased complexity, triggered by these parameters circumvents the applicability of analytical methods.

The following assumptions are based on the preceding literature review:

1. The software market is characterized by short innovation cycles. Improvements emerge frequently in a cycle of less than 12 months.
2. The software market is characterized by a high rate of incremental progress. Innovations in this market are profoundly sequential.
3. The market is characterized by a high degree of complementarity.

4. Research and development efforts in one generation become obsolete after a few (3) periods.
5. R&D-efforts have an extensive impact on finding future innovations (3 periods).

Based on these assumptions, we developed a bipartite economic multi-period model comparing a deregulated market without patents to a market using the patent system. The basic model was developed in [21] so only the main elements are presented here. In this paper we focus on simulation results regarding the impact of the length and scope of a patenting system on the firms' innovation behavior. The model encompasses I actors, representing software manufacturers in a particular segment of the software market (e.g. text processing). The model considers three different company sizes. Based on the topological data of the German software market the actors are organized into sectors of small (80%), medium-size (15%) and large companies (5%) [16]. In each period t one or several parallel innovations lead to the economic profit v_t which is assumed to be constant over time and will be split between the successful actors (analogous to [4]). Therefore, the actors compete with each other for the same innovation in one period. The planning horizon of the model is T .

Another parameter influencing the expected profit are the development costs c_{it}^d . The greater the efforts the smaller the profits, but the higher the probability of success. The amount of c_{it}^d depends on the company's size. The larger the company the higher the possible development costs. If patenting is possible the companies taking part in the patenting process further have to spend patent process costs c_{it}^p .

Based on the assumptions presented above the core of the model is formed by the innovation probability p_{it} which determines the innovation success of actor i finding the innovation in period t . p_{it} is functionally dependent of the following factors:

- A: The development costs, spent in t and in the former 3 periods (assumption 5).
- B: The innovation success in the preceding 3 periods, represented by the binary variables $x_{it-1}, x_{it-2}, x_{it-3}$. x_{it} is equal to one, if actor i found the innovation in period t (assumption 2).
- C: The patenting activities of the other innovators, represented by $\varepsilon_{it} = \{0;1\}$. If patenting without licensing is possible, incremental improvements of others in earlier periods (T_p represents the current time of patent protection, which actual amounts 20 years) have to be found in a complementary way, diminishing the chance of success. This effect decreases the probability, if the innovation in period t was patented by an actor $j \neq i$. The nearer ε_{it} is to 1.0 the lower is the difficulty for finding a complementary way (assumption 3) and therefore the smaller is the scope of patent protection.
- Various weighting (α, β, M) and discount factors (w_d, w_x) (assumption 4) assess the influence of the several parameters, as can be seen in equation 1.

The aggregates A and B are normalized by dividing them to the regarding maximum values. The derivation of equation 1 can be found in [21].

$$p_{it} = \frac{\alpha \frac{A}{A} + \beta \frac{B}{B}}{M} \cdot C = \frac{\alpha \cdot \frac{\sum_{\tau=t-3}^t c_{it}^d \cdot w_d^{(t-\tau)}}{\sum_{\tau=t-3}^t c_{it}^d \cdot w_d^{(t-\tau)}} + \beta \cdot \frac{\sum_{\tau=t-3}^{t-1} x_{it} \cdot w_x^{(t-\tau)}}{\sum_{\tau=t-3}^{t-1} w_x^{(t-\tau)}}}{M} \cdot \prod_{\tau=t-T_p}^{t-1} \varepsilon_{it}^{(\tau-t+T_p+1)} \quad (1)$$

with $\alpha, \beta \geq 0$; $\alpha + \beta = 1$ and $M \geq 1$

The innovation and patenting process consists of four activity steps in each period:

- I. Actor i has to decide whether or not to participate in the innovation process, i.e. spending development costs c_{it}^d .
- II. His research process turns out to be either successful or not, according to his innovation success probability p_{it} .
- III. If research is successful, the actor has to decide about taking part in the patent race.
- IV. Only one actor can win the patent race. The winner is determined randomly with the same probability for every actor participating in the patent race.

Steps III and IV only occur in the scenario which possesses a legal patent protection system. A risk-neutral actor i will only invest in R&D in period t if his expected net benefit $\text{Exp}[v_{it}^{\text{net}}]$ is positive. The expectation depends on the individual innovation probability, on the elevation of effort, and on the network size. The bigger the network, the more actors will find the innovation resulting in a reduced part of the economic profit.

$$\text{Exp}[v_{it}^{\text{net}}] = \frac{v_t}{\text{Exp}[\sum_{i=1}^I x_{it}]} \cdot p_{it} - c_{it}^d \quad (2)$$

As an estimator for $\text{Exp}[\sum_{i=1}^I x_{it}]$, the number of ac-

tors who found the innovation in the period before will be used. The expected value does not include resulting future benefits, because technological progress is difficult to predict and the complexity of the model would increase superproportionally. If the actors can take advantage of an installed patent protection mechanism, the model comprises an additional decision function (3) for evaluating the benefits of patenting, including the probability to win the patenting race. An innovator agrees to the patenting process if the expected actual economic profit minus the patent application costs c^p and plus the expected future benefits $\text{Exp}[BW_i^{\text{PZ}}]$ of establishing a temporary monopoly is positive. The detailed derivation again can be found in [21].

$$\text{if } \frac{v_t}{\sum_{i=1}^I x_{it}} - c^p + \text{Exp}[BW_t^{pZ}] > 0 \quad (3)$$

\Rightarrow actor i takes part in the patent race

4. Results

4.1 Parameterization

The following results are based on simulations, which emulate the behavior of 100 software developers in a particular market segment. The actors are grouped into three sectors of company-size (small = 80%, medium = 15%, large = 5%), resulting in different exemplary chosen ranges of development costs. The concrete values are equally distributed within the ranges given in table 4. Every simulation was run about 50 periods ($T = 50$). The total economic profit per period amounts to $v_t = 100$ resp. $v_t = 1500$ monetary units.

Table 4: Distribution of development costs

Company sector	Large	Medium	Small
c_{ti}^d upper bound	60	40	30
c_{ti}^d lower bound	30	20	10

We used the parameterization of the weighting and discount factors in equation 1 as shown in table 5. These values are based on no empirical evidence yet and are only chosen as a starting point for later sensitivity analyses. Using these values the different influence factors are weighted equally within the innovation probability.

Table 5: Constant probability parameters

Further parameters determining the innovation probability		
Weight of prior development costs	w_d	0.9
Weight of prior successful innovations	w_x	0.9
Relative weight of development costs	α	0.5
Relative weight of successful innovations	β	0.5
Market difficulty	M	1.0

4.2 Simulation Results

The following simulation results are shown for two different environments ($v_t = 100$ or $v_t = 1500$ in every period) to analyze markets with low and high profit potential. Both environments are simulated without (scenario I) and with (scenario II) the availability of a legal patent system. To analyze the impact of different system configurations in all cases the patent length T_p is varied from 1 to 20 periods (20 years is the actual current protection time), and the patent protection scope ε is varied from 1.0 (= no protection) to 0.9 (values lower than 0.9 would result in such a high patent scope, that no innovation activities, except by the first patent owner, were possible).

The first question of our paper focuses on the endemic propensity to monopolize. To examine this question the

Herfindahl index is applied. This index is commonly used to measure market concentration in industrial economics. The index is calculated by summing up the squared market shares of each innovator. In order to measure the stability of temporal monopolies we constructed an intertemporal Herfindahl index HKI which represents the distribution of the different patents (over time) in the network. $HKI = 1.0$ means every patent within the simulated periods was held by the same actor, while lower values represent changing patent owners over time.

Figure 2 shows the resulting values for $v_t = 100$ and $v_t = 1500$. The higher the patent scope and/or patent length, the higher the tendency of intertemporal monopolization, i.e. at low ε and high T_p rather only one actor will gain all innovations and patents over time. The trend of monopolization is much more distinctive in the low potential market ($v_t = 100$).

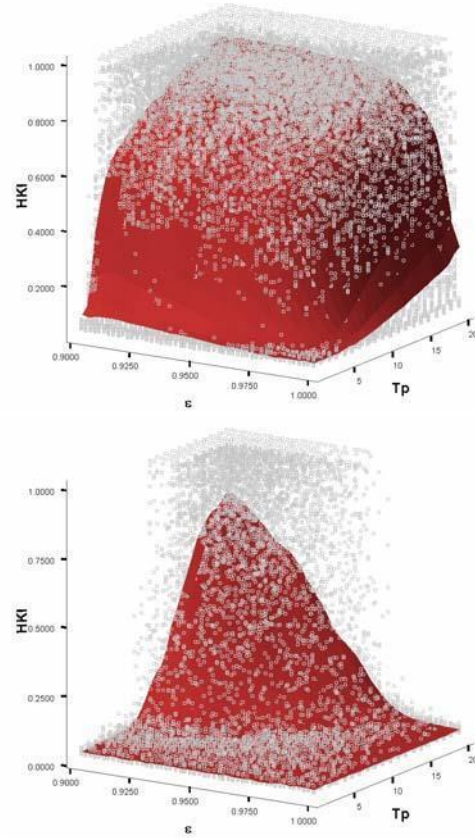

Figure 2: Market concentration index for $v_t = 100$ (upper diagram) and $v_t = 1500$ (lower diagram)

The second research question focuses on the relation between patentability and overall innovation rates. In order to answer this question, we measured the number of periods in which at least one actor found the innovation. We again compared the different market potentials ($v_t = 100$ and 1500) and did four views at two different scopes of patent protection (wide protection ($\varepsilon = 0.9$) and small protection ($\varepsilon = 0.99$)) and two different current times of protection ($T_p = 5$ and $T_p = 20$) while varying the other parameter (abscissa). Figure 3 and 4 show the results of the different constellations for a small market value ($v_t = 100$).

The upper diagram in figure 3 shows that by varying patent duration ($T_p=1$ up to $T_p=20$) with a constant small protection width ($\varepsilon = 0.99$) the scenario with patent protection performs better with a patent current time between 6-15 periods. Below 5 periods both scenarios have on average 25 periods with innovations found. (Caused to the low possible profit the decision function (eq. 2) leads to oscillations in decision and innovation behavior.)

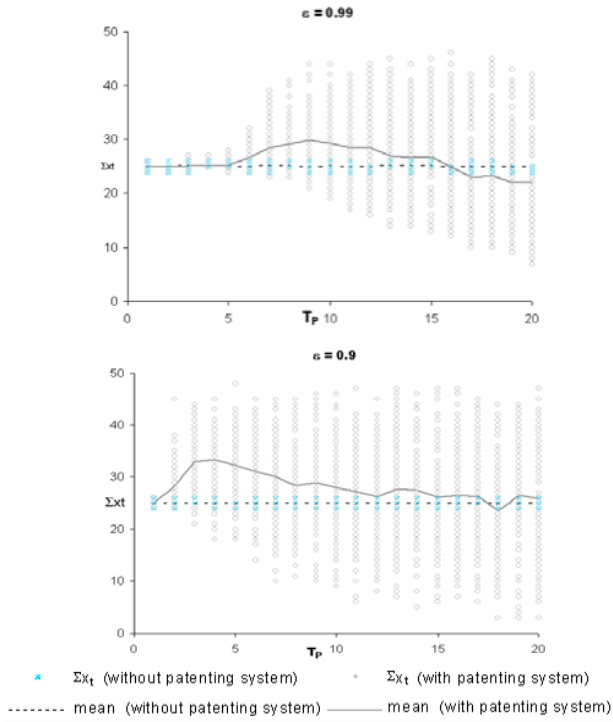

Figure 3: Number of innovations found with $v_t = 100$ (varying patent length T_p at two different levels of ε)

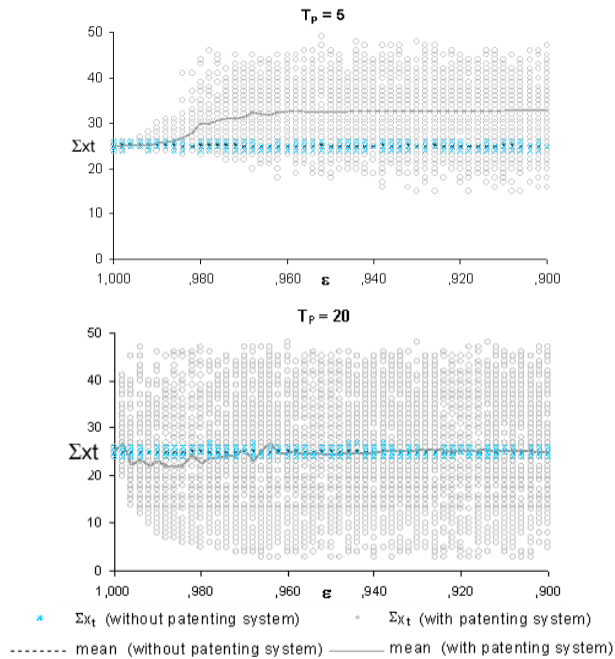

Figure 4: Number of innovations found with $v_t = 100$ (varying patent scope ε at different levels of T_p)

Figure 5 and 6 represent the corresponding results for the same parameter constellations in a high value market ($v_t=1500$).

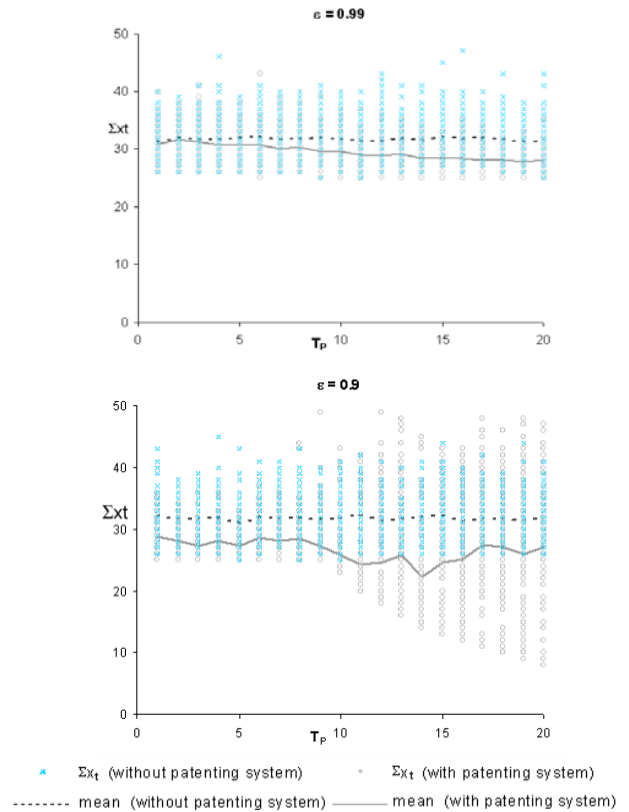

Figure 5: Number of innovations found with $v_t = 1500$ (varying patent length T_p at two different levels of ε)

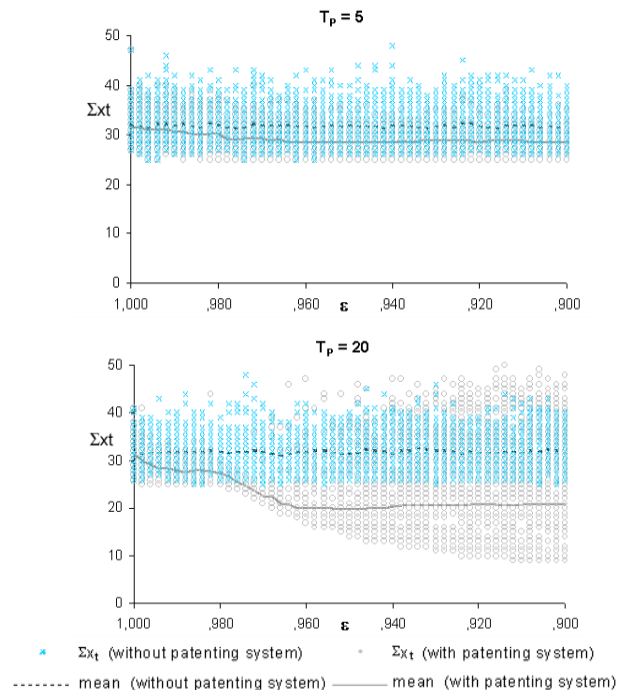

Figure 6: Number of innovations found with $v_t = 100$ (varying patent scope ε at two different levels of T_p)

In this situation the results have changed. The overall level of “innovative periods” is higher because the larger market potential provokes more actors to invest in R&D. The scenario without patent protection dominates in all cases. The innovations found on average always are higher. The longer the run time the bigger the difference in favor of the scenario without patents. With constant patent lengths ($T_p=5$ and $T_p=20$) the same results occur. It is noteworthy that at $T_p=20$ the patent protection system performs very badly between the patent scopes of $\varepsilon=0.98$ and $\varepsilon=0.9$. In this area only 20 innovations on average could be found. In markets with a high innovations value, the no-patent scenario dominates the patent scenario in every case. This is more with long patent current times and less with short run times. Comparing these results it can be summarized that within a low market potential combinations of rather high patent scope and rather short patent duration (3-5 periods) a legal patent system provides worse results (see figures 3&4) while it always results in positive effects in high value markets (figure 5&6).

In a next step, we analyzed the innovation success of the different market sectors in more detail, i.e. the relative innovation success between small, medium-size and large companies. For that purpose, the total number of innovations (including simultaneously found innovations) was counted and divided by the market share of the regarding company sector (i.e. small, medium or large companies). This success index was normalized to a value between 0 and 1.

$$\text{successindex(sector)} = \frac{\sum_{t=1}^T \sum_{i \in NW_{\text{sector}}} x_{it}}{\text{share(sector)}} \quad (4)$$

$$\forall \text{ sector} \in \{\text{small, medium, large}\}$$

As can be seen in figure 7, only in the $v_t=100$ environment the relative success of the respective sector changes with the patent length and scope. Without patent protection (the outer left dataset in each chart) in most cases the small companies are the most successful actors followed by the medium companies. In the case of a rather low patent scope ($\varepsilon=0.99$) and patent length of 6 to 10 periods the large companies reached relatively more innovations. At low ε the relations evolve inversely. Of course these results depend on the chosen cost structures, but it could be shown that in particular constellations and especially with constant cost structures the variation of patent system properties influences the success in a different way. This phenomenon has to be taken into account when designing welfare efficient patenting systems.

Figure 7: Innovation success by company's size for $v_t=100$ (different levels of ε)

Figure 8: Innovation success by company's size for $v_t=1500$ (different levels of ε)

5. Conclusion and Further Research

The goal of this paper was an analysis of the impact of software patents on the innovation activities of the software market. In this context, software development was characterized by its sequentiality, complementarity, utilization and availability of open code as well as the necessity to ensure interoperability. We developed a bipartite model for comparing environments with and without a legal patent system. Based on the characteristics (e.g. sequentiality and complementarity) we identified the development costs and the existence of previous innovations as the two key factors for innovation success. In the patent scenario the patent itself will have an additional effect. Computer-based simulations revealed that patent protection within low-potential markets outperforms the scenario without patenting system while the opposite holds for high-value markets. For both systems there is a propensity to monopolize, which is more distinctive in the low value market. The quantitative results of course are only interpretable within the chosen environment (parameterization, modeling of decision functions etc.). Nevertheless from the model the following general findings can be derived:

Patents lead to more or less intertemporal monopolies. Both the patent width and the patent length as key determinants of a legal patent system from a macroeconomic view can not be determined independent of the particular market properties (innovation difficulty, cost and market structure, market potential).

In some parameter constellations (lower market potential) a patent system leads to structurally different outcomes for the different market sectors.

As a next step, we will validate the findings using empirical data (esp. development costs and incentives for software producers) from conducted cases of software companies. Based on this research a sensitivity analysis of all parameters is necessary to determine the validity area of the made conclusions. Further the model will be extended about the possibility for cross-licensing and the actors' development costs will be endogenized to gain more favourable results about the individual incentive structure. Based on these steps of validation and extension the model could support in determining the necessity of a patent system or evaluating the optimal length of patent protection subject to the particularities of the software market.

Abstract

The concept of knowledge management (KM) is relatively a new one. But this concept has been widely discussed these days as it has been recognized that knowledge management is one of the important components of intangible assets of any business or non-business organization. In the business world, the earlier concept of knowledge has been changed where data, information etc. were treated as knowledge. Knowledge is now treated not as some data or information but this is power – a strategic (created) asset. Firms around the world are looking mainly for strategic assets rather than tangible resources. As a result, management of such an asset has become a challenge to the present world. There are controversies also exist across countries because of the fact that it is not objectively verifiable whether knowledge management adds value to the organization.

This paper attempts to conceptualize knowledge, its different types and the notion of knowledge management. This has been mainly done by the survey of literature on the basis of research work carried out around the world. However the main contribution of this article is that it has taken the Porter's Value Chain Model (1985) to evaluate if there is any relationship between this model and knowledge management or whether knowledge management adds value to the organization or not. A null hypothesis has been drawn assuming that there is no relationship between them. It has been found that the null hypothesis is not true and hence rejected. This indicates that KM adds value – the acceptance of alternative hypothesis (H_1).

1. Prologue

In the present day business world, organizations are constantly striving to create mechanisms for gaining competitive advantage over their competitors by differentiating their products or services in a common

market place. In this context, business enterprises are trying to optimize the exploitation of corporate assets. These assets can be categorized as financial, tangible and intangible assets. Financial assets comprise of cash, stocks, bonds etc.; plant, equipment, inventory etc. can be considered as tangible assets whereas core competencies & technologies, management skills, organizational culture, brand image, consumer loyalty, patents, distribution channels and the like are intangible assets. Knowledge is treated as a valuable intangible asset, which can be used as a strategic weapon in this turbulent environment of global economy. Such intangible assets are often called "Knowledge Capital" or "Intellectual capital" (Stewart, 1994) [20].

Knowledge Management is the systematic process for acquisition, distribution and utilization of knowledge in order to achieve the knowledge goals of the organization. It is the management of business, customer and process knowledge and its application for adding value and competitively differentiating product and service offerings [21]. As information technology revolutionizes today's businesses, flow of information is increasing through the technologies such as Internet and Intranets. Business processes and activities becoming more transparent and information asymmetries are blurring. Organizations are depending more and more on knowledge management to be competitive.

The Value Chain Model (Porter, 1985) [14] views the firm as a chain of some basic activities. Value addition refers to the difference between the products or service value before and after an activity is performed. All of these value chain activities are significantly adding value to a firm. This paper investigates the link between knowledge management and value addition to the enterprises through value chain activities in contemporary business world. An attempt is made to find whether knowledge management has any significant impact on the value chain activities of the firm so that it gives an advantage over competitors to business organizations. In this paper, A function is developed describing the relationship between value addition to the enterprises and

impact of knowledge management on value chain activities of the enterprises. A hypothesis is drawn about the impact of knowledge management on the value addition to value chain activities i.e. value addition to the firm. The impact of knowledge management on each of the value chain activities is logically tested without empirical analysis. An inference is drawn on the relationship between knowledge management and value addition process of the enterprises.

2. Conceptualizing knowledge and knowledge management

Knowledge is the whole body of cognition and skills which individuals use to solve problems. Knowledge can be defined as the sets of propositions that we are certain to be true. This certainty comes from the rules, standards and procedures that are embedded in and define natural, social and cultural sciences. Knowledge is based on data and information but it incorporates individual judgments that are influenced with experience, creativity and various social and cultural factors.

Understanding the concept of knowledge requires clearing the definition of data and information. Data represents raw facts that are out of context. Facts can be numbers, characters, character strings, text, images, voice, video and any other form in which a fact may be represented [2]. Information is data with a meaning, purpose and relevance. Mere information is not knowledge. Although knowledge is based on data and information, but unlike these, it is always bound to persons [17.p.24]. Understanding the underlying principles transforms knowledge into wisdom. The following figure might help to understand the concept of data, information, knowledge and wisdom.

Figure 1: Showing the relationship among data, information, knowledge and wisdom. [5]

Above figure shows that Merely the collection of data does not provide us any benefit until the relationship with the purpose is understood which lead us to information. When the pattern of this relationship is understood, it can be called knowledge. So knowledge is actionable information for intelligent decision-making. As we move from data to wisdom, context independency increases and better understanding is achieved.

Organizational knowledge resides in the organizational environment and information systems, which can be collected from databases, web sites, employees, business partners, strategic alliances etc. Such knowledge becomes not only embedded in documents or repositories but also in organizational routines, processes, practices and norms [21.p.35]. Utilizing these knowledge helps organizations survive and thrive in the volatile business environment.

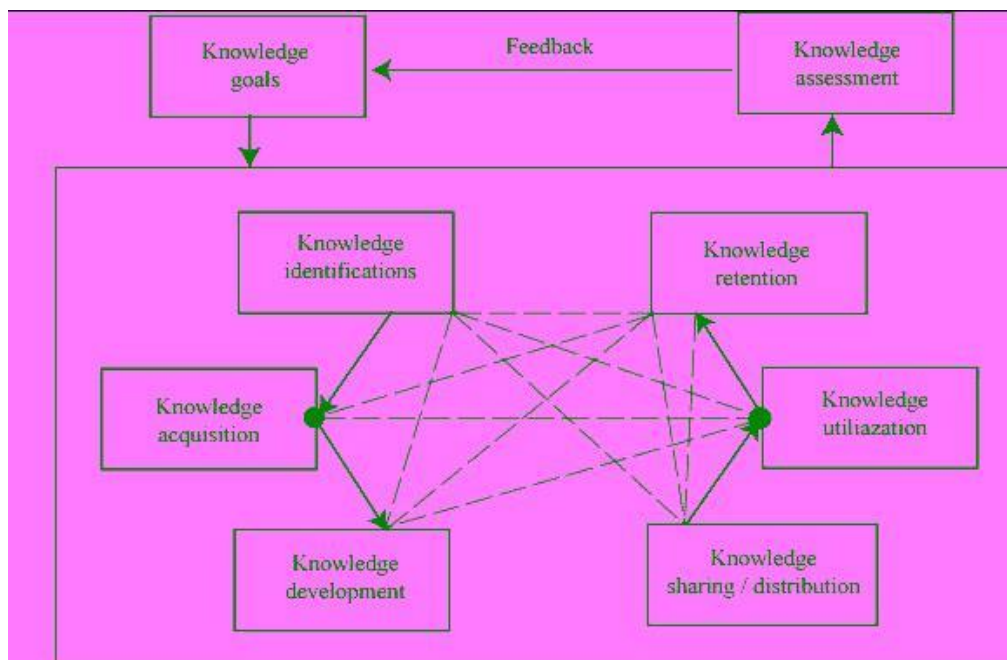

Knowledge can be divided into two major types - Explicit or codified and Implicit or Tacit knowledge [15][16]. Explicit knowledge can be expressed in words and numbers and shared in the form of data, specifications and the like. Explicit knowledge can be shared using Information & Communication Technology (ICT) like Internet, Intranets etc. Lubit (2001) [8] observes that the explicit knowledge is codified and stored in the "Organizational memory" and is available to employees throughout the structure. Documents, reports, databases, web pages, e-mails, charts, etc. holds this type of knowledge. Present information systems can easily support explicit knowledge.

On the other hand, tacit knowledge is highly personal and difficult to formalize, making it difficult to communicate or share with others. It exists in the mind of employees and deepens with attention, motivation, commitment, creativity and innovation over time. So, tacit knowledge is hard to manage (record, encode or articulate) using existing information systems. It is often deeply embedded in corporate culture and influenced by norms and values. It is unique to organizations and considered as the most valuable corporate asset. Because of formalization difficulty, inter and intra organizational transfer of tacit knowledge is very hard. In this volatile business world where globalization and digitization creates information symmetry, no organization can achieve sustainable core competencies that may act as competitive advantage for long. Tacit knowledge can make the difference among organizations because only 'knowing, how they are doing' may not blur the advantage that one has. It can be compared with swimming. A swimming instructor may help one to learn how to swim using email, manuals or even with photographs or videos, but the trainee will not be able to swim until he is in the water with the instructor. Tacit knowledge is hard to copy. That's why it is considered the most valuable asset for competitive advantage in this "knowledge era" of business.

Knowledge management is the set of systematic and disciplined actions that an organization can take to obtain the greatest value from the knowledge available to it [10]. It is a strategic weapon for gaining competitive advantage. Knowledge capital is composed of three elements; human capital, customer capital and structural capital (Saint-Onge, 1998) [18]. Human capital is defined by Saint-Onge as “the capabilities of the individuals in an organization that are required to provide solutions to customers”. Structural capital is defined as “The organizational capabilities of the organization necessary to meet market requirements” and customer capital is defined as “The depth (Penetration), width (coverage) and profitability of the organizations franchise”. According to Peter A. C. Smith (1998), human capital comprises transient knowledge and capabilities in the sense that they are free to walk out of the organizational door at close of business day [19]. Structural capital comprises the captured knowledge and capabilities that remain behind. So we can summarize that, knowledge management is the management of organizations human capital, structural capital and customer capital to develop the core competencies of the organization.

The major objective of the KM in the organization is to use knowledge as the productivity and efficiency enhancement strategic weapon to gain competitive advantage in the industry. Probst (2001) [12] considers it as a cyclical process, which consists some functional blocks.

All Building blocks of knowledge management should be directed towards the utilization of all organizational knowledge because without proper utilization, goals of knowledge management could not be achieved. This knowledge has to be preserved in an easily accessible format as much as it is possible. Knowledge measurement involves checking of all parts of knowledge strategy and whether they have succeeded in implementing these at the

Explaining the above figure, it seems that knowledge goals define what skills are to be developed in the firm and at what levels. There are three levels in developing knowledge goals – Normative, Strategic and Operational

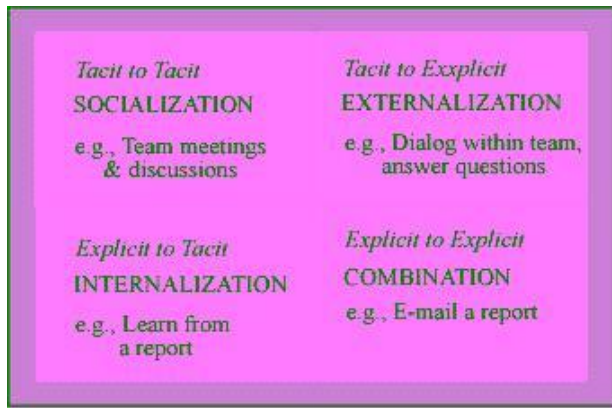

Figure 3: Conversion of knowledge between tacit and explicit form after Nonaka. [10].

In this process, assessment of knowledge outcomes provides constant feedback to knowledge goals of the organization. This feedback may refine the knowledge goals if necessary. In the "New World of business" with high levels of discontinuity and inability to predict the future, highly routine and structured forms of knowledge management should incorporate behavioral dimensions of human decision-making process to harvest the fruitful outcome of it.

Figure 4: Knowledge management solutions. [6].

Knowledge management solutions (figure 4) consider three key issues for successful implementation. These are Organization, Process and Technology. Within organization, knowledge needs, sources, organizational structure, culture and its barriers are considered. Business process includes product and service design and development, customer management, human resources management, business planning and forecasting. Technology addresses the computing and communication

technology for knowledge sharing, distribution and retention. Effective knowledge management solution is achieved where these three issues are properly melted.

3. The Value Chain Model

In the Value Chain Model, Porter (1985) [14] describes businesses as a chain of some activities where competitive strategies can be applied best. These activities are categorized into two types; primary activities and support activities. Primary activities are directly related to the production and distribution of the firm's products or services that create value for the customer. According to the value chain model, there are five primary activities; inbound logistics, operations, outbound logistics, marketing & sales and service. Inbound logistics are those activities that are required to receive and store raw materials for distribution to production system. Operations transform raw materials into finished products or services. Outbound logistics involve all processes of replenishing retailer inventory. Marketing and sales includes product promotion, market creation and expansion and selling activities of products and services. Maintenance and repair of the firm's products are the service activities.

Support activities are necessary for successful completion of primary activities. These activities include firm's infrastructure related activities, human resources management, technology related activities and procurement. Firm's infrastructure related activities are administration and management of the organization, human resources management activities are employee recruiting, hiring, training etc. Technology activities are related with improvement of products and processes. Procurement is about gathering the inputs.

Value addition refers to the difference between the products or services value before and after an activity is accomplished. Value addition can take place either by reducing the cost of any activity than competitors through better management, superior design or process or by increasing the revenue through product differentiation or other means. These nine strategically relevant activities adds margins of value to a firms products or services, which may gain competitive advantage to the firm.

4. Impact of knowledge management on value addition: A hypothesis

We can formulate the following hypothetical function where value addition to the enterprises depends on the value addition through knowledge management in the value chain activities.

$$Va = f(KMi) + g(KMj) \quad (1)$$

Where,

Va=Value addition to the enterprise.

KM_i=Value addition through KM in ith primary activity.

KM_j=Value addition through KM in jth support activity

i = IB, OP, OB, MS, SV; the primary activities of value chain: inbound logistics, operations, outbound logistics, marketing & sales and service respectively.

J = AD, HR, TH, PR; the support activities of value chain: administration & management, human resources, technology and procurement respectively.

Value addition through knowledge management will happen as long as

$$\frac{\partial f}{\partial KM_i} > 0 \text{ and } \frac{\partial f}{\partial KM_j} > 0 \quad (2)$$

i.e. The marginal value addition through knowledge management in each of the value chain activities is greater than zero.

So we can draw the following null hypothesis,

H₀: There is no difference in the value of the enterprise before and after KM is incorporated in the value chain activities.

motivation, commitment, creativity etc. Incorporating behavioral issues in knowledge management is necessary because without it KM generates mostly static outcome, which may be sufficient for businesses in continuously changing environment but not for 'new world of business' of discontinuous changing environment which requires dynamic adjustments in decision making. As quoted by Malhotra (1998), "Essentially, it (KM) embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings" [9]. According to this model, 'the world of re-everything', which challenges the assumptions underlying the "accepted way of doing things".This world is contrasted from the 'old world' by its emphasize on "doing the right thing" rather than "doing things right" [1.p.11].

Inbound logistics and procurement activities are related to the purchase, storage and distribution of necessary materials and inputs for production. Since we are in a demand-based economy, consumers determine what product will be produced and delivered to them. So inbound logistics and procurement activities are driven by market needs. For gaining competitive advantage by reducing cost businesses are managing inventory using systems like 'stockless inventory' or 'just in time'

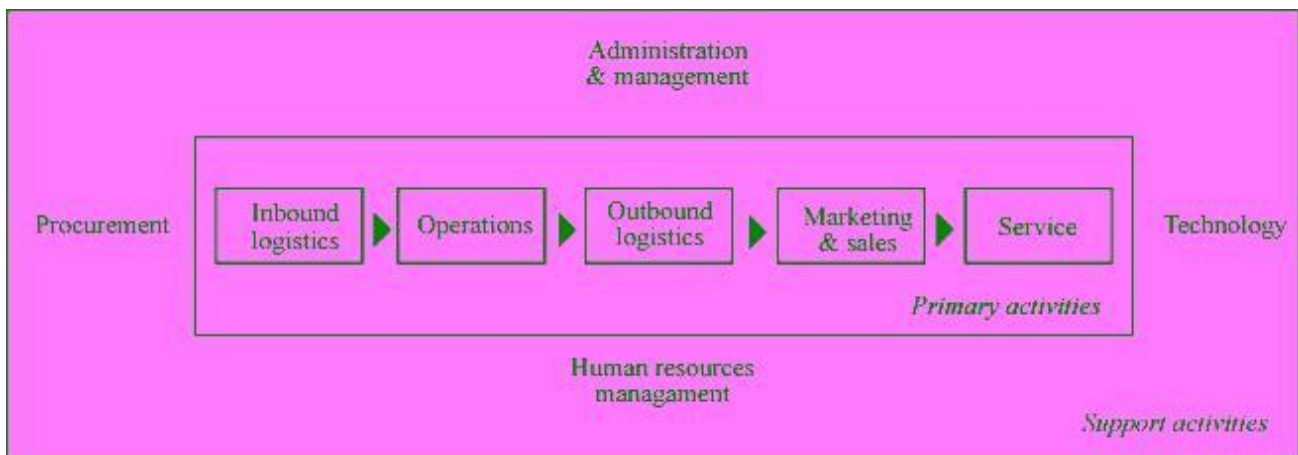

Figure 5: The Value Chain Model

5. Hypothetical analysis

In order to test the hypothesis, we will consider each value chain activities and try to find whether knowledge management has any impact to enhance the quality of the value chain activities so that it can add more value to the firm's products or services. This hypothesis is tested non-empirically using literatures and evidences.

To aid the testing of hypothesis, we can use the model of knowledge management of 'new world of business' [1.p.12]. In this model it is shown that, knowledge factors have shifted from highly routine structural forms to partly unpredictable behavioral factors like attention,

systems. This type of systems require synchronized flow of information along with proper knowledge sharing about the market nature and demand between supplier and manufacturer. As an example, Wal-Mart's (One of the largest retailer in the USA) 'Continuous stock replenishment system' sends orders for new merchandise directly to suppliers as soon as customers pay for their purchases in front of a point of sales (POS) terminal [7. p.54]. Another KM aided inventory management technique is vendor-managed inventory where supplier is responsible to make inventory replenishment decisions based on information supplied by sales transaction in POS terminals or any other means. It is based on the theory that, suppliers are the product or category experts and thus can do the best job of making sure that supply meets demand [7. p.59]. This expertise comes from the intimate knowledge sharing between supplier and

Summarizing the old version and new version of knowledge management models of Malhotra (2002), the following model for effective knowledge management can be drawn.

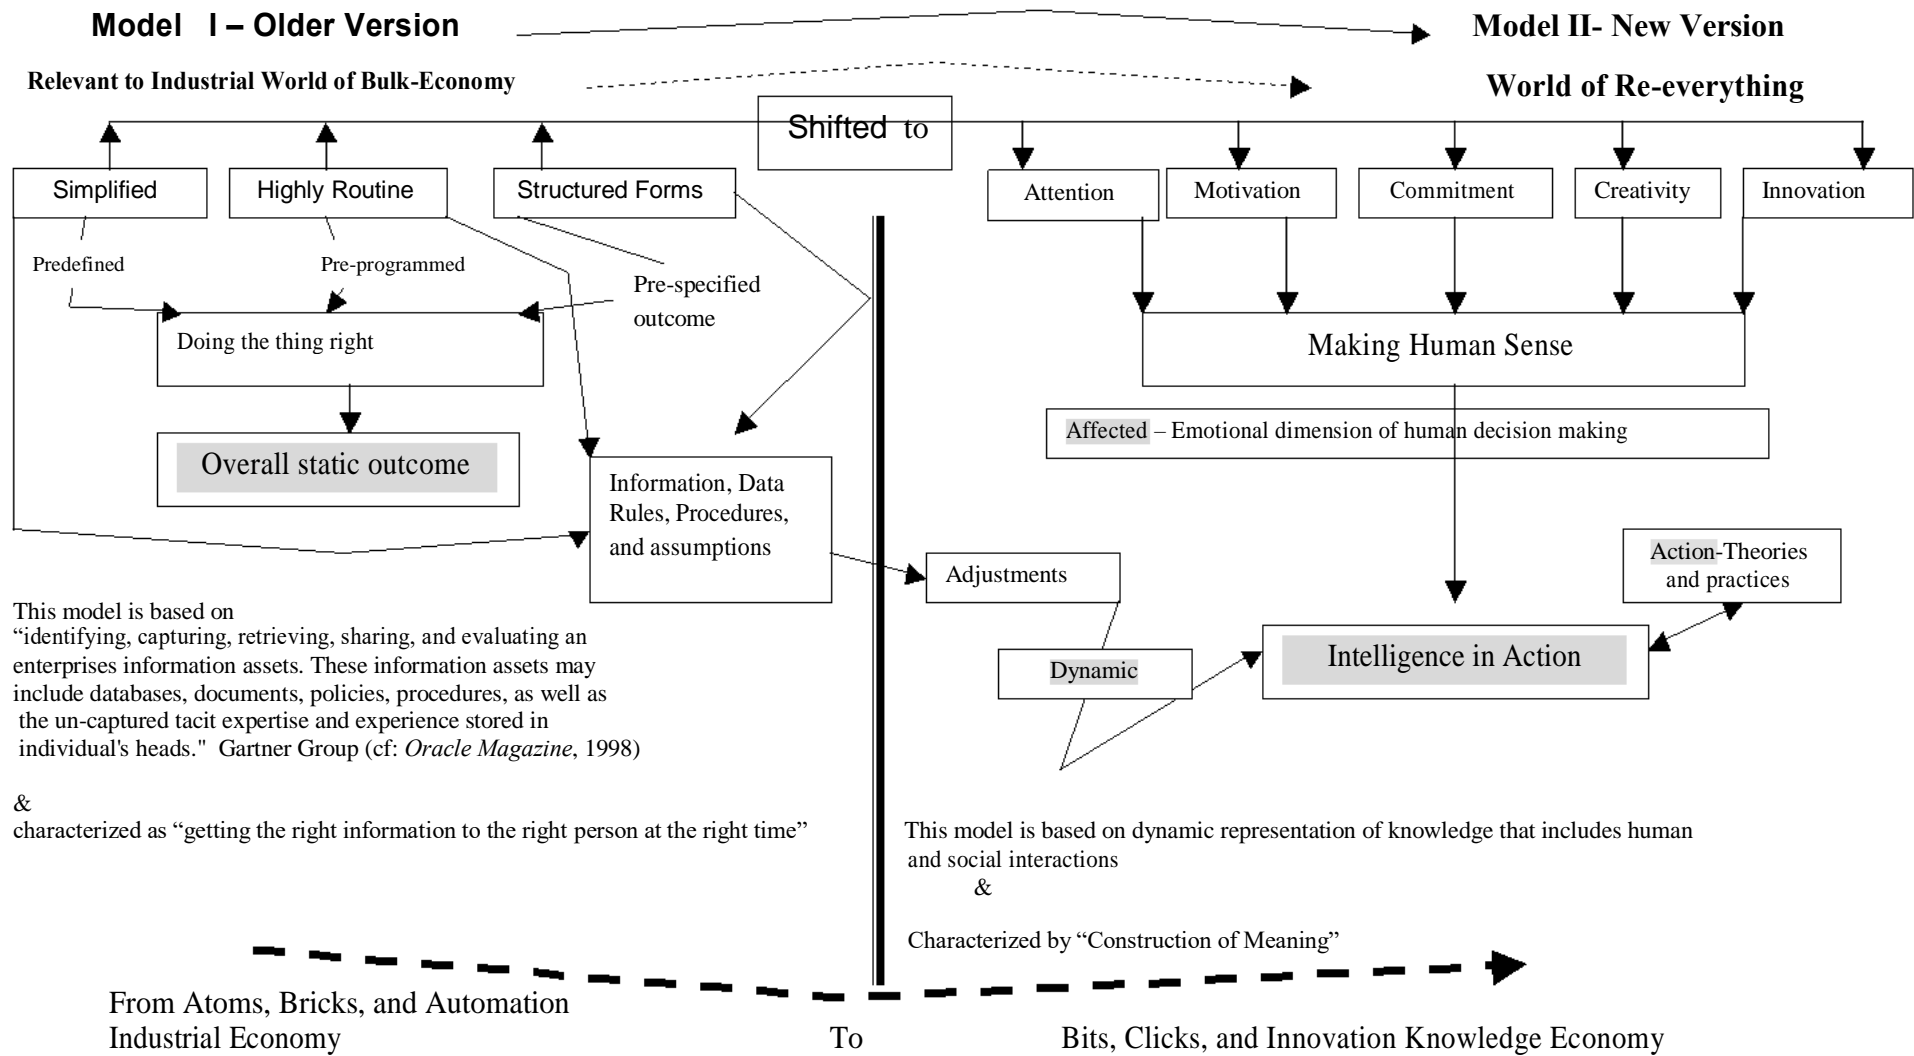

Fig. 6 – Shows the shifted model of knowledge management.[1. p.12]

manufacturer through successful knowledge management system. But the mere information does not add any value until this information is properly understood and the behavioral factors of knowledge management are incorporated for intelligent action. According to Yogesh Malhotra, founding chairman and chief knowledge officer for the BRINT Institute in Syracuse, New York, "Inert and static information lying in any kind of repositories including intranets and portals alone does not result in business performance. Even within stable business environments, users' commitment and motivation to effectively use that information is critical" [23].

Procurement information is very easily and cheaply available in this cyber business world. Large amount of information can be collected within a very short period of time very cheaply. Finding the right information for the business is a cumbersome and time consuming process. Content management can play a vital role to rescue us from the world of 'info-glut'. Content management is a primary component of knowledge management and a major issue for organizations because it brings to light the need to retire content when it becomes outdated and to hold someone accountable for maintaining accurate and up to date information. [22]. Knowledge management technology like Natural Language Processing (NLP) portals can generate meta-data (knowledge map or taxonomy; a hierarchically organized set of categories. exp. Yahoo!) of a particular domain. This type of technology may help in finding the appropriate and accurate explicit knowledge for procurement and inbound logistics. In the push process of raw material procurement cycle, inventory is replenished in anticipation of customer demand. This anticipation requires understanding and experiences about human behavioral pattern (tacit form of knowledge) along with proper information.

Operations are the activities performed to transform inputs into finished goods and technology is the aiding tool for improving products and production processes. Computer aided product design is a technology based new product creation performed by the knowledge workers of the organization. Products are getting more and more complex by adding more features due to competition. It is knowledge workers responsibility to add more value to them. According to Peter F. Drucker, "Productivity of the knowledge worker is not – at least not primarily – a matter of the quantity of output.quality is the essence of output." [3. P.142-143]. To do the task of adding quality, Drucker thinks, continuous innovation, continuous learning and continuous teaching have to be built into the knowledge worker's job [3 p.146]. Embedding knowledge in products, services and processes helps deliver higher quality individualized offerings that can lock in customers [21 P.41].

As quality adds more value to products or services, knowledge creation through innovation and creativity and knowledge sharing among knowledge workers can create

new products or services with better quality and can demand better payoff than competitors. So knowledge workers are the unique assets of the organization. "To be productive knowledge workers must be considered as capital assets", Drucker says [3. p.148]. As an Example, The Gillette Company, the famous grooming and oral care product manufacturer, produces value to the firm by raising quality of Gillette razors and blades. They are producing new types of products like Sensor Excel, Mach3 by adding new features and differentiating their products in the market place for competitive advantage. [7. p.42].

Knowledge creation can also enhance the production process, which adds value to products or services. Intel Corporation switched to new 130 nm technology from older 180 nm technology of producing processors to produce more cooler and speedier desktop processors than its competitor Advanced Micro Devices (AMD). But after a short delay AMD quickly followed Intel to blur that advantage.

Modular innovation (innovation and breakthroughs that are achieved by recombining and reconfiguring existing technologies in novel ways) [21. p.10] and knowledge-based individualization facilitated by KM, may create value and group of loyal customers. MP3 players and Levis custom fitted jeans can be two examples of these two techniques. Knowledge is a unique asset to organization but sometimes confinement of knowledge within the organization might not be profitable for the organization as well for the industry. Example can be taken from two knowledge intensive industries – PC and biotechnology industry- that emerged in the 1980s. The PC industry blossomed by giving away its secrets, with the singular exception of Apple, which guarded its designs only to lose out. The biotechnology firms on the other hand still exist, but unlike the multi billion-dollar PC industry, most of these companies have never turned a profit despite all their patents and legal forms of protection. The only way to protect your business knowledge is to apply, reuse, update, evolve and outdate it too fast for competition to be able to copy it. [21. p.8]. So knowledge management is important for value creation.

Outbound logistics are activities related to storage and distribution of finished products. Knowledge about customers buying patterns and buying characteristics can reduce the necessity of bulk storage. Necessary information might be collected from various repositories such as data warehouses and incorporating supply chain managers experiences with this information, business organizations can produce in depth knowledge about storage requirements and distribution patterns of the goods and services. Airlines yield management system can be a good example of management of explicit knowledge to gain competitive advantage. Yield management is the process of wringing the most profit out of every airline seat and determining when to drop or

increase prices to offer promotions. Rather than offer cut rate fares to fill up the plane, this system examines the historical pattern of that flight and determines how many seats the airline should set aside for executives willing to pay full fares at the last moment. [7. p.55]. 'Cross functional platform teams' combine expertise of different functional area such as product design and development, manufacturing, distribution, marketing and sales etc. Combination of cross-functional tacit and explicit knowledge can enhance the outbound logistics of the organization. Malhotra says that the synergy of 'Smart minds' and 'Smart technologies' also provides a basis for defining agile and adaptable supply chain networks that can withstand the challenges of a radically changing business environment. [22].

As we have stated earlier, human capital is an important element of knowledge management. It is the capability of human resources of the organization to solve problems. Same problems can be solved by different organizations differently. "No two executives organize the same information the same way" [3. p.126]. In order to add value through problem solving and meet customer needs, executives should incorporate innovation, creativity, motivation and experiences with the available information. Since much of the administrative and managerial activities require tacit type of knowledge, it is difficult to provide any hard and fast procedures for solving this kind of problems. Drucker says, "Innovation should be organized as a regular part of every unit within the enterprise and every level of management the test of an innovation is that it creates value" [3. p.85-86].

Through interactions with others, tacit knowledge is externalized and shared. [12]. Socialization (team meetings, informal discussions) and externalization (FAQs) help tacit knowledge to be shared around the organization. Shared knowledge can create collaborative expertise which can help to solve problems more accurately and efficiently using less time which can create economic value to organizations.

As we are moving from product to service oriented industry, leveraging knowledge is more important than ever for adding value to organizations. Firms require employees with experiences and in depth knowledge to survive and thrive. Human resources management activities (training, recruitment, hiring etc.) could be facilitated by horizontal knowledge transfer techniques such as twinning (organizing social or other visits) and secondments (temporarily transfer to other jobs from their responsibility). So incorporation of knowledge management techniques in human resources management activities could increase organizational efficiency and hence value to the firm.

Marketing activities create the awareness about the product or services of the firm. Identifying the customer needs and supplying necessary utility is the major task of marketing. Traditional marketing activities research,

strategy, planning, collateral development, lead generation are all done in vain if marketing can't effectively identify the organization's current and future customers, segment them, forecast accurately against those segments and inform the product development process so that the right product mix arrives in the marketplace at the right time for the right customer groups [4]. Click stream analysis (analyzing a series of mouse clicks of an individual in cyberspace to understand the buying pattern) can help to identify a potential customer. Knowledge enabled businesses can anticipate changes in customer preferences – an evolving social trend, a new management practice, a nascent technology rival innovations or economic development in a potential foreign market. KM tracks and maintains knowledge regarding the validity of assumptions about markets, customers, and business environments before critical decisions are made based on flawed ones [21. p.41.]. Knowledge enabled customer relationship management (KCRM) manages customer knowledge to generate value creating lock-ins and channel knowledge to strengthen relationships and collaborative effectiveness. [21. p.12]. KCRM treats customer as a value co-creator. Customer knowledge integration can create loyal customers who are willing to pay justifiable cost but not the least cost. As an example, 70 percent of *Amazon.com* customers return to pay more when many of them know of other places on the web where they can find same item for less [21. p.13]. Sales function records the transaction information, which can be fed to knowledge-based marketing system for producing better quality products and loyal customers. In this highly competitive business arena where switching cost is very low, knowledge-enabled marketing and sales activities can add value to the enterprises.

Service activities can generate huge amount of information through complaint reporting and resolutions. Service activities can add value by improving the quality of the products as this information can be used to develop better products and services. Software industry is using this type of approach. Service employee's experience can be a unique asset for the organization. A classic example of knowledge enabled service system is Xerox Corporation's Eureka system.

Eureka system enables the organization's 23,000 service engineers from around the globe to input product solutions into a knowledge base. When a machine problem arises with a Xerox product, the service engineer can access the knowledge base to find a product solution. The knowledge base currently holds 55,000 problem/solution entries. If it's a unique situation where a solution doesn't exist in the knowledge base, the service engineer will voluntarily input the solution into the system once the machine problem is solved. Xerox estimates savings between \$12 million and \$15 million per year as a result of its Eureka system. Much of the motivation lies behind having his or her name attached to the solution and becoming an author, and then having that solution tip validated by a senior manager.[22].

From the above example it is evident that, a knowledge base of service problems and resolutions can help firms to provide better and prompt service and it also converts the tacit knowledge into explicit form, which reduces the fear of non-existence of that expertise as the employee leaves the organization.

From the above discussions, we see that, knowledge management can significantly enhance the value chain activities: both primary and support activities. Enhancement in each of these activities adds margins of value to the enterprises in this volatile business environment. Using knowledge management techniques, enterprises can have unique advantages over competitors. So we can reject the null hypothesis and accept the alternative hypothesis i.e. knowledge management in value chain activities has positive impact on the value addition to the enterprises.

6. Conclusion

In this paper we have seen the differences between information and knowledge. We have also seen the creation and management process of knowledge along with its different dimensions and types. There has been a gap in understanding whether knowledge adds value to the firms or not. To evaluate this proposition, we have taken the Porter's Value Chain Model. In the model, there are two types of activities –primary and support. As we did not have numerical figures to test it mathematically, we have tested the proposition on the basis of different research works, our best judgments and different examples cited by various authors. To formulize it, we have drawn a function taking one dependent and some independent variables. At the end, it has been found that there is a relationship between value addition and knowledge management, that is, knowledge management adds value to the firms. We expect that potential researchers will statistically and mathematically prove the hypothesis in coming days.

Abstract

This paper presents a Balanced Scorecard (BSC) based approach for strategic IT-Controlling in the context of e-Business development. As today's first generation's e-Businesses implementations show, there is need for more IT- and Business Infrastructure Management to fit rapid changes in business strategy with the development of e-business. The theoretical deliberations done in this paper provide a step by step development of a BSC and illustrates a variety of goals, links of cause and relationships, evaluation criteria, and measures within the context of an Austrian beverage producing company's strategy regarding its e-Business strategic positioning. The e-Business deployment was an overall success with a few minor shortfalls in the areas of content actualizations and system downtime, both due to technical problems, and expected end consumer utilization. The calculated BSC was regarded as suitable for supervising the e-Business environment and the associated strategic goals by business management.

1. Introduction

The Balanced Scorecard (BSC) was first proposed in 1992 by [9] and soon after applied [11]. Today the BSC is a well established measurement method which links strategic objectives and performance measures across four different perspectives. In addition, the application of the BSC promises strategy mapping between each of the perspectives. The idea of a BSC is to find a set of measures that maintain a balance between short- and long-term objectives, between lagging and leading indicators, between financial and non-financial criterions, and between internal and external performance perspectives [10, 18].

The usefulness of the BSC method was shown in a variety of different settings such as for university [12], national health service [18], banking [13], public [7], and other sectors [3, 5, 20, 21]. Furthermore, [22] conducted a systematic comparative research to relate the value of the BSC, and the value of specific elements of it, to the context of the application. They concluded that the BSC appeared to be of value to all ten organizations analyzed (although in varying degrees). A critical reflection of the BSC can be found in [2, 17]. Some scientists question the concept itself [24]. They are pointing out that the BSC is not an elaborated system but a framework, respectively

diagnostic system, of performance measurement.

The BSC was also applied in the IT area, e.g. for strategic information systems [14], and in the ERP context [19].

This paper seeks to analyze an e-Business development, which is a task characterized by business process integration and automation issues [4, 8], and its performance with a BSC adapted to the special situation faced in the underlying company. Firstly, we will present an adoption of the general purpose BSC to the case of analyzing an e-Business implementation. Thereafter, the adapted BSC is calculated with the empirical data of the underlying case study. We conclude with implications on the usefulness of the BSC for e-Business performance analysis and the results of the BSC calculation for the case study.

2. An e-Business BSC

The original BSC proposed by Kaplan and Norton consists of four different perspectives: the financial perspective, the internal business process perspective, the customer perspective, and the learning and growth perspective [9].

Attempts to adapt the BSC to evaluate e-Business, either as a system or subdivision of an organization, have extended the traditional perspectives [6, 15, 16]. An important extension is the partner viewpoint, which takes into account the special role of diverse partners in e-Business environments, especially for e-Procurement. Another addition can be an implementation perspective, where project based evaluation criteria are pooled. This extension accommodates the complexity and difficulties observed, when introducing e-Business solutions to companies.

Table 1 shows the mentioned perspectives and illustrates the cause and effect relationship between them. Apparently, all e-Business aspects should ultimately have an effect on financial measures. Because the e-Business solution was already implemented in the case study, we have excluded the introduction perspective in the following analysis.

Table 1. e-Business perspectives, and cause/effect relationship

	e-Business System Implementation and Usage	Introduction/Implementation Perspective
	e-Business Potentials	Learning and Growth Perspective
		Internal Business Process Perspective
	Financial Effects	Partner Perspective Customer Perspective Financial Perspective

3. Case Study

In our case the BSC was calculated ex post 2.5 years after the e-Business system was deployed. All relevant information for this time period was available. In future, the BSC will be applied as an IT controlling instrument.

3.1 Company Background

The analyzed enterprise is a large Austrian beverage producer. The different brands are either distributed by food chains such as Billa or Merkur, or by catering companies. Thus the enterprise depends to a considerable degree on the successful co-operation with these partners. Sales are enforced by expensive marketing strategies especially to sustain and further improve the image of the corporation.

3.2 e-Business Deployment

The initial e-Business system was launched in the year 2000 and represented an internet-based information system for partners and customers as well as and an area dedicated only to business partners. The information on products and the company itself was stored in up to 10 different languages and can be edited by an overall editorial system.

The deployed e-Business system therefore supports Business to Business (B2B), Business to Consumer (B2C) and Consumer to Business (C2B), and Intra-business (Organization Unit to Organization Unit) communication.

3.3 Discounted Cash Flow (DCF) Analysis

A DCF analysis was undertaken prior to defining the BSC and 2.5 years after e-Business deployment for a time period of five years. Therefore, most of the considered factors were quantified exactly for the past 2.5 years, while all of them had to be estimated for the next 2.5 years.

The purpose of the DCF analysis was to identify and evaluate the predicted future cash flows resulting from the E-Business investment and discount them with an appropriate interest rate. The DCF analysis can of course not take into account important intangible benefits, such as an improvement of the company's image. Nevertheless, the application of the DCF analysis showed us

the criteria and their observed, respectively estimated, values which directly influence the financial aspects of the underlying investment. Two main areas of application potentials were identified: The level of e-Business utilisation by end consumer and business partners as well as improved process efficiencies. It was assumed that the level of achievement for each potential rises over time starting by 60% in the first year.

The DCF analysis yielded a negative net present value of the e-Business investment of -10,000 €, which would have suggested a rejection of the investment. Recent papers have shown, that the use of DCF based analysis alone does not suffice to assess the benefits involved IT decisions [23]. Newer IT applications such as e-Business solutions seek to provide a range of benefits including many intangible factors which can not be fully assessed by traditional methods such as the DCF based analysis [18].

3.4 Strategic Goals

The company aimed to achieve its competitive advantage by both operational efficiency and strategic positioning. The company defined the following primary objectives while making the e-Business adoption decision:

- Elimination of the e-Business gap to competition
- Establishment of a technological base to enable future e-Business developments
- Improvement of the image and awareness of the enterprise in the market place
- Creation of a permanent contribution to an increase of sales
- Improvement of communication (more efficient, error free, easier)

3.5 Strategic Goals for each BSC Perspective

The strategic goals determined by the company prior to e-Business adopting need to be extended for every BSC perspective. It is essential to have a common understanding of the company's strategy and the e-Business technology to achieve profound and well-defined goals related to each BSC perspective.

For the Learning and Growth Perspective the following goals were defined:

- e-Business system is „state of the art“
- High quality of e-business operations
- Low level of e-Business operating costs
- Up-to-date content through regular revisions
- High staff participation and accumulation of know-how

For the Internal Process Perspective the following goals were determined:

- External inquiries go directly to the correct internal contact

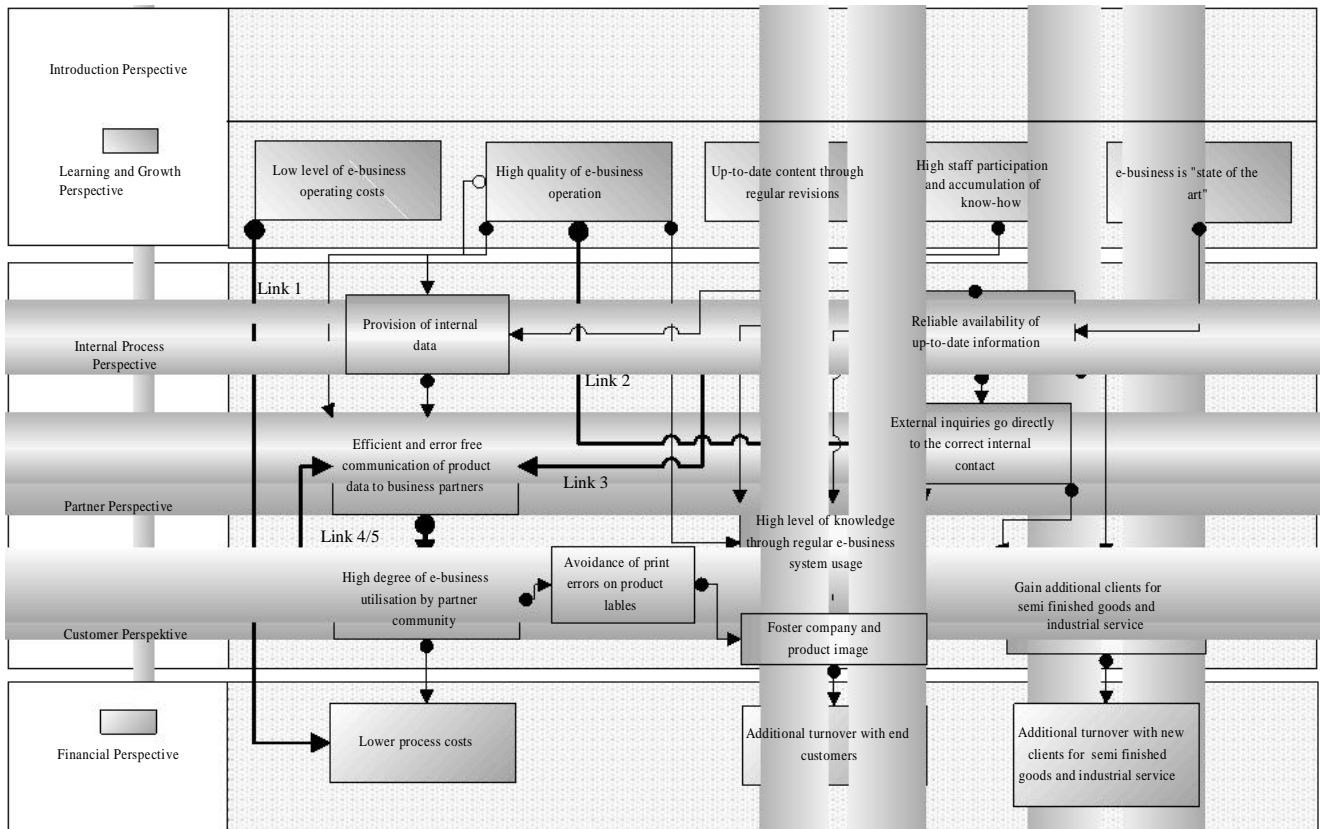

Figure 1. Chains of cause and effect between the determined e-Business goals

- Reliable availability of up-to-date information
- Provision of internal data

For the Partner Perspective the following goals were stated:

- High degree of e-Business utilization by business partner community
- Efficient and error free communication of product data to business partners
- Avoidance of print errors on product labels

For the Customer Perspective the following strategic goals were defined:

- Foster company and product image
- High level of knowledge in the end customer community through regular E-Business system usage
- Gain additional customers for semi finished goods and industrial service

To the Financial Perspective three final goals were added:

- Lower process costs
- Additional turnover with end customers
- Additional turnover from new clients for semi finished goods and industrial service

3.6 Chains of Cause and Effect

The BSC analysis also involved the forging of chains of cause and effect between the previously determined goals. Figure 1 illustrates the resulting network. Below we have extracted a few examples of the essential links identified:

Link 1: E-business processes are supposed to cause lower process costs than traditional business processes. Therefore by substituting traditional processes for e-business processes the overall process costs are reduced.

Link 2: It is assumed that high quality e-business solutions allow to redirect customer inquiries directly to the correct internal contact, represented in this case by a specific e-mail addresses.

Link 3: Only through reliable availability of the e-business system and information provided, it is possible to communicate product data to business in an efficient manner.

Link 4/5: The efficient and error free communication and the e-Business utilisation level depend on each other. Link 5 indicates that only if the system works properly it will be accepted by business partners as an alternative to sending printed product catalogues, e-mails or CD's. At the same time Link 4 assumes that the potentials of the e-business system can only be fully exploited if the system is used by nearly all business partners.

Table 2. Goals, their assignment to different perspectives, metrics, and levels of achievement

Perspective	Strategic Goals	Measures	Achievement
	Low level of e-Business operating costs	e-Business supplier costs	Green
		Errors with content updates in the business partner area	Yellow
	Up-to-date content	Amount of update activities	Yellow
	High staff participation and accumulation of know-how	Number of employees with unrestricted entrance to the editorial system	Green
	e-business is „state of the art“	Age of editorial system	Green
	External inquiries go directly to the correct partner	Forwarding of inquiries	Green
	Reliable availability of up-to-date information	Downtime per month	Yellow
	Business partner community: High level of knowledge through regular E-Business system usage	Inquiries with problems and questions as well as unnecessary mailings	Green
		User sessions	Green
		Downloads	Green
		New registrations	Green
	End customer community: High level of knowledge through regular E-Business system usage	User sessions	Yellow
		Downloads	Yellow
		New customer requests	Green
	Lower process costs	Costs for ISDN despatch	Green
		Effort for transmitting product data and pictures over traditional channels	Green
	Additional turnover with end customers	Valuation of end customer sessions	Yellow

3.7 Chosen Measures and Levels of Achievement

In Table 2 the chosen measures to clarify the achievement of goals are presented. Those metrics are linked to the determined strategic goals, which again are assigned to the different perspectives. It has to be noted, that some assignments in the BSC framework could have been defined differently. The chosen measures needed to be quantifiable (by cost-effective means), easy to understand and should reflect the identified chains of cause and effect [10, 18]. Therefore, it was not possible to account for every determined strategic goal in the framework, what can be seen as a drawback of the BSC approach.

For each of the used measures the company had to set the desired targets, which also reflect the final goal level to be achieved at the end of the strategic planning rhythm. For our case the level of achievement (green, yellow, red) is illustrated in Table 2 in the last column. As can be seen, there are no red markings, the e-Business components seemed to be more or less operating as planned. Some

problems were detected in updating and changing product information especially in the business partner section of the system. Those problems were based on data import problems between the AS400 and the e-Business server. Furthermore, the system downtime would need to be reduced to further improve reliability (as suggested by introducing a server cluster). Finally, the end consumers were expected to pay more attention to the new system. This shortfall was identified by a number of measures in the customer and financial perspectives. A possible reaction would be to increase the content extent and quality by more updates on a more regular base.

The achievements of undertaken actions should then be further evaluated and controlled by the continuous application of the BSC.

4. Conclusion

The management of the analyzed company regards the BSC as suitable for supervising their e-Business system and communicating their associated strategic goals. It

will be used as information-gathering tool on a regular basis serving to keep the management informed about the achievements of their system and could be extended for further business infrastructure management in the future.

A clear strength of the BSC is being an easily understood concept, which merges a set of measures contributing to the determined strategic goals under different perspectives.

The main weakness of the BSC is that it does not represent an elaborated, consistent and uniformly applicable system. Applying BSCs applied in other settings implies the risk, that not enough attention is paid to specific strategic goals and in succession to the companies' strategic position. Every BSC is per definition unique to the company involved.

Next, not all goals can be translated into measurable objectives in quantitative terms. Literature suggests, that in such cases, it is important to relate these attributes to other ones that can be quantified. This is not always possible, respectively does not in general uncover the level of achievement for the specific goal. Therefore, not all determined goals could be incorporated in the BSC. For example, the achievement of various quality related goals were too difficult to quantify on a regular basis. Also, the goal of attaining a better corporate image through the e-Business deployment seemed too difficult to assess within the BSC. The assessment of missing criteria will nevertheless be undertaken, outside of the BSC approach, leading to the application of more than one management tool. We have found little research on consolidating the results from different management tools into a consolidated view apart from [1]. It seems that the 10 year old BSC concept is still not fully developed.

Due to the fact, that we have undertaken an ex post analysis, the development of strategic programs based on the selected measures for achieving the strategic goals was not included. The company will define those strategic programs in order to attain the targets for the next strategic planning cycle.

Customer Participation in E-news Service --- Case Study in Taiwan

Phoebus Lee*

Dept. of Management Science

National Chiao Tung Univ.

Taiwan

phoebuslee.ms91g@nctu.edu.tw

Abstract

Asymmetric information in service sector can be found in PZB model and can be manipulated by service provider and customer. Participation as well as involvement in service is well studied in western literature but less reported in the field of e-news services in emerging economic. The case study via OLS and ANOVA about one of Taiwan's major e-news service provider implies the strong biased political involvement in service participation and provides information structure of the economical-political e-business model in Newly Industry Country. What we need is a rational order beyond the irrational game.

Key Words: Information asymmetric, Participation, Service, E-news, Involvement.

* **Correspondece:** Please send all correspondences to Mr. Phoebus Lee, National Chiao Tung Univ., Dept. of Management Science. No.1001, University Road, Shin Ju, Taiwan 300. E-mail: phoebuslee.ms91g@nctu.edu.tw

1. Introduction

Internet is widespread in recent years. Service sector is booming all around the world. Customer participation in the production of goods and services appears to be growing. The marketing literature has largely focused on economic implications of this trend and has not addressed customers' potential psychological responses to participation. The quality of products and services has great impact as well as attractiveness on customer participation. Information economic is well developed by the information service provider and government agencies. On the other hand Porter argues that there is no e-strategy and Greenspan advocates which internet is just one of new technology in 21 century.

The ill-defined empowerment toward customer participation through the service process can be found in the industry that is monopoly or oligopoly. The consumer surplus can be identified through the obstacles of non-tariff barriers. Deregulation in newspaper and development on ICT sector are the trends in the Taiwan. Several media groups extend their services channel toward E-news services beyond the biased free information environment.

2. Literature review

Solveig Wikstrom (1996) indicated buyer-seller interaction in industrial market is a widely applied work logic, which has been thoroughly researched both empirically and theoretically. It is applied in service industry either. Customer perceives services delivered by the provider when he/she participates in the service process. Leone and Bendapudi (2003) exam the effects of participation on customer satisfaction and find when given an identical outcome, customer satisfaction with a firm differs depending on whether a customer participate in production. This study further finds that providing customers a choice in whether to participate mitigate the self-serving bias the outcome is worse then expected.

Stiglitz (2001) advices information economic has changed the paradigm in economic of the market system. Asymmetric information can be eliminated by individual's involvement and participate in the transaction process as well as in the wide power distance political-economic system.

3. Method

The data were randomly collected from the e-news group named "Public Forum" in one of private media conglomerate named "A". In order to evaluate the data effectively and observe if there are manipulations, OLS regression (Table 1) is used on this study and ANOVA (Table 2) is used to detect if there are biased information that may result error implementations. We check the constant variance, independence, and normal populations of three inference assumptions (Figure 2) and find fitted in the model. We conclude that the OLS regression and ANOVA are proper methods for this case study research.

Table 1

Regression Result

Predictor	Coef.	StDev	t-ratio	P
Constant	0.101	1.248	0.08	.936
CustClik	0.055064	0.00202	27.27	.000

s = 7.082 R-sq = 95.4% R-sq(adj) = 95.3%

Table 2

Analysis of Variance

	DF	SS	MS	F	p
Reg.	1	37295	37295	743	.000
Error	36	2806	50		
Total	37	39101			

4. Result

Higher percentage R** were found in our model. We can find a linear relationship between customer click and participation (Figure 1). Outliers were founded in various forms. Some biased information vary from distribution of the samples are political related data.

Figure 1

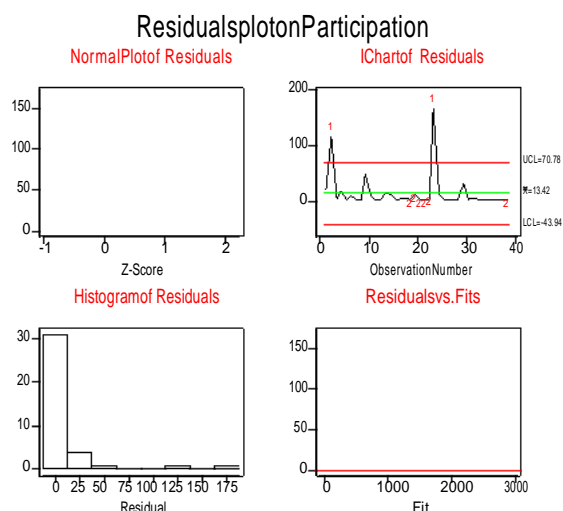

Figure 2

5. Discussion

Based on the analysis of ANOVA we find biased information from the participants who are political preference. Following the deregulation of the media and liberalization of political restriction, the relatively low entry barrier e-news group still confronts the interesting in political environment with biased data.

Abstract

Intensified competition, splintered mass market, shortened product life cycles, and advanced technology and automation let companies to increase the IT investment to meet the changes. Although IT investment increased, IS did not show the visible outcome. One of the major interests of IS managers is how to demonstrate the business value of the firm's investment in information technology.

This paper proposes the revised model of Nelson & Coopridge[13] that adds communication as an antecedent of regarding shared knowledge between IS and line groups. Knowledge can be shared through mutual trust, mutual influence and communication between these two groups. The revised model including communication is tested empirically using LISREL.

The results show that shared knowledge has an effect on IS performance mediating with mutual trust, mutual influence and communication. Thus, IS managers should develop mutual trust, mutual influence and communication between these groups to achieve more shared knowledge, which proceeds higher IS performance.

1. Introduction

Intensified competition, splintered mass market, shortened product life cycles, and advanced technology and automation increase the requirement of inter-organizational and intra-organizational mutual relationship. These strategic complexities of business and diverse requirement are increasing the importance of information systems and expanding the investment for IT[22].

However, despite the rising investment on information technology, the performance from IS expenditure resulted in no measurable impact. The facing issue of IS managers has become the demonstration the business value of the firm's investment in information technology. Boynton, Jacobs and Zmud[4] said that the primary means to link IT consistently with a firm's daily core business processes is to distribute IT management responsibilities to line managers. In other words, the close relationship between IS organization and line organization is crucial for meeting the organization's particular needs. Even though IS organization may have differentiated technical knowledge, the incorporation from line organization is essential to meet the organization's particular needs. Therefore, IS architecture should be developed according

to each organization's specific requirements [4] [9] [17]. This means the IS managers are facing the pressure of satisfying the requirements of line managers. Many research studies have tried to investigate how IS organizations can understand the requirements of line organization. Churchman & Schaintblatt[6] suggested that the shared knowledge can remove the barriers of communication between IS and line organization. Henderson[10] argued that building partnership between two organizations is critical to resolve the problems, and that this partnership can be developed and maintained through inter-organizational working relationships.

Previous studies simply defined the factors employed to improve the relationship between IS and line organization. On the other hand, Nelson and Coopride[13] proposed and empirically validated that shared knowledge is a key factor in influencing IS performance and building the relationship of mutual trust, influence and shared knowledge. The results show that shared knowledge mediates the relationship between IS performance and trust and influence, and that increasing levels of shared knowledge between IS and line groups contribute to increased IS performance. However, their model overlooked the importance of inter-group communication, even though they stressed it as an antecedent of mutual trust and influence [13]. This paper extends the research model of Nelson & Coopride by adding inter-group communication as an antecedent of mutual trust and influence and tests the modified model empirically.

2. Literature Review

2.1 IT investment and IS performance

IT investment over the last 20 years reaches billions of dollars. While the necessity and substantiality of IT investments have been recognized, the effect of investment on performance has been negative [12].

The Byrd & Marshall's study[5], which used structural equation analysis to empirically test a theoretical model, shows that IT investment does not directly influence organizational performance. This study proposes, instead, that the organizational factors such as relationship improvement between organizational employees and improvement of organizational structure and process should be followed. Kim's study, which classifies the relationship of IT-investment and IS performance into high-medium-low level according to the amount of organization's information requirements, also shows a negative correlation.

However, these two studies only suggest a future direction without specific solutions by solely examining the relationships on the IT investment-organizational performance relationship. Mukhopadhyay et al.'s research[12] provides the solutions defined the IT investment-organizational performance relationship in EDI environment. They suggest that the improvement of communication should proceed to increase IS performance resulting from IT investment. Later study confirms that an organization's communication is a major factor for competitive advantage[20].

2.2 Factors influencing IS performance

Many studies suggest that a good relationship between line and IS group has a positive influence on IS performance. Henderson[10] provides a descriptive model to build partnerships between line and IS managers. According to this model, key determinants of partnerships include shared knowledge, organizational linkage, mutual benefits and commitment. In a study by Aulakh and others, trust is examined as a key contributor for improving the inter-organizational relationship and organizational performance, the relational norms and informal monitoring mechanism are considered ex ante factors for building interorganizational trust and improving marketing partnership. This research proposes

that shared knowledge is an antecedent for organizational relationship improvement, and that interorganizational trust and influence are antecedents for shared knowledge.

2.3 Communication

Previous research confirms that organizational performance has a close relationship with interorganizational relationship improvement, which has major impacts on interorganizational communication. Roger & Allbritton[18] emphasizes the importance of interorganizational communication by demonstrating that facilitated communication due to the advent of such new technology as E-mail increases flexibility and organizational control. Nelson & Coopride[13] describes interorganizational communication as a crucial factor for building interorganizational mutual trust and influence that should precede shared knowledge.

3. Research Design

3.1 Research model

A major task facing managers of information systems organizations is to develop information systems based on effective relationship between IS and line groups. Figure 1 presents the research model of shared knowledge for increasing organizational performance. In addition, this model extends from Nelson's model by inserting the interorganizational communication as antecedents of

mutual trust and mutual influence.

3.2 Research Hypothesis

3.2.1 Communication, mutual trust and influence, and shared knowledge

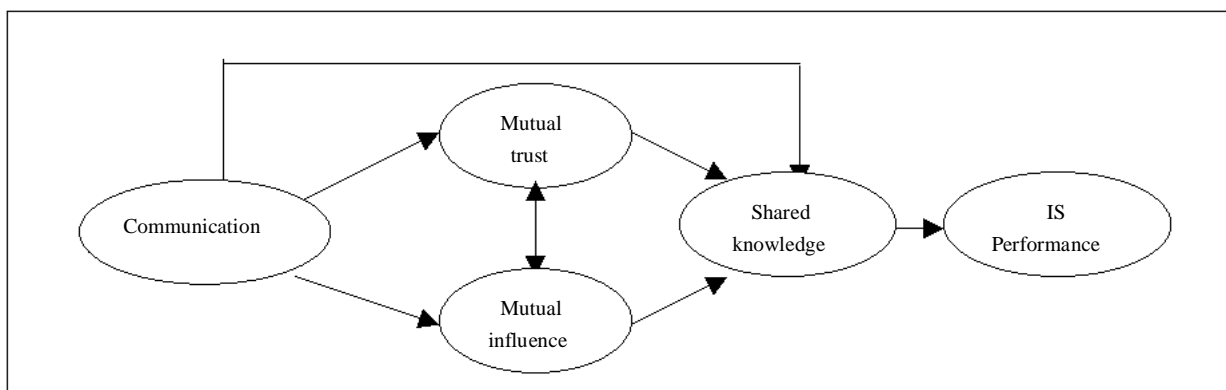

Communication is crucial not only to shared knowledge, but to the establishment of mutual trust and influence between IS and line groups [7]. Also, communication serves to supplement interorganizational shared knowledge, but not to directly influence IS performance[3].

The shared goal and frequent interaction can help build mutual trust, while the frequent communications can lead to mutual influence[19]. In other words, both mutual trust and mutual influence are affected by interorganizational communication, while they themselves somewhat influence each other [13]. Shared knowledge is developed from deeper communication using organizational information systems [20]. Therefore, communication positively influences mutual trust and influence between IS and line organization, and shared knowledge.

H1: Better communication leads to increased levels of mutual trust between IS and line groups.

H2: Better communication leads to increased levels of mutual influence between IS and line groups.

H3: Better communication leads to increased levels of shared knowledge between IS and line

<Figure 0> Research Model>

groups.

H4: Mutual trust and influence between IS and groups has positive correlation.

3.2.2 Mutual trust and shared knowledge

Mutual trust can be defined as shared expectations or interorganizational promises between IS and line groups [1] [8]. Repeated communications develop mutual trust which subsequently leads to sharing of shared knowledge. Mutual understanding gained by interorganizational mutual trust enables the establishment of shared knowledge. Therefore, interorganizational mutual trust has a positive effect on shared knowledge across IS and line groups.

H5: Higher level of mutual trust between IS and line groups leads to increased levels of shared knowledge between IS and line groups.

3.2.3 Mutual influence and shared knowledge

Understanding common goals and forming close working relationship generate mutual influence. Mutual influence is defined as the ability of organizations affecting key policies and decisions of each other [13]. Mutual influence is critical for mutual interests between organizations. Interorganizational mutual influence develops mutual understanding and unity between organizations in different environments by affecting organizational key policies and decisions, and such mutual is pivotal to shared knowledge. Shared knowledge is related to mutual influence derived from frequent and in-depth decision making processes beyond simple information exchange. Therefore, mutual influence between groups will have a positive effect on shared knowledge between IS and line groups.

H6 : Higher level of mutual influence between IS and line groups leads to increased levels of shared knowledge between IS and line groups.

3.2.4 Shared knowledge and IS performance

Communication has an important role for management [16]. But, communication itself cannot fully explain the organizational performance. Sharing knowledge, different from managerial communication in nature, moves beyond the level of simple information sharing. Shared knowledge is built with common language and symbol across groups, and has a positive effect on the level of organizational performance. Shared knowledge is derived from close communication between IS and line groups, and leads to positive organizational performance. For, without sufficient shared knowledge between IS and line groups, IS organization cannot define the business requirements of line groups. Therefore, insufficient share knowledge is negatively related to IS performance [11]. Conversely, shared knowledge between groups will lead to positive IS performance.

H7: Higher levels of shared knowledge between IS and line groups leads to increased levels of IS performance.

4. Methodology

4.1 Respondents

Respondents of the survey research are IS managers from domestic companies registered in public stock markets. They are chosen because of their responsibility for IS performance and their overall understanding and decision-making authority. For internal validity, the broad range of organizations and industry types are considered. In data collection, 200 companies are chosen and distributed for this study according to the proportion of industry. Surveys are provided to the selected companies that agree to participate. Complete surveys were received from a total of 94 peoples for a 47% of respondents rate. <Table 1> shows the industry distribution of firms in the sample.

<Table 1> Industry distribution of participants

Industry	Total	Received
Food & Beverage	13(6.5%)	2(2.3%)
Textile & Cloths	19(9.5%)	10(10.1%)
Chemical & Pharmacy	33(16.5%)	22(22.1%)
Mechanical, Auto, Electronics	67(33.5%)	24(26.2%)
Wood & Paper	8(4%)	4(4.5%)
Construction	13(6.5%)	12(13.1%)
Transportation & Telecommunication	4(2%)	2(2.3%)
Finance & Insurance	30(15%)	14(14.9%)
Others	13(6.5%)	4(4.5%)
Total	200(100%)	94(47%)

4.2 Reliability

Reliability test for each of the constructs measured in the study are performed before testing hypothesis. Reliability assesses the internal consistency of scale items. Cronbach's alphas are used to assess the internal consistency of the scales. As shown in Table 3, the reliability coefficients ranged from 0.65 to 0.84, which is significantly higher than the acceptable level of 0.6 [15]. We therefore conclude that the measures are reliable.

5. Results

The analysis of the model in Figure 1 is performed with a structural equation modeling technique using LISREL. LISREL is an appropriate method for specifying, estimating, and testing hypothesized correlations among a set of substantively meaningful variables. It can evaluate the fitness of the research model as well as the causal relationship among measurement constructs. Data analysis consists of two phases. The first phase is to check the fitness of the research model; the second phase is to verify whether hypotheses are supported in data set.

<Table 2> Reliability Estimates

Construct	Scales	Cronbach's alpha
Communication	6	0.6550
Mutual Trust	4	0.7301
Mutual Influence	4	0.7750
Shared Knowledge	6	0.7470
IS Performance	6	0.8439

While multiple regression, factor analysis or multivariate analysis techniques merely explain the relationship between dependent and independent variables, structural equation analysis technique can extend researcher's explainability and statistical efficiency by examining a set of related variables simultaneously. Therefore, this technique is appropriate in a case where dependent variables later become independent variables later. The correlational matrix for LISREL is presented as Table 4. Using this matrix, the fitness of the model is tested first.

<Table 3> Corelation among constructs

	Communication	Mutual trust	Mutual influence	Shared knowledge	IS performance
Communication	1.00				
Mutual trust	0.6923	1.0000			
Mutual influence	0.6417	0.4155	1.0000		
Shared knowledge	0.6659	0.7954	0.6501	1.0000	
IS performance	0.3071	0.2030	0.2472	0.7871	1.0000

5.1 Model Fitness

The proposed model should be evaluated to determine the fitness of the model. For evaluating the model fitness, the most typical index includes chi-square, GFI(Goodness on Fit Index), AGFI(Asjusted GFI :AGFI), RMSR(Root Mean Square Residual). For the null hypothesis to be true, the model should fit the data well and the probability value should exceed a standard value in the chi-square distribution(such as 0.05 or 0.01). Thus, in a model with good fitting model, the chi-square statistic will have a p-value of at least greater than 0.05 or ideally, above 0.01 [2]. The chi-square for this model with 10 degrees of freedom is significant (chi-square = 12.20, p = 0.067). GFI and AGFI are the next goodness-of-fit measures to be considered. The values for these indices should greater than 0.90 and 0.80 respectively [2]. Table 5 shows that the values of GFI and AGFI for the model are 0.95 and 0.84, which are over the recommended values.

<Table 4> Model fitness

Model fitness	value	DF: 10
χ^2	12.20(P=0.067)	
GFI	0.95	
AGFI	0.84	

5.2 Results and analysis

5.2.1 Communication, mutual trust and mutual influence, and shared knowledge

First 4 hypotheses are established to explain the relationship between communication and mutual trust and influence. The coefficient for the path from communication to mutual trust is 0.66(t=5.77) and has a positive correlation with the significance of 95%. Thus, H1 is directly supported, and this finding indicates that better communication leads to increased levels of mutual trust between IS and line groups.

The coefficient for the path from communication to mutual influence is 0.61(t=5.42) and has a positive correlation with the significance of 95%. Thus, H2 is directly supported, and this finding indicates that better communication leads to increased levels of mutual influence between IS and line groups.

The coefficient for the path from communication to shared knowledge is 0.209(t=1.98) and has a positive relationship with the significance of 95%. Thus, H3 is directly supported, and this finding indicates that better communication leads to increased levels of shared knowledge between IS and line groups.

H4 is established to examine the relationship between IS and line groups. The coefficient for the path from mutual trust to mutual influence is 0.19(t=1.44) and the coefficient for the path from mutual influence and mutual trust is 0.14(t=1.31). This value does not have a positive relationship with the significance of 95%. Thus, H4 is refused.

and line groups.

5.2.2 Mutual trust and shared knowledge

H5 is designed to examine the relationship between mutual trust and shared knowledge between IS and line groups. The coefficient for the path from mutual trust to shared knowledge is 0.31($t=2.02$) and has a positive relationship with the significance of 95%. Thus, H5 is directly supported, and this finding indicates that higher level of mutual trust between IS and line groups leads to increased levels of shared knowledge between IS and line groups.

5.2.3 Mutual influence and shared knowledge

H6 is designed to examine the relationship between mutual influence and shared knowledge between IS and line groups. The coefficient for the path from mutual trust to shared knowledge is 0.35($t=2.34$) and has a positive relationship with the significance of 95%. Thus, H6 is directly supported, and this finding indicates that higher level of mutual influence between IS and line groups leads to increased levels of shared knowledge between IS

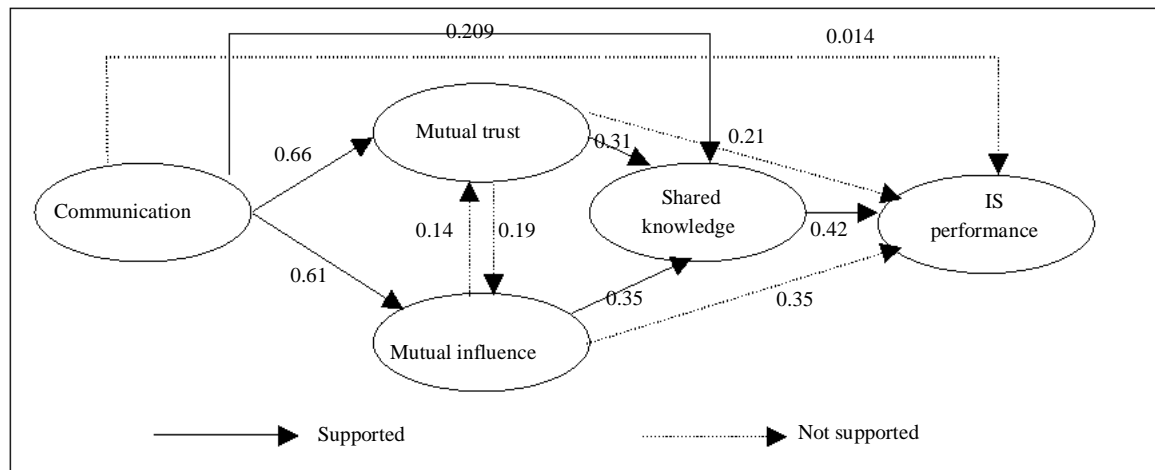

5.2.4 Shared knowledge and IS performance

H7 is examine the relationship between shared knowledge and IS performance. The coefficient for this path from shared knowledge to IS performance is 0.42($t=3.22$) and has a positive relationship with the significance of 95%. Thus, H7 is directly supported, and this finding indicates that higher level of shared knowledge between IS and line groups leads to increased levels of IS performance.

The coefficient for the path from communication to IS performance, the path from mutual trust to IS performance, and the path from mutual influence to IS performance is 0.012($t=0.12$), 0.21($t=0.23$), -0.055(-0.422) respectively. This finding indicates that communication, mutual trust and mutual influence do not have a direct effect on IS performance, although they affect IS performance indirectly through shared knowledge. Above results are summarized in table 6 and figure 2.

<Table 5> Summary of Results

Hypothesis	Path		path coefficient	T value	Hypothesis Support
	From	To			
1	communication	mutual trust	0.66	5.77	support
2	communication	mutual inf.	0.61	5.42	support
3	communication	shred know.	0.21	1.98	support
4_1	mutual trust	mutual inf.	0.19	1.44	Not support
4_2	mutual inf.	mutual trust	0.14	1.31	Not support
5	mutual trust	shred know.	0.31	2.02	support
6	mutual inf.	shred know.	0.35	2.34	support
7	shared know.	IS performance	0.42	3.22	support

<Figure 2> Path Coefficient

6. Conclusion

Demonstrating the business value of information systems is a major issue facing managers of information systems because the performance of information systems is still low compared to increasing IS investment.

This model has implications for both researchers and managers. We propose that good relationship between IS and line organization increases IS performance through shared knowledge, which is affected by mutual trust and mutual influence. Our research model extended from Nelson & Coopride's model[13] by empirically testing the relationships among communication, mutual trust, mutual influence and shared knowledge between IS and line groups. In particular this study includes communication, which is an antecedent of both mutual trust and mutual influence. Communication was excluded in Nelson & Coopride's model even though their model suggested the importance of that variable. The results support our hypotheses in the following: First, good working communication leads to higher levels of interorganizational mutual trust, mutual influence and shared knowledge. Second, higher levels of mutual trust and mutual influence between IS and line groups increase

shared knowledge between two groups. Third, higher levels of shared knowledge between IS and line groups leads to better of IS performance. These results suggest that shared knowledge directly affect IS performance, while communication, mutual trust and mutual influence affect IS performance indirectly.

The findings in this study have contributed to the issue of whether IT investment can bring positive outcomes to Korean firms. Through repeated communications, IS and line groups have the opportunity to develop mutual trust and influence. This interaction generates shared information regarding business and IS opportunity. Still, the current study has several limitations that can be cleared by future studies. First, bias of the respondents is not fully excluded since only one person per firm has responded to the survey. Thus, future studies should include a more comprehensive stakeholders including employees of IS group and user groups. Second, IS performance is measured by the cognition of the respondents. However, the respondents are IS managers who are responsible for IS performance evaluation and strategic decision-making in overall IS processes. IS managers are producers rather than consumers. Thus, the subjectivity of the response can undermine the explanatory power, and the future research has to consider complementary measures for IS performance.

Third, sample size is not large enough for analysis with LISREL, even though this method proposes at least 50 as an absolute minimal value. Future research should examine a larger sample including at least above 200 firms, which is more recommendable range.

Abstract

Nowadays, e-commerce and its applicability are in controversy throughout the world. Firms in all sizes are facing with various barriers in adopting e-commerce. For case of small and medium sized enterprises (SMEs), there are much more obstacles than large companies have face with, therefore, the model that is fit and effective for SMEs may quite different from large enterprises' ones. This paper takes up case of Japanese distribution channels to illustrate the major impact of information technology on SMEs, finds out the role of e-commerce within SMEs distribution systems in Japanese economy, and then, points out some major barriers that prevent SMEs from entering into e-commerce. Finally, we propose an analytical framework for e-commerce penetration into SMEs as a guideline of future research in this area.

1. Introduction

Recent years have seen a dramatic increase in the role of information technology (IT) over every business activity and business process. Particularly, quick and efficient commercial transactions can be accomplished by exploiting the state-of-the-art internet-based IT, through evolutionary improvements of the present ways of trading in traditional markets and the multitude of internet-based online auctions in emergent electronic marketplaces. Many companies now are in enthusiasm to capitalize on new possibilities offered by IT development and enter the novel business activity, namely electronic commerce or e-commerce.

While the potential of e-commerce is quite clear and luring companies, however, the number of companies, especially small and medium sized enterprises (SMEs), which have gained actual benefit from business-to-consumer (B2C) marketplaces, is rather limited even in the new economy. Recent empirical surveys held by various governments or consulting organizations throughout the world pointed out a number of different reasons such as lack of e-commerce awareness and IT expertise in general,

poor business and IT infrastructure, lack of people with right skills, difficulty getting reliable advices and assistance, no clear business models for e-commerce, lack of finance resource for investment in people and technology, and lack of interest in business growth and development. The barriers that prevent SMEs from entering into e-commerce are also quite different from country to country. Whereas SMEs in the US are in fear of the cultural barriers, international trade barriers, interoperability with complementary companies, and so on, the most frequently considered barriers for SMEs in Japan are privacy and security. The difference among countries is clearly based on the distinctions of market, business characteristics, customer behavior, the limitation of payment system, and incomplete public key infrastructure. Above all, the reason may initiatively stem from the fact that e-commerce now predominantly focuses on the local market, not having a perspective open enough for the global market.

Observations of the real status of e-commerce in different countries, therefore, brought out a universal requirement of finding out the way to improve effectiveness of e-commerce marketing channel. Recently, five business models of e-commerce can be often used to represent various ways of matching trading parties and organizing commercial transactions. They are business-to-business (B2B), business-to-customer (B2C), customer-to-customer (C2C), business-to-government (B2G), and intra-business (organizational) e-commerce of large corporations. In order to do business via internet, a firm may use website, email, electronic data interchange (EDI), or other internet tools to gain a higher profit and other benefits. Earlier researches talked much about the potential of e-commerce and its general impact on business activities, but they did not mention to an effective model for SMEs. Because SMEs face much more obstacles than large companies do, the model that is fit and effective for SMEs may quite different from ones for large enterprises. This study, in order to construct a reasonable business model of e-commerce for SMEs, will focus on clarify the

characteristics of SMEs in new digitalized economy, referring to some cases in Japan.

2. Existing e-Commerce Distribution Channel Models

With two powerful tools that may help to increase the sales of companies, namely website and email, companies now can select internet as an alternative channel to provide directly products and services to either industrial customers or end-users. The new form of distribution channel through internet is considered as e-marketplace. The name of new distribution channel helps us clearly imagine the initiative activities in e-commerce that are not so different from transactions recurring in the conventional market.

From literature review, there are a number of categories of the so-called e-marketplace. [1] refers to the firm that operates an e-marketplace as the “intermediary”, which may be a market participant (i.e. buyer or seller), an independent third party or a multiform consortium. [9] further differentiates the market participant into a friendly participant (complementary to other participants), a hostile participant (competing against other participants), a single-buyer participant (buy from multi-sellers), or a single-seller participant (sell to multi-buyers). [3] classified e-marketplaces into three categories: the e-broker (cybermediary) model (e.g. amazon.co.jp), the manufacturer model (e.g. Toshiba), and the auction model (e.g. yahoo.co.jp). [4] also looked into the success factors of an e-marketplace as strategic factors, technical factors, and functional factors. Strategies include first-to-market, brand establishment, customer focus, targeted marketing, outsourcing, and development of a customer or user community. Technical issues encompass quality-of-service items such as response time, throughput, and reliability. Functional factors include facilitation of product customization, support for negotiation, and access to a similar interest user community.

Getting right back to basics, e-commerce is another channel to market or sell to customers and consumers. Websites and emails are the two main e-commerce applications that are used together to promote and advance the selling process to closure. Grasping the knowledge and know-how of applying these powerful tools will help SMEs benefit from e-commerce, and at the same time can avoid the dark side of digitalized era.

There are several ways that websites can be used as a new sales channel for a business. They are website sales models, sales support websites, e-catalogue and e-marketplace. Website sales model is the part played by a website in the sales process, which depends on the product and service offering, and its value. Many ingenious ways have been developed by businesses to create unique offerings from a website. Nissen.co.jp is one of these sites.

Sales support web sites are developed with the purpose of providing an on-line profile of the business, its product and service offerings. These sites are valuable marketing communication channels, which assist prospects and

customers in researching and evaluating competitive offerings. A typical example of this kind of website is www.kakaku.co.jp. The objectives of these web sites are, to motivate the prospect to contact the business, by either completing an on-line enquiry form, sending an email, or making a telephone call; maintain and develop customer loyalty by presenting new offerings; and increase awareness of the business and provide an easily accessible corporate information resource for prospects, customers, journalists, and shareholders.

The most common approach to selling on-line is to use an e-catalogue, which replicates the main features of the familiar paper catalogue. Offerings are grouped and categorized, with a powerful on-line web site searching facility to assist the visitor to quickly find what they need. Photographs and offering descriptions, with multiple layers of detail available through links to other web pages, are orchestrated to help the visitor quickly make an evaluation and a decision to purchase. An example of this type includes www.amazon.co.jp. Many of the traditional skills of successful retail can and should be mapped to web site.

Other popular ways of buying and selling on-line are e-marketplaces, which bring buyers and sellers together with various rules of engagement. Auction websites, exchanges, sales training websites are typical examples of such e-marketplaces.

Auction websites enable personal traders and businesses of all sizes, to negotiate prices for purchasing and/or selling direct materials, capital, or services. An example of this website is Yahoo! Japan Auctions that is considered as the most profitable internet business in Japan today.

Exchanges offer a similar matching of buyers to sellers, except, usually, the price is predefined by at least one of the parties. Price-line has successfully applied this concept for consumers who want to buy airline tickets, hotels rooms, and car hire. Here, the consumer enters the price they want to pay and other parameters, such as dates, etc., to define their requirements, and if a match is found, the purchase is immediately made, as credit card details are taken upfront. www.castour.co.jp is a typical example.

Sales training web sites can be used to inform sales teams and staffs in remote offices of new procedures, campaigns, products, services, and corporate changes. Information can be updated immediately and accessed globally by all employees at convenient times.

Beside website, another powerful application - emails can be used for generating traffics to websites and supporting the sales process. Firstly, newsletters, special offers and insider information can be sent out cheaply by email to customers and prospects, to maintain awareness or to promote a specific line. The content of each email can be personalized for each individual, using business database records to increase relevancy and produce a higher click-through rate to the web site. Secondly, periodic emails can also be sent out to remind customers of an order action that they need to make, such as renewing a subscription, making a check-up, or even considering what

to buy for a partner's birthday next week, with discounts offered for customer loyalty. Besides, product, literature, plans, reports, proofs, quotations, and orders can all be sent as email attachments, to speed up the sales process. In addition, retailers, suppliers, and sales teams can email feedback on new marketing promotions, techniques, or point-of-sales methods, so that appropriate changes can be made to maximize the effectiveness of a campaign.

Enterprises may change their business model into one of above mentioned models of e-commerce distribution channels, based on the following four factors: (1) characteristics of the firm; (2) competitiveness and management strategies of the firm; (3) influences of internal or external parties on the adoption decision process; and (4) characteristics of new model adopted. For SMEs, the adoption of e-commerce model may depend on the fifth one, considered as the most important factor, the innovative attitude and knowledge about IT of the CEO.

3. General Status of SMEs in Japan

As is the case with other countries in the globe, SMEs had played an increasing role in development of Japanese modern economy. SMEs, which are defined in Japan as having less than 300 employees or invested capital of less than 100 million yen for the most cases, account for over 99% of all the companies in Japan and employ 77% of the nation's labor force.

Besides, Japanese SMEs are well-known for their creativity as having come up with many of the ingenious innovations around us. Toothpaste, vacuum packed boil-in-the-pouch food, the vending machine, the bread-making machine, capsule hotels, karaoke, and so forth are typical innovations that proved the plentiful creativeness of SMEs in Japan. With these major participations, SMEs are in the high consideration in every aspect of economic studies including e-commerce as a new motivation raising new economy.

With the implicit potential of creativity and support of the government, Japanese SMEs may be more encouraged to adopt e-commerce than SMEs in other advanced technology countries. However, one of the initiative factors that impulse SMEs into engaging e-commerce is the way to reach customers' needs and wants, and serve them in high level of satisfaction. This factor is not familiar with SMEs, especially in new digitalized economy. Next parts will discover the distinctive characteristics of Japanese distribution systems in order to clarify the way that SMEs use to adopt e-commerce in Japan. At the same time, the paper also answers the question of "are they successful in this new type of retailing channel or not?"

4. Characteristics of Japanese Distribution Channel

Japan is a highly attractive market. However, its multi-layered distribution system is quite complex and costly. That results in a supply chain in which most products change hands at least two or three times before

reaching the retail outlet, consumer prices rise up and productivity of retail sector is quite low. One of the reasons of this complicated distribution system in Japan stems from Large-Scale Retail Stores Act. The Act imposes social/environmental criteria to limit the entry of large-scale retailers. The Act bears most directly on the density of retail stores in Japan. It is the initiative reason why Japan has far fewer department stores and general merchandise super stores per person than the US, when at the same time it has much more other retailing stores per person. The Large Scale Retail Store Law was the latest in a succession of Japanese laws over the last sixty-five years that imposed bureaucratic obstacles to the establishment of large stores. The Large-Scale Retail Stores Act, whereas lowering the efficiency of department stores, general retail stores, specialty shopping centers and other large-scale stores, and then the efficiency of Japanese whole retailing sector, plays an important role to the thriving of SMEs.

Another potential explanation could be made by the so-called "keiretsu" as one of the most distinguished characteristics of Japanese distribution system. There are two distinctive types of industrial organization seem to have evolved in the world economy. The major difference between them lies in whether the manufacturer or retailer has the upper hand in the distribution channel and bears the major risk.

4.1 Retailer-Controlled Channels

This first type of distribution channel is very popular in the United States and European countries. The retailer determines the specification of the products they wish to sell, and purchase them from the lowest bidder among the manufacturers. The retailers also determine the various after-sale services that accompany their products.

However, the retailer cannot directly control the quality of products they purchases. Without any control, quality will eventually deteriorate and this will hurt retailers. In order to check for quality, the retailers must institute costly inspection mechanisms. They may also be able to persuade their suppliers to invest in expensive machines, which produce more reliable products, by incurring part of the investment cost. Such addition expenses incurred so as to maintain quality are not present in the case of vertical integration.

In this mode of distribution, the major risks are born by the retailers. Well-diversified large retail companies, often equipped with better standings in financial markets than most manufacturers, are capable of absorbing the risk of occasional over- or under- production. It is this capacity to absorb risk that allows the retailers to buy their supplies at lower prices than otherwise, since they implicitly provides insurance for the manufacturers.

4.2 Manufacturer-Controlled Channels

The second type is the distribution channel in which the manufacturer has the upper hand over the retailer. Japan represents for this type of distribution channel with the well-known "keiretsu". Keiretsu refers to a uniquely

Japanese form of corporate organization. A keiretsu is a grouping or family of affiliated companies that form a tight-knit alliance to work toward each other's mutual success. The keiretsu system is also based on an intimate partnership between government and businesses. It can best be understood as the intricate web of relationships that links banks, manufacturers, suppliers, and distributors with the Japanese government.

Keiretsu operate globally and are integrated both vertically and horizontally. They are organized around their own trading companies and banks. Each major keiretsu is capable of controlling nearly every step of the supply chain ranging over a variety of industrial, resource and service sectors. Horizontal keiretsu have been headed by major Japanese banks and include the "Big Five" - Mitsui Sumitomo, Tokyo Mitsubishi, Fuyo, Sanwa, and Dai-Ichi Kangyo Bank Groups. Vertical keiretsu are industrial groups connecting manufacturers and part suppliers or manufacturers, wholesalers and retailers. These vertical keiretsu include car and electronics producers (Toyota, Nissan, Honda, Matsushita, Hitachi, Toshiba, Sony) and their "captive" subcontractors. Distribution keiretsu, a subgroup of vertical keiretsu, control much of Japanese retailing, determining what products will appear in stores and showrooms and at what price.

While some think keiretsu are a threat to trade, others see them as a model for change. Features common to most keiretsu include "main bank", stable shareholding, and seconded directors. Some keiretsu concepts, such as "general trading company", have no American parallels. The keiretsu system is one of the profound differences between Japanese and US business structures.

In reality, of course, both types of industrial organizations coexist in the same economy. Changes in product standardization and reliability may instead cause the distribution sector to alternate between the two models.

In Japan, such complicated distribution system has great impacts on e-commerce adopting process, especially for case of SMEs. Whereas benefit that keiretsu bring to SMEs such as overcoming the difficulties of capital shortages, protecting domestic manufacturers against foreign competitors, and easing customer relationship management (CRM), its affect on e-commerce engaging process is not so clear. Maybe it becomes a tough barrier that prevents SMEs from engaging e-commerce. Maybe it will strengthen advantages of enterprises including SMEs in the new competitive environment. The following part will answer this debate by drawing the real status of SMEs e-commerce distribution channel in Japan with its

distinctive characteristics.

5. e-Commerce as a Competitive Distribution Channel for Japanese SMEs

E-commerce has been appearing in Japanese market for not so long time (since 1995, lag behind US for 5 years), but is showing a great potential prospect. This type of retail will see an up-front increase in the whole market including books, music, computers and auxiliaries, car, apparel, housing service, tourism, and so on. In spite of the slight increasing in sales volume, Japan's e-commerce showed an unbelievably increasing in term of growth rate (B2C increased by 80% and business-to-business (B2B) increased by 34% in comparison with previous year and e-commerce in general increased three times as the number of 1999), which led Japan to the region's e-commerce leader (see Table 1 below).

By the way, the characteristics of Japanese e-commerce is that the major companies who enter e-commerce market are mostly huge or big companies which have large capital and enormous potential human resources to be mobilized for both delivery and information technology. There may thus be a particularly strong rationale for governments to address the problems that impede SMEs from adopting and using electronic commerce. And this is also the reason why the adoption and use of e-commerce raise special issues for SMEs.

In Japan, due to the rapid development of technology advance, the diffusion of information and communication technology (ICT), and the custom of buying via telephone or TV, there exists a high motivation enforcing a great number of SMEs to use internet. However, because of their small size, SMEs have less scope to manage the fixed costs and benefits of investing in new technologies. SMEs are also less able to defend themselves against security and liability problems. On the other hand, the adoption of e-commerce prevails in areas such as access to new markets and gathering and diffusing information on an international scale. While almost Japanese SMEs (79.1%) adopt internet and they well know that having a web presence improves business activities, therefore, the majority still uses it only for basic functions such as advertising, exchanging operational data with suppliers, rather than engaging on the practical e-commerce, especially B2C. Among the companies engaging in e-commerce, 77.06% deal with other companies (B2B) and only 38.13% have a contact with final consumers (B2C) as shown in Figure 1. Therefore, it is said that today Japanese SMEs are in the first stage of e-commerce.

Table 1
e-commerce market situation in Japan

Descriptions	1998	1999	2000	2001	2002

Figure 1
e-commerce status of SMEs in Japan
 (Source: *Census of Commerce*, 2001)

Unlike small firms in the US, which tend to operate independently, Japanese small firms engage in critical business alliances. There are four different types of business alliances in Japan: (1) the keiretsu, a network of large and small companies; (2) sanchi, a cluster of small firms in a related field of business; (3) kyodokumiai, cooperatives of small businesses; and (4) shita-uke, a subcontracting arrangement where many small firms rely on one large company. The purpose of these alliances is to provide support and mutual gain for all involved, and laws are written in their favor. For instance, the cooperatives are exempted from anti-trust legislation and a network of legal and financial assistance supports members (see [2]).

In the subcontracting system, the main fields of outsourcing by large companies include IT; equipment, management and security; general affairs; logistics; receptionist and secretarial services; manufacturing; education of employees; design and product planning; and research and marketing.

To adopt e-commerce as a new high-tech marketplace these business alliances still facilitate SMEs to acquire various knowledge of new technologies and unexperienced business activities. Many kinds of local e-commerce business communities, such as procurement, mall, brokerage and agent type communities have been supported by the government and other organizations. Policies targeting SMEs in Japan have reduced the gap between SMEs and large enterprises by providing immediate support for the self-help efforts.

A mall type e-commerce business community such as Rakuten, which is called a cyber mall, is considered as a typical B2C in Japanese SMEs. The cyber mall is a representation of a marketplace, a department store, or the like on the internet. Visiting virtual mall, consumers can enjoy online shopping, choosing what they want in

webpages with little time. Presenting as a collection of shops, a virtual mall has various advantages including low development costs, ability of grasping customers from both domestic and foreign countries, and being more interesting than conventional market. At the same time, however, it will become increasingly difficult for consumers to find the products and services they want in giant mall. As a result, a system will be necessary to help them find the items that meet their specific needs. For SMEs who are in lack of capital and qualified human resources, e-business communities become a good choice that bring various expected benefits.

It is obviously that although the potential of e-commerce is quite persuasive, however, number of companies, especially SMEs, which have engaged in e-marketplaces, is rather limited in Japan. Lack of access to bank loans and venture capital, shortage of skilled workers, and low level of business and technology skills are cited as reasons for the difficulties in adopting e-commerce of SMEs. Among the reasons, the most rise-up issue is the trustworthiness of on-line activities. On-line transactions and exchange relationships through internet are not only characterized by uncertainty, but also by anonymity, lack of explicit control, and potential opportunism, which makes reduction in risk and promotion of trust crucial elements of e-commerce, particularly for B2C. On-line transactions often do not involve simultaneous exchange of goods and money. Spatial and temporal separation between exchange partners is common. Consumers are required to disclose sensitive personal information (such as credit card number), although on-line vendors are often located far from consumers, even in different countries and show only a limited history of prior on-line transactions on their websites. Those factors affect opportunities and barriers to

enter into e-commerce and prevent SMEs from developing e-commerce as a strategic distribution channel.

Another difficulty that Japanese SMEs usually face is a financial issue. Today, the trend that SMEs can join and introduce themselves or even sell their products or services in a share website becomes popular in Japan. The famous website of such marketplace where SMEs can exchange their information are kakaku.com, rakuten.com, and so forth. However, for small Japan-based merchants hoping to enter into the e-commerce marketplace, the options are limited, expensive, and generally unprofitable. In the US, small merchants can open an online store for as little as \$25 monthly. In Japan, the cost skyrockets to around \$500 monthly at popular shopping malls like Rakuten, and then goes up to an extremely high level (\$50,000 or more yearly) to run a customized storefront. To make matters worse, small Japanese merchants typically operate on bare-bone margins. This makes them instantly gobbled up by website development or hosting fees and the large amount of per-transaction commissions Japanese e-commerce providers and credit card companies charge.

Please follow the formatting guidelines carefully. Papers should be prepared in conformity with this instruction sheet. If you have any questions, please contact with the organizer of ICEB2003.

6. Conclusion

As a new distribution channel with a great number of prospects, e-commerce may represent a considerable share of total economic activity and improve the quality of distribution system in Japan in the near future. SMEs now cannot further ignore the potential prospects that

e-commerce may bring anymore. However, engaging e-commerce is not an easy work, especially for SMEs, because of the existing of numerous barriers. Considering carefully determinants of its strategic use such as communication requirements, intensity of competition, support and incentives may help SMEs select the right business model to perform.

As mentioned above, e-commerce in Japan now is just in the first stage for every type of enterprises, including SMEs. Although almost SMEs are using internet, and Japanese government attaches importance to upgrading ICT infrastructure as well as facilitating payment systems, just a few small enterprises do have experiences with e-commerce. They also do not gain much benefit from e-commerce at the same time. However, whereas other distribution channels face with the stagnant demand, e-commerce is still being one of the most effective distribution channels of Japanese enterprises these days with the highest growth rate.

To intensify effectiveness of e-marketplace for SMEs, this paper suggests integration of some possible e-commerce models that use website and email as practical e-commerce tools in tandem with finding experiences of Japanese SMEs. By engaging in business alliances, Japanese SMEs find a novel way that facilitates e-business. Well-established traditional alliances help SMEs overcome a number of barriers such as lack of investment capital and qualified human resources, their lower known reputation, and/or lack of well-known brands, as well as help SMEs set up effective customer relationships even while they do not learn well about purchasing behavior of the new type of customers.

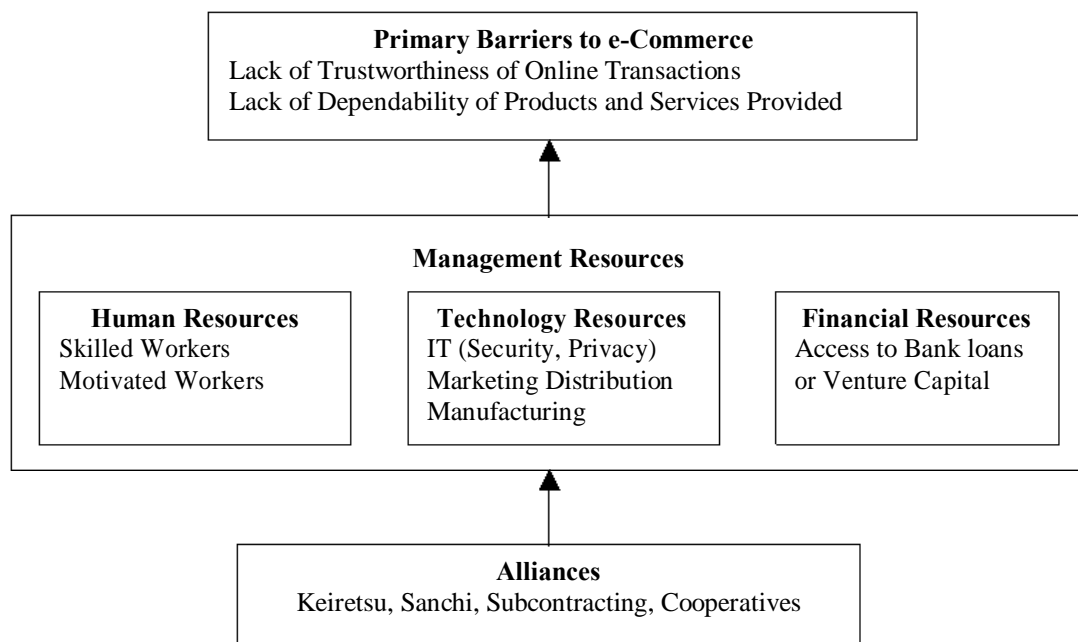

Figure 2
Analytical framework for e-commerce penetration into SMEs

As we know, new start-ups in electronic retailing that are disadvantaged by their lack of an established reputation can reduce consumers' perceived risk of purchase by carrying only well known brands. Consumers derive utility from the shopping experience and are more likely to shop on-line for products/services that are low in purchase risks. They are also more likely to shop on-line for products with well-known brands than lesser-known ones. However, they are less likely to shop on-line from lesser-known retailers who carry well-known brands, than from reputable retailers, even if the latter carry lesser-known brands. Thus, forming new business alliances will take positive effect for SMEs. Selling via a well-known website may help SMEs increase their sale and profit. These considerations lead to a research framework for analyzing e-commerce business models by SMEs, as shown in Figure 2.

In this paper we could not look into the effectiveness of business alliances to e-commerce, but are bounded in pointing out a new model of e-business that may be an effective way to accelerate SMEs performance. From this knowledge of e-marketplace and the practical performance within Japanese SMEs, the further research may explore potential productivity of e-commerce, and then design an effective e-commerce model for SMEs that is now taking notice of SMEs themselves and government of every country.

Abstract

The widespread implementation of supply chain management induced company to move beyond the national boarder and enticed the global competition in business. It has been proven that the supply chain management enhances the improvement in terms of cost reduction and other competitiveness. Applying supply chain management on overall organizations, companies generally considered themselves successful in managing their supply chains. However, while they have achieved the improvement in organizational performance, they have not reached the magnitude of improvements or the desired results ascribed to supply chain management [12,38,39]. Supply chain concerns and problems were first studied in the year 2002. The results showed that the most concerned items were Supply Chain Coherence such as lack of cooperation among supply chain members, Information Capability such as lack of sophisticated information system, and Geographical Proximity such as customer and supplier geographical distances. All of these concerns, related to some basic infrastructures of the company, the supply chain knowledge and operational skill before implementation [38,39,41], affected the effectiveness of supply chain practices and performances.

In this research, we study the infrastructures that enhance the success of supply chain implementation, which influence the supply chain and organization performance. In this work, the author adopts 3 categories of infrastructure as the critical success factors of supply chain implementation. Man is defined as people's skills and education. Machines or tools are defined as supporting items for instance software and tools. Management refers to the supporting factors that drive the man or employee to work according to the strategies. The EQS is used to analyze the data collection. Total 114 data were completed and the result shows the significant related of operational infrastructures and success of supply chain management

1. Introduction

Supply chain management addresses the fundamental business of supplying to meet demand in a complex and uncertain world. Supply chain management emerged in the early 1980s due to the rapidly changing and business competition environments in various industries. In order to improve the overall performance towards the ultimate consumer in the marketplace, supply chain management is a consequence of the cooperation between and across

companies' business activities in marketing channels. The significance of supply chain management has been substantial importance since the early 1990s, although the approach or the concept was introduced back in the early 1980s. Supply Chain Management is an influential ingredient in today's literature and thinking in the field of logistics [1,18,38]. Supply chain management is delivering major economic benefits to business as diverse as manufacturing, retailers, Service Company, etc. The competition has become fierce as companies can go beyond national borders. However, the organization realized that the most immediately benefits that businesses can expected from strategic supply chain management are lowered inventory risks and costs, along with reduction in warehousing, distribution, transportation costs, etc. Over the time, firms will also experience sustainable cost savings through increased productivity and streamlined business processes in procurement and purchasing order fulfillment, accounts receivable and payable, and exception management. Subtler benefits can include accelerated product delivery times, more efficient product development efforts, and lower product manufacturing costs. In the long term, the most significant benefits to businesses with advanced supply chain management capabilities will be dramatically improved customer responsiveness, increased flexibility for changing market conditions, improved customer service and satisfaction, increased customer retention, and more effective marketing [7,19,27,32].

However, most of companies implemented the supply chain management can not reap the supply chain benefits expected. The supply chain concerns and obstacles were first studied in year 2002. The results shown that the most concerns items are Supply Chain Coherence such as lack of cooperation among supply chain members, Information Capability such as lack of sophisticated information system, and Geographical Proximity such as customer and supplier geographical distances. All of these concerns impact to the effectiveness of supply chain practices and performances[39]. Most of the concerns and problems are some basic infrastructures of the company as well as the supply chain knowledge or operational before implementation [18,33,39]. The information exchange is consistently mentioned as a key requirement of successful supply chain management implementation, the main premise of supply chain management is that the sharing of information and the coordination of strategies among firms in a supply chain can both reduce total logistics costs and enhance value

delivered to the customer, which can lead to sustainable competitive advantage for the firm [7,13,34]. The organization characteristics, larger organizations tend to be more diverse and complex and the increased availability of resources can lead to more risk taking by management because potential failure is less hazardous to the health of large organization. Some researches found that the larger organizations adopt more innovations [13]. The management commitment is the key critical factor in supply chain implementation, the budget, vision, information are all derived from the management through the employees. As the above basic infrastructures required, we study the critical operational infrastructures enhancing the supply chain practices and performances. The existing researches on supply chain management pay scant directly about the infrastructures of supply chain management and practices. The literature review of *Journal of Business Logistics* and *Journal of Supply Chain Management* from 1970 - 2003, there were no evidence about the studying of the infrastructures enhancing the supply chain practices. In this work, the author adopted the 3 categories of infrastructure of the critical success factors in supply chain implementation. Man is defined as the operational staff worker's knowledge, experiences or etc. Machine is defined as a operating tools for supply chain managing. Management is defined as the commitment from the top level in order to support the supply chain activities and implementations. The supply chain management in this paper, we define the two layers of management. The first layer is the infrastructures level which we define the man, machine and management as the basic infrastructures. Another layer is the supply chain level which we classify as a supply chain practice and a supply chain performance. The research model developed from the Croteau's research model. This research model studies the relationship between basic supply chain infrastructures and the supply chain practices and performances. The research objective is to validate the infrastructures related to the supply chain practices and performance by using the structural equation modeling with - EQS technique.

2. Literature Review

The supply chain company comprises geographically dispersed facilities where raw materials, intermediate products, or finished products are acquired, transformed, stored, sold and transported to the customers. These activities are the connected facilities along the products flow. The facilities may be operated by the company or vendors, customers, third-party providers, or other firms which the company has business arrangements. The company's goal is to add value to the products through the supply chain and transport them to geographically dispersed markets in the correct quantities.

In the 1950s and 1960s, most manufacturers emphasized on the mass production to minimize the unit cost of production, with the low product flexibility. The information sharing to supplier or partnership was

considered risky. In the period, there was a little to find the cooperative and strategic buyer-supplier partnership and it is rare to find the supply chain organization [38].

In the early of 1970s, the emphasis of competitive strategy was shifted from productivity and mass production to quality emphasis and cycle time reduction [4,5,11,38]. The material requirement planning (MRP) was developed and managers realized the impact of huge WIP inventories on manufacturing cost as well as the product quality, product development and delivery lead-time [1,2,21,28]. All of above inconsistency performance of the supplier or partnership direct and indirect effected to the company in term of the cost, customer satisfaction and management issue. In this period, manufactures resorted to new material management concepts to improve the company performance.

In the 1980s, the global competition forced world-class organization to offer low-cost, high quality and reliable products with the greater design flexibility. The JIT was developed to support and improve the manufacturing efficiency and cycle time [8,15,27,37,38] as well as minimize and manage the inventory. In this period, the buyer-supplier relationship was accountability. The supply chain concept emerged as the experiment in manufacturing. Additional, the procurement professional, logistics experts carried the further step in order to incorporate the physical distribution, transportation and warehousing functions [37].

The evolution of supply chain management continued into the 1990s due to the intense of global competition. The higher demanding from customer to get the product, service at the right time in the lowest cost, the organization or manufacturing realized to improve the overall organization efficiency as well as the efficiency of their partnerships both customer and supplier. The long term and closely working relationships are developed to keep the competitiveness within the chain. In this period, the supply chain management was continued from 1980s and further extended best practices in managing corporate resources to include strategic suppliers and logistics function.

In the end of 1990s to 2000s, several developments in material management were emerged. MRPII and ERP were developed as a tool in managing the material. The advanced supply chain management and logistics were studied to improve the efficiency of process such as the lean logistics, agile supply chain, etc. Currently the supply chain is the new business process management in almost organization regardless to the business types or products. The literature review in supply chain management area was conducted in reviewing *The Journal of Supply Chain Management* since 1993 to 2003. And *The Journal of Business Logistics* since the Year 1970 to 1997 that analyzed by Stock in 1997 [2]. There are 1589 citations in total.

Table 1. Supply Chain Revolution

Period	Cooperative Characteristics	Authors
1950s–1960s	-Low cooperative strategy between buyer and supplier -Emphasize on the mass production to minimize cost with low product flexibility -No supply chain developed	Tan 2002
1970s	-Emphasize on high quality product -MRP is developed supporting the WIP managing -Initiate the cycle time reduction, accurate lead time delivery, product development concept	Carter et al 1996, Tan 2002
1980s	- High global competition forced - Market need Low cost , High Quality, Reliable , Higher flexibility - JIT developed to minimize and manage the inventory - Realized the buyer and supplier relationship in cooperate management	Tan 2001, Tan 2002
1990s	-Higher demand of quality product, service in the right time at the lowest cost -Partnership management emerged, the long term, partnership relationships, closely working with the supplier was developed - Supply Chain Management was continued from Period 1980s	Inman and Hubler 1992, Morgan and Monczka 1995, Onge St. A. 1996
2000s	- MRPII, ERP were developed to support the material management - Supply Chain Management is the new business process mgt.	Tan 2002, Elmuti 2002, Li 2002.

The most popular topic is the transportation, purchasing & inventory, logistics, information system, channel of distribution, MRP, DRP, JIT& Kanban, location analysis, supplier management, customer service, human resource & organization, supply chain concept, and others respectively. The number of citation VS the subject area is shown in the following table.

Table 2. Literature Review in Supply Chain

Subject Area	No of citation (s)
Transportation	406
Purchasing & Inventory	384
Logistics	184
Information System	163
Channel of Distribution	132
MRP, DRP, JIT, Kanban	71
Location Analysis	59
Supplier Management	50
Customer Service	42
HR and Organization	34
Supply Chain Concept	27
Miscellaneous	19
Packaging	8
Quality	7
Outsourcing	3

From the literature review, there were very rare the supply chain infrastructure topics. This paper focused on the infrastructure factors that impact on the successful supply chain implementation.

3. Supply Chain Management

3.1 Supply Chain Performance

Managing a supply chain is becoming the important issues for organizations. Several researches mentioned that the competition is no longer between organizations but among supply chains [19]. Wisner and Choon suggested that the intense global competition of the past decade has let organizations to create the cooperative, mutually beneficial partnerships with suppliers, distributors, retailers, and other firms within the supply chain. The objectives of those partnerships are to offer the lower-cost, higher quality products and services with greater design flexibility [3,12,15], cycle time improvement, higher productivity, waste reduction, efficiency of work, and product quality [19,26,27,31]. Supply chain implementation objective is also to achieve the financial and level of firm revenue as to maximize over time ratio of the annual revenue, less operation costs [3,5,36], sales, sales per staff, gross sales, operating income before depreciation, return on assets, net income (Ross 2002), saving, ROE, ROI and margin [1,19,29,33]

Several researchers focused on supply chain performance measurement and firm performance improvement objectives [2,6,8,17,28,29]. In 1995,

Mcmullan studied about the supply chain management practices in Asia Pacific, the researcher investigated the four key areas; management issue, role and responsibilities, competitive strategies and performance management. McMullan [29] also suggested that in order to achieve a competitive advantages, the firm is required to change their organization structures, relationships with supply chain members and performance measurement systems as well as the new information technology to enhance communication throughout the supply chain which will be increased the service levels and reduce the operating costs. Lambert et al described the supply chain is to maximize the profitability at each line, supply chain performance migrates toward management's objectives and maximizes performance[27].

The customer management and satisfaction is the objectives of supply chain implementation [3,14,27,29] in order to deliver the on time delivery product, reduced the customer complaints, provide the inventory accuracy and reduce the total cycle time [29,37]. The supply chain implementation in manufacturing can also reflect to the customer satisfaction by increase sale volume, cost reduction so sell higher margin products, reduce safety stock, improve asset utilization, product development, investment plan, resource effectiveness [16,27,29,]

For the supplier management, many researchers identified that it is the critical success factor in supply chain management [1,7,9,18,23,25]. The objectives expected from the supply chain management program are to acquire the right quality products in the right supplier, time, price and services [10,11,2137]. The impact of supplier selection criteria and supplier involvement can be impacted to the firm performance by reduced the production rework cost, reduced the production costs per unit, decreased the work in progress inventories, material handling and increased the quality of outgoing product and delivery performance from the accuracy in delivery from the supplier [3,12,22,39].

The warehouse and transportation is the one component in supply chain integration, the most common measured in warehouse performance are inventory accuracy, on time delivery, shipping error, warehouse cycle time, etc [16,24,27,32]. Some researchers identified the benefits of supply chain in warehouse and transportation as to lower inventory cost and risk, warehouse cost reduction, cost saving from overtime through increased productivity and streamlined business processes in procurement and purchasing. The logistics system can be saved for the operation cost [19,34] by implementing the freight and transportation management. There are some researchers studied about the third party service provided in helping cost and efficiency improvement.

The warehouse management seems to be related to the Information Technology. Some companies have implemented the software in managing the warehouse and inventory processing, the software in Inventory Management is the most application to supply chain organization [29]. So the Information Technology is one of the key success factors to supply chain management. It

is as the medium for coordination among and within organizations but the larger of IT investment seems not to lead the higher financial performance [22,36]. So the firm should consider the investment level of Information technology in achieve the highest benefit return. Some usage of Information Technology in supply chain such as the Internet which provides the opportunity for demand data and supply capacity data to be visible to all company within the chain [21,35]. Other applications of Information Technology in supply chain management concerned in usage of Warehousing management, fleet management, facility network planning, MRPII, Barcoding, Radio frequency, EDI [4, 29, 26, 27].

Table 3. The Literature Review in the Supply Chain and Firm Performance

Supply Chain Performance	Descriptions	Authors
Financial Performance	The overall profitability or cost reduction after the supply chain implementation in term of ROI, ROE, Profit sharing, etc	Mcmullan 1995, Lee 2002, Elmuti2002, Lambert 2001,
Managerial Performance	The effectiveness and efficiency in overall managing from the first process of purchasing through the final process of transportation and logistics to end customer	Lambert 2001
Competitive Performance	The strength of company in order to win over the competitors	Hewitt 1999,
Customer Relation Performance	The relationship and efficiency in managing to achieve the customer expectation	Hewitt 1999, Elmuti2002, McMullan1995
Warehouse and Transportation Performance	The effectiveness and efficiency in material from supplier and finished product to customer	Mcmullan, 1995, Tan et al 1998,
Technological Performance	The utilization of technological hardware and software in order to maximize the efficiency and effectiveness in supply chain implementation	Ellram 2002
Supplier Relation Performance	The supplier's consistency in delivering materials, components or products as well as developing the long term partner.	Lambert 2001, Power 2001, Talluri 2002,

From these benefits, the advent of information technology and intense global competition has enticed

many world-class manufacturers, service providers [39,40] adopt an integrated strategic approach to supply chain management. To achieve these benefits, the supply chain strategies were implemented and studied by several researchers in how the practices related to firm performance or individual studied the supply chain practices for implementation.

3.2 Supply Chain Practices

The facing of competitive global market, revolution in manufacturers, downsizing and lean in organization, to achieve the competitive advantage the organization need to adapt and implement some value-adding activities. In order to achieve the financial performance, firm should focus on the profit maximization, cost reduction in manufacturing, operating cost, cost of quality, etc [18, 22]. Some manufacturers are practicing the process cutting by adding some processes to supplier capacity [33] such as the part preparation before production.

The most practices in customer management are to identify the customer needs, reduce the customer complaints, full score of delivery performance [4,38]. These activities the firm expected the repeated order in long term. In the other hand, firm also need the strongly support by their suppliers. The supplier will be monitored by the firm since the starting of business, many firms implemented the supplier selection program and set up the team to control the supplier performance as well as the reducing incoming inspection lot at firm's receiving, provide the supplier certification for the excellent supplier performance [32, 38, 39,40]. Currently, the suppliers are treated as the partnership in business, some purchasing roles in organization had been changed such as purchasing from individual plant source in low cost items, decentralized the purchasing, annual price negotiation activities [38,39].

The outsourcing is another premise of supply chain management for the cost reduction, the outsourcing can be applied to transportation function, warehousing function or human resource management [19] and Information technology. Some researchers [17,18] identified the information technology that purchasing and supply management use in 6 items. The cost reduction was initiated in the JIT program to keep less inventory and lower risk as well as the transportation which the consolidated and postponement strategy were selected to perform the cost reduction. Generally, the supply chain practices and activities were emphasizing in internal competencies which it requires greater reliance. In an empirical survey, Tan et al 1998 identified 10 SCM practices and showed that some of the practices affected firms' performance. Later in 2002, Tan studied the 25 supply chain practices related to the firm performances and concerned, the result shown that the "determining the customers' future needs" was the most practice items of the survey respondents and it is strongly to customer service and competitive position performance of the firm. The "use of third party SCM specialist" is the lowest activities rating from the survey respondents and no any

relation to the any firm performances [39,40].

3.3 Supply Chain Infrastructures

From the past researches, there were no supply chain infrastructures found in the literature review. In this paper, the researchers define the supply chain infrastructures into 3 parts as the followings

3.3.1 Man Infrastructures

Man infrastructure is defined as capability of people in supply chain organization. In this research, we focus on the followings

- (a) Skill and experience
- (b) Education and training

3.3.2 Machine Infrastructures

Machine infrastructure is defined as the equipment, tools or necessary things to support the supply chain activities. In this research, we focus on the followings

- (a) Equipment, tools, computers, etc
- (b) Software, computer program, MRP, ERP, etc

3.3.3 Management Infrastructures

Management infrastructure is defined as the management vision to the supply chain management and implementation. Due to the supply chain management is required the investment so the budget for the implementation is significant impacted to the overall success. In this research, we focus on the followings

- (a) Management commitment
- (b) Management strategy

In this research, we study the infrastructures that directly impact to the supply chain practices and supply chain management. The research model categorize into multilevel of supply chain. The basic level is the supply chain infrastructure. The intermediate level is the supply chain practices and the supply chain performance is the latest level.

4. Study Tool

The study tools in this research are the Q Methodology in clustering the basic infrastructure as the classified category. The structural equation modeling is used to validate the research result.

4.1 Q Methodology

Q methodology was invented in 1935 by British physicist-psychologist William Stephenson in 1953 and is most often associated with quantitative analysis due to its involvement with factor analysis. Statistical procedures aside, however, what Stephenson was interested in providing was a way to reveal the subjectivity involved in any situation -- e.g., in aesthetic judgment, poetic interpretation, perceptions of organizational role, political attitudes, appraisals of health care, experiences of bereavement, perspectives on life and the cosmos, et cetera ad infinitum. It is life as lived from the standpoint of the person living it that is typically passed over by

quantitative procedures, and it is subjectivity in this sense that Q methodology is designed to examine and that frequently engages the attention of the qualitative researcher interested in more than just life measured by the pound. Q methodology "combines the strengths of both qualitative and quantitative research traditions" and in other respects provides a bridge between the two [27,37]. Some of the quantitative obstacles to the wider use of Q methodology have recently been rendered less daunting by virtue of software packages which have converted to button presses what before were tedious calculations. One such package, Q Method (Atkinson, 1992), is available as freeware from Kent State University's List server, and the way in which Q Method facilitates Q-methodological inquiries, as well as the way in which such inquiries proceed. The formula for calculating the sample kappa (k) is

$$k = \frac{N \sum X_{ii} - \sum (X_i + X_{+i})}{N^2 - \sum (X_i + X_{+i})} \quad (1)$$

For kappa, no general agreement exists with respect to required scores. Landis and Koch (1977) have provided a more detailed guideline to interpret kappa by associating different values of this index to degree of agreement beyond chance. The following guideline is suggested:

Table 4. Guidelines for Kappa Value

Value of Kappa	Degree of Agreement Beyond Chance
0.76 – 1.00	Excellent
0.40 – 0.75	Fair to Good (Moderate)
0.39 or less	Poor

4.2 Structural Equation Modeling

The growing interest in Structural Equation Modeling (SEM) techniques and recognition of their importance in empirical research, Structural Equation Modeling (SEM) techniques such as LISREL, EQS, Partial Least Squares (PLS) are second generation data analysis techniques that can be used to test the extent to which the research meets recognized standards for high quality statistical analysis. The test is for statistical conclusion validity. Contrary to the first generation statistical tools such as regression, SEM enables researcher to answer a set of interrelated

research questions in Single, Systematic and Comprehensive Analysis by modeling the relationships among multiple independent and dependent constructs simultaneously. This capability for simultaneous analysis differ greatly from most first generation regression model such as linear regression, LOGIT, ANOVA and MANOVA, which can analyze only one layer of linkages between independent and dependent variables at a time. SEM tools are increasingly being used in behavioral science research for the casual modeling of complex, multivariate data sets in which the researcher gathers multiple measures of proposed constructs. Several literatures suggested that SEM has become a tool in validating instruments and testing linkages between constructs. Consistent with [37], the qualifying criteria for the sample were that the article employed either:

- (a) Correlation or statistical manipulation of variables
- (b) Some form of data analysis, even if the data analysis was simply descriptive statistics.

From the above table, it is shown that SEM has been used with some frequency for validating instruments and testing linkages between constructs in two of three widely known Information System Journals. In ISR, 45% of the positivist, empirically-based articles used SEM. In MISQ, it was 25%. From the first appearance of SEM in 1990 in the major Information System journals [37], usage had steadily grown. By the mid of 1990s SEM was being used in about 18% of empirical articles across the three journals, with PLS and LISREL being the two most common techniques. Other SEM tools, such as EQS and AMOS, were used less often, but this is most likely because of the slowness of diffusion of innovation and is not a statement about the power or capability of these particular packages [37].

4.3 Research Model and Hypothesis

In this paper, the multilevel supply chain is integrated. The proposed research model is illustrated in Figure 1. From the statement of the problem, do the Man, Machine and Management infrastructure influence the effectiveness of supply chain management? The model is designed to study the supporting of operational infrastructures in term of man, machine and management in supply chain implementation.

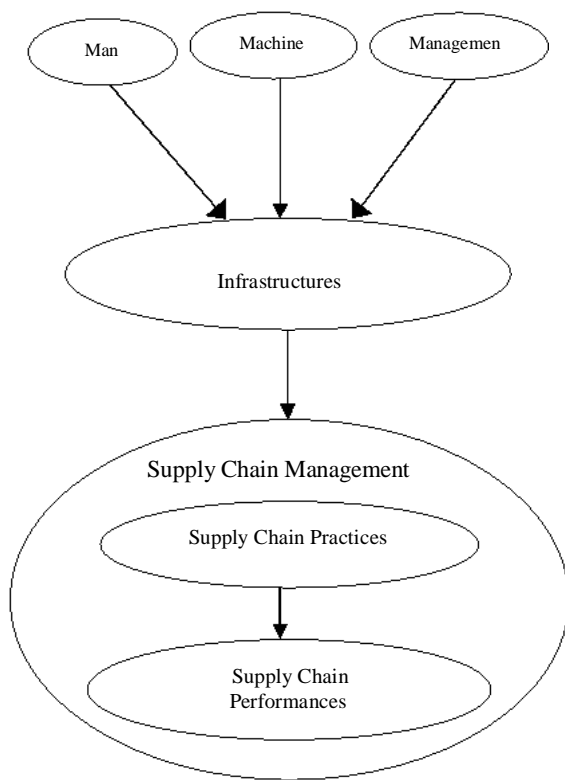

Figure 1. Research Model

The model is analyzed the basic infrastructures need for supply chain activities enhancing the effectiveness of supply chain practices and their performances. The man, machine and management infrastructures are studied the covariation to the supply chain management. From the research model, the hypothesis is established:

H: The higher supply chain infrastructures preparation, the higher effectiveness of supply chain management

We also study the correlation between the infrastructures, supply chain practices and supply chain performances.

4.4 Survey Methodology

A survey instrument in form of a questionnaire was designed based on the integrated model described. The respondents were asked to indicate the level of company practices and performance achievement after supply chain implementation using five-point Likert scale (1 = strongly disagree, 5 = strongly agree). The six infrastructure variables were constructed. The questions about man, machine and management infrastructures were asked to indicate the five-points Likert scale as well as the four group questions of the supply chain practices and performance. This survey data was collected from a single respondent from each target firm, the target respondents are in the purchasing and sale departments because they were assumed to fully involve the company's supply chain activities. The objective in

collecting the single respondent from one firm is to minimize the variation in data bias [41].

The variables were checked the validity by 4 practitioners and academicians, the Q-sort methodology was used to ensure the variables by improving the k values from the first to second rounds. The questionnaire was pre-tested to check the content validity and revised where necessary to ensure the content validity. The surveys were sent refer to the industrial estates list, totally 114 from 986 surveys usable (11.56%). The last wave of surveys received was considered as representative of non-respondents [9]. The 30 survey items were selected for analysis randomly. Each sample was split into two groups on the basis of early and late survey return time, then the t-test were used to analyze. The t-test yielded no statistically significant differences between early and late response groups. The non-affect of non-response bias was recommended. The profile of company and respondents were asked. The firms were mainly from the manufacturing and trading industries. The respondent's profile is shown in Figures 2:

Figure 2. The Respondents' Origin Country

Figure 2 represented the firm's country of origin, they are from Taiwan, Singapore, Japan, China and Thailand, respectively. The Figure 3 shows the driving force of supply chain implementation, the highest driving force is from the customer requirement, cost reduction, delivery management, inventory management accordingly. Figure 4 shows the business function of the supply chain implementation is in electronic industry, plastic industry, trading industry and packaging industry respectively.

4.5 Analysis of the Research Model

The simultaneous estimation methodology is applied to test the measurement and theoretical. All data from 114 firms sampled to obtain the maximum likelihood estimates of the path coefficients (γ), loading (λ), correlations, error variances, and χ^2 goodness of fit test [12]. All of these parameters were derived from the EQS, which it is one program of structural equation modeling program. The advantages of EQS other than other

structural equation modeling are the simpler represented system on two or three sets of parameter metrics. Also, the less limitation in the type of structural coefficients make the EQS easily interpret the statistic result in the small number of variables [12,37].

The reliability, convergent validity, unidimensionality of infrastructure alignment and supply chain practices are analyzed by examining the level of sub model fit and estimated loading [12]. The unidimensional reliability is a model comparison with significant smaller χ^2 in the proposed measurement model with the alternative measurement models. For the model fit is assessed using chi-square statistic estimated for the hypothesized model. However, the χ^2 is sensitive to the sample size so it is a caution to only rely on the χ^2 . The value of χ^2/df can be used to improve this limitation if the ratio is inferior to 5 [12]. In EQS, the Bentler's comparative fit index (CFI) is approached to reflect the fit at all sample sizes. The CFI formula is:

$$CFI = |(\chi_0^2 - df_0) - (\chi_k^2 - df_k)| / (\chi_0^2 - df_0) \quad (2)$$

Where χ_0^2 is the null model and χ_k^2 is the hypothesized model. Model fit is acceptable at CFI is higher than 0.90 level. For the structural equation modeling assessed of this model results in Figure 2. A significant value of 112.4 at $df = 53$, $p(0.01)$ is the chi-square result and confirmed fit is the χ^2/df ratio at 2.18, which this CFI = 0.91 is adequate supported the unidimensionality of alignment and practices.

Figure 3. The Supply Chain Driving Forces

For the convergent validity, the underlying construct or trait are described in percentage of variance in term of loading squared. In this model, the loading range is from 0.51 to 0.84. The loading of operational infrastructures Man, Machine and Management are significant in enhancing the supply chain practice. A result higher than 0.5 shown the measurement is captured by the constructed variance [12]. In this model the ρ ranged

from 0.51 - 0.74 that confirmed the reliability of this model. As shown in the Table 5, the correlation ranged from 0.42 to 0.74 at 99% confidence interval. The largest correlation is between the supply chain practice and supply chain performance, the values shown the acceptable discriminant validity.

Figure 4. Respondent's Business Function

For the theoretical model, the linked between operational infrastructure to the supply chain practices reflect the terms of competitiveness performance, cost management and inventory control performance. The hypothesis was confirmed by the significant path coefficient of 0.74 at 99% confidence level that enhancing of operational infrastructures of man, machine and management to the supply chain practices support the supply chain performance of organization [12,27,37].

5. Discussion

The tested model shows the significant man, machine and management infrastructures enhancing the supply chain management. The research results indicated the operational infrastructures are highly impact to the supply chain practices that reflect the success in supply chain performance. In this paper the supply chain performance, the inventory control performance is highly significant variable.

For the further research, this model can be analyzed in term of mathematically equation in order to be the indicator of infrastructure preparation before entering the supply chain program as the following;

$$F(x) = \{\text{Man, Machine, Management}\}$$

Where $F(x)$ is the readiness indicator of infrastructure preparation.

The research will be more contribution if linking to the supply chain performance

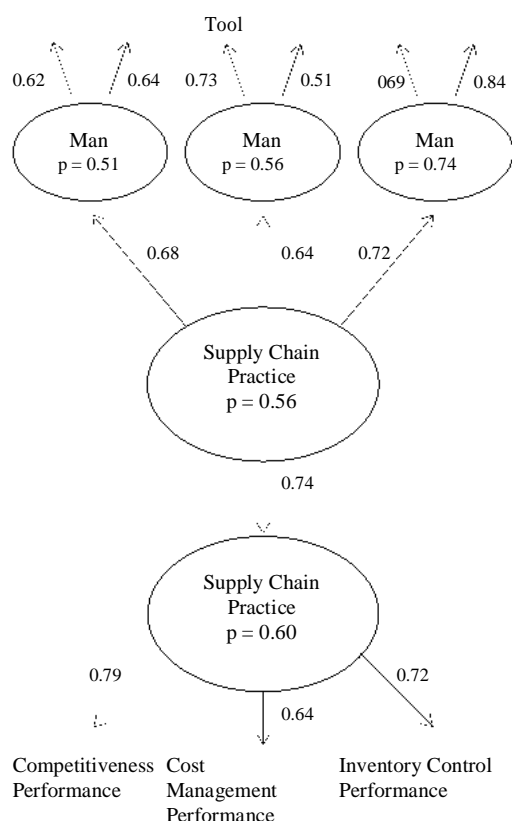

Figure 5. Operational Infrastructures Enhancing Supply Chain Management

Table 5. The Correlation Analysis of the Constructs

	1	2	3	4	5
1. Man	-				
2. Machine	0.46	-			
3. Management	0.51	0.42	-		
4. Supply Chain Practice	0.68	0.64	0.72	-	
5. Supply Chain Performance	0.48	0.49	0.52	0.74	-

A Methodology for Developing an Integrated Supply Chain Management System

Yi-chen Lan

School of Computing and Information Technology
University of Western Sydney
Australia

yichen@cit.uws.edu.au

Abstract

Integrated Supply Chain Management (ISCM) involves the linking of suppliers and customers with the internal supply processes of an organisation. ISCM solutions allow organisations to automate workflows concerning the execution and analysis of planning, sourcing, making, delivering, returns handling and maintenance. Many of today's ISCM systems use primarily web technology as the supporting infrastructure. Undoubtedly, the electronic (Internet-based) ISCM systems deliver the enterprises with a competitive advantage by opening up opportunities to streamline processes, reduce costs, increased customer patronage and more thorough planning abilities. However, there has been significant customer backlash concerning the inability of software vendors to deliver easy integration and promised functionality. Although various researchers have suggested strategies to overcome some of the failures in operating ISCM systems, there was a lack of architectural investigation in the analysis stage. The methodology proposed seeks to resolve these gaps and provides a fundamental framework in analysing ISCM systems.

1. Introduction

Please follow the formatting guidelines carefully. Papers should be prepared in conformity with this instruction sheet. If you have any questions, please contact with the organizer of ICEB2003.

The evolution of Internet technology has enabled enterprises in operating inter-organisational activities efficiently. Given the cost of logistics and its importance in order fulfilment process, organisations may take this opportunity to reengineer their supply chain operations to sustain in the global competitive challenge. With this invigorated growth of e-business, software vendors and consultants have promised the Internet-based supply chain systems, which provide businesses with the capability to respond in real-time in changing product demand and supply, and offer an easy integration functionality with backend information systems [15] [19].

Although a number of Internet-based supply chain systems (or integrated supply chain management systems – ISCM systems) are available for adoption, enterprises are not guaranteed to implement the systems in conjunction with their existing information systems. Furthermore, the ISCM systems may not fulfil the connection and implementation requirements between

participants in the supply chain.

After the e-commerce hype had dissipated, surveys undertaken in 2001 tend to paint a different picture as to the success of these implementations. Smith [17] concludes that at least 15% of supply chain system implementations during 2001 and 2002 were abandoned in the US alone. Although several reasons can be identified as the cause of implementation failure, the main problem rests on the fundamental analysis of ISCM operations and requirements.

The purpose of this paper is to debunk some myths proposed by vendors with regards to the implementation of Integrated Supply Chain Environments (ISCE) and propose an analysis methodology for Integrated Supply Chain Management systems.

Firstly, the paper will examine some of the available literature regarding ISCE. The fundamentals of ISCE – technologies and processes, will be investigated in some detail. Vendors were quick to promote the benefits of ISCE, yet were not so forthcoming as to possible barriers and other issues to watch for. Both of these will also be discussed in this paper.

Secondly, an analysis methodology is proposed, which intends to address some of the issues identified previously, and construct a theoretical model for enterprises to adopt in the analysis phase of developing ISCM systems. This paper concludes with a future research direction in investigating technological issues of ISCM systems operation.

2. Integrated Supply Chain Management Overview

ISCM involves the linking of Suppliers and Customers with the internal supply processes of an organisation. Internal processes would include both vertically integrated functional areas such as materials, sales and marketing, manufacturing, inventory and warehousing, distribution or perhaps, other independent companies, which involved in the supply chain (ie. channel integration). Customers at one end of the process can potentially be a supplier downstream in the next process, ultimately supplying to the end user [9] [19].

2.1 ISCM solutions

Whilst ISCM systems, in many cases are still in its infancy, the concept of establishing information flows between points in the supply chain has been around since the 1980's. Through Electronic Data Interchange (EDI),

customers and suppliers have communicated supply data through direct dial-up interfaces and other mediums [21]. However, the ability for the Internet to create a common communication infrastructure has made integration much more cost-effective. Hence, ISCM has the ability to deliver the right product to the right place at the right time and at the right price.

From the supply chain software development perspective, there are generally 4 large vendors identified, which namely Oracle, SAP, PeopleSoft and Ariba and a multitude of medium-sized vendors in the ISCM solution space [2]. All claim that ISCM will enable the enterprise to respond, in real time, to changes in demand and supply.

For instance, current ISCM solutions allow organisations to automate workflows concerning the execution and analysis of the following business activities [8] [15].

1. Planning: demand & supply planning, manage planning infrastructure
2. Sourcing (buy-side) - strategic sourcing, eprocurement, services procurement, catalog management, collaborative contract / supply management, settlements / vendor payments
3. Making (in-side) - product lifecycle management, demand planning, production management, production planning, flow production, event management
4. Delivering (sell-side) - inventory, order management, promotions management, warehouse management, transportation management, delivery infrastructure management, ebill payment, scm portal
5. Returns handling (from customers)
6. Maintenance

2.2 ISCM systems architecture

Turner [19] quoted that information systems would be the enabler of integrated logistics. Armstrong [2] affirms that Turner's view has come to fruition. Many of today's ISCM systems use primarily web technology as the supporting infrastructure [6]. It is not uncommon in these instances, to develop a 3-tier or n-tier network architecture in order to provide robust support for ISCM systems.

For example, Advanced Software Design Inc. [1] illustrated the 3-tier ISCM integration architecture (Figure 1) in use by the US Department of Defence (DoD). Suppliers and customers alike, access the DoD ISCM through the use of Web portals (the 1st tier of the ISCM). Web portals provide the necessary web services to establish a common Graphical interface for the DoD's stakeholders in accessing supply chain data. Customers, suppliers, distributors and delivery agents can all access custom information and services supplied by the ISCM. Supplier services could include access to business-to-business (B2B) marketplaces, support and other push/pull supplier functionality. Alternately, customers can customise the site in order to access catalogues from the organisation and external suppliers,

customer transaction details and other product, customer and technical support.

The portals are supported by messaging infrastructure (2nd tier), which provides the link to the underlying applications layer (3rd tier). The applications layer is independent of any particular interface (eg. portals) and contains the necessary business logic and data access in order to perform operations. This includes access to SCM functionality, ERP systems and decision support systems. Data and business logic are also independently stored.

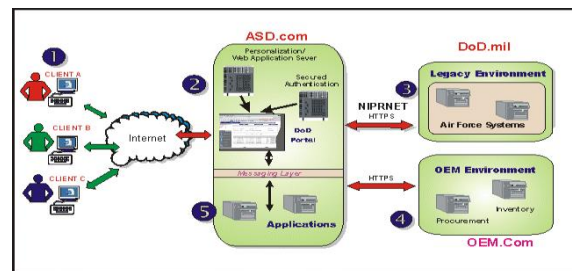

Figure 1. ISCM integration architecture [1]

The software architecture is mostly constructed in web-based environment that involves HTTP, server-side Java and XML. ISCM systems are generally no different than other business applications but still require some interfacing with old technologies such as aging ERPs and legacy systems [21].

2.3 Benefits of ISCM systems

ISCM delivers the enterprise with a competitive advantage by opening up opportunities to streamline processes, reduce costs, increase customer patronage, and more thorough planning abilities [19]. The benefits of ISCM systems are categorised into a number groups including financial, customer, planning, production, and implementation. Each of these groups is further discussed in the following subsections.

2.3.1 Financial

Cost reduction

In some manufacturing organisations, the cost of the supply chain can represent 60-80% of their total cost base [5]. One of the core benefits for driving efficiency through the supply chain is cost reduction. ISCM allows the organisation to maximize profitability through Reduced Customer Service, Administration and Inventory costs. Less staff are required to maintain the supply chain and order/inventory details can be made available to customers directly without human intervention [5] [8]. Some organisations have quoted 25% cost reductions per transaction, despite a 20% increase in orders [19].

Quality financial information

Another benefit is the improvement and reliability of financial information. ISCM systems maintain centralised databases, which are linked to other enterprise systems (eg. ERP, CRM) providing integrity, consistency and real-time

data access to managers so that they can manage the supply chain with an organisational perspective [19].

2.3.2 Customer

Retention

Supply chain systems, through customer portals, provides customers with an instantaneous and holistic view of the progress of their transactions within the organisation. This level of service (coupled with benefits derived from Production) result in higher customer satisfaction levels and in turn, improve the firm's ability to attract new customers and importantly, retain them. Organisations have achieved Customer Service Levels of 97% following the introduction of ISCM systems. This retention translates into greater revenue. [3] [8] [5] [19].

Behaviour

The ability to capture customer transactions and preferences online, provides the organisation with the facility to track their behaviour and in turn, customise products & services to cater for them [4].

Promise

Because of the level of workflow automation and inventory statistics, organisations are able to provide accurate estimates of when orders will be fulfilled at the time of ordering. This is known as 'capable-to-promise' (CTP) capability. This capability allows the organisation's customers to then plan more effectively [8].

2.3.3 Planning

Companies with ISCM systems have the ability to mathematically and graphically observe the performance of the supply chain giving the manager the power to "plan and make things happen" [19]. ISCM systems provide the organisation with the capabilities to derive more accurate demand planning with improved precision, create shorter planning and production cycles, establish one central data repository for the entire organisation and facilitate enhanced communications through rapid information dissemination [4] [8].

2.3.4 Production

ISCM provides the ability to holistically manage the supply chain allowing managers to dynamically respond to any situation that may arise so as to minimise its impact on production.

Inventory Management

By measuring the level of inventory and analysing turnover, supply chain systems can improve turnover by reducing the need for 'safety stocks' and the risk of retailer 'out-of-stocks'. Inventory items need to be consistently numbered to facilitate measurement and tracking. These benefits reduce the overhead required to store high inventory levels [5] [8]. Turner's [19] research claimed a 37% reduction in inventory levels as a result of ISCM implementation.

Efficiency

ISCM systems measure the performance of the supply chain through the generation of supply chain metrics. This allows process quality issues to be tracked and rectified, isolates bottlenecks in the process and measures lead times so that they can be aligned with available capacity to maximise plant utilisation. All of this ensures 'quicker time-to-market' for the firm's products. [5] [8].

Other efficiency benefits include no data rekeying through simplified automated order placement, order status inquiries, delivery shipment and invoicing [4] [8]. ISCM implementations have resulted in a 50% overtime reduction for some organisations [19].

2.3.4 Implementation

Consultants promise responsiveness and 'Plug & Play' integrations. However, documented examples of supply chain failures by organisations such as Siemens AG, Nike, OPP Quimica and Shell are evidence that the implementation of ISCM systems is not as easy as vendors claim. Claims of "rapid integration" and "seamless linking" seem to significantly underestimate the effort required to integrate ISCM with the rest of the enterprise [13].

For Nike, "i2" ISCM software required a significant degree of customisation in order to integrate the software to the rest of the organisation. Customisation to enterprise software comes with great risk and significant cost for ongoing maintenance. Nike's summation of the software was that it "just didn't work". OPP Quimica (a Brazilian Chemicals Company) required the use of 3rd-party integration software in order to assimilate i2 to the rest of the enterprise architecture. Shell's implementation proved problematic with the need to tie 85 ERP sites to a single SCM platform [17].

3. Issues and Barriers in ISCM Analysis

Similar to the hype attached to Enterprise Resource Planning (ERP) applications, there has been significant customer backlash concerning the inability of software vendors to deliver easy integration and promised functionality [17]. Turner [19] believes that "few companies claim to have fully implemented SCM and have sustained the benefits proposed ISCM would create". In fact, Fontanella [7] indicates that only 25% of ISCM users are utilising the full suite of supply chain applications and that only 12% of users are receiving data from inbound suppliers and customers – far from an integrated supply chain.

Many of these issues stem from a failure to undertake thorough analysis in the following key areas.

- Focus on transaction systems over strategic systems to manage supply chains
Organisations are not taking a strategic view of ISCM systems. More so, they tend to only focus on transactions systems (eg. inventory control, order processing etc.), which provide little visibility of the

enterprise [7] [19].

- Failure to pre-empt change to business processes
In a majority of implementations, analysis has focused on the technical aspects of integrating ISCM systems with the remaining architecture. One area that has been neglected has been the effect on business processes. Organisations expect either staff to just “accept change” or “customise” the software – both of these options are generally flawed. In order to reap the cost savings from ISCM systems, significant analysis must be conducted regarding process reengineering in order to ensure collaboration and continue to sustain benefits [7] [11] [19].
- Failure to appreciate geographical, relational, environmental considerations between buyer and supplier

The nature of ISCM (especially with multinational corporations), involves transacting across the world – “24 hours a day, 7 days per week, 360°”. Analysts fail to appreciate the geographical, relational and environmental “inhibitors” for ISCM implementations of this scope [11].

- Cross-borders logistics, culture, language and economic & regulatory climate are just some considerations which can affect the integration of business processes between regional offices & external organisations, creating communication issues throughout the supply chain. One ill-performing participant in the supply chain will affect the performance of the entire supply chain [18].
- Failure to accurately identify the costs and benefits of ISCM implementation

Many implementations have been classed as failures because of ISCM systems perceived inability to reap benefits and produce cost savings as expected. However, in many cases, it is the initial analysis of cost and benefits that have been flawed. Because of the nature and scope of ISCM implementations, it is difficult to accurately quantify attributable cost reductions from ISCM because they could be derived throughout the supply chain and be complicated to calculate. In the same light, determining benefits share similar traits with some having the additional complication of being intangible (eg. benefits of a central database) and therefore, difficult to quantify [12].

- Insufficient Capability
The implementation and support of ISCM systems can be rather complex and therefore demands sophisticated resources and incremental implementations. Unfortunately, during the planning and analysis phases of implementation projects, organisations have failed to properly appreciate the level of complexity involved, resulting in significant under-resourcing. As a result, many organisations have suffered material cost overruns and delayed “go-live” times [7].

4. Proposed Methodology for ISCM Systems

Analysis

Due to the extent of failed ISCM system implementations, it is imperative to construct an appropriate analysis and development methodology, which can be adopted as the roadmap for enterprises flourishing in ISCM systems development and operations. The proposed methodology demonstrates an overall picture for constructing an ISCM system from recognising problems, analysing requirements to the implementation and operation, and it embraces seven phases:

1. Identifying information management structure
2. Identifying connecting components
3. Ensuring appropriate business processes
4. Establishing and developing interfaces
5. Developing new business processes
6. Confirm strategic alignment
7. Implementing ISCM systems

Following is a discussion and culmination of those seven phases within the proposed iterative framework.

4.1 Identifying information management structure

Given the global nature of supply chain systems and its level of required integration, a common ICT (information and communication technology) infrastructure must be able to extend around the globe, be able to support open and rapid communication, and to integrate easily with the architecture of not just the organisation, but also with the architecture of customers and suppliers. This will be conducive to information sharing.

The enterprise’s information systems architecture must be properly analysed to ensure that it satisfies the needs of ISCM systems and can support security boundaries, hugely distributed database operations and event-driven applications. The architecture needs to be durable, flexible and embedded with the appropriate middleware in order to integrate as easy as possible [21]. It must also be sufficiently robust to cater for firewalls and other security measures, 24/7 global access and have redundant systems and processes to handle events when ISCM systems need to be offline for maintenance, emergency and recovery purposes.

In accordance with the criteria specified above, the Internet-based structure can be considered the most appropriate platform to satisfy these requirements. Nevertheless, participants in the supply chain have various capability and maturity levels in information management structure. Hence prior to adopt the Internet technology for integration, the existing information management structure of each participant must be determined.

4.2 Identifying connecting components

One of the most critical functions of supply chain management is to ensure the effective integration of

information and material flows through the system. This includes understanding the value added to products and its related information flows (inputs and outputs) as it progresses through the supply chain [10]. This embraces analysis on the supply chain's real costs, and cost & performance drivers [16].

Turner [19] identifies some of the key components, which need to be 'functionally' integrated. These components are also considered as the connecting components (or connecting business functions) between participants in the supply chain. These components include order management, customer service, invoicing, forecasting, distribution requirements planning (DRP), warehouse and inventory management, manufacturing planning, production control (MRPII) and integrated logistics.

4.3 Ensuring appropriate business processes

In order to enhance the supply chain processes, it is important to understand what happens currently. Generally supply chain processes may include the procurement, production, ordering, delivery and inventory paths, both within the company and external parties.

Firstly, analysts should analyse the supply chain processes and be able to appreciate the company's mix of products, end configurations, volumes, lifecycles, channels, customer segments and delivery outlets [20].

Each process should then be prioritised and broken down into its sub-processes, identifying each of its sources, outputs, transformations, timings, resources utilised and requirements. This would also be an opportune time to gather metrics concerning each of the processes in order to establish a baseline for identifying problems and to measure future process improvement.

Additionally any opportunities to benefit from "quick-wins" should be taken advantage of at this point [10].

4.4 Establishing and Developing Interfaces

Once architectural issues have been resolved and data requirements have been determined, a structure needs to be established to enable common linkages between both data providers and data recipients of the ISCM (ie. customers and suppliers) and linkages within ISCM processes. This will require the need to ascertain whether there are any missing links and determine how the data required will be sourced or provided and in which format.

The emerging technology for interface communications is XML (eXtensible Markup Language). XML uses HTML tags to enable the "definition, transmission, validation and interpretation of data". However, effort for this task should not be underestimated [21]. Significant resources may be required in analyzing sources from ERP and antiquated EDI systems. It has been suggested that 3rd party interface tools (eg. Informatica & Brio) can be used to ease the transition for these types of systems [21].

4.5 Developing new business processes

After conducting detail analysis of existing supply chain processes and identifying any inefficiencies and/or gaps in the process, a proposal should be created for the design of new processes. Not only should new processes cater for anticipated ISCM processing, but should be sufficiently visionary to accommodate for other strategic initiatives (CRM, Supplier Management, Knowledge Management).

The new supply chain should be modelled in a manner so that supply chain "blue prints" can be generated [21]. Tyndall et.al. [20] suggest an iterative approach to process design whereby a process is broken down into stages and then defined, analysed, executed, assessed and then re-defined. This cycle continues until the appropriate performance expectations have been achieved. This process can become quite complex and convoluted once organisations begin to incorporate back-end systems and the processes of other organisations.

Based on metrics determined during the initial business process review, goals should be set for process improvement.

4.6 Confirm Strategic Alignment

At the completion of most of the analytical work, It is important to revisit some of the groundwork that would have been completed during the planning phase activity in the traditional SDLC.

It has been included this framework to highlight the importance of ensuring an alignment between business strategy and expectations with the outcomes of the ISCM implementation – supply chain strategy is interdependent on the business strategic direction.

Analysts need to confirm that 'value' is being delivered through ISCM by conducting critical analysis on proposed benefits and costs to ensure that they are still realistic [20]. So as to prevent misalignment of resources and skillsets, analysts also need to confirm that the business problem can still be solved with its current complement of staff.

4.7 Implementing ISCM systems

This phase involves determining what activities will need to be undertaken to facilitate implementation of ISCM system – creating an action plan.

There are a number of factors should be considered in this final phase of the methodology such as setting up communication standards, developing business operation procedures, and establishing training programmes.

Furthermore, this phase should be expanded to incorporate activities that can assist in the detail analysis of implementation risk of the system. Conducting analysis in areas such as change management is one example. Inability to manage the implementation of change has been a key factor in project failure. Any enterprise systems place great strain on the organisation to adapt to

reap the benefits. Change Management involves more than simply conducting user-training programmes, but involves a continuing consultative relationship with end users to secure buy-in.

5. Conclusion and Future Challenge

This paper endeavours to propose an analysis and development methodology for ISCM systems. The discussion started with review and investigation of the current ISCM solutions and architectures, and identified a number of benefits, issues and problems regarding to the implementation of ISCM systems. Based on the examination of existing ISCM status, the proposed methodology for ISCM systems analysis is constructed by a seven-phase development framework. The methodology tends to illustrate a systematic roadmap for enterprises in developing ISCM systems.

The future challenge for enterprises in operating and maintaining ISCM systems stressed on the overall maturity of technological availability and the flexibility of business processes aligning with the ISCM architecture.

The Influence of Web Sites and Internet Advertising on Brand Memorability

K. Asoka Gunaratne
UNITEC Institute of technology
kgunaratne@unitec.ac.nz

Abstract

Internet advertising allows marketers to reach the mass market like any other medium that has preceded it. The two-way dialogue in the Internet permits the personalisation of messages making the promotion element of the marketing mix the component that has the greatest potential for transformation. Companies use a multitude of methods to advertise on the Internet the most common of which is the banner Ad. It is believed that when consumers like an advertisement about a brand they develop positive brand attitudes and willingness to buy the brand. A positive attitude towards a brand appears to improve the consumer's ability to recall the brand. Extending the paradigm of attitude towards the Ad to e-commerce Bruner and Kumar (2000) proposed that attitude towards the web site is positively associated with attitude towards the Ad, the brand and purchase intentions.

This study, therefore, was designed to discern the features of quality web sites, the advantages and disadvantages of web advertising, the influence of web sites on attitudes towards Internet Ads, and Ad recall. Focus groups and a questionnaires administered to 254 respondents were used to gather the required information.

The findings of the study, which include the quality features of web sites that encourage web surfer revisits, the advantages and disadvantages of Internet advertising, the effect of Internet advertising on brand evaluations and Ad recall, are discussed.

1. Growth of Online Marketing

The phenomenon of globalisation is being embraced by most countries and provides endless opportunities to many business enterprises. Innovative managers looking for unique ways to compete in this new environment are turning to technological advances in computers, telecommunications and Internet to make their business dreams a reality. Of the new technologies, the Internet, in particular, provides information on everything imaginable at a very low cost driving the global electronic market [20]. Internet has increased opportunities for firms to increase business by providing 24 hour access for shoppers supporting business across different time zones globally.

Although growing, there is no uniformity in the extent of online shopping across the globe. It appears many factors contribute to this discrepancy. The long tradition of catalogue shopping, faith in technology, and the distance Americans may have to travel to reach a store given the large size of the country, make online shopping more acceptable in America. However cultural influences such as the social values attached to shopping may be an impediment to the growth of online shopping in Asia and Latin America. The low usage of credit cards for shopping in many parts of the world probably restrict retail spending online in such countries.

Companies use e-mail, bulletin boards and interactive advertisements to expand their business through the Internet, which now represents a multi-billion dollar market. Internet enjoys global popularity for marketing as advertisements displayed on it by firms, individuals or organizations can be accessed by anybody with appropriate technology. The capability of the net to compile statistics help companies to track their advertising effectiveness in terms of its reach and frequency. These are some of the many reasons why businesses rapidly adopt Internet as an efficient and economical medium to conduct marketing.

The ease of access, and minimal regulation to go online is another formidable reason that helps to accelerate the rate at which businesses are connecting to the Internet. It allows companies to avoid the regulations and restrictions normally encountered by companies who physically enter other countries to do business. This proliferates the use of Internet for advertising and sales transactions by individuals and companies.

2. What are The Good Web Sites?

Electronic marketing grabbed the attention of commercial enterprises in the 1990s with the advent of the World Wide Web. Bhatt and Emdad (2001), predicting a rapid growth in online sales, forecasted that the value of goods and services traded via the Internet is likely to reach \$1 trillion in the year 2005 [2]. To boost online sales companies should make sure that their site is one of those consumers use prior to making a purchase decision. Online shoppers will visit again and again the sites where they have had positive experiences.

There are the good, the average and the poor web sites. Good web sites that induce consumer revisits contribute to the growth of company sales and profitability. The average and the poor are those designed the way technology dictates without due consideration to online consumer needs and behaviour patterns.

The foray into web site development by many companies is fuelled to a degree by the prospect of doing business online. An increasing number of organizations feel it is desirable for their companies to have a Web presence [9]. Often the justification for development of a Web site is to strengthen the company's competitive position [15]. Web sites developed for such a purpose should not neglect the needs of the audience for which they are developed. Niederst (1996) commented on the need for Web designers to have an understanding of the human-computer interface issues of Web design, which include its function, graphics, and the ease of navigation [18]. Chung (1998) argued that designers could avoid producing messy Web sites by acquiring navigational design skills [8]. The above studies, however, did not address well the issue of the features that should be built into Web sites to meet the user needs. A site that fails to meet its users' needs is unlikely to meet its business objectives. Nielsen (1998b) estimated that 90 per cent of commercial Web sites failed to meet the needs of the users [19].

To gather the required information on prices and the availability of alternatives, a consumer may visit two or three web sites prior to deciding to buy a product. If a web site cannot be accessed quickly, it is likely the buyer will move to another site that downloads faster. A Boston Consulting Group study has found that if a buyer cannot find a product within 5.8 minutes at a site, they move away to another [1]. The ease of navigation of web sites contributes greatly towards positive evaluations by online shoppers. Consumers visit again and again the sites where they have had positive experiences and find that browsing through these sites to gather information is easier and more pleasant than they expected.

A web site is considered to be the public face of a company and should showcase its content in the very best form to the target market. To maintain corporate image the in-built quality features of the web site must exceed customer expectations and outperform the competition. Many web sites continually disappoint customers and fail to meet their expectations. If firms are serious about online marketing they should present their product offerings to customers on user friendly web sites with interactive search utilities on each web page that guarantee easy navigation. The quality of search tools and the time taken to download a web page are two key reasons that influence the return of an online buyer to a web site [25].

3. Online Advertising

Traditional marketing is undergoing a noticeable transformation with the advent of the Internet. This new medium allows marketers to reach the mass market like any other that preceded it. It has an effect on all four components of the marketing mix. The two

way dialogue in the Internet permits the personalisation of messages making the promotion element of the marketing mix the component that has the greatest potential for transformation.

Revolutionary advances in technology have led to huge growth in the use of the interactive World Wide Web forcing marketers to re-evaluate the methods used for communicating with the target audiences. As a result, online advertising has now become an integral part of the communication strategy of most organizations. Tedesco (2000) forecasts online advertising sales to reach \$22 billion by the year 2004, [26]. Cavanagh (2000) reports that traffic to major portals such as Yahoo, Lycos, and AltaVista will increase by 20% by 2004 [6]. This will further foster the growth of online advertising. However, everything is still not bright on the Internet as only a small proportion of advertising dollars are spent on the Internet. But, it is forecasted to be a growing medium, which businessmen and householders will use increasingly for advertising and home shopping with continuing advances in technology [20].

There are many methods of advertising on the Web and Internet advertisements come in many different shapes and forms. New ones emerge everyday. Commonly available among the endless possibilities of online advertising are banner ads, buttons, rectangles, pop-ups, interstitials, sky scrapers, webmercials, e-mail, sponsorship, key words and links. Of these the most prominent method of advertising on the web is the banner advertisement. It provides a link to the company's web site and is usually placed at the top or the bottom of a web page. Full banner, half banner, square banner and vertical banner are some of the many forms of banner advertisements. Briggs and Hollis (1997) found banner ads to be effective in creating awareness and positive brand attitudes, even when e-commerce was at its infancy [3].

Marketers use entertaining or informative messages on the Internet to attract customers to their sites. The final objective of their efforts is to expose the customers to their brands or to strengthen their association or affiliation with the brands. A survey of 500 Internet users found that more people are attracted by informative messages than entertaining advertisements [14].

Companies use online advertising to create brand awareness, preference and choice. Even though companies spend vast sums of money on Internet advertising no universally agreed upon way has appeared to evaluate its effectiveness [7]. There have been very few systematic studies to determine the various dimensions of web advertising effectiveness [11]. Some have raised serious doubts about web advertising effectiveness and its ability to persuade consumers to buy [12]. Hwang and Kranhold (2000) criticised Internet advertising as nonsensical, uninformative, unfocused, forgettable and generally ineffective [13]. Others have described online advertising as ineffective due to low click through rates for banner ads, their dullness, lack of information, its offensive nature and also because at times it causes confusion [16] [5]. Rettie (2001) found that the

disruption in the flow or the enjoyment of using the Internet caused by banners, interstitials, pop-ups and other types of Internet advertisements can create negative attitudes towards online advertisements [21].

In spite of these perceived negative sentiments the impressive growth of consumers surfing the web suggests to companies that the Internet provides an expanding meaningful audience for the promotion of their products and services. Some have suggested that advertising on the Internet is effective because of the interactive nature of the medium [22], while there are others who have found the web Ads to have the potential to be as effective as the Ads in the traditional media [10].

When consumers like an advertisement about a brand they develop positive brand attitudes and a willingness to buy the brand. A positive attitude towards a brand appears to improve the consumers' ability to recall the brand. Mehta (2001) proposed that consumers who have positive attitudes towards an Ad are more able to recall a brand than those with negative attitudes [17]. Extending the paradigm of attitude towards an Ad to e-commerce, Bruner and Kumar (2000) proposed that attitude towards a web site is positively associated with attitude towards an Ad, the brand and purchase intentions [4]. This study, therefore, was designed to discern the features of quality web sites, the advantages and disadvantages of web advertising, the influence of web sites on attitudes towards Internet Ads, and Ad recall.

4. Methodology

The population from which the sample is drawn for this study is the Internet user. Due to difficulties encountered in obtaining a random sample, this study used a convenient sample of tertiary students in New Zealand who were Internet users. The author screened the students for their web use and their ability to remember being exposed to Internet advertisements. The survey questionnaire covered many aspects of Internet use. It included questions that examined which quality features of a web design induced them to visit and revisit sites, the advantages and disadvantages of Internet advertising, and measured the impact of respondents' attitudes towards web sites on attitudes towards the brands advertised, and their recall of web advertising. Additionally, it gathered demographic information on the respondents such as age, gender and ethnicity.

Using a focus group the author at first determined (a) the features of a web site that encouraged visits and revisits to the site, (b) the advantages and disadvantages of Internet advertising, and (c) the brand names recalled from the advertisements seen on the Internet. The approach used in this study was

adapted in a study conducted by Goldsmith and Lafferty (2002) [11].

The quality features of web sites identified by the focus groups were (a) excellent visual presentation of the site (b) attractiveness of web pages (c) moderate use of colour (d) an informative homepage that describes what a viewer may find in the website (e) a homepage that informs the viewer what they could do using the website (f) web pages that explain what they can find and what they can do (g) sites that provide convenient navigational aids in each page (h) accuracy of information (i) Web sites using familiar language (j) download time not excessive (k) clear links to different destinations and (l) easy manoeuvring between related pages.

The subsequent survey that covered 254 respondents evaluated the importance attached to the above features by the on-line purchasers. They rated their expectations on the above features on a 5-point rating scale where the end point "five" was labelled extremely important and "one" labelled not at all important. Their perceptions of the sites used were then recorded using a 5-point rating scale where end points were labelled "5-extremely satisfied" and "1- extremely dissatisfied".

From the focus group discussion on the advantages and disadvantages of web advertising emerged a list of 10 items that consisted of 6 advantages and 4 disadvantages. The 6 advantages were: (1) Easy to find information (2) Easy to make comparisons (3) Enjoyable information gathering (4) Fast decision making (5) Low cost information (6) Helps private assessment. The 4 disadvantages were: (1) Advertising too cluttered (2) Invades privacy (3) Boring (4) Irritating. The respondents to the survey were asked to indicate the advantages and disadvantages in the given list of 10 items that they have experienced when they viewed an advertisement on the Internet as compared to traditional media such as TV, radio and print.

One question asked the survey respondents to indicate how advertisements they had seen on a web site they liked influenced their views about the brand. They were given the following three choices. (1) Improved the evaluation of the brand (2) Had a negative effect (3) Had no effect.

To measure top-of-the mind awareness or ability to recall an Ad, which is an important component of advertising effectiveness, the dependent variable recall of web advertisements was operationalised using a list of 10 brand names (International and New Zealand owned) selected from the focus group study. The respondents were asked to select from the list the brands they could recall seeing on the Internet.

5. Results and Discussion

A total of 254 students completed the questionnaire. The sample consisted of 52.3% males and 47.7% females. Most of the respondents (81.2%) were under 35 years of age.

The positive paired mean differences and the p-values = .000, for 6 (pairs 3, 6, 7, 9, 10, 11) of the 12 items measured (Table 1) indicate that the perceived level of satisfaction of online purchasers is much lower than their expectations for those important quality features of web sites. The high mean expectation values (over 4.6) for excellent visual presentation (Table 1: 4.66),

and moderate use of colour (Table 1: 4.70) confirm that visual presentation is an undeniably important element of a good web design. Many people still use a web site as a source of information, therefore, there is no substitute for accurate content in a web site. Accuracy also refers to the availability of up-to-date information. This is reflected in the high expectation mean value of 4.97 attached to accuracy of information (Table 1).

Table 1 – Mean Levels and Mean Differences of Expectations and Perceived Satisfaction regarding Web Sites

Feature	Mean Level of Expectations	Mean Level of Satisfaction	Paired Mean Difference	Sig (2-tailed)
Pair 1 – Visual presentation	4.66	4.76	-.1	.041
Pair 2 – Attractive web pages	4.59	4.61	-.02	.601
Pair 3 – Moderate use of colour	4.70	4.28	.42	.000
Pair 4 – Informative home page that describes what the viewer may find in the Web site	4.47	4.60	-.13	.013
Pair 5 – Homepage that informs the user what they could do using the Web site	4.55	4.68	-.13	.006
Pair 6 – Accuracy of information	4.97	4.67	.30	.000
Pair 7 – Web pages explain what they can find and do	4.22	3.91	.31	.000
Pair 8 – Sites that provide convenient navigational aids in each page	4.51	4.53	-.02	.716
Pair 9 – Web sites using familiar language	4.52	4.29	.23	.000
Pair 10 – Download time is not excessive	4.96	4.55	.41	.000
Pair 11 – Manoeuvring between different pages made easy	4.33	3.93	.40	.000
Pair 12 – Clear links to different destinations	3.65	3.80	-.15	.036

Most people prefer fast loading web sites (Table 1: expectation mean value = 4.96). The results of the regression analysis (Table 2: $t = 10.840$, $p\text{-value} = .000$) suggest that “download time not too excessive” is significantly related to overall customer satisfaction. This implies the need to design web pages that download in an

acceptable time period through a slow connection, and nearly instantly on a fast connection, as suggested by Rowan (2000) [23]. Sending less data is the key to building a fast loading web page. Reducing the size of the graphics file and building relatively small web pages that connect to the larger web site through hyperlinks are methods recommended to accomplish this.

Table 2 - Results of Regression Analysis – Importance of Quality Features of a Web Site on the Overall Satisfaction of Online Purchasers

Multiple $R = 0.853$ $R^2 = 0.728$		Sum of Squares	Mean Sum of Squares	F	Significance
Adj. $R^2 = 0.711$	Regression	42.296	3.525	41.93	.000
SE = 0.29	Residual	15.803	8.406E-02		
No.	Feature	B	Beta	t	Significance
1.	Accuracy of Information	.541	.475	10.704	0.000
2.	Download time is not excessive	.439	.467	10.840	0.000
3.	Site that provide convenient navigational aids in each page	.147	.147	3.474	0.001

Significant at the 0.05 level

Dropping a GIF file from 256 to 129 will not reduce the size of the image file but sizeable savings can be achieved by dropping from 129 to 128 colours (Sullivan, 2000). Meaningful file size savings can be achieved at 16, 32, 64, or 128 colours. JPEG, a graphic compression technique, enables images to be compressed into a fraction of the original size. All of these will help to reduce the download time.

The other predictors that are significantly related to overall satisfaction are accuracy of information (Table 2: $t = 10.704$, $p\text{-value} = .000$) and the provision of convenient navigational aids (Table 2: $t = 3.474$, $p\text{-value} = .001$). This suggests the firms that provide accurate information could significantly increase customer revisitations by incorporating appropriate navigational aids to ensure that visitors can easily find the useful content on the site. An approach to achieve this is developing Web pages that convey a clear message, which enable visitors to navigate easily, logically, and effectively through the use of buttons, arrows and text.

The results of a regression analysis of the quality features of web sites against the perceived satisfaction of online purchasers, suggest that the "12 item - predictor model" explains 71% of the variance (Table 2: adjusted $R^2 = .711$) of the overall satisfaction rating.

5.3 Advantages of Web advertising

"Easy to find information" was the advantage of web advertising most often checked (61.8%, 157 respondents) by the participants. In the second place was "low cost of information" (50.8%, 129 respondents). Eighty eight (34.6%) respondents selected "fast decision making" as an advantage of advertising on the Internet as compared to other media.

A t-test was conducted to compare the mean number of advantages reported between the two groups that reported that visiting web sites "improved their evaluation of the brand" and those who reported "no effect". More advantages were checked by those who reported, "improved their evaluation of the brand" (mean = 3.2, SD = 1.6) than those who said "no effect" (mean = 2.1, SD = 1.7). A p-value of 0.001 for the t-test suggested that the between group difference was statistically significant.

When the "improved their evaluation" and "no effect" dichotomy was tested using cross tabulation, it was found that the first group disproportionately endorsed the advantages, "easy to find information" and "low cost of information".

5.1 Disadvantages of Web advertising

"Advertising too cluttered" was reported most often (40.9%, 104 respondents) as a disadvantage of

advertising on the Internet. This was followed by "invades privacy" (36.6%, 93 respondents).

The disadvantages reported by the two groups ("improved their evaluation of the brand" and "no effect") were compared using t-tests. A p-value of 0.002 indicated that the difference between the two groups was statistically significant. The group that reported "improved their evaluation of the brand" (mean = 1.4, SD = .61) checked more disadvantages than the group that found "no effect" (mean = 1.1, SD = .64).

5.2 The impact of attitude towards the web site on attitude towards the brand advertised

Of the 254 respondents, 45.7% (116 respondents) agreed that viewing a brand on a web site they liked improved their evaluation of the brand. Fifty per cent of the respondents (127) confirmed that liking a web site had no effect on a brand. According to eleven respondents (4.3%) viewing a brand on a web site had a negative impact on the brand. The majority (243 respondents) response was that web sites they liked either had a positive effect or no effect on the brand advertised.

5.4 Ad recall

A between group study was made on Ad recall using t-tests. The two groups compared were, those who reported that visiting web sites "improved their evaluation of the brand", and those who reported it had "no effect". P-value of 0.001 indicated that there were significant differences in Ad recall capability between the two groups. The recall of advertisements by the "improved their evaluation of the brand" group (mean = 4.3, SD = 1.9) was significantly higher than the recall by the "no effect" (mean = 3.1, SD = 1.8) group.

6. Conclusions

The results of this study have implications for both Web developers and companies who plan to boost online sales by encouraging their customer revisits. This study has established support for the view that visual presentation of Web sites is an important determinant of online customer satisfaction. It will, therefore be beneficial for online marketers to make a deliberate effort to design more inviting Web pages by improving their visual presentation. As too many colours and loud backgrounds are likely to clutter the interface to the dislike of online purchasers, companies could seize greater opportunities to please their customers by taking these factors into account when designing their web pages.

The study has also found accuracy of information to be an important predictor of online buyer revisits. To online marketers this will mean the development of systems and

in-house procedures to carefully upgrade and scrutinize the data at regular intervals to guarantee accuracy. Many online shoppers make in-depth price comparisons before switching retailers at a mouse-click and would inevitably look for accurate price information at each Web site. A more important issue is a buyer's inability to evaluate first-hand the quality and benefits of the products purchased online due to lack of opportunity to physically see and touch them. Under such circumstances, the authenticity of information becomes paramount. Additionally, the Internet allows companies to enter into a dialogue with their customers, and the accuracy and the speed of responses will determine the customers' comfort level to revisit the sites.

Effective Web sites that have accurate content, should ideally complement this with easy navigation and high-speed downloading to further stimulate customer revisits. Online buyers want control over what they do on the Internet. They appreciate every navigational support provided to them. Companies, in order to make navigation a pleasant experience resort to the use of multiple approaches. GIF animations, which are fun when first seen, can be annoying when they delay downloading. Online marketers, therefore, to avoid irritating the online customers need to consider their use wisely.

The companies that continuously innovate to stay ahead of competition in the above areas are likely to be more successful in encouraging customer revisits. Such improvements, which translate acquisition and analysis of information into a pleasant experience, will eventually contribute to gaining quick payoffs on Internet investments.

Respondents reported on both advantages and disadvantages of advertising on the web. Most respondents reported that advertisements on the Internet enable them to get information easily at a low cost. The main disadvantage reported was the clutter of Internet advertising. This suggests that, in spite of its many advantages, marketers still need to deal with the clutter of Internet advertising to improve customer evaluation of the brands advertised on the Internet.

The advertisements on the web sites consumers like appear to improve the brand evaluation of some consumers. A negligible number reported a negative impact after viewing an advertisement for a brand on a web site they liked. This suggests that advertising on web sites mostly contributes to enhancement of brand evaluations.

Another positive finding of the study is that consumers, who enhanced their brand evaluations after seeing an advertisement on a web site, appear more likely to recall the Ad. It may be that good web sites help to improve the memorability of the brands advertised on the web.

A key weakness of the study was the use of a convenient sample, which makes generalisations inappropriate. Another important issue was the restriction of participants' responses to specific questions. This may have reduced the extent of exploration of some issues considered as important by the participants. Nonetheless, the results of the study have provided useful information on web site development and Internet advertising to those interested in e-marketing.

Abstract

Firms can create additional customer values by changing the visibility characteristic of business transactions. Both visible and invisible transactions can provide distinctive values to the customers. Visible transactions are those that are open to the customer: the customer can see the detailed logic of the transaction and may manipulate specific variables to control the transaction process. Invisible transactions mean that customers have little ability to control the transaction flow and may even be insulated from seeing the transaction.

This paper pursues finding out the contingencies of successful transaction visibility change by answering to the following question; “when does increasing (or decreasing) transaction visibility make sense to customers?” This archival case study finds out that transaction visibility change should fit to the need and capabilities of customers. Increasing transaction visibility makes sense when customers need a certain supplier’s performance and have a confidence in the capabilities of executing the performance. And, decreasing transaction visibility makes sense when customers have substantial troubles in conducting their current transaction actions or when customers don’t feel it necessary to conduct them separately because they can be derived from other action.

1. Introduction

Computers have taken large part in facilitating business transactions. Electronic commerce has evolved in various physical forms from automatic teller machine, to electronic data interchange, and to World Wide Web over Internet. The big change caused by recent Internet-based electronic commerce is the lethargy of traditional intermediaries (travel agents, car dealers, stock-brokers, and industrial-parts distribution). Their turf has been intimidated by the birth of new Web-savvy middleman (like Amazon.com, Buy.com, etc.) and the direct connection has been promoted between end-customers and producers. Hamel & Sampler [12] argued that Internet is shaping re-intermediation not dis-intermediation of retailing industry and asked retailers

to move close to their customers instead of awaiting customers to move to them.

This study proposes a new perspective regarding the role of visibility characteristic of electronic transactions, which has substantial implications for new roles of intermediaries in the electronic environment. The customers come to possess different visibility on new transactions using new electronic media: customers can see more of what they want to bother with during transactions, and also customers can pass to their counterparts what they don’t want to bother with during transactions.

This study makes a couple of contributions. First, this study calls attention to the fact that, during visualizing the underlying actions, information technology can also make some relevant actions invisible. For example, by exposing sales record to vendors, grocery stores can eliminate some transaction actions like writing purchase order or making calls to order. So, people can garner two different (actually, opposite) benefits from the visualizing forte of information technologies. Second, if information technology has double-faced forte regarding visibility, we may well investigate the appropriate conditions for successful transaction visibility change (i.e., increasing or decreasing visibility). Our research question is “when does increasing (or decreasing) transaction visibility make sense to customers?” The answer to this question can help the business organizations “implement” successfully their plans to increase customer values by changing transaction visibility.

2. Theoretical Background

2.1 Transaction

Transaction can be defined as “the act of doing business” (The American Heritage Dictionary, 2nd edition). People conduct a transaction when they need certain performances of others in achieving desirable outcomes because they don’t have enough capacity to conduct these performances by themselves. From the perspective of transaction cost economics [18][19], transaction is not

necessarily confined to the moment when two counterparts conduct the economic exchange.

2.2 Transaction Visibility

Visible transactions are those that are open to the customer: the customer can see the detailed logic of the transaction and may manipulate specific variables to control the transaction process [1]. *Invisible* transactions are those that customers have little ability to control the transaction flow and may even be insulated from seeing the transaction. These invisible transactions will be taken care of only by suppliers, and be regarded as an aspect of suppliers' performances. Thus, transaction visibility can be defined as the degree to which the detailed logic of transactions is open to view and subject to manipulation of customers. It determines not only the amount of *information* about processes, but also the *capability for interacting* with these processes.

2.3 Changing Transaction Visibility

Chatterjee [5] argues that by changing the visibility of business processes from the standpoint of customers, organizations can provide distinct values to their customers, and improve their competitive advantage. Changing visibility from the customer's standpoint takes only two "binomial" forms at the level of transaction components. However, visibility change at the whole business process level is "continuum": i.e., the visibility of the whole business processes can be *increased or decreased* by *making* some components of the processes *visible or invisible*.

Making transactions *visible* invites customers' participation, empowers the customer, and thereby facilitates the customers' self-fulfillment. According to the concept of encapsulation in the object-oriented perspective, *making visible* means moving some of the supplier's implementation activities into the interface of customers (making the scope of interface wider). An example of making visible is Toyota's (in Japan) IS by which customers choose and specify the attributes of their cars as if designing them. Making transactions *invisible* relieves the customer from participation and thereby delivers a sense of freedom to customers. From the perspective of object-orientation, *making invisible* means transferring some portions of the interface to the implementation domain of suppliers.

Two different types of making invisible were identified: connecting the relevant or subsequent services, and eliminating the contact point function from customer's standpoint. The first pattern of making invisible is connecting relevant or subsequent services to the customers' contact point processes by "packaging" some activities within a visible activity. Therefore, if certain transaction actions are related to other actions as derivatives, those derivative actions may well be embedded into the primary actions. For example, filing purchasing orders is a

derivative action when inventory goes down below a certain level. However, inventory level can be calculated derivatively from sales record and purchasing record. Connecting all these relevant actions and minimizing separate transaction actions are the key art of this type of making invisible. The second way of making invisible is more aggressive. It relocates the contact point with the customer further up-stream in the process and eliminates day-to-day customer involvement completely. A typical example is the inventory management system linking Proctor & Gamble (P&G) and Wal-Mart.

3. Influential Factors on Transaction Visibility Change

According to the theory of self-efficacy [2], people take action when they expect given actions to produce desirable outcomes and believe that they can conduct those actions [2, p.24). This theory provides two "conditions" for customers to accept more visibility in transactions: 1) customers' *need for supplier performances*, and 2) customers' *capabilities* in those *supplier performances*. If both of these conditions are satisfied, customers could be better off by being provided more information or by being allowed more participation in what suppliers do. If customers do not need certain supplier performances, customers may not want to bother with transactions. Besides, it may not be appreciated to customers if suppliers try to increase visibility of their performances that challenge customers' current capabilities.

3.1 Customers' Need for Supplier Performances

Why do customers need certain supplier's performances? A performance is desperately needed by customers when the outcome from it is *desirable*, especially when the outcome is critical for customers' overall business. If people believe some information is critical for their businesses, they may intend to even pay money for it. This kind of information can be sold unlike the information that just supports on-line trade [9].

Another reason why customers need a certain performance is that it is *very likely to produce* the desirable outcome [2]. There is no single relationship between performance and outcomes: it depends on how tightly contingencies between performances and outcomes are structured [2, p.23]. If outcomes are not responsive to performances, people turn to protest social practices or to be apathy to such an outcome.

In short, customers may need certain suppliers' performances if customers believe suppliers' performances are critical for their survival, and that those performances are sure to produce desirable outcomes. If anyone of these two conditions is not met, customers may be hesitantly in need of such performances.

3.2 Customers' Capabilities in Supplier Performances

Psychological involvement triggered by necessity does not necessarily mean physical participation, as Barki and Hartwick [3][4] called attention to distinguish between involvement and participation. Bandura's [2] theory of self-efficacy applies here. According to the self-efficacy theory, action occurs when people have high self-efficacy that means the confidence in one's ability to organize and execute given types of actions [2, p. 21]. Asking incapable customers for more participation can work adversely because it only increases customers' frustration with transactions. In this case, suppliers can reduce customers' uncertainties and frustrations by relieving them of the burden of performing those actions. However, if customers have enough capabilities in certain actions, suppliers can improve customers' satisfaction by allowing them more interactions to manipulate and customize the products. A couple of issues need to be elaborated to clarify the concept of the capability in performances.

First, in the context of mutual relationship, the capability in performances should be judged in the *relative* terms: i.e., who is more capable, supplier or customer? It means not just who can do it, but also who can do better. The concept of core competency [11] may fit to this issue. Second, if customers have to endure huge cost inefficiencies in getting new access to supplier performances, they may not believe they possess enough capabilities to run the new change. Therefore, capability is a comprehensive concept that contains various economic concerns in the *present* and *future*.

The following proposition relates to the conditions of increasing visibility.

Proposition 1. It makes sense to increase visibility of the supplier performance actions, when customers need supplier's performances and also when customers have capabilities in those supplier's performances.

Proposition 2. It makes sense to decrease visibility of the transaction actions that customers do not have enough capabilities or that they do not need.

In general, the model suggests that increasing transaction visibility may be a preferred mode. The main reason is that knowledge emerges as the critical asset in an organization's survival and progress [15], and that knowledge acquisition or sharing can be facilitated by making transactions more visible.

Figure 1. Research Model:

4. Research Methodology

This study takes the case study method to test the propositions generated in the previous section. The cases will be addressed in the narrative forms, so-called in linear-analytic structure. Linear-analytic structure [21] is the standard narrative presentation, which is providing model, hypotheses, and analysis of pattern-matching.

For the number of cases, Yin[21] recommends multiple cases unless a single case is available which is critical, extreme or unique, or previously inaccessible. Through literature review of ABI/Inform and Lexis/Nexus databases, 12 cases were chosen. These 12 cases have been regarded as representative successful SIS cases. They have been reported, cited, and updated extensively through many publications.

Pattern-matching is the most fundamental and powerful strategy for the analysis of case evidences [20, 21]. Pattern-matching compares an empirical pattern with a predicted one (or with several alternative predictions). Ideally, the comparison between rival theories is the most convincing strategy because most case studies eventually aim at identifying which rival theory can explain best the empirical patterns. Rival theories can be either a null hypothesis or an alternative theory. The rival theory of this study is the null hypothesis which means that visibility change occurs by luck or without any regularities. Pattern-matching will be conducted in a valid way, minimizing personal subjectivity in interpretation.

For the sake of valid data interpretation, five more people were hired to make judgments about the propositions at each case. All of them were MBA students at a management school of New England area who have majored in MIS for the last two semesters. Three of them were males of mid-thirties (one Korean, one American, and one Mexican), and two of them were female Chinese students of mid-twenties. Each student was assigned to each one of the five different cases. They were given the brief illustration of research model, and had enough conversations with the first co-author to clear their understanding of the model. And then, cases were given to them with brief explanation of each case. This workshop took about 20 minutes for each person. They were asked to read those cases very carefully, and to assess each proposition at each case. All of those five MBA students were allowed to have a week before we get together to have intense discussions.

Meetings with each student occurred between 7-10 days later, and lasted for about 40 minutes in average. Discussions were focused on the evidences that help assess the propositions of each case. This discussion is expected to decrease the subjective or ungrounded arguments about the support of each proposition.

5. Case Profiles

5.1 Cases of Increasing Visibility

5.1.1 Airline Reservation Systems

The airline reservation systems provide a case of increasing visibility, which opened the internal management information of airline companies to their customers, travel agencies. Travel agents needed to streamline their transactions with airline companies because they had to deal with abundant air-flight information in a very efficient way. Due to the Airline Deregulation Act of 1978, travel agents could not maintain their conventional ways of transaction practices for airline reservation because the Deregulation opened up pricing competition and made travel agencies swamped with too much information about airfares and schedules. Effective and real-time reservation of air-flight seats became critical for the business of travel agency. Even after the Deregulation rule, travel agencies were still familiar with what airline companies were providing over the information systems. In other words, travel agencies could still give consults or connect flights for their patrons to satisfy idiosyncratic travel schedules and styles. Travel agencies just needed some efficient instrument that helps deal with abundant air-flight information and reserve air-flight seats. Airline companies were able to satisfy these needs of travel agencies by exposing their internal management information of air-flights to travel agencies.

5.1.2 The Union Bank Of Finland (UBF)

UBF launched the first electronic banking system (EBS) in Finland, which covered the entire range of banking operations. Using a chare card, customers could access from any terminal linked to the public banking services network. Through electronic banking, it was possible at any time to pay bills, transfer funds from one account to another, and monitor the status of accounts. After banking hours, information could also be accessed regarding the status of loans. Stocks and shares services were also available, including the instructions for buying or selling, and the real-time access to share indexes and company information. For the personal clients, ATM (Automatic Teller Machine) services can also take some credit in improving business efficiency. Collaboration among the Finnish banks in the use of ATMs was also progressing: by 1990, all the banking chains in Finland joined a single network.

The UBF case provides an example of increasing visibility, which allowed patrons to manage various financial accounts and financial transactions in person. The patrons of UBF used to go through intermediary clerks in conducting transactions. UBF recognized the reengineering the entire operating processes by information technologies could help the organization not only by reducing its operating costs, but also by improving its service to customers. The new reengineered process was to replace

manual works of staffs with computerized self-account maintenance by customers. Customers could benefit from this change because they needed banking services anytime (even after banks are closed) and effectively. Customers already knew where to use their money (such as on stock investment and on various other financial products), and how to manage their account (such as balance management, paying money by gyro). To these customers, it made sense to pass the responsibility of managing account from UBF to customers.

5.1.3 Federal Express

FedEx Ship allowed customers to complete entire shipping transactions electronically from their desktop PCs, including printing out the shipping labels. In November 1994, FedEx launched its Internet home page (<http://www.fedex.com>) on the World Wide Web that allowed customers to check the status of a FedEx package over the web. In 1996, the company introduced FedEx InterNetShip, the first automated shipping transaction available on the Internet. By entering a valid FedEx account number, customers could complete the entire shipping function directly from the Web page. That included preparing all paperwork on-line, printing a bar-coded label, scheduling a courier pick-up, and uploading the billing information to FedEx. The site also enabled users to download FedEx software such as FedEx Ship, FedEx Tracking software, or FedEx Document Preparation software.

The FedEx case provides an example of increasing visibility, which allowed FedEx's patrons to check out the package delivery status. Since the inception of its business, FedEx managed to check the delivery status at every node of logistics chain for internal management purposes using sophisticated information systems. Capabilities required for this transaction (i.e., checking out the delivery status by getting access to information systems) are not that hard for customers: i.e., they just had to remember their delivery service ID number. Therefore, it really made sense to customers if they are allowed to access to the delivery information systems directly.

5.1.4 Dun & Bradstreet (D&B)

D&B began developing electronic delivery systems in 1976 to give customers direct access to the data-base and to increase revenue. In 1978, the company announced the first of these services, DunsDial. DunsDial allowed subscribers to call an 800 number and get on-line access to the database through an operator. To bring the electronic message directly to users' desk-top computers, D&B developed DunsNet, a packet-switched telecommunications network that became available in March 1985. The system originally targeted financial departments. Using this network, subscribers could pull reports from the D&B's mainframe to the remote terminals through DunsPrint.

The D&B case provides an example of increasing visibility, which allowed their patrons to get in and manipulate their data. Patrons depended on D&B for business credit and financial information. They appreciated the data mines that D&B stored, but not the ways D&B reported to its patrons. D&B used to satisfy their customers by collecting huge amount of data and generating report in a certain format. Customers just received the report that they wanted, but the contents and format were decided by D&B. Customers, most of whom were financial departments, already knew what kind of data they needed. Therefore, the best way to resolve their dissatisfaction was to allow direct access and manipulation of data. To maximize its change, D&B itemized data rather than bundling data at the report level.

5.1.5 National Bicycle Industrial Company (NBIC)

The first mass customization factory was built in 1987 and named the Panasonic Ordering System (POS). This factory was directly linked to customers via retail outlets. The factory directly received a customer's selection of options, colors, patterns, and models. The firm estimated that a customer could choose from about eight million possible variations based on model types, color, frame size, and other features. In this factory, the production process began only after the arrival of the customer's order and specifications. Craftsmen on the factory floor were very agile in setting up each machine required to complete each order. Customer service, appropriate pricing, and extensive communication had to be all an integral part of the NBIC's mass-customization strategy.

The NBIC case provides an example of increasing visibility, which allowed their customers to design bicycles in person. Customers needed to purchase bicycles that fit to their preferences in terms of style, color, size, and features. Some proficient customers had to shop around the market or spend substantial amount of time by intense searching until they could find what they wanted. NBIC did not lose this niche and developed an information system that allowed customers to design what they wanted. This new business process was not possible if NBIC was not equipped with flexible manufacturing capabilities to deliver the item in 2 weeks. NBIC had manufacturing capabilities, and customers knew what they wanted. The new business process was arranged to take advantage of relative strengths of both sides. Therefore, it made sense to open designing module to customers.

5.1.6 Netscape: Software Giveaway

Netscape announced that it would post the Communicator source code on the Web under the aegis of a Netscape developer group known as Mozilla.org. on January 22, 1998. Netscape's giveaway had only one major condition: Anyone who downloads the code and modifies it has to make his or her modifications available to Netscape and the world. Developers would now be able to

modify Netscape's code and incorporate it into their own products. In return, they would be required to submit all modifications to Netscape so that Netscape could decide which changes to be incorporated into the next official Communicator release. The software giveaway was a bold effort to stave off failure by tapping the energy of tens of thousands of technologists, inside and outside the company, who were loyal to Netscape's products.

To manage the process of incorporating outside work, Netscape set up an internal team called Mozilla and posted its source code on the mozilla.org Web site. In mid 1998, the group consisted of eight engineers (six developers, one IT person, and one tester) and one customer support person. Most contributions from outside developers were features or bug fixes on existing features. In those cases, the Mozilla team consulted with the original Netscape developer or the current Netscape person overseeing that area for the check-in. Three senior developers on the Mozilla team made most of the final decisions on whether or not to accept an outside contribution to the code.

Netscape retained the rights to the Netscape, Navigator, and Communicator brand names and logos, as well as the rights to distribute future products based on the code. But others could now build or distribute their own browsers based on Netscape's source code. And unlike most other free software, Netscape allowed companies to sell products based on the modified or unmodified code. The Mozilla Public License was free forever.

Software developers apparently welcomed this move, downloading some 250,000 copies of the Communicator 5.0 source in the first month. Moreover, Microsoft's decision to tie Internet Explorer more tightly to the Windows operating system in 1998 made it virtually impossible for Microsoft to respond in kind. If Microsoft revealed its source code for Internet Explorer, it would risk undermining its proprietary technology in Windows.

The Netscape case provides an example of increasing visibility, which opened the source programs and allowed patrons to customize the programs. There were many computer geeks who love to manipulate the source programs to customize them to their applications or systems. A couple of well-known cases (Apache and Linux) encouraged Netscape to open their source programs of Communicator 5.0. Customers already appreciated the innovation of Netscape, and had enough capability to customize the programs. Therefore, Netscape's decision to open the source codes off Communicator 5.0 was welcome by the customers. This new business process cannot succeed if patrons do not have enough capabilities to customize the source codes of Web browser.

5.2 Cases of Decreasing Visibility

5.2.1 ASAP (Analytic Systems Automatic Purchasing)

AHSC (American Hospital Supply Corporation) was a health-care distributor company and ran the ASAP system (Analytic Systems Automatic Purchasing). ASAP was

initially developed in the 1960s to solve AHSC's operational problems, such as incomplete orders and late delivery, especially with one of its major customers, Stanford Medical Center. By 1980, a quarter of the company's incoming purchase orders came through ASAP. After Baxter bought out AHSC in 1985, Baxter transformed ASAP to a multi-vendor universal distribution system and competed with other electronic distribution channels. The ASAP system eventually transformed into strategic collaboration with its customers, redefining the conventional relationship with customers.

This strategic transformation was marked by the deployment of Baxter's ValueLink program in 1990. The focus of information systems shifted from the efficient distribution of products through automated order entry toward the integrated materials management service to guarantee product availability and information-based logistics services. Previously, customers of Baxter (i.e., hospitals) had to check out inventories, search for appropriate items over the market (or computerized ordering systems), make orders, and wait for deliveries. All these transaction actions became eliminated by JIT (Just-in-Time) inventory systems of Baxter. Baxter committed to providing a 100 percent fill rate and to lowering inventory levels, associated operating, and fixed costs by developing customized delivery procedures to each user department (e.g., operating rooms, laboratories, X-ray units, etc.).

ASAP provides a case of decreasing visibility, which passed the burden of inventory management of certain brands to the supplier, Baxter. The customers of ASAP, hospitals, still concerned about inventory management, but did not sway a good command of it. They had to deal with too much information of products after many rivals of Baxter (such as Abbott, 3M, and Johnson & Johnson) withdrew from ASAP and launched open-protocol information systems. The economic logic for the inventory management had shifted from economies of scale (i.e., automating the purchasing order activity) to economies of scope (i.e., customized materials management), which required more intensive information searching and management. In addition, hospital did not feel the value in traditional ways of inventory management such as checking out inventory levels, writing and mailing purchase orders, and inquiring order status. Those transaction actions were regarded cumbersome, time-consuming, and non value-added. Hospitals were lack of capabilities to manage inventories in new business environment but also could not sustain the old methods. By the new change, inventory management was passed from hospitals to their supplier, Baxter.

5.2.2 McKesson Corporation

Economost was launched in 1976, and was the genesis of McKesson's family of information systems. It was an electronic system for direct customer order entry, but also helped pharmacists and drugstore operators keep track of

current selling records, reorder the right time, and have their orders delivered with the price and shelf location tagged on the products.

Customers of Economost systems made orders by a hand-held order entry device, noting from the available stock on his shelves. Customers transmitted the order information in hand-held device to McKesson's national data center. The same or following day, McKesson delivered the items ordered. The requested items were delivered in cartons that matched the aisle arrangement and major departments of the drug store, so no sorting was required and the shelves were restocked with a single pass. Electronic order entry was extremely welcome by McKesson's retail customers, well evidenced by the fact that more than 99% of McKesson's orders came in electronically.

The more dramatic improvement was opening McKesson's up-to-date sales information to its suppliers. McKesson recognized that the up-to-date sales information had immense value to the manufacturers. They used it to make more timely shipments to McKesson in much the same way as McKesson had done with the drugstores. Meanwhile, suppliers could schedule production more efficiently and streamline their inventories. This new system eliminated previous transaction actions of McKesson's customers (drug-stores): checking out inventories, making purchasing orders, and inquiring delivery status.

McKesson provides a case of decreasing visibility, which passed the burden of inventory management and insurance claim from McKesson's customers to McKesson's suppliers. Customers of McKesson – independent retail drugstores – did not feel the value in traditional ways of those two processes.

The more capable approach for inventory management came from McKesson's JIT (Just-in-Time) that restocks products at the last minutes when customers' inventory was almost gone. This new system could be completed by the involvement of McKesson's suppliers because it is McKesson's suppliers who actually manufacture and deliver products. McKesson's suppliers used to be segregated from their end-consumers (independent retail drugstores), and could only reach them by the mediation of McKesson.

5.2.3 Wal-Mart and Procter & Gamble (P&G)

1987 was the big year for both Wal-Mart and P&G to launch this remarkable project for streamlined inventory management systems. In the early 1990s, the project was finished and started to produce tangible benefits to both companies. EDI took an important part in P&G's strategy of CRP. But EDI alone could not take the whole credit in improving this process because the organizational linkage was much tighter than the relationship with non-CRP customers using EDI. In 1992, Wal-Mart declared to do business only with vendors that invested in customized EDI

(electronic data interchange) technology and put bar codes on their products. Because of the volume and growth Walmart delivered, manufacturers had little choice but to fall into line. The combined changes in systems, strategy, organization, and policies also resulted in a dramatic improvement in total order quality at P&G. Billing errors decreased by more than 50% from 1992 to 1994, and the percentage of billing disputes resolved to P&G's favor increased by more than 300% during the same period.

The Wal-Mart and P&G case provides an example of decreasing visibility, which passed the burden of inventory management from Wal-Mart to P&G. In 1987 when Wal-Mart and P&G started to discuss and embark on their JIT inventory systems, Wal-Mart did not possess such a fabulous inventory systems. Eventually, Wal-Mart could improve their inventory management system by asking P&G to take over this responsibility. Until 1987, P&G was only reactive to the request of Wal-Mart. To implement JIT successfully with Wal-Mart, however, P&G needed access to the sales and inventory information of Wal-Mart.

5.2.4 Saturn

The Saturn Dealer Information Systems is a network of several subsystems: SALESLINE, SERVICELINE, and various transaction processing systems. With SALESLINE, the salesperson can use a microcomputer to connect to other dealerships computers and search their inventories for the desirable car and features. SERVICELINE allows customers to promptly receive information about anything that has to do with the car: new or used cars that the customer may want to purchase; service for the current vehicle; the availability of a car with specific features; and the availability of a certain part.

SALESLINE also provides the dealers with inventory management services similar to MRP. The dealers can carry only minimum levels of parts for serviced cars, because they can connect directly to the parts factory via satellite. Through the inventory information systems connected directly to suppliers, dealers could place replacement orders automatically when those parts were running low. Suppliers received daily electronic transmissions regarding how many parts had been used in completed cars, and once a month received payment over the electronic network. The formula of the system was simple: no purchase orders, no invoices, no checks, lots of trust. There was huge cost saving such as no receiving department and no clerks to handle purchase orders, invoices, and billing. And with everything done electronically, audits were simplified. By such partnership, Saturn could reduce the purchasing cost by 5% annually.

The Saturn case provides an example of decreasing visibility, which passed the burden of inventory management from Saturn to its suppliers. U.S. car manufacturers needed the function of inventory management, but did not like the traditional ways of inventory management. In other words, car manufacturers

could not maintain robust inventory management systems with the traditional capabilities. They learned from Japanese companies that JIT (just-in-time) technique can improve the inventory management function substantially.

5.2.5 CMA (Cash Management Account)

Merrill Lynch offers a broad range of services to meet the financial and investment needs of individuals, corporations, and institutions. Merrill Lynch made an arrangement with Banc One Corp. in 1976, a processor of Visa card, to expand and diversify its business domains. In 1977, Merrill Lynch announced its innovative Cash Management Account (CMA), an information-system-based product that provided under one umbrella three appealing services to investors: credit service through a standard margin account; cash loan by check or Visa debit card; and stock investment for dividends and transaction margins. This product can relieve patrons from the traditional transactions for financial account management: withdrawing and depositing money clumsily and repeatedly.

This one-stop account let a qualified person, who could afford to open an account with \$20,000, enjoy a combined checkbook and securities margin account. For \$4.17 a month, an account holder could buy and sell stocks, write checks with no minimum, and use a supplied credit card under the CMA umbrella. CMA account holders were given checks with a Banc One code number, even though they did not actually have an account there. CMA account holders could have their checks processed by Banc One. But it was not the bank that actually cancelled the checks, only Merrill Lynch did for Banc One. Merrill Lynch maintained a zero-balance account by borrowing money daily to cancel the millions of dollars of checks. All transactions appeared on one monthly statement. And all cash in the account earned money-market rates. The computer swept daily through the received card charges, checks, securities, and deposits to deliver an updated credit limit for each account holder.

The CMA case provides an example of decreasing visibility, which passed the burden of money account management from customers to Merrill Lynch. There was a couple of attractiveness in CMA. First, Merrill Lynch recognized that their customers do not want to bother with redundant and cumbersome transaction actions for financial account management. For that purpose, Merrill Lynch planned to provide the flexible money movement services between checking account, credit account, and stock investment account. Therefore, the burden of account management was passed from customers to Merrill Lynch. Second, CMA clients could take advantage of both high interest rates in the money market, and investment in stocks: i.e., they could benefit from both stock market and high interest rates just by CMA. The burden of moving money for better investment was removed from individual customers.

5.3 Cases of Both Increased & Decreased Transaction Visibility

5.3.1 MSAS Cargo International

MSAS provided air and sea forwarding services for international trade. Since the mid 1980s, MSAS recognized the world-widely increasing challenges of the cost pressure from both carriers and shippers, the increased competition triggered by the collapse of the boundaries between trade-related transportation businesses, the consolidation of freight forwarding industry, and increasing partnership of forwarders.

To handle with these changes effectively, MSAS started to develop UNITEL 21 since 1991, new integrated information system for managing airfreight operations. UNITEL 21 automatically documented 16 different control points for each airfreight shipment. As the shipment moved through a control point, information on the system was updated automatically or by station personnel. If there was any delay in the shipment, MSAS could immediately notify the customer why the delay occurred. Everyone was able to know the location of every item of freight at any time: i.e., the system permitted clients to track specific shipments, a task that used to be very difficult even for MSAS personnel. The system could also make it possible to accept initial bookings automatically, schedule the transportation automatically, and obtain customs preclearance on the documents before the merchandise arrived at its destination. There were useful accounting features as well. For example, because of its global operations, MSAS used 45 different currencies. The new system automatically translated all currency transactions into a common company standard. Therefore, at any point in the shipment process, MSAS could see how much that shipment cost.

The MSAS Cargo case provides an example of decreasing visibility, which reduces all the various contacts with many different transportation-related companies (such as customs brokerage, consolidation, packing, currency hedging, insurance, labeling) to a single contact point with MSAS Cargo. To make orders and check out delivery status, cargo entrusting companies needed to contact each of transportation companies. It was such a cumbersome job to contact all the relevant transportation companies individually. MSAS Cargo realized it could create substantial values by working as a close partner of customers by providing a comprehensive package of transportation services across all the value chains of its clients' business activities (from receiving orders to delivery to the final destination). Thanks to this comprehensive service, cargo entrusting companies were able to reduce lots of inefficient bottlenecks in international transportation (such as insurance, declaration, and mis-carriage).

This case also relates to the increased transaction visibility because MSAS's patrons got direct access to the delivery status information without intermediaries. MSAS

Cargo could increase customer values by taking over the cumbersome job of coordinating all the transportation activities, and providing direct access to the information of package delivery status. This new comprehensive service made visible the package delivery status, and also made invisible all the chores of contacting each transportation company.

6. Discussion

Proposition 1 is supported by all the seven cases of making visible. So, we can conclude that it makes sense to increase visibility of the supplier performance actions, when customers need supplier's performances and also when customers have capabilities in those supplier's performances. Proposition 2 is related to the case of making invisible. The proposition is supported by all the six cases of making invisible. So, we can conclude that it makes sense to decrease visibility of the transaction actions that customers do not have enough capabilities or that they do not need.

The same kind of problems can be resolved either way of increasing visibility or decreasing visibility. The choice of solution depends on the context, which is the need and capability of customers. For example, in helping customers deal with information overload, airline companies took the approach of increasing visibility, whereas Baxter (ASAP) decreased visibility using JIT technology. In designing a new financial accounts management systems, Merrill Lynch and UBF also took opposite approaches: CMA of Merrill Lynch relates to decreasing visibility, whereas EBS of UBF relates to increasing visibility. The key difference in each pair is whether customers had need and capability for certain actions in dealing with the problems. Travel agencies needed air-flight information, but was swamped with too much information because they did not have an appropriate instrument to deal with it. They had a capability to understand air-flight information. In that case, exposing air-flight information on line to travel agencies made sense. Meanwhile, hospitals did not have enough capability to improve their inventory management because there were too many different products in the market. Rather than being provided with more market information, hospitals could be better off by passing the inventory management to Baxter. Merrill Lynch could successfully liberate customers from financial account management efforts because customers were sick of such chores. On the other hand, UBF could successfully implement EBS because their patrons knew how and where to use their money and to manage their accounts.

7. Conclusion

When does changing transaction visibility make sense? As for this question, customer's need and capability were

found important: i.e., making visible makes sense when customers have need and capability for supplier performance, and making invisible makes sense when customers do not have need and capability for their own transaction actions.

This study produces important implications for electronic commerce over Internet. The first implication is that retailing is not displaced, but will be more important in electronic commerce. Retailing companies can produce added-value by changing visibility of the supplier or product information. Sony's web site, where customers only can buy Sony CDs, languishes, whereas CDNow.com, which offers 250,000 titles from all five major labels, grows because customers have more choices of CD products [12]. PcOrder.com, Inc. allowed PC dealers to scan and choose 600,000 different parts from 1,000 manufacturers, considering availability and price. PC dealers then electronically pass the order to the distributor, and eventually their orders will be forwarded to the PC maker. This system made a surprising success because PC dealers can get the computers that they want to sell [15].

Both success stories (Cdnw.com and PcOrder.com) provide the examples of increased visibility, by which customers can collect and use more information from more sources. In both cases, customers needed suppliers (for CD and PC manufacturing), and also possessed substantial knowledge about these products. In this case, increased visibility can be an attractive feature in transactions between customers and suppliers. Hagel & Singer [10] expected the burgeoning of new type distribution channel, *infomediary* (meaning the information intermediary). They anticipated this new distribution channel will replace the existing middle-men. The above rules of this study can give a hint regarding what are the niches for infomediaries and how they should run business.

Another implication to electronic commerce is that there should be some considerations in interface to embrace diverse levels of users' capabilities. For example, instead of just letting customers access to a certain web site, computer interface can provide intelligent agents that help customers filter information and support decision making. In this case, the interactivity at interface should be allowed to users as much as they can handle. For others, let the intelligent agent take care. Comparing the success of AOL and the demise of Netscape, Cusumano & Yoffie [7] concluded Netscape missed huge amount of gap existing between web browser and end-users, which was filled in by AOL. PcOrder.com contains artificial intelligence inside that recognizes which of the thousands of computer parts will work together best [13]. Various technical frills may well be supplied as options so that customers can adjust their current capabilities in conducting electronic commerce.

The third implication to electronic commerce is that the concern of visibility should not be confined to the contents of information, but be extended to the structure or organization of information. Information accessibility is

regarded as one of the important features of successful information systems [8][20][21]. However, information does not just mean the contents of some topics, but also includes the index of those contents. Accessibility of those indices would improve customer's overall satisfaction over the contents of information. For example, customers of Farcast can use a search engine named "droids" to search a variety of information sources. Farcast's value is not just showing web-sites but rather organizing an index for the web-sites to visit. Farcast sells this service for about \$13 a month. The Farcast case tells well that sometimes the content is free but the organization is valuable [16].

Visibility can also work as a new perspective in identifying strategic opportunities by information technologies. Especially, changing visibility can be used for business process reengineering. Business reengineering is related to changing visibility because it is actually reshuffling the location of actions between customer domain and supplier domain. Reengineering requires adaptation of traditional internal processes to the new system, which must cause substantial costs [14]. Therefore, reengineering with visibility change relates to the change in coordination mechanisms between customers and suppliers [6]. Again, the same rules apply: "Suppliers release some of their functions if customers want and can conduct them. Suppliers take over the customer's functions if customers do not need them, or cannot perform properly."

There are limitations in this study. First, only successful cases have been considered in this study. All the 12 cases are the successful anecdotes of using information technologies for competitive advantage. But, those 12 cases may not be large enough. The difficulty of collecting data was aggravated because the failure cases are hard to get in general. Using only published data could be a problem, too. Any extra interviews or unpublished data were not included in this study.

Second, only the representative case of each organization was reviewed. For example, Wal-Mart must have implemented many similar transaction visibility changes with other organizations. However, only the case with Procter & Gamble was discussed in this study.

The transaction visibility model will be continuously developed in the future study. The biggest challenge is to test whether changing visibility helps organizations improve. Success measures have been defined differently in many studies: profit, revenue, psychological measure of customer satisfaction, usage of information systems, to name a few. Different success measures may have different causal factors. More detailed break-down of success measures and causal factors may well be considered in the future study. Another agenda is to apply transaction visibility onto knowledge management: e.g., what kind of knowledge emerges visible, and what kind of knowledge tends to disappear as organizations learn.

Capability in actions can be a candidate for future research, because it is an important factor in changing

visibility. Bandura[2] put more emphasis on the confidence in capabilities rather than capability itself. Recent TV commercial of Excite.com promotes Internet usage by introducing nutty Internet users. That commercial could increase the self-confidence of TV viewers in Internet if they believe they must be better than such nutty people. Capabilities may not necessarily mean the absolute amount of knowledge or experience embodied in people: rather, it's a matter of attitude. Therefore, an insightful study could be produced if theories of attitude are combined with studies of self-efficacy in figuring out how to improve capabilities.

Last, relational factors can be included to give a better explanation of transaction visibility change. Especially, trust must work critically in the case of making invisible. Customers may not allow to pass their activities in their authority to their counterpart unless they have enough trust. If more comprehensive factors are included in the model, the possible clash or trade-off between factors need to be investigated as well.

Abstract

The Internet has grown explosively since its inception in early 1990s. In this study, we investigated the psychological mechanism to explain Internet usage. Web-site Acceptance Model (WAM), which is extended from Technology Acceptance Model (TAM), is presented by including the construct of perceived social influence (PSI). We investigated the relationship between PSI and two major belief constructs in TAM – perceived usefulness (PU) and perceived ease of use (PEU). Using a structural equation modeling, we found that (a) PSI does not have the significant direct effect on WWW usage, (b) PSI has stronger indirect effect on WWW use through PEU than through PU. These two results show that PEU is a complete mediator between PSI and WWW usage, and that WWW usage can be explained and predicted with the affect-related factors rather than the task-related issues.

1. Introduction

The Internet has grown explosively since its inception in early 1990s. The total value of goods and services traded in the US alone is estimated around US\$327 billion with an average annual growth rate of 110% (Forrester Research, 2000). However, despite the hype of the Internet technology, Internet adoption is not as smooth sailing as many business organizations assumed it would be [34]. Therefore, understanding the influential factors for web site usage is a timely important issue in the IS research area.

Studies and models are abundant in explaining and predicting IS acceptance or use. One of the popular frameworks is the Technology Acceptance Model (TAM) [13][14][15]. TAM is an individual psychological model to predict individual's adoption and usage of information technologies. And, perceived ease of use (PEU) and perceived usefulness (PU) are two major variables explaining attitude and intention of IS use. The subsequent TAM studies established the robustness of TAM through several applications and replications [1][15][21][31][44][50]. Although a few studies have already investigated influential factors for the use of

WWW, the robustness to explain Internet usage is not proved yet[2][10]928][33].

Internet usage is different from automation tool such as spreadsheet and word processor. While these programs are often used to conduct task, web sites are being used not only as a "tool" to conduct tasks, but also as a "media" to communicate [4][39]. According to media selection theory, social influences have an effect on individual's adoption of web sites. Therefore, our study proposes and tests empirically the modified TAM, which is called Web-site Acceptance Model (WAM), including the perceived social influence constructs to explain and predict of Internet usage.

2. Perceived Social Influence (PSI)

Social influence can be defined as "an individual's internalization of the reference group's subjective culture, and specific interpersonal agreements that the individual has made with others, in specific social situations" [48]. A recent longitudinal TAM study by Venkatesh & Davis [51] found that social influence is changeable; its impact is significant in the early stage of IS adoption, whereas its impact dissipates as IS usage gets matured. However, they conceptualized social influence only as subjective norm without considering other dimensions of social influence.

In an effort to operationalize social influence, we focus on the following three issues. First, aligned with other psychological models regarding IS adoption, social influence should be perceived prior to any features which has effect on individual's IS usage. So, we call this construct as perceived social influence (PSI). Second, PSI is a multi-dimensional construct including subjective norm (social norm), visibility, and image from the related IS adoption theories such as TAM, TRA, TPB (Theory of Planned Behavior)[3], the decomposed TPB [45], and innovation theory[33]. The subjective norm of TRA is the representative construct. It is defined as "the individual's perception of a referent other's opinion about the individual's performance of the behavior." [18, p.302]. Although Davis et al. [15] insisted no significant relationship between social norms and usage, they attributed this unexpected finding to the weak psychometric properties of their social norms scale and

the particular IS context of their research (i.e., use of a word processing system). Davis called for further research to assess generalization of this finding, and to investigate conditions and mechanisms effecting on social influences[15].

Two other dimensions of PSI are from Moore & Benbasat's[33] study: image and visibility. Image is defined as "the degree to which adoption/usage of the innovation is perceived to enhance one's image or status in one's social system." [33, p.195]. This is close to Chau's[9] long-term PU and Tornatzky & Klein's[47] social approval. Chau[9] proposed that near-term PU is related with functionality of computer systems on improving job performance or enhancing job satisfaction, whereas long-term PU is related with improving one's social status. Tornatzky & Klein[47] identified social approval is addressed most frequently in over 100 innovation studies.

The third dimension of PSI is visibility. Visibility means "the degree to which the innovation is visible in the organization": i.e., the more a potential adopter can see an innovation, the more likely she/he is to adopt it [33, p.195]. Visibility is the very close concept to "critical mass"[29] and "network externality"[39] that assert the usefulness of a network is primarily a function of the number of participants in the network.

3. The Research Model

Figure 1 is the research model including PSI, PEU and PU. In this model, like other studies of TAM[1][9], the attitude construct is excluded to simplify the model. And, Internet use, not behavioral intention, is chosen for the dependent variable because it may be the more appropriate measure of technology innovation diffusion rather than the early adoption or acquisition [17].

3.1 Impact of PSI on PU & PEU

In TRA, all the external stimuli are assumed to influence behavior only indirectly via attitude or subjective norm [18, 396]. TAM inserts two cognitive factors (PU and PEU) between external stimuli and attitude, and insists that external stimuli influence a person's attitude toward a behavior indirectly through PU and PEU.

In TAM, external stimuli have been defined diversely such as the various individual differences, situational constraints, managerially controllable interventions [15], the task and user characteristics and so on [44]. While TAM is focused on individual psychological features, media selection theories also argue that the characteristics of media depend on the perceptions of the user, and the meaning of media is socially constructed [8]. These perspectives insinuate that individual's beliefs are socially constructed through interactions with others. Thus, we predict that these social influences must have an effect on the PU and PEU.

H1: PSI will have significant effect on determining PEU of the Internet.

H2: PSI will have significant effect on determining PU of the Internet.

3.2 PEU and PU

Davis [13] proposes that PEU influences PU, but not vice versa." [13, 477-8]. This theoretical relationship has been supported by numerous empirical studies even though some studies argue the opposite relationship [9][12][13][14][31][44][45][50]. Like previous theoretical and empirical arguments, our study also assumes that PEU influences PU, not vice versa, under the Internet environment.

H3: PEU will have significant impact on determining PU of the Internet.

3.3 Influence of PU & PEU on Internet Use

Traditionally, TAM research has argued that PU influences IS use, whereas PEU does not [2][9][12][14][44]. Davis[12] assumed that PEU does not influence on IS use, even though it influences PU. Adams, Nelson & Todd[1] warned not to focus on PEU in identifying the antecedents to IS use. However, several TAM studies empirically suggested the significant influence of PEU on IS use[46][47]. All these empirical findings and theoretical arguments imply that PEU could also influence the Internet use.

H4: PEU of a system will have significant impact on Internet use.

H5: PU of a system will have significant impact on Internet use.

3.4 Impact of PSI on Internet Use

Adams, Nelson & Todd[1] and Subramanian[43] reported that PU and PEU explain only explain around 30% of the variance of IS use. These results imply that there must be additional factors that influence individual usage of IS. We can find a possible answer (i.e., missing factor) from other IS use theories: TRA, TPB, and Innovation perspective. Commonly these alternative theories include the "social influence" factors as an antecedent of IS use. Moore & Benbasat's[33] innovation perspective includes two important social influence constructs – visibility and image. Agarwal & Prasad [2] found that the current usage is influenced by perceptions of visibility. Numerous studies also reported subjective norm is an important determinant of IS adoption or use [12][22][27][45]. Some studies delicately tested the influence of subjective norm by differentiating IS use in terms of chronological diffusion of technology, and identified that subjective norm influences only early IS adoption[22][26]. Media selection theories have consistently insisted the direct impact of social influences on the selection of media. Our study includes visibility, image, and subjective norm as three dimensions of PSI, and tests how this composite construct, PSI, works with other individual perceptions.

H6: PSI will have significant impact on the Internet use.

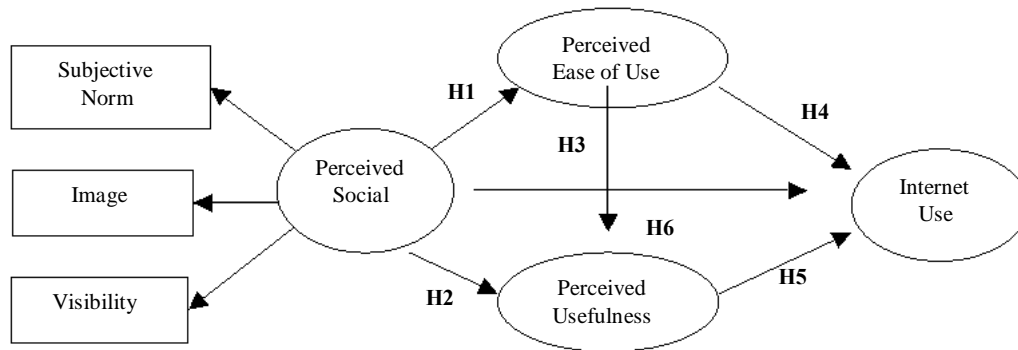

Figure 1. Research Model

4. Methodology

4.1 Data Collection

A total of 420 questionnaires are distributed to under-graduate students who major in MIS in a college of management in New England area. Samples are homogeneous in terms of demographic features such as age, grade, and major. We explain the objective of this research and the meaning of each measurement item. Students are asked to fill out the survey anonymously on the voluntary basis. In total, 206 valid questionnaires are returned out of 420 handouts, recording 49.0% of return ratio.

4.2 Reliability and Validity

Reliability assesses the internal consistency of scale items[35]. Cronbach's alphas are used to assess the internal consistency reliability of the scales. As shown in Table 1, the reliability coefficients ranged from 0.65 to 0.96, which is significantly higher than the acceptable level of 0.6 [36].

Table 1. Reliability Estimates

Construct	Items	Cronbach's alpha
PU	4	.9571
PEU	4	.9065
Image	4	.9188
Visibility	3	.7985
Subjective Norm	2	.8415
Internet Use	2	.6485

* PU = Perceived Usefulness, PEU =Perceived Ease of Use, IMG = Image, VS = Visibility SN = Social Norm

Convergent validity is assessed by factor analysis of the scales. The factor loadings are shown in Table 2. Through Varimax rotation, the 25 items are cleanly loaded onto 6 factors - PEU, PU, image, visibility, subject norm, and IS use.

5. Data Analysis

Our empirical test consists of two phases. The first phase is to check the fitness of the model and examine the support of hypotheses in our dataset.

5.1 Test of the Proposed WAM model

Some measures are suggested to test model fitness [5][6][19][23]. The chi-square for this model with 22 degrees of freedom is not significant (chi-square = 17.309, $p = 0.746$). However, for large samples, the chi-square statistic frequently indicates poor model fit even though the model fits the data well [7][30][38]. Instead, Chi-square divided by degrees of freedom is recommended with the value below 5 [53]. In our dataset, the value of Chi-square divided by degrees of freedom is 0.787, which satisfies the criterion value. GFI and AGFI should be greater than 0.90 and 0.80, respectively, and RMSEA should be lower than 0.08 [7][25]. In our dataset, GFI is 0.983, and AGFI is 0.964, and RMSEA is lower than 0.08. These four measures indicate that our model fits to the dataset (Table 3).

Table 3. Fit Measures for the proposed model

Fit Index	Fit Measures
Df	22
χ^2	17.309
P value(>0.05)	$p=0.746$
$\chi^2/df(<5)$	0.787
GFI(>0.90)	0.983
AGFI(>0.80)	0.964
RMSEA(<0.08)	0.000

5.2 Results and Analysis

Test results of our hypothesis 1-6 are summarized in Table 4 and figure 2. The results are not entirely consistent with our hypotheses.

Table 4. Summary of Results (path coefficient)

		Path Coefficient	Remarks
H1	PSI -> PEU	0.39**	Supported
H2	PSI -> PU	0.51**	Supported
H3	PEU -> PU	0.25*	Supported
H4	PU -> USE	0.05	Rejected
H5	PEU -> USE	0.44**	Supported
H6	PSI -> USE	0.02	Rejected

* $p<0.1$, ** $p<0.05$

The paths from PSI to PU and PEU are significant with 0.51 and 0.39, respectively. Therefore, both hypothesis 1 and 2 are supported: i.e., PSI has an effect on PEU and PU. The path from PEU to PU is marginally significant, supporting hypothesis 3. Hypothesis 4 and 5 get the partial support: i.e., PEU influences WWW adoption, whereas PU doesn't. These two results suggest more on PEU than PU in WWW usage. The relative importance between PU and PEU on IS use has been a long argument in TAM studies. Our result suggests that the conflicting results can be attributable to the nature of the technology itself. The Internet is for personal purposes such as fun and sympathy. Also, it is being used to communicate with virtual community or to search personally useful information [4][39]. Our results address that WWW usage goes through different psychological mechanisms from those of task-related usages. Perceived ease of use promotes revisiting of web sites more than task-related usefulness does. Finally, the path from PSI to IS use (hypothesis 6) is not supported in our sample.

This result implies that people do not use computer systems blind-folded. Even though they may refer to someone else's opinions, but their decision for a web site is based on personal recognition of functional ease-of-use. We can conclude that PEU influence on WWW usage mediating Perceived Social Influence.

Figure 2. Path Coefficient of Internet Usage

6. Discussion and Conclusion

TAM is a parsimonious framework that explains and predicts individual's voluntary adoption of technologies and tools. We combined this framework with the media selection theory to explain individual's adoption of web sites (not the WWW technology itself). We found that individual psychological procedures of adopting tools and technologies are different from those of adopting web sites. Most noticeably, WWW use is more influenced by PEU than by PU. Also, PSI has only indirect effect on WWW usage through PEU on mediating with PSI. We could draw the following three generic implications from these results. First, the findings of traditional media trait theories are also effective in explaining the adoption of web sites. Media theories have insisted that ease-of-use and accessibility are more important than the quality of information and task-support in media selection. This coincidence verifies our argument that we cannot understand the web site usage enough as long as we presume WWW as a technology. Second, web site is not just about information, but about the way information is communicated. Users will choose information of inferior quality just because acquiring it requires less work than high quality information. Currently, web usability is one of the promising research agenda. We argue that it is not surprising to tap this issue from the standpoint of ease-of-use. Even though all the web sites run on the same IT

infrastructure (Internet, WWW, multimedia, etc.), the longevity and popularity of web sites depend on how much they can make users feel comfortable. Third, we may well be more attentive to the affect-related stimuli if we intend to enhance PEU of web sites. The current usage of web site is more related to the personal fun or curiosity reasons rather than the task-oriented reasons. This "emotional personalization" may be ascribable to the perceived ease-of-use of selected web sites. This analogy proposes that the features or designs of web sites should be based on users' affective responses not on the task-related performances or technical productivities. Web site is not just an instrument to procure information, but also a communication media to exchange personal emotions and privacies. Personalization techniques have been used as an enhancement of transaction processing systems. Emotional personalization is a new domain where new techniques should fill in.

Like other social studies, this study has several limitations. First, we used only perceptual measures of IS use. Many studies have shown that individuals' perceptions of IS usage are sometimes quite different from their actual usage pattern [11][16][42][49]. Second, our results might be exacerbated by our sample characteristics. The subjects in our sample are undergraduate students. They use the Internet for personal purposes such as chatting and searching information for fun or simple curiosity. Besides, their major (MIS) may have aggravated the sample bias. Considering the

background of our sample data, our study confirms that social influence turns weak as users become experienced with information systems. Organizational issues are not considered in our study. IS implementation studies have emphasized the importance of organization issues (such as structure, size, industry, support, change management, etc.). These issues may have to be considered in the future study. Third, since we used a cross-sectional data set, with both independent and dependent variables collected contemporaneously, the results are susceptible to the same method bias. That is, the correlation between independent and dependent variables, and the explained variance of the dependent variable, might have been inflated because these were all measured at the same time within the same questionnaire. Fourth, a more detailed WAM should be developed. As we conceptualized web site as the combination of technology and media, more psychological constructs other than PEU, PU, and PSI could be included. Furthermore, antecedents to PEU of web site should be investigated comprehensively and intensively.

Abstract

This study explores the effects of IT on buyer and supplier partnerships in the Taiwan e-business environment. The survey data reveals that the integration of IT and partnerships into supply chain management applications can improve e-business performance. Specifically, the study finds that IT utilization as well as buyer and supplier partnerships within supply chains are matured in the participating firms, as evidenced by their enhanced productivity, reduced cost and increased profit. Keywords: information technology, IT strategy, buyer and supplier partnership, e-business performance

1. Introduction

Due to the continuous innovation of technology and the characteristics of e-commerce, many companies have introduced the enterprise resource planning (ERP), supply chain management (SCM), customer relationship management (CRM), e-business and related electronic operating systems to upgrade their competitive advantage. All companies utilize IT to facilitate communication and data sharing between subsidiaries and the parent company in order to earn the greatest profit within the shortest time. In Taiwan, globalization and entering the WTO have made companies compete with not only other local firms, but also international competitors.

The manufacturers invest in advanced manufacturing technologies (AMTs) to smooth their production scheduling, standardize the production process, achieve punctual delivery and reduce costs. The information technology (IT) is evolving as a powerful force in the new marketplace where the nexus of competition has changed from individual firms to efficient supply chain networks both between firms and within industries. Among various channels, the supply chain has the closest partner relationship, because the interactive buyer-supplier relationship among companies is a mutual relationship instead of the traditional cooperation method.

This paper studies how advanced technology and IT applied by manufacturers will affect the partnership relationship and supply chain (SC) performance. We use a questionnaire sampling from manufacturers to collect information related to the degree to which firms use advanced technology, IT strategy models, partnerships with upstream suppliers and downstream buyers, as well as supply chain performance evaluation of the firm.

Statistical analysis is applied to evaluate the correlation and significant deviation and investigate whether advanced technology and IT strategy models will improve the partnership relationships and the supply chain performance.

2. Literature Review

2.1 IT and e-business

With the popularity of the Internet as a low-cost and easy-to-use media, e-business methodology helps companies reduce cost, as well as improve service quality and efficiency [6].

E-business transforms the conventional business process into a supply chain management and establishes a more dynamic buyer-supplier relationship and a strategic partnership [10]. The influence on customer relationship management includes the factors of accelerated information exchange, high degree of interaction and flexibility, as well as removal of time and geographical barriers [1].

According to the International Data Corporation [5], the number of Internet users will soar from 100 millions in 1998 to more than 500 millions in 2003. The open and global characteristics of the IT allow companies to provide e-business to users anywhere at any time with unprecedented width and depth.

A high level of IT capability has been shown to provide a clear competitive advantage, and it can be a differentiating factor in terms of company performance [7]. Bowersox and Daugherty [2] identified IT as one of the common factors associated with advanced logistics practices.

Specifically, the type of IT used largely determines the nature and quality of interactions the company has with customers, suppliers and trading partners. Prahalad and Krishnan [9] referred to IT as the company's "digital nervous system". However, although IT is a critical element of SCM, IT is not a source of value by itself. Rather, the proper selection of IT supports and enhances the functioning of value-added processes.

Managers are often faced with the challenge of selecting appropriate IT applications and setting realistic expectations of performance measures. Exacerbating the difficulty of this process are rapid changes in technology, proliferation of software intended to improve SC functioning, and a plethora of self-proclaimed success

stories [4] [13].

2.2 The partnership of buyer and supplier

Wong [17] showed that a real partnership should consider mutual requirements, the capability and target of each partner, as well as creating clear and definite vision. Vokurka [15], Maloni and Benton [8] described the supply chain partnership as the mutual relationship of two independent business entities, normally the supplier and the customer or buyer, in order to accomplish some certain target and profit. These entities share information with each other, improve the financial and operation performance of both sides via cost and inventory reduction, and undertake the risk together.

(1) The power of the partner

The relationships between buyers and suppliers are moving towards a reduced number of suppliers, long-term relationships, reduced inventories and involvement of suppliers in design. The power of the partner includes relationship between players and how the relationship is managed. The existence and position of power in the SC is an example of SC relationship. Chow et al. [3] concluded that there were related variables, like SC formalization, SC intensity, SC frequency, SC standardization and SC reciprocity.

(2) Supplier involvement

Vonderembse and Tracey [16] evaluated the correspondence between the supplier involvement and manufacturer performance. The suppliers were involved in product design and continuous improvement activities. Tracey and Tan [14] studied the relationship of supplier involvement with the customer satisfaction and performance. They also noted that the supplier involvement included the participation on product design and continuous improvement activities.

(3) Information exchange

Sandhya and Mrinalini [12] pointed out that the connections between manufacturer, supplier and buyer improved the efficiency of data transmission, and caused the information to be transmitted and shared immediately. Sanders and Premus [11] investigated the application IT to supply chain management, finding that the utilization of e-technology made the information flow smoothly, and made the firm or organization perform better in many ways. Collaboration of supply chain goes beyond mere exchanging and integrating information between suppliers and customers, and involves tactical joint decision making among the partners in the areas of collaborative planning, forecasting, distribution, and product design.

Sanders and Premus [11] also found that the investment and application of IT assisted the company or organization to perform better in terms of quality, flexibility, innovation capability, product entrance opportunity and new technology. The Supply Chain Council of the US also developed 12 indexes to measure the supply chain performance. Therefore, this paper

proposes the following hypotheses: with different IT portfolios, the performance of e-business will be affected by a supplier or buyer partnership.

H1: IT portfolio will affect the supplier or buyer partnership.

H1a: Higher involvement with IT will lead to closer supplier partnership.

H1b: Higher involvement with IT will lead to closer buyer partnership.

H1c: IT strategy model will affect the supplier or buyer partnership.

H2: IT portfolio will affect the performance of e-supply chain.

H2a: Higher involvement with IT will result in better performance of e-supply chain.

H2b: IT strategy model will affect the performance of e-supply chain.

H3: The supplier or buyer partnership will affect the performance of e-supply chain because of different IT portfolios.

H3a: The supplier partnership will affect the supplier performance on e-supply chain because of different IT portfolios.

H3b: The buyer partnership will affect the buyer performance on e-supply chain because of different IT portfolios.

3. Survey Methodology

This paper empirically investigates the relationships among variables and Figure 1 illustrates the architecture of this study. The major variables used have included: (1) the independent variables of supplier and buyer partnerships, which include the power of the partner, supplier involvement and information exchange; (2) the medium variables of the degree of e-business/IT, which includes the level of involvement with IT and the IT strategy model; (3) the dependent variable, which is performance evaluation of e-business, including information management, order fulfillment, inventory, distribution, product development, supplier management, customer satisfaction and after-service.

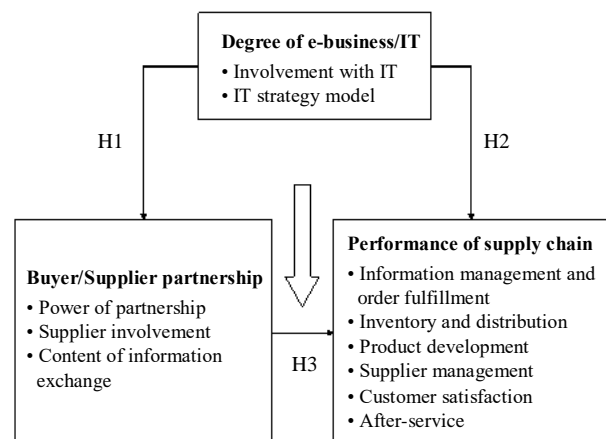

Figure 1 Architecture of this study

The questionnaire design has four parts: (1) the degree of e-business, (2) supplier partnership and its performance, (3) buyer partnership, and (4) the background of the company. The objects are sampling from the purchasing departments of 1000 major manufacturers in Taiwan, including food and drink, textile and garment, chemistry and petroleum, construction materials, pharmaceuticals, metals and machinery, as well as electronics and electric industries. Of the 945 questionnaires sent out, 22

questionnaires were returned due to change of address or failed e-mail address. Of those returned, 4 responses could not be used. There were 113 questionnaires returned, not including the invalid ones, for a valid response rate is 12.29%. The returned questionnaires were received from companies of different industries that is compliant with the spirit of sampling.

Table 1 Performance evaluation of e-business

Object	Dimension	Mean	Standard deviation
Supplier	Information flow management	3.457	1.992
	Order fulfillment management	3.681	2.075
	Inventory and distribution	3.555	2.038
	Product development and feasibility	3.454	2.018
	Partnership management	3.746	2.056
	Customer relationship management	3.673	2.005
	After service	2.296	1.292
Buyer	Information flow management	3.657	2.835
	Order fulfillment management	3.527	2.043
	Inventory and distribution	3.555	2.057
	Product development and feasibility	3.790	2.106
	Partnership management	3.725	2.000
	Customer relationship management	3.921	2.762
	After service	3.823	2.069

Table 2 Degree of IT application by industry

Dimension	Sub-dimension	Electronics & Electric industry	Traditional industry	Trading industry & others
IT application degree	Network establishment	60%	55%	48%
	Network method	30%	26%	18%
	Website establishment	100%	100%	100%
	Product inquiry service	83%	82%	75%
	Information outsourcing	27%	17%	26%
	Sharing information with partnership	35%	23%	29%
	Procurement management	23%	28%	17%
	Sales management	32%	30%	28%
	Production management	20%	24%	22%
	Logistics management	32%	30%	27%
	Communication and support service	60%	58%	55%
Supplier involvement	Product development/ design	32%	29%	26%
	Technology resource/information sharing	32%	38%	35%
Sharing information with supplier	Price	40%	37%	34%
	Delivery	61%	59%	60%
	Quality	41%	46%	37%
	Quantity	43%	36%	39%
	Sales planning	45%	36%	40%

	Delivery	60%	56%	58%
	Quality	38%	35%	31%
	Quantity	28%	37%	29%
	Sales planning	54%	47%	50%

Table 3 Supplier performance vs. supplier partnership

Industry	Dependent variable	E-business degree	Prediction variable	R ²	β	t value	p value
Electronics & electric industry	Supplier performance	High	Supplier partnership	0.704	0.799	10.543	0.000***
		Low		0.477	0.305	2.675	0.000***
Traditional industry	Supplier performance	High	Supplier partnership	0.506	0.754	9.452	0.000***
		Low		0.384	0.296	3.068	0.000***
Trading industry & others	Supplier performance	High	Supplier partnership	0.604	0.706	8.643	0.000***
		Low		0.393	0.231	3.172	0.000***

* $p \leq 0.1$ (close but does not reach the level of significance); ** $p \leq 0.05$; *** $p \leq 0.01$.

Table 4 Buyer performance vs. buyer partnership

Industry	Dependent variable	E-business degree	Prediction variable	R ²	β	t value	p value
Electronic and electric industry	Buyer performance	High	Buyer partnership	0.501	0.602	6.013	0.000***
		Low		0.302	0.502	6.011	0.010***
Traditional industry	Buyer performance	High	Buyer partnership	0.492	0.701	5.017	0.040**
		Low		0.328	0.304	3.026	0.024**
Trading industry & others	Buyer performance	High	Buyer partnership	0.502	0.601	5.74	0.005***
		Low		0.387	0.259	3.016	0.030**

* $p \leq 0.1$ (close but does not reach the level of significance); ** $p \leq 0.05$; *** $p \leq 0.01$.

4. Data Analysis

Table 1 illustrates the relative performance of different operation areas of the supply chain. Among the surveyed entities, 28 companies are coming from electronics and electric industry, 69 are from traditional industry and 16 are from trading industry or others. The important items include customer relationships, after-service, product development, supplier partnerships and order fulfillment. Table 2 shows degree of electronic IT application in the electronics/electric industry, traditional industry and trading industry. The comparison indicates that the electronics/electric industry has greater IT application in the e-business environment.

From the survey, we find that IT strategy (product and marketing innovation strategy, manufacturing innovation strategy and operation efficiency improvement strategy) has no significant correspondence with either supplier or buyer. However, "manufacturing innovation strategy" is significantly correspondent to "supplier performance". For the partnership, Table 3 and Table 4 illustrate the significant effect between performance and buyer/supplier partnership for different degrees of e-business application.

5. Conclusions and Suggestions

Surveying IT application degree, partnership and the performance, we conclude as follows:

(1) The correspondence analysis indicates that "IT

application degree" has positive correspondence with "supplier partnership" and "buyer partnership", which also means that "IT application degree" has positive correspondence with "supplier involvement" and "content of information exchange". Furthermore, "IT application degree" and "partnership" have positive correspondence with "e-business performance", namely, either supplier or buyer partnership will have positive correspondence with e-business performance.

- (2) "High degree of IT application" has stronger impact on supplier partnership than on buyer partnership, whereas "Low degree of IT application" affects buyer partnership more than supplier partnership. Supplier performance and buyer performance also have the same trend.
- (3) The impact of supplier partnership, supplier involvement and information exchange on the performance of e-business is affected by the degree of commitment to IT. A higher degree of commitment indicates better performance. Different IT portfolios will also affect the performance of the e-supply chain.

Abstract

This study explored the effectiveness and efficiency of information technology (IT) and information systems (IS) in supply chain management (SCM) in Hong Kong firms.

The research model is comprised of three parts. The first part relates to the relationship among the three different functions of IT/IS utilized in a supply chain. The second part demonstrates to the relationship between IT/IS utilization and supply chain performance. The third part relates to relationship between organizational factors and different roles of IT/IS utilization. Several hypotheses have been set up for the model.

In the research, 36 measurement items extracted from literature to specify the characteristics of information systems utilized in supply chain management and structural relationship between these latent variables. Factor analysis, reliability test, correlation matrix, path analysis were used to analyze the data and model testing.

The results justify the acceptance of the proposed research model and some of our hypotheses, they are, IT/IS for organizational value creation management has significant contribution to SCM performance. IT/IS for logistics operations and value creation management have significantly mutual influences each other. IT/IS for organizational infrastructure only influences the value creation management. In addition, they also confirm the contributions of IT/IS in SCM performance, and further this study develops and validates a measurement scale for IT/IS utilizations on SCM performance. The scale provides a preliminary foundation for facilitate research and in IT/IS utilizations in logistics operations in wider spectrums.

This research also empirically justifies that IT/IS for infrastructural support and logistics operations has indirect effects on SCM performance through value creation management. This gives an insight that IT/IS is fundamental for organizational value management, through value creation and growth, SCM performance, and further organizational performance can be enhanced. Finally, knowledge of IT/IS utilization and organizational factors can be contributed to their consideration and planning for IT/IS strategy and adoption.

Recommendations for further research and organizational IT/IS strategy are suggested based on these outcomes, such as supply chain integration, and consideration for implementation of IT/IS. IT/IS utilizations with strategic planning are believed to be more efficiency and effectiveness in SCM performances for the organizations.

Keywords: Information Systems, Information Technology, Logistics, Supply Chain Management

1. Introduction

1.1 General Background

Many firms today were effective management of logistics and supply chain activities both as a prerequisite to overall cost efficiency and as a key to ensuring their ability to competitively price their products and services. Information systems (IS) and information technology (IT) are being used by leading-edge firms to increase competitiveness and developed a sustainable competitive advantage [9]. Although capabilities relating to information systems and information technology have traditionally regarded also as key strategic resources, expertise in these areas is now thought to be among the most valuable and essential of all corporate resources.

In the previous studies, the introduction of information technology by a firm for integrated supply chain management could lead to better efficiency and effectiveness [21]. Integrated supply chain management utilizing information systems can enable the company to identify optimal inventory levels, reduce warehouse space, and increase inventory turnover [23][24][39]. Porter and Millar [33] suggested the utilization of IT has significant influence on the relationship among value chain activities and Porter and Millar believes that management of information systems focusing on cost reduction.

IS must have a potential to be a strategic weapons for improving supply chain management performances. In Hong Kong, a great numbers the companies focus on their efforts on value-added activities such as international marketing, product planning product R&D so on. Hong Kong companies also concerned about how information technology/information systems can enhance the competitiveness and efficiency of supply chain. [25]

This paper is organized as follows. First, previous research on the role of functional information systems for supply chain management is discussed. Next the characteristics of information systems utilized for supply chain management are identified, based on factor analysis of sample data from 71 of Hong Kong firms. Third, a conceptual model and hypotheses relating to utilization of information system and supply chain management (SCM) performance and tested using path analysis. A set of discussion and recommendations are explained and based on the results.

1.2 Objectives of study

The objectives of study are to 1) to test a research model of organizational factors with IT/IS utilization in SCM performance; 2) to develop recommendations for companies in Hong Kong to establish IT/IS utilization strategy for SCM performance; 3) to find out the critical factors of IT/IS in SCM; and 4) to establish the performance measurement criteria for using IT/IS in SCM.

2. Literature Review

2.1 Supply Chain Management

Supply Chain Management (SCM) deals with control of material and information flows, structural and infrastructural process relating to transformation of the materials into value added products and delivery of finished products through suitable channels to customers in order to maximize customer value and satisfaction. [34]. As Council of Logistics Management noted that: Logistics is that part of the supply chain process that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers' requirements.[31] By Integration of internal functions within an organization (e.g. marketing, manufacturing, product design and development) and effectively linkage them between suppliers and customers, SCM can help to enhance competitive performances and meet the customers' requirements.[34] The benefits of SCM can be obtained through the information linkage among various supply chain activities utilizing information technology and construction of integrated supply chain information systems. [9]

2.2 Information Systems and its Roles in Supply Chain Management

Information systems in logistics and supply Chain can be defined as: an interacting structure of people, equipment and procedures that together make relevant, timely and accurate information available to logistics manager for purpose of planning and implementation and control. [29][41]

According to Computer Sciences Corporation [15], suggested that the highest priorities of critical current issue in information systems are on customers, productivity, and performances. These issues show that they can affect the use and function of information systems in SCM. Information systems were viewed as

providing infrastructural support to the value chain and having impact on competitiveness of products. Companies started to utilize information systems to directly influence the processes comprising the value chain [37] [45].

Earl [18] classified the scope of information technology into following categories according to whether information technology is widely used in the value chain or used for only information processing and whether it is applied for value creation or applied for connection of value chain activities: 1) Information Technology (IT) that automates or improves every activity; 2) IT is used for connecting each value activity 3) Information systems facilities support, management and implementation of value chain activities, and 4) Information systems optimize or adjust the connection of each value activity. Earl can be applicable to internal value chain, but also be extended to the company's supply chain.

Porter and Millar [33] suggested that utilization of IT has significant influence on the relationship among value chain activities as well as on the physical aspects of individual value chain activities. The following proposition can be made: 1) Competitiveness comes from creating customer value; 2) value creating activities are interdependent in the value chain 3) Firms can optimize or integrate their value chain through IT to improve their competitiveness and efficiency. Porter and Millar suggested that proper use of information minimize the costs while maximize the value, optimizing value chain activities and improve the efficiency.

From the work of Earl, Porter and Millar, the utilization of information systems shows the enhancement of competitiveness and improving efficiency in the value chain. To better understand the utilization of IS, the general research questions should be considered. How can IS applications support through information processing, value creation management for improving the value activities and logistics operation connection of activities? What are the performance measures for proving that IS influence in the supply chain? Porter and Millar believe that management of information systems focusing on cost reduction. The ability to pursue the cost reduction should be criterion of IS utilization.

2.3 Performance Measurement

Apart from the cost reduction, performance measures can be used to indicate the SCM performance in order to illustrate the IS utilization influence. According to University of Tennessee Logistics Survey[44], a list of measures varying degrees of utilization among companies. "Outbound Freight Cost", "Inventory Count Accuracy", "Order fill" are the highest three priorities for performance measures capturing on a regular basis within the company. Logistics Metrics suggested to use to measure the performances with Logistics Key performance indicators (LKPI). [20] The logistics Metric was divided into four categories: Finance (Cost), Productivity, Quality, Response Time.

2.4 Organizational Factors

The role of individual and organizational factors may also be played in the benefits of SCM. These Factors highlights the importance of organization's experience to implement information systems to enhance the competitive advantages and efficiency. [38] A creativity framework has been adapted from organizational literature will be used to illustrate the implementation effort of IS in the company. The individual and organizational characteristics used to improve the implementation of IS. [46] Amabile [1][2][3][4][5] conceptualizes individual creativity from the framework. The framework includes three major components – domain relevant skills (task knowledge), creativity (cognitive abilities) and task motivation (intrinsic and extrinsic). Intrinsic motivation is individual baseline attitude toward to the task and extrinsic motivation is individual perceptions of undertaking the task in a given instance. Organizational characteristics create the contextual influences that operates whole organization members to influence creativity. Organizational creativity is group of creativity influences such as leadership, reward, availability of information and so on. [46] Kartz and Allen [27] indicated that the importance of leadership and management is influenced on the interaction of other components of organization and acquisitions of resources. Another way to improve organizational creativity is through the structure and culture. [10][11][32]. More organic structure, lack of formalization and high levels of complexity establish an linkage between high level of organizational creativity.

2.5 IS in Supply Chain Management in Hong Kong

In Hong Kong, a great numbers the companies focus on their efforts on value-added activities such as international marketing, product planning product R&D so on. Hong Kong companies also concerned about how information technology/information systems can enhance the competitiveness and efficiency of supply chain.[9] In the meantime, Hong Kong SAR Government proposed the development of Digital Trade and Transportation Network (DTTN) for companies which provide a neutral e-platform and IS for facilitating information flow and service integration locally and globally.

In summary, influence of IS utilization (i.e. effectiveness and efficiency) can be shown through different roles of IS applications in supply chain value-creation management, logistics operation and infrastructural support through using different performance measures, such as financial and non-financial indicators.

3. Research Model, Hypothesis and Methodology

3.1 Research Model

The research model is comprised of three parts. The first part relates to the relationship among the three

different functions of IS utilized in a supply chain. The second part demonstrate to the relationship between IS utilization and supply chain performance. The third part related to relationship between organizational factors and different roles of IS utilization.

3.2 Hypothesis

This research model is derived from prior studies discussed in the literature review section [13][30][33]. Information systems for information processing provide the basis for establishing strategic competitive advantage. IS utilization makes it possible for achieving strategic competitive advantage. IS plays roles as infrastructural support for direct IS utilization in supply chain functions

H1: IS/IT utilization for infrastructural support has a direct influence on IS use for value creation management.

H2: IS/IT utilization for infrastructural support has a direct influence on IS use for logistics operation

Prior research on the process of supply chain integration illustrates show that internal integration with the company should precede external connection with suppliers and customers. [9] To identify the casual relationship between IS for values creation management and IS for logistics operation, we should consider the reciprocal relationships between two variables.

H3: IS/IT utilization for value creation management has a direct influence on IS use for logistical operation.

H4: IS/IT utilization for logistical operation has a direct influence on IS use for value creation management.

The pervious studies introduce the relationship between IS/IT utilization of IS/IT in value chain processes would eventually enhance the company's supply chain activities. [9][13][30][33] The focus of IS utilization should shift form information processing to value creation and value connection. The change of IS/IT utilization focus would make it possible for IS/IT utilization have a direct effect on supply chain competitiveness and efficiency.

H5: IS/IT utilization for value creation management has a direct influence on supply chain performance.

H6: IS/IT utilization for logistical operations has a direct influence on supply chain performance.

According to Legare [38], organizational factor is contributed to the implementation of IS/IT in order to enhance competitiveness and efficiency of work. Organizational factor is contributed by individual characteristics and organization characteristics within an organization[46]. So the following hypothesis can be assumed:

H7: Organizational factor for an organization has a direct influence on IS/IT infrastructural support.

H8: Organizational factor for an organization has a direct influence on IS/IT utilization for value creation management.

H9: Organizational factor for an organization has a direct influence on IS/IT utilization for logistics operations.

3.3 Research Methodology

3.3.1 Measurement

a. IS/IT utilization level

Based on prior research, [34] which classify logistics activities in integrated supply chain management and functional information systems for logistics management, 12 traditional uses for information systems in supply chain management were identified: plant and warehouse location selection, order processing, resource management, production plan and process control, inventory and warehouse management, distribution and transportation management, sales and price management, consumer service and customer management, and forecasting. network planning and design system, office information system, and accounting information system.

b. SCM Performance Measurement

The approach to measuring SCM performance has been used by previous researchers [9][20]. Measures [8][20][43][47] consisted of cost reduction, cycle time reduction, on-time delivery of materials from suppliers and customers, product quality, response time for customers and suppliers, the speed of suppliers' order processing, the reduction degree of response time of suppliers and customers, the accuracy of order processing for customers, the speed of order handling, and perfect order fulfillment.

c. Organizational Factors

The measurement based on the vision, sense of business urgency, authority and responsibility, reward, skill knowledge, cognitive abilities, motivation, resources, structure and culture [38][46]. Knowledge, cognitive abilities, motivation are items for individual while resources, structure and culture are the items for organization.

3.3.2 Questionnaire Design

The questionnaire is composed with two parts. In part I, it consists of three general questions. First, respondents were asked to whether they have experience of using information systems in logistics before. Secondly, respondents would answer the current business type for their company. Finally, the position the respondents are. In Part II, it consist of 36 measurement items that used to measure the extent to which items described are information systems application, organizational issue and supply chain management performance. The scale ranges from Strong Disagree (1) to Strongly Agree (7). Respondents are needed to rank them.

3.3.3 Sampling

Target Corporations to be sampled were large and small-medium corporations which can carry out or provide value-added activities in a supply chain to other company in Hong Kong. The data were collected through questionnaires sent to supply chain managers. In order to raise the reliability of measurement, respondents will be requested to consult with others in

the SCM department or functional executives to answer the questions.

The group of respondents is from randomly selected the companies under web directory and company directory in Hong Kong Trade Development Council's official website.

3.3.4 Data Collection

For the replied respondents, 72 copies of paper questionnaire have been collected in the total of 200 copies of distribution (36% response rate), 1 of them were invalid due to missing data contained (35.5% useable response rate), so that sample size of respondent was 71.

4. Research Findings

4.1 Descriptive Analysis

Of the 71 questionnaires from the respondents' company, all of them had experience to use information systems applications in logistics. In current business type, A quarter (25 %) of them was logistics service providers, 22.5% of them were distribution and transportation, nearly 20 % of them are retailers. In the current position of respondents, nearly half of them (49.3%) are information technology or information systems manager, and while nearly 41% of them are operation managers. Less than 10% of them are general manager. Neither of them are Chairman nor Chief Executive Officer. In Organizational factors, Authority, responsibility and policies have a higher means in the factors. In SCM performance, Perfect Order Fulfillment, Accuracy of order processing, and reduction of response time from customers have a higher means in the factors.

4.2 Factor Analysis

Factor analysis by Varimax rotation was used to assess the constructs of 12 measured degrees of functional IS utilizations. The eigenvalues and the cumulative variance were shown in Table 1. According to Bryman and Cramer, factors that have eigenvalues greater than one were selected and extracted for further analysis. As a result 3 factors were extracted, with 68.417% of total variance.

All 12 variables were found to be loaded on one of 3 factors with factor loading greater than 0.5 which is consider significant.

The 12 functions identified can be divided into 3 major utilization areas. The detail discussion about classification of characteristics of IS for supply chain management will be founded in the discussion part.

Table 1: Convergence/divergence of extracted factors

	Components (Extracted Factors)		
	1	2	3
Distribution and transportation management.	.904		
Resource management	.870		
Forecasting	.848		

Order processing	.810		
Plant and warehouse	.707		
Accounting		.895	
Networking planning and design system		.827	
Office management		.784	
Sales and price management			.743
Inventory and warehouse management			.722
Service and customer management			.703
Production plan and process control			.650
Cronbach Alpha	0.8991	0.8149	0.7299
Eigenevalue	4.357	2.414	1.439
Cumulative variance %	36.309	56.428	68.417

4.3. Reliability

The reliability test result shows that the alphas of factor 1 to 3 are already greater than the reliability ratio (0.7)

4.4 Path Analysis

The multiple regression analysis technique was used to model the interrelationship among the latent variables. The R^2 were shown in Table 2.

Table 2: Path coefficients of all variables

Variables	IS for Infrastructural Support	IS for Value Creation Management	IS for Logistics Operations	SCM Performance
Organizational Factors	1.868x10 ⁻²	0.199	-2.756x10 ⁻²	0.445*
IS for Infrastructural Support	---	0.227*	-3.422x10 ⁻³	0.445*
IS for Value Creation Management	---	---	0.448*	0.445*
IS for Logistics Operations	---	0.333*	---	0.445*
R2	0.00	0.260	0.180	0.180

P < 0.05

To conclude, the organizational factors do not have a significant direct effect on the IS for Infrastructural support, Value Creation Management, and Logistics Operations respectively. IS for Infrastructural support has a significant direct effect on the IS for Value Creation Management. IS for Value Creation Management has a significant direct effect on the IS for Logistics Operations and SCM Performance. IS for Logistics Operations has a significant effect on the IS for Value Creation Management.

After that, the total effect of each variable was calculated by sum of the direct effect and indirect effect

of variables. So total effect of IS for Value Creation Management was 0.560 (0.227+0.333 = 0.560). The total effect of IS for Logistics Operations was 0.550 (0.448+ 0.448 x 0.227=0.555). The total effect of SCM performance was 0.694 (0.445 + 0.227 x 0.445 + 0.333x 0.445 = 0.6942).

5. Discussion and Implications

5.1 Discussion

a. The classification of the characteristics of IS utilized for supply chain management

The 12 functions identified can be divided into 3 major utilization areas. The first is the IS/IT utilization for logistics operations that focuses on the connection among value chain activities within and outside of a corporation (plant/warehouse location, resource management, order processing, distribution and transportation management, and forecasting). The second is IS/IT utilization for value creation management that focus on automation and improvement of the physical aspects of individual value chain activities (product/process control, inventory/warehouse management, sales/price management, and consumer service/customer management). The third is the IS/IT utilization for infrastructural support which provides infrastructural foundation for the effective operation of value chain activities (network planning/design system, office information system, accounting information system).

The above classification into 3 clusters of utilization areas has validity in light of the previous studies on the classification of logistics activities and functional information systems for logistics management [6][9][14][22][31][36][41]. The functional information systems comprising the same factor has high-level factor loadings on the factor, thus a high validity.

The result from the research model confirms H1, H3, H4, H5, but do not lend support for H2, H6, H7, H8 and H9.

b. IS/IT for infrastructural support

First, IS/IT for infrastructural support does not have a direct effect on SCM performance. However IS/IT utilization for infrastructural support has a direct effect on IS/IT utilization for value creation management, and IS utilization for value creation management has a direct effect on supply chain management performance. This means that IS/IT utilization for infrastructural support may play an indirect effect in enhancing supply chain management performance through IS/IT utilization for value creation management. The validity So it can be served as the foundations for IS/IT utilization for infrastructural support provides the basis for establishing strategic linkages that direct IS/IT application to value chain activities which can help increase the supply chain performance and consequently gain competitive advantage [13][17][18][33]

c. IS/IT for value creation management

Second, It is about the structural relationship among the three IS/IT latent variables showing IS/IT

utilization in a supply chain. The paths that are statistically significant indicating the structural relationship: infrastructural support \rightarrow value creation management \rightarrow logistics operations. This implies that IS for infrastructural support enhances the utilization level of IS for value creation management brings about use of IS/IT for logistics operations. The result shows that IS utilization for value creation management is a precondition for the utilization of IS/IT for logistics operations. In other words, IS/IT utilization for value creation management should be established in order to make sure that utilization of IS for logistics operations work properly. This coincides with the previous studies, which emphasize that improvements of each internal function should be preceded by the external connection with suppliers and customers, IS/IT utilization strategy should be step by step in the processes [9][12][40].

d. IS/IT for logistics operations

Thirdly, the relationship between use of IS/IT for logistics operations and supply chain management performance. The result shows that the path coefficient is not statistically significant. This can suggest that benefits of IS/IT for logistics operations on supply chain management performance are not supported in the study sample. Partial explanation for this result was shown in the previous studies. The majority of the items related to aspect of supply chain over which the logistics function does not exercise direct control. Another explanation could be that IS/IT utilization for logistics operations and its influence could be related to the firm's stage of supply chain integration. That means it can be speculated that IS/IT utilization for logistics operations is more beneficial in firms that are pursuing external integration than in firms that are pursuing internal integration [40].

Fourth, the relationship between utilization of IS/IT for logistics operations and IS/IT for value creation management. The relationship was not shown in the previous studies, especially utilization of IS for logistics operations \rightarrow IS for value creation management. The path coefficient is statistically significant on these utilizations. This situation can be explained that the logistics operations in several areas such as order processing, resource management, distribution management which can support the IS/IT for value creation management. Functional support of logistics operations serve as a factor for value creation management such as inventory and sales which give provide the value-added service to customers. The recursive relationship between utilization of IS/IT for logistics operations and IS/IT for value creation management shows that the both functions of IS should not be ignored in the supply chain activities and well-established in order to utilize both functions. Although the relationship between use of IS for logistics operations and supply chain management performance is not valid, IS/IT for logistics operations can be served as an indirect effect on supply chain performance, so the logistics operations have some degrees of effect of the performance such as time and costs.

e. Organizational Factors

Finally, the relationship of organizational factors with IS utilization of infrastructural support, IS for value creation management and IS for logistics operations. There are no statistically significant effects on these IS utilizations. Some reasons can be explained in the following:

First of all, the respondents were mainly small and medium enterprises in Hong Kong. The size and structure of the organization are small. The functions of IS and IT are limited for their current business. Functions of IS and IT can be accepted if the sales and revenues can be generated and recover the revenue. The functions and scope of IS and IT are limited due to size of organization and amount of investments. A small group of staff are responsible for all functions in the business. Organizational factors, such as leadership, motivation, policies, skills and knowledge may not fully be utilized and concerned by top managements in the companies.

Secondly, the respondents are from different business in Hong Kong, and from the descriptive analysis, there is no dominated business groups in the study, so that no clear dominated organizational factors can be found in the study. This may minimize the effect of organizational factors to different functions of IS utilization.

f. SCM Performance

From data analysis, respondents mainly concern about supply chain performance. Perfect order fulfillment, accuracy, reduction of response time have a higher ranking which mainly concerned by the management in the company. The major concerns for the company are customer-orientated measurement.

To conclude, the companies mainly concern about customer orientated performance measurement because customers are sources of generating revenue and sales. Because of limited customer resources for small and medium enterprises, if they lose the customers, they suffer the loss on sales and profits. This can motivate them to provide an excellent customer services with IS utilizations to gain their competitive advantages.

5.2 Implications

First of all, this research develops and validates a measurement scale for SCM performance on IS utilization in Hong Kong enterprises. This scale will give a preliminary foundation for facilitating research and analysis on SCM performance in Hong Kong, and examines its casual relationship and its effect on SCM performances. Research model adapted by previous studies will enrich current findings and clarify the IS influences on SCM performances thus enabling the further studies and theory development.

Secondly, this research provides empirically justified studies so that Hong Kong companies can understand that IS utilization are likely effect on SCM performance. From result of data analysis, IS/IT for infrastructural support and logistics operation has an indirect effect on SCM performance through value creation management while value creation management

has a direct effect on SCM performance. This gives an insight that IS value creation management is supported by infrastructural support and logistics operation in IS/IT functions and in order to provide an improved SCM performances.

Finally, knowledge of IS/IT utilization and organizational factors can be contributed to their consideration and planning for IS/IT strategy and adoption. IS strategy requires system preparations in term of gathering information about supply chain processes organization, environments, user and customers requirements [17]. Through these processes, company can understand the user requirements and customer requirements on IS/IT functions in order to full utilized the systems and improve SCM performances, i.e. efficiency and effectiveness of supply chain activities.

6. Recommendations

6.1 Supply chain integration

In order to full utilization of information systems in the supply chain management, top management should consider development of integration of supply chain. The existing study on supply chain management emphasize that supply chain integration should be accomplished sequentially from internal integration to external integration. [40]. In the sense, Stevens presents the integration process of supply chain management comprehensively starting with integration of related function to internal integration and on to external integration. Internal Integration is characterized by fully system visibility with a focus on tactical rather than strategic issues and emphasis on efficiency rather effectiveness. External Integration is characterized by completely sharing information on products, processes and specification changes; technology exchange and design support; a focus on strategic rather than tactical issues and long term planning. Management should have operational, tactical and strategic issue in the processes and IT development.

6.2 Continuous support on IS/IT development

Government and SMEs should cooperate together for continuous development of IT/IS in Hong Kong. According, to Hong Kong Logistics Council, Digital Trade and Transportation Network study completed in December 2002 confirmed the strategic value of the initiative and the importance of jump-starting the project so as to enhance HK's competitiveness as an international logistics hub. It is kind of e-platform for logistics system to facilitate information flow and sharing amongst the trade and logistics industry stakeholders. These features can be suggested to implement through Digital Trade and Transportation Network in Hong Kong for SMEs provided by Hong Kong SAR Government. This can increase the efficiency and effectiveness of processes and organization, which can enhance the competitiveness, and SCM performance of the company.

6.3 Considerations of implementing the IS utilization

The utilization of IS can actually have an effect on SCM performance, but how can we make sure that IS can be fully utilized? The several suggestions can be raised as consideration before implementing IS utilization which fulfill the organizational requirements and performance requirements.[16]

- a. It is important to have a scientific as well as an intuitive understanding of customer and supplier requirements, as well as all supply chain participants. Information systems and technology should be flexible and adaptable, depending on specific sets of needs.
- b. It is important to see that logistics organizational strategies move from a functional to a process orientation. Emphasis on the latter assures a more meaningful measurement of relevant processes and assures more timely and accurate process feedback and process knowledge.
- c. It is necessary for firms to create opportunities for interaction and team efforts among logistics managers and those others most knowledgeable about information technologies. Logistics managers need to know more information systems and information specialists must develop greater insight in to types of problems faced on the daily basis involved in managing in the logistics process.
- d. Financial resources are needed to assure a smooth, full implementation. The employees' cooperation and make use the systems also are very critical.

7. Conclusion

This research also empirically justifies that IT/IS for infrastructural support and logistics operations has indirect effects on SCM performance through value creation management. This gives an insight that IT/IS is fundamental for organizational value management, through value creation and growth, SCM performance, and further organizational performance can be enhanced. Finally, knowledge of IT/IS utilization and organizational factors can be contributed to their consideration and planning for IT/IS strategy and adoption.

Recommendations for further research and organizational IT/IS strategy are suggested based on these outcomes, such as supply chain integration, and consideration for implementation of IT/IS. IT/IS utilizations with strategic planning is believed to be more efficiency and effectiveness in SCM performances for the organizations.

A Stage Model of Knowledge Management Systems Diffusion Process: Findings From An Australian Study

Mohammed Quaddus and Jun Xu
Graduate School of Business
Curtin University of Technology,
78 Murray Street, Perth, WA 6000, Australia
Email: quaddusm@gsb.curtin.edu.au

Abstract

This study presents a stage model of knowledge management systems (KMS) diffusion process. It then provides empirical test of the sequence of KMS diffusion process in Australia. Structural equation modelling (SEM) using LISREL is used as the analytical tool for the empirical tests. The results show that all the hypotheses related to the sequence of the KMS diffusion process are significant. This is an important and significant finding. It clearly demonstrates how KMS adoption and diffusion phenomenon should be planned in Australian organizations. The results of the study add value to the literature of knowledge management. Also, the results provide practical and applicable suggestions to those companies, which are embarking on the adoption and diffusion of knowledge management system in Australia or elsewhere.

Key words: Knowledge Management Systems, Adoption and Diffusion, Structural Equation Modelling, LISREL

1. Introduction

As a result of the tough competition in the market place and the shift from resourced-based economy to knowledge-based economy, companies are looking at more and more in gaining competitive advantage through managing and maximizing their most valuable asset – “knowledge”. Although knowledge and knowledge management are not new concepts, knowledge management systems (KMS), which involve the application of IT systems and other organizational resources to manage knowledge strategically in a more effective and systematic way (Alavi & Leidner 1999), are relatively recent phenomenon. While the KMSs (or some variations) are widely applied in organizations, the topic of KMS has not been well explored by the researchers and scholars in an empirical way. Among the limited literature on KMS, which centers on cases of successes and failures of KM project applications and/or presents factors of successes and/or failures, there is a scarcity of empirical studies of KMS, especially in the area of adoption and diffusion of KMS. This paper reports the findings of an Australian study of the factors impacting on the diffusion of KMS in organization.

The paper is organized as follows. Section 2 presents relevant background to the study on knowledge management systems and model of innovation diffusion. The research method, which combines exploratory filed study, empirical pilot study, and national survey, is presented in section 3. Section 4 presents the development of the proposed hypotheses tested in the study. Results are presented and discussed in section 5 in detail. Finally, conclusions are presented in section 6.

2. Background

Knowledge Management System (KMS) is a broad way or approach to deal with the generation, preservation, and sharing of both tacit and explicit knowledge within and outside of the organization, which essentially involves the applications of Information Technology systems and other organizational resources (Alavi & Leidner, 1999). While the publicity related to organizational learning, intellectual capital, and knowledge management may pass with time, the need to effectively and systematically manage the knowledge will not diminish. Knowledge is more and more recognised by the organization as a key organizational asset for sustaining its competitiveness in the market place (Huber 2001). At present, applying computer-aided knowledge management system and the aggressive acquisition and retention of knowledge workers are two major knowledge management activities (Huber 2001). Companies are embarking on knowledge management systems to seek competitive advantage (Gottschalk 1999).

Alavi and Leidner (1999) report a survey regarding the issues, challenges, and benefits of knowledge management systems by collecting data from 109 participants of an executive development program, who are chief information officers (CIO), information systems managers, and general functional managers, representing a range of countries (Australia, Canada, Germany, Israel, Luxembourg, the Netherlands, Saudi Arab, South Africa, Spain, Switzerland, and the United States), industries, and organizations. The results of the survey indicate that, given the fact that knowledge management systems are only recent phenomenon, more and more companies were

adopting knowledge management systems. 44.63% of the respondents indicated that their organizations either have an existing KMS or are considering developing a KMS. Meanwhile 10.91 % of organizations are developing a KMS. The survey also uncovers some other interesting findings of the characteristics of KMS: (1) KMS were most commonly initiated by senior management (such as senior general managers, senior IS managers, and senior functional managers), (2) the range of investment on KMS was from US\$25,000 to 50,000,000. But KMS budget was related to size of the organization, the current level of infrastructure, and the scope of knowledge management initiative, (3) the most common KMS technologies were browser, electronic mail, and search retrieval tools. The authors also report that KMS were designed to gain the benefits in the perspectives of process results and organizational outcomes. The perceived KMS benefits for organizational outcomes included increased sales, decreased costs, higher profitability in financial area, improved customer services, better targeted marketing in market area, and improved project management, personal reduction in general areas. Meanwhile, the perceived benefits of KMS for process were primarily referred to the improvement in the communication (i.e., enhanced communication, faster communication, more visible opinions of staff, increased staff participation) and enhanced efficiency (i.e., reduced problem solving time, shortening proposal times, faster results, faster delivery to market, greater overall efficiency).

Some of the common applications of KMS are: (1) organizing and sharing/transferring of internal benchmarks/best practices (2) constructing corporate knowledge directories, such as corporate yellow pages, people information archive, etc. (3) creating knowledge networks and knowledge maps; among many others (Alavi & Leidner, 2001). In the past, many information systems (IS), such as management information systems, executive information systems, decision support system, knowledge-based systems, etc., have been focusing on the codified/explicit knowledge. Knowledge management systems provide the opportunities to extend the operating scope of information systems through facilitating organization's effort in managing both tacit and explicit knowledge (Alvi & Leidner, 2001).

Some examples of KMS applications in organizations include: Beckman Laboratory's "K-Entex" to share and disseminate knowledge (Pan & Scarborough, 1999); Xerox's "Eureka" to allow its 25,000 service representatives to share their collective technical wisdom (Bowen, 1999); Ernst & Young's "Ernie", an Internet based consulting service, resulting in a complete redefinition of the consulting industry and lead to what could be called "retail consulting" (Sarvary, 1999); AMP's "AMP Connect", a multilingual Internet catalogue of AMP products, to allow customers to access the information 24 hours a day; British Petroleum's

"Virtual Teamwork Project" using videoconferencing to speed up the solution of critical operation problems by saving millions of dollars in travel costs and downtime each year; Anderson-consulting's "Knowledge Exchange" to assist its clients in using knowledge to improve their operations and develop long-range strategies; Kim's "K-World" to manage knowledge globally (Thierauf, 1999); among many others.

Although KMS has been studied widely over the last several years, it has not received considerable scholarly attention. The existing research and studies on KMS consist primarily of general and conceptual principles of KMS and case descriptions of such systems in a handful of leading organizations. Those case descriptions also mainly focus on the issues of the process of implementing KMS (e.g., Davenport 1998, Ernst & Young, 1999), objectives of KMS (e.g., Davenport, 1998; Thierauf, 1999), critical factors of the successful KMS (e.g., Davenport, 1998; Skyrme & Amidon, 1998; Brand, 1998; Pan & Scarbrough, 1998), the characteristics of KMS leaders and laggards (e.g., Skyrme & Amidon, 1998), KMS applications in various business areas (e.g., Thierauf, 1999). The majority of research, (such as Thierauf, 1999; Chait, 1999; Pan & Scarbrough, 1999; and Sarvary 1999), have only covered the general and conceptual principles of building/creating and implementing knowledge management systems. Literature on the KMS diffusion could not be found at present, except the work by Scarbrough & Swan (2001). The authors used management fashion model to explain the diffusion of knowledge management.

In this paper, we focus on the diffusion process of KMS in Australia. Specifically, we want to identify the sequence of stages of KMS diffusion process.

Literature suggests that past research on diffusion of innovations have focused on the relationships of various factors (i.e. what factors influence and determine diffusion process) (the factor approach) or on understanding the various stages of diffusion process (the stage approach). Research on the factor approach generally resembles the typical diffusion studies which examine some form of adoption of innovations by individuals, which is the dependent variable. While research on the stage approach has studied the processes by which new technologies and systems are created and incorporated into the organizations (Prsecott & Conger 1995; Wolcott et al. 2001).

It is believed that KMS adoption and diffusion is a multifaceted phenomenon that takes place in a variety of ways over time (Wolcott et al. 2001). Rogers (1995) suggests a five-stage of innovation diffusion model: agenda-setting, matching, redefining/restructuring, clarifying, and routinizing. The five stages model can be simplified into three broad phases: Initiation, Adoption,

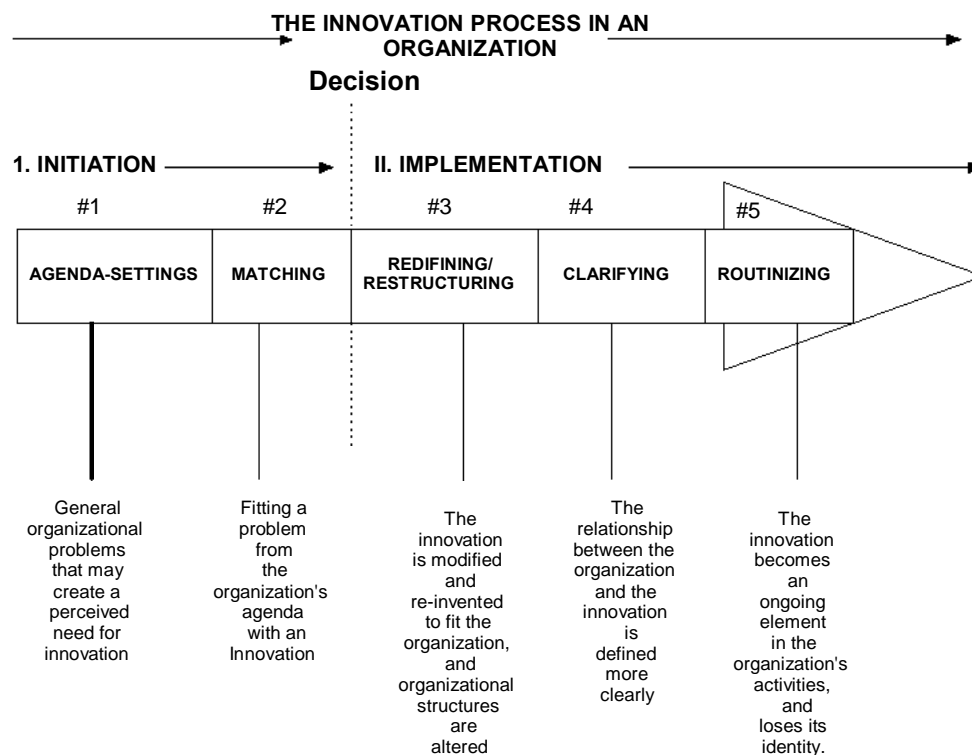

Figure 1: Five Stages of the Innovation Diffusion Process (Rogers 1995)

and Implementation. The initiation stage deals with the information gathering, conceptualizing, and planning for the adoption of an innovation, leading up to the decision to adopt (adoption stage). In the implementation stage, all of the events, actions, and decisions involved in putting an innovation into use are executed (see Figure 1).

At the same time, past studies, such as Kwon & Zmud 1987; Huff & Munro 1985; Cooper & Zmud 1990; Nilakanta & Scamell 1990; Brancheau & Webtherbe 1990; Gerwin 1988; Cash & McLeod 1985; Lewin 1952; Nolan 1973; Kanter 1988; Walton 1989; Applegate 1992; Grover & Goslar 1993; Rogers 1995; Rai 1995; Carter et al. 2001, among many others, have provided some various stage models of innovation diffusion, but they basically start with the initiation stage and finish with the diffusion stage. For example, Kwon and Zmud (1987) report such a stage model for innovation implementation process of initiation → adoption → adaptation → acceptance → use → incorporation. The study reported in this paper tested a six-stage of KMS diffusion process of initiation → adoption → pilot implementation → organic growth → organizational implementation → diffusion (sustained use), which is part of a comprehensive KMS adoption and diffusion model (see Figure 2) and is derived from field studies and literature review (Xu 2003).

3. Research Method

This study uses a mixed methodology approach. The research was carried out in three stages: field study, pilot survey, and national survey (top 1500 companies). In the first stage, a comprehensive model of KMS diffusion in organizations through a combination of literature review and qualitative field study was produced. Six companies took part in this phase, which resulted in eight interviews with key person(s) in the companies. The interviews were transcribed by the researchers and the contents were analysed thoroughly using a structured process. The content analysis and further refinement resulted in 16 factors and 72 unique variables. Company specific individual diffusion models were first developed which were then combined to develop a comprehensive KMS diffusion model. In the second stage, a questionnaire was developed based on the combined model. Twelve West Australian companies were randomly selected for the pilot study. The questionnaire was distributed to 125 functional and senior level managers in these companies. 25 valid responses were received. The results of the pilot survey proved the effectiveness of the questionnaire. Finally, the data of the study is collected through surveying the top 1,500 organizations (based on revenue) in Australia. The questionnaires were distributed to 1500 managers in those companies, who appeared to be most relevant to our study. In the end, there were 285 valid responses. The data of the national survey was analysed

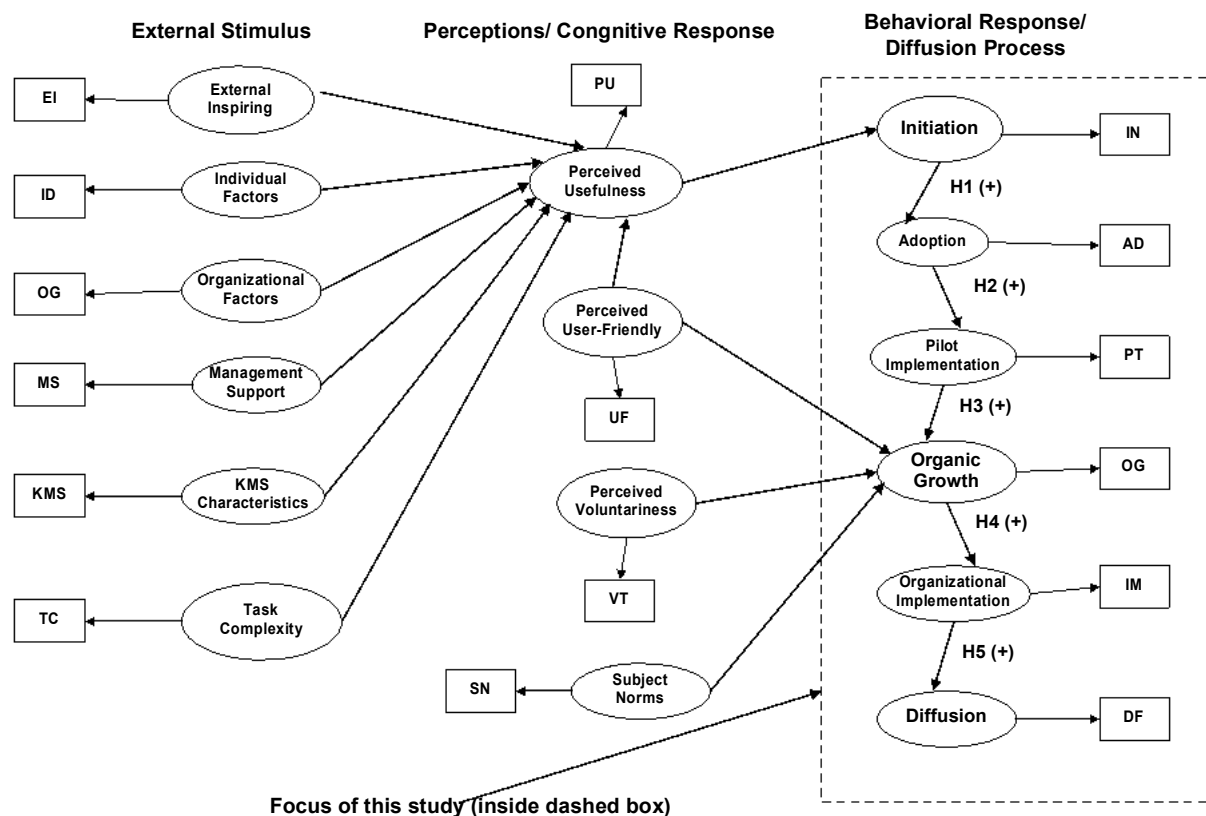

Figure 2: The Research Scope of This Study

through Structural Equation Modelling approach using LISREL, which resulted in a valid KMS adoption and diffusion model. The details of the three phases of the study can be found in Xu, Quaddus & Wood (2001); Quaddus, Xu & Wood (2002); and Quaddus & Xu (2002), respectively.

4. Hypotheses Development

During the field studies many participants talked about their organizations' dream of knowledge management system. There exists a shared opinion among the interview participants that organizations should have a knowledge management system to manage and control their knowledge in a more systematic and effective way. Brooking (1999) suggests that the best way to initiate a knowledge management system is to look at the real knowledge resource in the organization and see how that resource can be best managed.

After organization's effort in scanning the alternative solutions to effectively manage knowledge and researching in people's knowledge needs as well as available applications, a decision is made whether to adopt a KMS or not. In the case of successful initiation of

KMS, which is reflected by that KMS meets the organization's needs to manage knowledge and KMS is the best solution to control its knowledge assets, organization will make an adoption decision.

Organization should go through pilot tests until satisfaction of people's knowledge management needs is met (Phillips Fox 1998). Organizations should build their knowledge management systems with the users. When they are developing their knowledge management systems, they should listen to the users and act on what they suggest. That will help enhance the value of the systems and facilitate the users' 'buy-in'/acceptance of the systems.

When an organization is implementing a knowledge management system, it has the option to try and test the knowledge management system in smaller subset of users to begin with, instead of targeting all the potential users in the entire organization. The organization may limit the initial use of KMS to a single function (i.e., production, marketing, R & D) to a single division, and expand the use of KMS into the whole organization after having adequate experience with the system (Bansler & Havn 2002). The process of pilot-testing of a KMS with smaller and usually more homogeneous subset users may greatly facilitate the success of starting up the system. Benefits of

going through pilot-testing stage in a smaller and more homogeneous group users are: Firstly, it enables the system designers to better address individual users' interests and needs and achieves a good "fit" between the system and organizational context. Secondly, it can entice and educate the users to use the system by allowing organization to focus on certain part of the organization and thus take into the local characteristics of that specific part of organization, such as circumstances, values, etc., into consideration when the organization is planning to implement the system. Thirdly, the success of the first implementation in one part of the organization will have a positive influence on perceptions of the system in other parts of the organization, which will in turn lead to subsequent implementations. Fourthly, in the worst scenario, even the pilot implementation is eventually not successful in spite of careful planning and intensive efforts in achieving the critical mass of KMS use, the losses are more limited and in a smaller scale (Bansler & Havn 2002).

Meanwhile, organizations should persuade and educate people to use the knowledge management system. The most difficult part in knowledge management systems from cultural perspective is making people to understand that sharing knowledge and using the systems will bring benefits not only to the organization but also to themselves (Brooking 1999).

Pilot implementation is important in putting a knowledge management system into organization since it provides organization opportunities to optimise their knowledge management system and make adjustment on their structure and culture to facilitate the successful implementation of knowledge management system in organization. Meanwhile organic growth plays important role in putting a knowledge management system into organization, since it makes people interested in knowledge management system. Also, it gives people the capability to use the system.

Following the stages of pilot implementation and organic growth, it is time to implement the knowledge management system in the whole organization since both organization and individuals are ready for the knowledge management system. Organizational implementation deals with putting knowledge management system in every corner of the organization and every one in organization is expected to use the system. In organizational implementation stage people normally try to use all the functions of the system instead of limited usage in the stage of pilot implementation. It is noted that, factors such as optimized knowledge management system, pro-knowledge management structure and culture, people's willingness and interests in using the knowledge management system, and people's ability to use the system, can not guarantee the success of organizational implementation of knowledge management system. In order to successfully implement knowledge management system in the whole

organization, organizations should take pro-active actions.

One of the most frequently asked questions about knowledge management systems is "how do you know people will use them"? (Brooking 1999, p.128). Instead of compensating employees for sharing their knowledge, organization should make people understand that use of knowledge management system is part of their job to comply and is a part of culture - "the way we do things around here" (Brooking 1999, p.128).

After organizations implement the knowledge management system in the whole organization, people in the organization start to use the system. At this stage, organizations face another challenge - how to make sure people's sustained use of knowledge management system. Sustained use of knowledge management system means that people will use the system and using system has become a part of business as well as a part of people's life. For the purpose of achieving people's sustained use of the system, organizations should promote best practices of knowledge management and knowledge management system, keep on providing what people want in knowledge management system, encourage people's more usage and involvement in knowledge management and knowledge management system, make using the system as a part of the business, and make using the system a part of people's life in organization.

Gray (2000) suggests that increased number of employees specializing in knowledge management arising from the use of KMS will result in more increased use of the system. The author proposes that increased solution effectiveness through the use of KMS will lead to the enhanced perceptions of usefulness of KMS, which links to the higher level use of KMS.

As per the above the discussion, the following five hypotheses, related to the sequence of the KMS diffusion process, are suggested:

Hypothesis 1: Successful "Initiation" of KMS positively influences the "Adoption" of KMS in organizations.

Hypothesis 2: Successful "Adoption" of KMS positively influences the "Pilot Implementation" of KMS in organizations.

Hypothesis 3: Successful "Pilot Implementation" of KMS positively influences the "Organic Growth" of KMS in organizations.

Hypothesis 4: "Organic Growth" of KMS positively influences the "Organization-wide Implementation" of KMS.

Table-1 Results of Hypothesis Testing

Structural Relations Independent → Dependent Variables	Hypothesis	Standardized Path Coefficient β (t-value)	Significance of Hypothesis (5% level)
Initiation → Adoption	H1	0.872 (20.291)	Yes
Adoption → Pilot Implementation	H2	0.915 (20.429)	Yes
Pilot Implementation → Organic Growth	H3	0.171 (2.101)	Yes
Organic Growth → Organizational Implementation	H4	0.994 (26.816)	Yes
Organizational Implementation → Diffusion	H5	0.995 (28.018)	Yes

Hypothesis 5: “Organization-wide Implementation” of KMS positively influences the “Diffusion” of KMS in organizations.

5. Results and Discussions

5.1 Hypothesis Testing

The set of hypotheses (H1-H5) deals with the diffusion process of KMS and is tested using the t-value. The path is statistically valid or significant at the level of 5% if the t-value is greater than ± 1.96 . Results of the structural model analysis in LISREL are presented in Table-1. A number of previous studies have dealt with various stages of the diffusion process in general and in specific applications (see Rogers 1995 and Quaddus 1995; among many others). To the best of researchers' knowledge no empirical test of the sequences of these stages are available in the literature. Almost every diffusion process starts with initiation of some kind and ends with the large scale spread in use of the technology. In this study similar approach in determining the diffusion stages of KMS had been taken. However, it is noted that the diffusion stages in this study are first determined from the literature and then further refined during the qualitative field study process. The results show that all the hypotheses related to the sequence of the KMS diffusion process (H1 – H5; Table-1) were significant.

5.2 Further Analysis by Examining Direct, Indirect and Total Effects

After testing hypotheses, the model of KMS adoption and diffusion is further analysed by examining the total (i.e., direct and indirect) effects of structural part of the model. Total effect is the sum of direct effect and indirect effect. Direct effect is between two latent variables, which are connected or linked by a directed line or one-way arrows. In LISREL, a direct effect is measured by structural coefficients. An indirect effect between two latent variables, where there is no single straight line or arrow directly linking them, is defined when the second latent variable may be reached from the first latent variable through the mediation of one or more other variables. An indirect effect is reflected by the product of the structural

coefficients of all involved latent variables (Joreskog & Sorbon 1996a; Schumacker & Lomax 1996).

The effects among stages of KMS diffusion process are reported in Table-2. Initiation of KMS had significant direct effect on adoption (H1, $\beta = 0.872$ with $P < 0.001$). Initiation had significant but indirect effects on pilot implementation (0.798 with $P < 0.001$), organic growth (0.136 with $P < 0.05$), organizational implementation (0.135 with $P < 0.01$), and diffusion of KMS (0.135 with $P < 0.05$), mainly through adoption. The total effect of initiation on adoption (0.872) is greater than its total effect on pilot implementation (0.798), organic growth (0.136), organizational implementation (0.135), and diffusion of KMS (0.135). This implies that Adoption is the best choice after the initiation in the KMS diffusion process rather than pilot implementation, organic growth, organizational implementation, and diffusion of KMS. In other words, when an organization embarks on the adoption and diffusion of KMS, it is necessary to go through the stage of initiation before it proceeds to other stages of KMS diffusion process. Similarly adoption had significant direct effects on pilot implementation (H2, $\beta = 0.915$ with $P < 0.001$) and significant indirect effects through pilot implementation on organic growth (0.156), organizational implementation (0.155), and diffusion of KMS (0.155). The total effect of adoption on pilot implementation (0.915) is greater than its impact on organic growth (0.156), organizational implementation (0.155), and diffusion (0.155). This indicates that pilot implementation is the next stage of adoption in the KMS diffusion process rather than organic growth, organizational implementation, and diffusion. While pilot implementation had significant direct effect on organic growth (H3, $\beta = 0.171$ with $P < 0.05$) as well as significant indirect effect on organizational implementation ($\beta = 0.170$ with $P < 0.05$) and diffusion (0.169 with $P < 0.05$), organic growth is the best candidate for the subsequent stage after pilot implementation in the KMS diffusion, since its total effect on organic growth (0.171) is greater (even slightly) than its total effect on organizational implementation (0.170) and diffusion (0.169). Organic growth had significant direct effect on organizational implementation (H4, $\beta = 0.994$ with $P < 0.001$) and significant indirect effect on diffusion (0.989 with $P < 0.001$). Organizational implementation is

Table 2: Prediction of Stages of KMS Diffusion Process

Independent Factor→Dependent Factor	Direct Effect	Indirect Effect	Total Effect	Tested Hypothesis (Accepted ?)
Initiation → Adoption	0.872***	0	0.872***	H1 (Yes)
Initiation →Pilot Implementation	0	0.798***	0.798***	
Initiation →Organic Growth	0	0.136*	0.136*	
Initiation →Organizational Implementation	0	0.135*	0.135*	
Initiation → Diffusion	0	0.135*	0.135*	
Adoption →Pilot Implementation	0.915***	0	0.915***	H2 (Yes)
Adoption →Organic Growth	0	0.156*	0.156*	
Adoption →Organizational Implementation	0	0.155*	0.155*	
Adoption → Diffusion	0	0.155*	0.155*	
Pilot Implementation →Organic Growth	0.171*	0	0.171*	H3 (Yes)
Pilot Implementation → Organizational Implementation	0	0.170*	0.170*	
Pilot Implementation → Diffusion	0	0.169*	0.169*	
Organic Growth →Organizational Implementation	0.994***	0	0.994***	H4(Yes)
Organic Growth → Diffusion	0	0.989***	0.989***	
Organizational Implementation → Diffusion	0.995***	0	0.995***	H5 (Yes)

*P < 0.05, ** P<0.01, ***P<0.001

the better immediate linking stage after organic growth than diffusion in the KMS diffusion process, since the total effect of organic growth on organizational implementation (0.994) is higher than the total effect of organic growth on diffusion (0.989). Finally, organizational implementation had significant direct effect on the diffusion of KMS (H5, $\beta = 0.995$ with $P < 0.001$). In summary, KMS diffusion consists of six stages: initiation, adoption, pilot implementation, organic growth, organizational implementation, and diffusion in that order.

6. Conclusions

This research identified six stages of KMS diffusion based on the results from selected Australian companies as: initiation, adoption, pilot implementation, organic growth, organizational implementation, and sustained use/ diffusion of KMS. The identification of six-stages of KMS diffusion process is an important finding. In prior studies, researchers have come out with various stage models of innovation diffusion. But this study brings out a new stage of diffusion -organic growth, which reflects the individual learning and use of KMS. It also highlights the need for pilot implementation before the whole organizational implementation. The KMS adoption and diffusion model shows the detailed stages of KMS diffusion from “initiation” to “sustained use”. The direction of arrow indicates the sequence of the KMS diffusion stages.

The results have both managerial and research implications. The results of this study will add value to the literature of knowledge management. Organizations, which are practicing knowledge management or are

preparing to embark on knowledge management system should plan the process carefully in accordance with the sequence of these six stages. A clear planned sequence, as follows, can be adopted for the effective diffusion process of KMS.

- ⇒ Research the organization’s challenges and people’s needs regarding knowledge, i.e., identify the important knowledge domains for organization.
- ⇒ Search for suitable applications for KMS.
- ⇒ Develop a KMS plan/strategy.
- ⇒ Allocate a budget for KMS.
- ⇒ Appoint a Knowledge Manager or a Chief Knowledge Officer.
- ⇒ Build up/ Set up KMS.
- ⇒ Test KMS through pilot implementation on a limited basis in the organization and optimise the system according to feedback.
- ⇒ Work on the organizational culture and structure to facilitate the implementation of KMS.
- ⇒ Entice and educate people to use the KMS.
- ⇒ Provide people with continuous training and support to encourage their use of KMS.
- ⇒ Encourage people to go through the process of self-learning.
- ⇒ Implement the KMS throughout the organization.
- ⇒ Cut off people’s old means of accessing knowledge.
- ⇒ Develop organizational wide interest in using a KMS.
- ⇒ Monitor and check people’s usage of KMS.
- ⇒ Keep on providing the knowledge people want in the KMS.

- ⇒ Promote best practice.
- ⇒ Develop and encourage people's sustained use of KMS.
- ⇒ Make KMS and using KMS a part of business.

Finally, even though the research was conducted in Australian organizations, its results will apply to different organizations in various countries across the globe because of its generic approach.

Abstract

E-business is fast becoming an important initiative for companies to consider, one that impacts every aspect of how a business is run. This report investigates the impact of e-business implementation on various aspects of the organisation including; strategy, human resources, customer relationship management, the IT department, technology, the business environment, trust, service management and performance metrics. Implementing e-business applications will require process redesign, organisational restructuring and alignment, new job descriptions and reviewed and revised policies. Organisations will also have to examine tax, legal and security issues. E-business is changing all the rules and models. An organisation's ability to embrace new technology and business models is key to increasing the organisation's productivity. The Internet economy necessitates a fundamental transformation of traditional organisations. The true benefit of e-business is achieved through the digitisation of the entire value chain. For a successful e-business implementation it is important that decision-makers understand the nature of these changes, their potential impact, plan for them and manage the entire process in such a way as to ensure buy-in of all the relevant stakeholders. The decision to implement an e-business initiative should not be undertaken lightly and the benefits that can be gained from such a venture must be investigated thoroughly before deciding to go ahead.

1. Introduction

Timmel [24, p.22] quotes W. Krenz, Vice President of A.T. Kearny as saying "In 1999, the best chemical company had the best chemists. In 2005, the best chemical company will have the best e-professionals." This is true not only for companies in the chemical industry, but for all companies in all industries. E-Business is fast becoming an important initiative for companies to consider, one that impacts every aspect of how a business is run. This report investigates the impact of e-business implementation on various aspects of an organisation. The way in which companies and end-users conduct business will change, ultimately driven by the emergence of new business models brought on by the evolution of the Internet.

Hecker [10] defines e-business as any process that a business organisation conducts over a computer-mediated network. It includes buying and selling, as well as a wide range of customer-, production- and management focused processes carried out by for-profit, government or non-profit entities. E-business is based upon the processing and transmission of digitised information, including text and visual images from one computer or some other electronic device to another. E-commerce is that part of e-business which involves buying and selling goods and services. According to Agarwal, e-business is any net-enabled business activity that transforms internal and external relationships to create value and exploit market opportunities driven by new rules of the connected economy. Furthermore, e-business involves the continuous optimisation of an organisation's value proposition and value-chain position through the adoption of digital technology.

Implementing e-business applications will require process redesign, organisational restructuring and alignment, new job descriptions and reviewed and revised policies. Implementing e-business applications will also require organisations to examine tax, legal and security issues [13]. E-business is changing all the rules and models. An organisation's ability to embrace new technology and business models is key to increasing the organisation's productivity.

E-business impacts the value-chain processes in the exchange of goods, money, services and information. Basic market elements – who, what, when, where, how and why – are being radically altered by e-business. As companies incorporate e-business into their processes, a number of unique secondary effects are taking place. These effects include customers becoming more empowered, product development processes becoming more collaborative and marketing techniques becoming more targeted [12].

E-Business is focused on improving business performance through connectivity by deploying new technologies in the value chain to achieve transparency / visibility and also by connecting the value chains between and across external businesses and between business partners in order to obtain competitive

advantage, generate top line growth, reduce overall costs and open new channels. This definition of e-business extends well beyond the buy-sell relationship to include a transformation of the way to do business. If properly implemented, e-business can help an organisation to improve relationships with customers, increase revenues and cut costs.

E-business influence on an organisation can impact business efficiency and should be felt across the organisation ± from the time the sales force initiates a transaction, through the manufacturing and service cycles, right up until the time when the customers pay their bills. The impact of e-business on a company's effectiveness is found in its overall financial well-being. E-business is not just about buying over the Internet; it is about increasing the value of the organisation by improving the way it operates.

According to GMT [9] and Dalton [6] using ICT technology businesses can achieve significant improvements and cost reductions in several key functions in various departments, including

- Human resource services such as benefits, retirement planning and job postings.
- Internal communication.
- An executive information system.
- Purchasing.
- Sales force automation and management.
- Product development teams.
- Knowledge management.
- Improving relationships with partners.
- Improving time to market.
- Reducing operational costs.
- Increasing employee communication and satisfaction.
- Maintaining a competitive edge.
- Improving customer satisfaction.

The Internet economy necessitates a fundamental transformation of traditional organisations. The true benefits of e-business are achieved through the digitisation of the entire value chain [2]. Some of the most common benefits of e-business include streamlined sales processes, enhanced customer relationships, reduced operating expenses and dramatic improvements in productivity and operating efficiency [26].

2. Strategy

The implementation of an e-business has a significant impact on a company's existing strategy as well as strategy formulation. The basis for an effective e-

business strategy is an understanding of the company's business goals ± not its e-business goals. E-business is a way to facilitate improvements in a company's processes, in addition to allowing a company to expand market penetration, geographical markets, etc. Therefore, the processes that will be integrated into the e-business infrastructure must be both known and ready for integration. To implement e-business without understanding the company's business goals or processes is likely to lead to e-business failure [15]. Much like long-range business planning, e-business plans must be re-evaluated and adjusted on a regular basis. An e-business strategy is not a one-time event. It is an iterative process. In today's e-economy traditional planning horizons tend to be too long for the very fluid state of e-business. Continuous planning with feedback has evolved as the strategy of choice for the fluid and volatile e-environment [23].

In a survey conducted jointly by Information Week and Business Week, IT and business executives from all industries agree that generating new sources of revenue isn't the main goal of deploying e-business initiatives. In fact that ranked well behind creating or maintaining a competitive edge, improving customer satisfaction and keeping pace with the competition [6].

The ability to react and change direction is critical. Speed is everything. Grounding the organisation with sound, winning strategies is key [1]. E-business enabled organisations must be ready and able to adjust their business and IT strategies rapidly, depending on unpredictable competitors and market pressures. Today's e-business climate requires the continuous optimisation of an organisation's business and IT strategies. Because IT now has such a significant impact on every business process ± from order taking to inventory to billing ± both business and IT strategies are now developed in parallel.

The lack of a well-thought-out e-business strategy has led to some disastrous missteps [18]. In the past, businesses had the luxury of developing business strategies in the boardroom and information technology (IT) strategies in the IT department. They then brought these strategies together to run the overall business. A company implementing an e-business strategy cannot afford this luxury. Technology is no longer an afterthought in formulating business strategy, but the actual cause and driver [23].

According to Agarwal strategy and execution are key to developing and sustaining a successful e-business initiative. Only those organisations that successfully integrate key business strategy and processes dramatically increase their efficiencies. To be successful, organisations must also form the right strategic relationships and develop efficient business processes with robust back-end solutions that are able to meet users' demands for real-time service today and into the future. According to Barua, Konana, Whinston & Yin [2]

the achievement of e-business operational excellence will lead to improved financial performance. Based on this premise, the central task for senior managers lies in understanding what drive operational excellence in the e-business realm, and then committing the necessary resources to the development of the drivers.

E-business plans must be devised as part of the corporate strategy and must take into consideration the impact e-business will have on processes, governance and people. It is important that companies create a single coherent plan, formalise decision-making procedures and communicate e-business initiatives across the organisation and integrate the e-business plan with corporate goals [21].

An e-business implementation will also result in a company redefining their partner relationships, resulting in more cohesive, mutually beneficial partnerships [21] and management having to re-think all channels (Internet, telephony, store, mail order, etc.) and redesign how and who delivers their product or services [21].

Developing and communicating a strategy has become essential to realising the benefits that e-business can provide. Regularly reviewing and updating the e-business strategy is equally important because the competitive landscape and Internet environment are constantly changing [18].

According to GMT [9] the following must also be considered once a company has decided to embark on an e-business initiative.

1. Industry and company readiness: Is our company or industry prepared for e-business? Should we rapidly develop e-business capabilities? How will our internal processes and skills need to be altered to make a successful transition to e-business?
2. Channel conflict: How will our channel partners react to our entrance to the e-business realm? How large a risk is channel conflict? What steps can we take to mitigate that risk?
3. Prioritising e-business initiatives: Which elements of e-business need our immediate attention? Which projects should be funded and which need to be placed on hold?
4. Market models: Which models are successful for an organisation such as ours? What considerations need to be made before adopting a market model?
5. Organisational design: What changes need to be made to our existing internal structure to facilitate our e-business initiative? Which organisational structures work and which do not? How can we ensure employee buy-in?

Wilder [25] reports that the Internet and communications technology have changed the way

companies view their IT investments. For many companies launching e-business initiatives that advance strategic goals are more important than getting a hard-dollar return. As companies launch electronic-business projects, many are discarding their conventional thinking about the need for a return on investment and focussing on how the initiatives advance their overall business strategy ± whether it is to improve customer satisfaction, increase brand awareness or open new sales channels.

2.1. Assessment of company operations.

Implementing e-business requires that managers assess a company's operations by looking at both traditional and e-business measures. While most companies have a handle on the former, many are less focused on tracking e-business measures, including the percentage of an organisation's total business that has been transacted online, the percentage of goods purchased online from suppliers, the number of existing customers doing business online, the number of new customers acquired online, and the percentage of customer service requests handled online [2]. In order to achieve e-business excellence, managers must focus on three areas, namely e-business processes for customers and suppliers; IT applications for customers, suppliers and internal operations (all of which must be integrated); and the e-business readiness of customers and suppliers [2]. To achieve operational excellence and subsequent financial gains, managers must evaluate how processes align with e-business transformation, while encouraging the participation of suppliers, customers and internal constituents [2].

2.2. Major success factors for e-business

The following major success factors identified by Phan [17] must be incorporated into a company's strategy to ensure success:

- Internet technology fully integrated into the company's overall strategy.
- Competitive advantage maintained in both operational efficiency and distinctive strategic positioning.
- Basis of competition not shifted from traditional competitive advantage such as cost, profit, quality, service and features.
- Company's strategic positioning well maintained.
- Support from top management.
- Buyer behaviour and customer personalisation.
- Quick time to market.
- Right system infrastructure.
- Good cost control.

- Good e-business education and training to employees, management and customers.
- Customers' and partners' expectations well managed.
- Good products and services offered by e-business.
- Current e-business systems expanded to cover entire supply chain.
- New competitors and market shares tracked.
- Website of high quality that meets or exceeds user expectations.
- Company's virtual marketplace established.

2.3. Requirements for a sound e-business strategy

Ernst & Young reports that without a clear e-business strategy, there is a real risk that the link between the existing business strategy and any e-business initiatives will be unclear or even non-existent. It is likely to be difficult to define and measure how initiatives will benefit the organisation if the strategic goals they support have not been defined. Ultimately this means inefficient use of both funds and talents. In addition, development of a strategy typically forces consideration and acceptance of risks. E-business presents greater uncertainty. This reinforces the need for formal risk management strategies, which regularly assess and monitor the profile of new and identified risks whether internal or external. Ernst & Young has identified the following eight steps to a sound e-business strategy:

1. Develop an e-business strategy that is part of or fits with the main business strategy. The time horizon is likely to be shorter than those in the past. There may be a greater number of options considered and initiated, often referred to as a portfolio approach. The strategy may need to be expanded from the traditional content to consider risk around confidentiality and availability of information.
2. Assess the impact of e-business initiatives on existing internal and external processes and channels to ensure they are complementary and not counter-productive. A good website can be let down by inefficient or poorly interfaced supporting business processes. Evaluate options and be realistic about benefits and costs.
3. Consider the business organisation and the competitive landscape. Rapid changes force frequent review of goals and potentially require greater courage to discontinue less successful initiatives and start new ones.
4. Apply the same rigor and challenge to your e-business strategy as you would to other business programmes and initiatives. Use robust project

management to monitor costs and timescales on projects that typically have shorter timescales. Honest reporting is key to making tough decisions and halt projects if necessary.

5. Reassess your current risk culture to assess whether it meets the needs of a business model that is open to third parties through enhanced connectivity. Develop an enabling risk management strategy and framework that robustly consider the real likelihood and impact of risks.
6. Consider the impact of others on your brand and reputation, as well as the impact of your organisation on their environment.
7. Build in security at the outset \pm the common guidelines about it being significantly more expensive to add controls after implementation still apply.
8. Be innovative, but don't make unfounded assumptions. While you should not ignore your usual processes and controls, you should not be resigned to them.

3. Human resources

It is important to have the right people in place to take on the significant changes demanded by e-business [21]. Because of the fast change e-business related technology is going through, more is expected of employees than before, and today's expectations won't be the same tomorrow [3]. In this evolving economy, workers are constantly asked to update and expand their own skills sets, much as companies are shifting business processes to meet market demands. Cross-functional training and empowering employees are techniques that can be used to improve employee skills sets. Boomer [3] reports that 76% of IT professionals feel that e-business facilitates cross-functional work teams, which has a significant impact on employees' workloads and the company culture. Cross-functionality also provides many employees exposure to new issues. The E-business Agenda survey conducted by Information Week and Business Week reported that 82% of IT professionals surveyed agree that growth and change are making more work for all employees, up from 77% 18 months ago. Employees have more tools at their disposal to help complete daily tasks. There are intranets to simplify internal issues, the Internet to do outside research, and word processing programmes that virtually write letters and reports on their own.

The survey conducted by Information Week and Business Week found that e-business is having a significant impact on most employees. 80% of surveyed companies said that employees are burdened by new skills requirements, 73% said that e-business has spurred additional employee training and 55% of respondents said that e-business has forced individual employees to take on more responsibilities. IT and business executives reported that e-business increases the need for technology

skills, employee training and the need to work cross-functionally.

Setting up cross-functional groups is easy, getting them to operate smoothly is not; the challenges are enormous. Different members of a group may have conflicting ideas about how to code certain documents and regulate access to them via the company's intranets or extranets. Resolving problems requires a common view of the organisation from the perspective of the customer base [6]. Fostering cross-cultural operations may require formation of a hybrid group in the IT department consisting of employees who have both technical expertise and business acumen. Each person should be aligned with various business functions such as fulfilment, supply chain, and finance and work with process advisors from those areas to help leverage technology to improve productivity. Today, cross fertilisation between business and IT is happening at the most senior levels. Historically this did not happen [6].

Because of its increasing pervasiveness, e-business may be affecting output per worker and employment in virtually every industry. E-business is leading to the automation of some job functions and replaces others with self-service operations, raising output per worker and dampening employment requirements in some occupations [10]. E-business which automates many administrative support functions or makes them self-service, is expected to have a dampening effect on employment in administrative support occupations such as secretaries, general office clerks, human resource assistants, order clerks, bookkeepers, accountants, auditing clerks and word processors and typists. The reason is that much of the information that administrative support workers collect, manipulate and distribute can be digitised and transmitted over networks. Self-service systems permit an organisation's employees, customers, business partners and others to input and retrieve information from the organisation's computers without involving administrative support workers. This means that fewer workers are needed to answer questions, look up or enter computerised information, make reservations, produce and process documents and prepare mailings [10].

E-business applications in Human Resources are rapidly progressing toward an electronic delivery concept sometimes referred to as eHR [11]. The eHR model takes advantage of IT technology as a catalyst to redesign processes, empower employees at all levels and develop HR strategies that favourably impact the bottom line of the organisation. Initially eHR starts with putting content, transactions and modelling tools on the web (intranet). Ultimately an eHR organisation functions in real time where interactions are completed online through an aggregated and personalised portal. In an eHR model, technology drives capabilities out to the end users, enabling them to make fact-based decisions. The

technology also changes what is required of HR professionals and can support them in their new role.

4. Customer relationship management

The Internet has radically changed the notion of value as perceived by customers. Businesses have realised that today's consumer requires convenience in the shopping process: they require personalisation, want competitive prices and expect speed in service. Each business needs to evaluate how it can deploy technology in order to tip the value equation in its favour [23].

E-business is having an impact on customer relationships on various levels. The concept of customer sovereignty and the absolute necessity of firms satisfying customer needs is becoming a reality and it is changing marketplace behaviour. Furthermore a breakdown in specialised economic role of producers and consumers is occurring. Additionally, a system is emerging in which firms and customers increasingly interact and participate together in the design and delivery of offerings. Finally, as a consequence of both the process of interactivity and the development of "smart" or information-intensive goods, successful companies treat consumers as individuals and not as parts of larger aggregates or segments. Customer relationship management, one-to-one marketing and valuing the customer as the "new asset" ± as opposed to the product ± are becoming paramount to the organisation in the growing Internet world [12]. Customer relationships are becoming a more important factor in differentiating one business from another. In order to stay competitive, companies with e-business initiatives in every industry have begun to analyse these relationships with customers. Customer relationship management enables an organisation to adopt a comprehensive view of its customer to maximise the customer's relationship with the organisation and the customer's value to the company.

While e-business is reshaping the corporate landscape, it is also changing customer behaviours and expectations. This is specifically relevant for organisations involved in B2C e-commerce because the Internet has created an extremely demanding and information-sensitive customer [19]. Never before have so many value alternatives been available with such a level of convenience [26]. Organisations selling products or services online must be prepared to offer customers the best of both worlds: the ease of use of the Internet, combined with the high service levels they receive from brick-and-mortar retailers [9].

In a survey conducted by Information Week and Business Week, improving customer satisfaction ranked second only to creating a competitive edge as the best reason for an e-business initiative. Also, three out of four respondents said that as a result of their company's e-business deployments, they are listening more closely to their customers [6]. Technology not only increases the

ability of customers to communicate with companies, but free up customer-oriented personnel for more intensive responsibilities. As companies interact with their clients through electronic means, salespeople have increased face time and improved relationships with customers because many administrative tasks such as checking the status of orders are done on the Internet. However, as companies move many of their operations to the Internet, customers have easier access and insight into their inner workings. That means it is incumbent on businesses to know what they're doing. If fulfilment systems and procedures, for example aren't integrated with online storefronts, customers will be able to see that from the Web.

E-commerce is changing the way companies and their customers interact with each other. Traditional distribution channels, especially in the business-to-business sector, are being challenged. The Internet allows manufacturers to sell directly to their end-users. Buyers and sellers who used to rely on brokers, dealers, wholesalers and field salespeople now deal directly with each other [22].

4.1. Efficient consumer response

Until now the efficient consumer response (ECR) strategy has stressed the need to increase the end-to-end efficiency of the value chain in order to meet consumer needs better and faster. It has emphasised the importance of new replenishment processes, such as continuous replenishment programme (CRP), cross-docking and direct store delivery, as well as the need to establish electronic communication links in order to support them. The e-business paradigm goes well beyond that, relying not on the mere existence of electronic links between companies, but on the integration of processes at an inter-organisational level. It requires that information should flow continuously across the value chain in both directions, so that demanding operations at the interface with the consumer, such as home delivery, personalised service, lower prices, etc. are met faster, better and at less cost. This need becomes even greater for traditional companies in the sector, which have to compete with new distribution channels as well as cope with new competitive structures and new dynamics in the value chain [19].

The Internet forces companies to work directly with suppliers and customers in order to respond rapidly and intelligently to change. In addition e-commerce forces streamlining of the physical supply chain. In order to deal with change, companies and autonomous business units need an effective business design that allows them to react rapidly and continuously, innovate ceaselessly, and take on new strategic imperatives faster and more comfortably. In striving to succeed in the digital economy and gain a market advantage, companies must exploit the potential of successful partner relationships [19].

5. IT department

E-business is fundamentally changing the way IT departments function resulting in a realignment of the department's role within the business hierarchy [16]. This change is inevitable because the notion that e-business tools and concepts can be bolted onto current practices is a fallacy (Habershon in MacMillan 2000). IT and business must work together seamlessly, instantly updating inventory, processing complex orders and manufacturing on the fly. This represents a big change from the traditional manufacturing model.

e-business is placing increased pressure on IT by causing IT departments to reengineer and making greater demands on all workers in terms of job responsibilities and expanding skills [6]. As a result IT departments are hiring people with a mix of backgrounds and skills. Dalton [6] reports that regardless of industry, CIOs agree that achieving the right balance of skills in their departments is one of their toughest challenges. This is complicated by the fact that e-business increases the need for staff training.

Many IT managers have aspired to a greater role in the strategic business decisions of their organisations ± and thanks to e-business they are getting that wish. Due to e-business IT is becoming more tightly associated with business decisions. This is different from the past, when IT was simply given a project and left on its own to deliver it. IT needs to be part of business strategy sessions, both in terms of where the Web can take a company and delivering what customers want. Technology managers are expected to be more aware of the alternatives and opportunities for change and to enlighten business people about what they see evolving. In a survey conducted jointly by Information Week and Business Week, more than 70% of the 250 IT managers surveyed say that e-business has thrust their departments into a business decision-making process, almost 60% say e-business has forced IT to lead business-process engineering, 61% say that e-business has forced the IT department to reengineer and 60% said e-business has significantly changed the role of the IT department [6].

The survey also reported that 58% of IT executives say their staffs feel more empowered to engender change in the organisation due to the increased involvement of IT in the business reengineering process. The bad news is that 60% of IT respondents say that the constant change wrought by e-business increases job stress. Jim Noble, global head of IT strategy at General Motors Corp reports (in Dalton 1999) ^a that a sense of urgency pervades our IT function. We have to think in much shorter time cycles because the business wouldn't tolerate the latency we used to have.^o

While offering many advantages, e-business is creating a lot of challenges for IT managers, relating mainly to internal change and increased workload. It is

also requiring IT managers to communicate more effectively with staff and with the business side.

6. Technology

E-business is causing a change in how companies think about technology. This change is inevitable as the notion that e-business tools and concepts can be bolted on to current practices is a fallacy [16]. IT and business must work seamlessly. No longer relegated to the back office, technology has become an integral part of e-business enabled business processes. Reengineering is a tall order in any company, but integrating business and technology functions is especially difficult.

In trying to bring about e-business transformation, companies have generally focused too much of their attention on technology. But systems do not work in a vacuum, and senior managers must recognise the complementary nature of technology, business processes and e-business readiness throughout the value chain. By taking a more holistic view, managers can turn those facets of a company's operations into the drivers of e-business excellence.

Companies implementing an e-business initiative will have to replace or integrate formerly disparate systems and applications to improve decision-making capabilities and minimise redundant data entry and maintenance. Without seamless interfaces to administrative systems from Internet-based applications an e-business initiative will not succeed. As a result companies must address how e-business applications can be quickly be integrated with what already exists with minimal disruption to everyday operations and pre-existing investment [13]. It is critical to ensure that a company's technology and infrastructure competencies are adequate to support the planned e-business initiatives [21].

In an e-business initiative, technology shouldn't just be used to create the product. Technology must be used to innovate, entertain and enhance the entire experience surrounding the product, from selection and ordering to receiving and service [23].

7. Financial evaluation

According to Cohan [5] their research has found that large organisations are finding that traditional capital budgeting methods are difficult to apply to projects that employ Internet technology. E-commerce forces executives to adopt a non-traditional approach to measuring the payoff of a project. In traditional financial analysis, managers project the cash out- and inflows associated with projects. Discounting for the time value of money, managers calculate the net present value (NPV) of the project. If the NPV is positive, then managers should fund the project because it will generate value for the company in excess of the cost of the capital required to fund the project. If the NPV is negative

managers should decline to fund the project because it will subtract from the company's value.

If managers attempt to apply this traditional approach to analysing e-commerce projects they run into some practical difficulties. While the cash outflows associated with the project may be quantifiable, it is virtually impossible to estimate cash inflows that the project will generate. In the case of e-commerce for service provision, the future "cash inflows" are estimates of the number of people that will not need to be hired because the e-commerce application will perform a traditional process more efficiently. In the case of e-business for selling and distribution, the "cash inflows" may be measured in terms of the value of not falling behind competitors who are pursuing e-business initiatives. Because of these difficulties in estimating the cash inflows associated with e-business initiatives, Cohan [5] found that executives are developing new ways of measuring the payoff that leads to the decision whether or not to fund e-business initiatives.

Cohan's [5] research found that many executives view the cash outflows of an e-commerce initiative to be relatively small. Executives in established companies appear comfortable spending a relatively small amount of money to learn and experiment. With the experimentation come ideas for modifications to the original e-commerce project. These modifications also cost a relatively small amount of money, and result in an ongoing cycle of modest spending that generates useful insights for how to improve the e-commerce application. So the financial evaluation of the cash outflows for an e-commerce project has evolved into a process of quantifying the costs of a sequence of small learning experiments.

Similarly, the financial evaluation of the cash inflows from an e-commerce site has evolved into a process of estimating the likelihood that using the Internet to solve specific operating or competitive challenges facing the company would ultimately translate into some form of quantifiable value at an undetermined point in the future. This is a far cry from the traditional process of estimating future cash inflows and discounting them back to the present using the appropriate annuity discount factor.

8. Change management

In the modern e-business environment traditional change efforts don't work anymore. The speed of today's business environment means that companies must replace sequential change processes with parallel processing. That is, organisations must create strategy, build business and technical architectures and develop new cultures, skills and measures simultaneously. Strategy requires experimentation rather than months of analysis [4].

9. Business environment

E-business is changing the business dynamic and at the same time the Internet changes the traditional landscape of the business environment from that of being a marketplace to one that is more of a marketspace. This marketspace is an information and communication-based electronic exchange environment occupied by sophisticated computer and telecommunication technologies and digitised offerings (Berkowitz in Singh). The impact of this digitisation is evident in the following changes:

- The content of the transaction is different \pm information about the product often replaces the product itself.
- The context of the transaction is different \pm and electronic screen replaces the face-to-face transaction.
- The enabling infrastructure of transactions is different \pm computers and communications infrastructure may replace typical physical resources especially if the offering lends itself to a digitised format.

In marketspace the constraints of time, place, and geographic boundaries are completely eliminated [23].

10. Function lines in company

According to Rosen [20] the creation and maintenance of an e-business initiative can defy traditional functional lines within an organisation. The sales, support, operations and information services operations are directly affected by the e-business initiative. The likely effect on these operations is:

- Sales: Orders can be processed directly by customers. Sales cycles shorten and the number of customer calls decrease and their nature change. Customers don't require brochures, specifications and support sheets by mail since they can access this information from the company web site.
- Customer support and product service: Due to online shopping, the nature of questions will change. So will the access method, since customers will be asking questions through e-mail. Customers who shop online expect to be supported online. The support department needs staffing that can provide a quick response to e-mail questions.
- Operations: Traditional methods of ordering and fulfilling product orders will need to be integrated with new procedures developed to support the e-business.
- Information technology: Critical to the success of an e-commerce initiative is the integration of

e-commerce with existing computers and the identification of new processes and services. Web servers and web-enabled applications will need to be developed and supported. The IT department needs to be involved from the beginning to identify technologies and then integrate current and future systems.

Online shopping and purchasing affect the workings of the sales, support, operations and IT departments. In most traditional organisations these functions work apart from each other. An effective e-commerce service is the intersection of these departments.

11. Trust

E-business requires a greater degree of trust between a business, its partners and customers than in the traditional business model. Many businesses are therefore reluctant to fully embrace e-business. They feel uncomfortable in this new environment, and are concerned that better safeguards are required to protect against emerging, unfamiliar risks [14]. Even firms currently participating in e-business exhibit a fundamental lack of trust in many e-business processes. They worry about the confidentiality and authenticity of transactions conducted online and they have serious concerns about the fate of personal and confidential information once it enters cyberspace. Despite the tremendous growth projections for e-business, its full potential will only materialise if business partners truly trust e-business transactions. Trust is a fundamental component of any e-business strategy. Among e-business partners, trust is the product of each organisation's history, reputation, track record and patterns of behaviour [14]. Businesses that fail to assure third parties of the integrity, security and reliability of their operations run a very real risk of failure in their e-business initiatives. When deciding to embark on an e-business initiative it is therefore important for a company to address the trust and security issues in detail.

12. Service management

The concept of service management doesn't necessarily change in the e-business environment. Rather, the fundamentals become more crucial than ever and should be expanded to include all facets of the organisation. According to Habershon (in MacMillan 2000, p.6) ^a service management really does underpin e-business^o. E-business is forcing IT to stretch service management practices [16]. IT enabled service management (e-ITSM) should be based on processes that ensure the business runs successfully rather than on technical issues. What is different in an e-business environment is the scope of service management. To that end comprehensive risk and problem management should be conducted across the enterprise. e-ITSM should be equipped to handle quick changes and scalability issues. Service management must be uniform across all departments accessible through a common interface.

With respects to selecting service management tools, it is advisable to follow the best of breed approach.

13. Supply chain management

Integration of supply chain management (SCM) functions is emerging as one of the greatest challenges of companies embarking on e-business initiatives. SCM is the integration of business processes from end user through to original supplier. The goal of SCM is to create an end-to-end system that automates all the business processes between suppliers, distribution partners and trading partners. In an effective e-business initiative, the following SCM independent processes must be highly integrated: demand management, supply management and inbound/outbound logistics [1]. The digital economy has forever transformed the role of SCM. E-business and supply chains have merged, creating a network of immense opportunities. Supply chain structures have changed, and improving the performance of these supply chains is dependent on the use of e-business technology and innovation. Today's supply chain management systems, relying on technological breakthroughs, will propel the 21st century organisation into the digital world, where it's both a buyer's and seller's market. The companies who capitalise will have a dynamic, sophisticated supply chain aligned with their e-business strategy.

When implementing supply chain management, a company's management team must:

- Recognise the benefits an organisation can experience by incorporating the Internet and other IT technologies into its supply chain operations.
- Recognise the benefits of effective supply chain activities in an e-business environment.
- Match the business changes resulting from the use of technology and the Internet to organisational practices that reflect each.
- Match the three areas of impact to the value each adds to an e-business' supply chain.
- Identify the strategies for using technology to improve a supply chain's effectiveness.
- Use technology to effectively influence customer demand and fulfilment within an organisation's supply chain.
- Identify the strategies for effectively using technology to improve supply chain performance.
- Apply strategies to use technology within a supply chain to improve its performance in a given scenario.

14. Performance metrics

Although business fundamentals still exist and apply, companies that choose to change their business to utilise new technologies should be prepared for the fact that they will be judged and measured under a whole new set of rules. With technology and electronic transactions comes an expectation of immediate fulfilment. Managers, buyers and vendors believe that "all information is in the computer" and expect immediate status reports, reconciliations, etc. The electronic environment is real-time. Timeframes to produce and measure the success and failure of an E-business initiative are much shorter. E-business by nature is not entirely business as usual [15].

15. Conclusion

Incorporating electronic business in an organisation invariably has a significant impact on various operations and aspects of the organisation, causing changes in areas such as human resources, strategy planning, technological infrastructure and customer service. For a successful e-business implementation it is important that decision-makers understand the nature of these changes, their potential impact, plan for them and manage the change process in such a way as to ensure buy-in of all the relevant stakeholders. The decision to implement an e-business initiative should not be undertaken lightly and the benefits that can be gained from such a venture must be investigated thoroughly before deciding to go ahead. E-business plans must be devised as part of the corporate strategy and must take into consideration the impact e-business will have on processes, governance and people. It is important that companies create a single coherent plan, formalise decision-making procedures and communicate e-business initiatives across the organisation and integrate the e-business plan with corporate goals.

Abstract

The purpose of this study is to propose a fuzzy clustering model of information appliances (IA). There are two sub-models, saying information appliance cluster engine (IACE) and user interactive model (UIM), in this model. The function of IACE is to process the users' recognitions of IA devices. The UIM is the interface of IACE with the IA intelligent agents (IAIA). Via the proposed model, the IAIA can be more humanistic, and convenient for user. Also, via the implementation of this model, we can have the analysis of the optimal effectiveness.

1. Introduction

Along with the prosperity of internet, information appliance (IA), plays an important role for the future. The IA devices can be expanded to related information products. A satisfactory IA control mechanism can promote the integrity IA facilities, also, it enable the home network system more comfortable and convenience.

Lee and Huang [1] proposed an IA controlling model (IACM), which can control IA devices through home management broker. Chang [4] proposed the controlling mechanism of UPnP network under client-server architecture. Lee and Chen [2] presented IA intelligent agents (IAIA) to ensure the security and convenience of home environment. Wu and Jan [3] proposed home network management system integrating WAP and SMS by mobile communication devices. The home network has been expanded from local control to remote control, and from physical control to wireless control.

In this study, we propose a fuzzy clustering model of IA (FCIA). Via the proposed model, the IAIA can be more humanistic, and convenient for user. Also, via the implementation of this model, we can have the analysis of the optimal effectiveness.

2. FCIA

We proposed the fuzzy cluster model of information appliance (FCIA) is in information appliance control model (IACM) as shown in Figure 1. FCIA can promote the group capability of IA intelligent agent for managing IA devices to receive the user's requirements for clustering of IA devices and response clustering results.

Figure 1 IA controlling model

There are two sub-modules, saying IA clustering engine (IACE) and user interaction model (UIM) in FCIA, as showing Figure 2. Also, there is an IA device database (IADD). The functions of these components are as the followings:

Figure 2 Fuzzy clustering model of IA

- IACE: IACE is the core of this model. The users' recognitions of IA device are clustered through fuzzy cluster.
- UIM: UIM plays the interface among users, IAIA, and IACE. The various operating parameters of IACE can be defined via UIM.
- IADD: IADD stores the individual user's recognitions of IA devices and the clustering results of IACE.

According to user's submission, UIM will request the clustering demands to IACE, then, IACE will response clustering results to UIM.

2.1 IACE

The IACE is responsible for clustering works of IAs. It processes user's recognitions of IA to cluster IA devices, and it facilitates the management of remote control. The Figure 3 illustrates the operation flow of IACE:

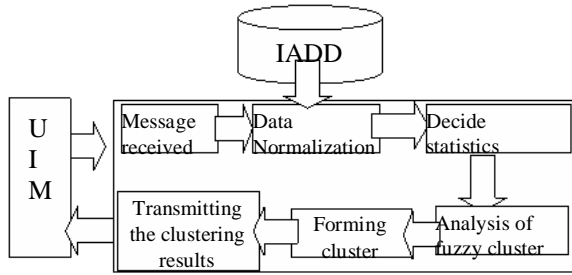

Figure 3 The operation flow of IACE

When the recognition of user are put into the IACE, the input and output will be transmitted to user through UIM. The format of data input, which is accepted by IACE, is shown in figure 4:

User_Name	Group_Numbe	λ-Valuee	Mode
-----------	-------------	----------	------

Figure 4 The Format of Data Input for IACE

User_Name represents the user who enters the engine. Group_Number is the cluster quantity of definition result. λ-Value is used for analysis of fuzzy cluster and the size of λ-Value will decide the number of cluster's category. The value of λ is between 0 and 1, larger the λ, less general the category, and smaller the λ, more refined the category. The Mode is responsible for distinguishing the mode of IACE used the current time, for example, 0 means proceeding clustering for all factors, 1 means proceeding clustering only for user's recognition with devices, 2 means proceeding clustering for data of hardware equipments.

As the user's recognition data are put into the IACE, the input and output will be transmitted to user through UIM.

After IACE receiving data, the step of entering IACE is – message received. The data received in the message format will be analyzed on this step, and then the command will be transmitted to the data normalization. The data will be acquired from IADD according to the command received. After acquiring the user's data from IADD, the procedure will enter into the step of data normalization, the data acquired from IADD will be normalized. The data format of IADD is shown in figure 5, $X_i (i|j>0)$ represents the category of IAs, and $Y_j (j|j>0)$ represents the conditions of measure. For the data normalization, we employ the formula (1) [7] to proceed normalization:

$$X_{ij} = \frac{X_{ij} - \{X_{ij}\}_{\min}}{\{X_{ij}\}_{\max} - \{X_{ij}\}_{\min}} \quad (1)$$

{Xij} Min represents the minimum of actual measurement value in row j
 {Xij} Max represents the maximum of actual measurement value in row j

After normalization, the data will be transmitted to the step of deciding statistics. The normalized data will be used to calculate the similarity of respective measurement attribute among IAs, consequently the fuzzy similar matrix is generated. For the IACE's deciding statistics, we apply the max-min method [7] as shown in (2):

$$r_{ij} = \frac{\sum_{k=1}^n \min(X_{ik}, X_{jk})}{\sum_{k=1}^m \max(X_{ik}, S_{jk})} \quad (2)$$

The fuzzy similar matrix is transmitted to the step of analysis of fuzzy clustering. The fuzzy similar matrix is clustered via the fuzzy clustering. We apply the netting method [7] and the maximum number method [7] for fuzzy clustering.

Finally, the clustering results are transmitted to UIM via transmitting procedure. IACE will generate the cluster of IAs.

	Y ₁	Y ₂	...	Y _n
X ₁	R ₁₁	R ₁₂	...	R _{1m}
X ₂	R ₂₁	R ₂₂	...	R _{2m}
...
X _n	R _{n1}	R _{n2}	...	R _{nm}

Figure 5. The storing method of IADD

2.2 The Weighing Factors of FCIA

This research incorporates the recognition conditions of security, entertainment, information acquiring, necessity for life, communication, comfort and convenience of devices and the recognitions of individual user of IA devices, as shown in Figure 6. The clustering information is acquired through IACE. Due to the different recognitions of individual user, the clustering results are different.

Figure 6 User's recognition

We ranged the user's recognitions of IA into seven grades, as shown in Table1. In many cases, we cannot express uncertainty problems simple by using the concept of probability. With the availability of concept of fuzzy set theory, we can solve the problem under fuzzy circumstances. Moreover, fuzziness can be quantified by using the properties of fuzzy numbers. We made the

linguistic values 1, 2, ..., 7 into corresponding reasonable fuzzy numbers with triangular membership functions.

Table 1 The Table of comparisons for semantic and fuzzy number

Fuzzy Number	Grade of relevance
$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$

Table 2 IA device of user's recognition

Device	Grade of relevance
$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$

The data will be stored in IADD. After normalizing user's recognition with IA devices, the data is presented in Table 3.

3. Implementation of IACE

In this section, we detail the practical environment for the model, and calculate the acquired data that describe AI's fuzzy clustering model by steps illustrated in Figure 6. Two clustering models are analyzed by maximum trees and netting mode, by substituting different λ interceptive value, different clustering models and the corresponding λ interceptive value can be obtained to represent the relationship between the clustering results. UIM's Web interactive Main interface will be presented at the end of this section.

Table 3 Normalization of user's recognition with IA devices

Device	Grade of relevance
$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$

3.1 Practical Environment

For the purpose of ease manipulation, cross-platform, and remote-control capability, we have applied Java Server Page (JSP) and Java Servlet written Web Server structure, and Java 2 Platform Standard Edition v 1.4.2 API Specification is utilized for constructing FCIA's model. This model is constructed upon Tomcat server software that employs browsers as its interface; above-mentioned are done with a Pentium III 700GHz Notebook that is powered by OS Windows Professional and Microsoft Access 2002 database.

3.2 Calculating Procedure of Empirical Data

IACE's fuzzy calculation is illustrated in this part as shown in Table 2. The diversity recognitions based on users' recognition on IA machine that may give a relevant level for machine and assessment factors.

Table 4 Matrix of IA device's fuzzy relation

Device	Grade of relevance
$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_1 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_2 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_3 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_4 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_5 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$
$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$	$\tilde{A}_6 = \{ \langle 1, 0.5, 1 \rangle, \langle 2, 0.3, 0.7 \rangle, \langle 3, 0.1, 0.9 \rangle, \langle 4, 0.1, 0.9 \rangle, \langle 5, 0.3, 0.7 \rangle, \langle 6, 0.5, 1 \rangle \}$

After data normalized, the similarity between each data would be calculated. This study would employ max-min method for showing the distance between each data, as in Table 4.

In addition, we show two fuzzy clustering methods as netting mode and maximum trees by fuzzy relation matrix R , and substituting different λ interceptive value, the compared and contrast diagram is shown in Figure 7.

Figure 7 Diagram of with different λ interceptive value

With maximum numbers method and $\lambda=0.5$, then we obtained cluster result as in Table 6.

Table 5 maximum trees and $\lambda=0.5$ interceptive value

Cluster 1	Digital Washing Machine, Digital Microwave, Digital Fridge, Digital Deco Lamps, Digital Light,
Cluster 2	Home Server, PDA
Cluster 3	Digital TV, Notebook, Set-top Box, mobile phones.
Cluster 4	DVD Player, Game station
Cluster 5	Digital Air Condition
Cluster 6	IR Sensor, Temperature Sensor, Smoke Detector

3.3 System Prototype

This study designs the Fuzzy Clustering Models, as an UIM screenshot in Figure 8, which facilitate user's ease interactivity with IACE. Since it is web base, it is even more user-friendly.

Figure 8 Prototype of FCIA System

4. Conclusion

This study presents a prototype for FCIA model, and shows its feasibility empirically with the result analytically assessed. We made some comments about this model.

- (1) It would be more convenient to provide quantities of clustering instead of applying λ interceptive value.
- (2) As Figure 7, the suitable clustering results for two methods are between $\lambda=0.4$ and 0.6. In this range, maximum number method of clustering is more stable

than netting clustering method. Besides, maximum trees method is more economical in terms of calculating system data. Therefore, maximum trees method is preferable in this model.

- (3) As in Figure 6, the model presented in this study can cluster AI devices according to user's recognition. Clustering results may be assigned for different types of users.

As above mention, the FCIA makes IAIA be more humanistic, and convenient for user.

Extending an E-Learning Model into Enterprise Resource Planning (ERP) Curriculum

Brendan McCarthy
School of Information Systems
Victoria University
Melbourne, Australia
Brendan.McCarthy@vu.edu.au

Abstract

The expansion of global education has created a new market for the e-education industry. Many universities have introduced distance learning programs and are trialling e-learning tools to support this expansion. Certain curriculum is more suited to the application of e-learning. The curriculum associated with the teaching of Enterprise Resource Planning (ERP) systems is one such area.

ERP systems offer a software-based system that handles an enterprise's total information system needs in an integrated fashion. Many universities have joined alliances with ERP vendors to allow the integration of ERP systems into their programs. This paper outlines the experiences of Victoria University in offering ERP education through a strategic alliance with the ERP vendor, SAP. The University is extending its offshore programs by offering ERP education in the Asian region and has developed an E-learning model to assist this expansion. The ERP e-learning model blends synchronous and asynchronous content. Asynchronous e-learning does not involve the presence of a teacher. Typically the learning content is located on a web server that students can access using the Internet. Synchronous e-learning requires the learner and teacher to be present in the event at the same time. It is a real-time, instructor-led online learning event in which all participants are available at the same time and can communicate directly with each other. The model uses four technologies to facilitate teaching: application service provision (ASP), web-CT, computer-based training and virtual classroom technology. The ERP e-learning model provides an innovative and efficient means to deliver ERP curriculum. It is able to provide greater flexibility in offshore subject delivery and to maximise student learning outcomes. This is particularly relevant in light of recent international medical (SARS) and terrorists incidents.

1. Introduction

The expansion of global education has created a new market for the e-education industry. Many universities have introduced distance learning programs and are trialling e-learning tools to support this expansion. Many studies have

been carried out on the effects of e-learning on a university's education strategy. Chan and Welebir [4] describe the effects of the Internet and online distance education on a university's overall strategy. They present a strategic agenda that traditional universities can follow to develop e-learning programs including the suggestion of forming a strategic alliance to enter the e-education market and expand globally. Gibson [6] suggests that the virtual classroom will eventually replace the traditional classroom. His study explores methods to enhance the distance learning experience and create a competitive advantage.

Curriculum associated with the teaching of Enterprise Resource Planning (ERP) systems is more suited to the use of e-learning tools than many other areas especially where the curriculum is expanded beyond the traditional boundaries of universities [9]. ERP systems are modular application software that helps businesses increase the productivity of such mission-critical components as human resources, finance, parts purchasing, inventory control, supply chain and customer relationship management. ERP systems are enterprise-wide and claim to incorporate best business practice that replaces legacy systems and current business processes. The leading ERP vendor is SAP. SAP maintains about 35% of the worldwide ERP market [7] and its ERP product is called SAP R/3.

SAP R/3 is based on an overall business model that makes possible a uniform view of all data and business processes in a business. SAP R/3's integration allows information to be entered into the system only once; this information then becomes part of the entire business's information system. SAP maintains a presence in all kinds of organizations such as: automotive, consumer products, chemical, manufacturing, oil and gas, high-tech pharmaceutical, and communications.

The variety and extent of ERP systems throughout the world offers university graduates having knowledge of ERP systems viable employment opportunities and career paths.

2. ERP Curriculum in Universities

Many universities have identified the value of incorporating ERP systems into university curriculum. ERP systems can be used to reinforce many of the concepts covered in the business discipline [2]. The systems incorporate “state of the art” technology providing a comprehensive teaching tool for computer science and information systems subjects [10]. Universities that have successfully incorporated an ERP system into their curricula find unprecedented student demand for those subjects.

Even though the value of including ERP systems into the curriculum has been identified, there are a number of barriers preventing this from happening. One significant hurdle is the limited knowledge and experience of academic staff charged with the responsibility of integrating ERP curriculum into their courses. ERP systems are complex and the time required by staff for developing curriculum is far in excess of the time experienced for curriculum development in other areas. The shortfall of academic skills and experience is further compounded by the limited access to relevant ERP professional development activities and the continual upgrade of software.

Another significant barrier to the use of ERP systems in universities is the perceived need for students to gain “hands-on” experience to master the concepts inherent in these types of systems [15]. In the past, if a university decided to incorporate a major software product into its curricula, it would have purchased the software and set up the necessary infrastructure to support it. ERP systems themselves are expensive but there are the additional associated costs of hardware and professional development for the computer support staff together with the necessary incentives to retain these people once they are skilled. Many universities find that the barriers associated with introducing ERP systems are just too great!

An increasing number of universities are investigating strategic alliances with ERP system vendors to provide the support for incorporating ERP knowledge into their curriculum [8]. The ERP vendor benefits from these alliances by increasing the supply of skilled graduates that can support their product thereby enhancing its marketability. Chan and Welebir [4] highlight the competitive advantages universities can gain by forming alliances, particularly their benefit in leveraging into the global e-education market.

The SAP University Alliance Program in Australia is an example of a strategic alliance between a number of universities and an ERP vendor. As part of the alliance, SAP provides approximately \$2.5 million worth of its product and technical and professional support for the

integration of SAP R/3 into the curriculum. However it is still the responsibility of individual academics to develop the necessary curriculum and the university to provide the necessary infrastructure to support the system.

3. The SAP Alliance at Victoria University

The Faculty of Business and Law on behalf of Victoria University joined the University Alliance Program in 1998. Up until then university alliance members had focused SAP R/3 around one particular department rather than an overall faculty. The faculty approach was believed to be a better method to facilitate the incorporation of SAP R/3 into curriculum. ERP systems support the various business processes within an organization. The respective departments within the faculty teach these processes and therefore the faculty approach enables each department to focus on the aspects of the software which is relevant to them.

Since joining the SAP University Alliance Victoria University has developed a Graduate Certificate, Graduate Diploma and Master of Business in Enterprise Resource Planning Systems as well as incorporating SAP R/3 into several undergraduate subjects. Currently we have 15 staff teaching more than 20 subjects at both the undergraduate and postgraduate levels to approximately 700 students.

Many higher education institutions are making plans to globalise their courses. Victoria University is no exception and offers a broad range of academic programs throughout the Asian region. The international programs involve over 3000 students from Malaysia, Singapore, People’s Republic of China and Bangladesh. Many of these universities have indicated that they wish to include ERP related subjects in their courses. While there have been indications that the high growth rates in the ERP market of recent years have somewhat dwindled, good growth has been maintained in many Asian markets with the expectation of continued growth in the foreseeable future [13]. SAP has established a University Alliance Program in many Asian countries to assist with provision of appropriately educated consultants to support this increased market. However even though these alliances have been established many of the universities have had difficulties in developing curriculum due to lack of skilled staff and available resources. Increasingly Asian universities are forming partnerships with western universities in an endeavour to broaden their curriculum offerings and add value to their students. Clearly there are advantages to be gained by both parties in setting up a partnership to teach different aspects of ERP systems. The provider is able to derive income to recoup some of the cost of developing curricula and maintaining systems while the receiver obtains the benefits of their students acquiring ERP education without the need to

invest in hardware, staff training and curriculum development.

In 2002 Victoria University commenced the Master of Business in ERP Systems at Sumbershire Business School, Singapore. In addition an agreement has been signed to commence our ERP masters program at the Northern Jiaotong University, P.R. of China in 2004.

4. ERP E-Learning Model

Many e-learning models have been developed and trials conducted in recent years. Neubauer and Lobel [11] describe a highly structured synchronous model for teaching and doing research on medium to large sized groups over the Internet. Arnone [1] reports on the technical standards being developed to allow colleges in the US to customise distance-learning programs by blending online-learning software from several vendors. Ehrmann and Collins [5] describe examples of virtual classrooms that use the Internet to create new kinds of collaboration and learning. Tansley and Bryson [14] evaluate the implications of replacing traditional modes of small group teaching with “virtual seminars”.

Victoria University has developed an e-learning ERP model to facilitate the teaching of ERP systems in our offshore ERP programs. This model uses a number of e-learning technologies that blend synchronous and asynchronous content. Asynchronous e-learning does not involve the presence of the teacher. Typically the learning content is located on a web server that students can access using the Internet. The content can be interactive but the presence of the teacher is not required. Typically asynchronous e-learning is implemented by Web-based training (WBT) and may include online forums, threaded discussions and download materials. Synchronous e-learning requires the learner and teacher to be present in the event at the same time. It is a real-time, instructor-led online learning event in which all participants are available at the same time and can communicate directly with each other.

To support offshore teaching a model for ERP e-learning has been developed and has been applied in Singapore since 2002. It is also used in a limited way in an offshore program in Hong Kong. The model blends synchronous and asynchronous content and integrates four major technologies which provide a comprehensive medium for online learning. The technologies are:

4.1 Application Service Provision

Application Service Provision (ASP) is responsible for providing the necessary technological infrastructure and support to host a particular software product. This enables the clients of the ASP to remotely access the software via the Internet. One of the barriers to ERP education mentioned earlier was gaining access to the ERP system and providing the necessary infrastructure. The ASP model provides a solution to overcoming this barrier.

Victoria University has configured one of its SAP servers to support the role of an ASP to its partnering universities in Asia. Students from these universities can access the SAP software at Victoria University via the Internet once they have installed the SAPgui software on their local PC's. Students can access the SAP software from anywhere in the world as if they were sitting in front of a PC at Victoria University.

The control and administration of the ERP system is still the responsibility of Victoria University and allows our Asian partners to access SAP R/3 without the need to purchase an expensive computer server and employ the necessary support staff. Through the use of clients in the SAP R/3 the system can be individually configured to suit the learning objectives of each offshore institution.

4.2 Web-CT

Web-CT is a web based tool which acts a repository of learning materials to assist students with their ERP education. Web-CT has tools for storing and delivering course materials including text, graphics, audio and video. Material can be released according to various criteria, such as date and student name.

Web-CT also has tools for organising and enhancing course material, communication tools so that chat, “internal” mail, discussion groups and whiteboards can be made available for use by students and instructors and tools for monitoring student progress and providing feedback.

In terms of ERP delivery the Web-CT site allows students to view and download subject outlines, assignments, past examination material and lectures in various formats. Students can submit assignments via the site and then view their results once the assignments have been marked. Chat facilities can be enabled to allow students to discuss set tutorial questions and discuss issues they have encountered. This interaction may occur between students within their tutorial, university, other Asian universities, or Victoria University.

Web-CT is used as the foundation to deliver the asynchronous e-learning content in the ERP offshore program.

4.3 iTutor

This tool is used for developing interactive tutorials in a simulated SAP environment. It enables the lecturer to record an action or transaction within the SAP environment and capture the screens involved to form the basis of a tutorial. After recording the tutorial, the iTutor Editor is used to edit the structure of the tutorial, define alternative paths (branching), edit instructional texts and create additional supplementary descriptive texts. This facility allows educational concepts to be inserted into tutorials using tools such as PowerPoint. The computer-based tutorials enable students to combine ERP theoretical concepts with the appropriate SAP screens and actions. Students can replay the tutorial as many times as necessary to understand the concepts.

The iTutor tool enables staff in the Asian location to have access to a repository of ERP educational materials overcoming the lack of resources barrier identified earlier. The Virtual Classroom technology is used for plenary sessions to reinforce the concepts covered and answer any questions coming out of the iTutor tutorials.

This tool has the added benefit of capturing and storing a lecturer's knowledge that can then be reused by others at a later stage either in a different subject or to assist if the lecturer is no longer available.

4.4 Virtual Classroom

There is a growing trend amongst academics to use the Internet to increase access to educational materials in a variety of ways to support the learning process [12]. The ASP enables access to the ERP system while the Virtual Classroom technology provides access to the curriculum.

The virtual classroom tool enables synchronous e-learning whereby the learner and teacher are present in the event at the same time. It is a real-time, instructor-led online learning event in which all participants are available at the same time and can communicate directly with each other. This virtual classroom capability is facilitated by the Centra Corporation virtual classroom software (Central Symposium) which provides the capability to deliver live, instructor-led classes direct to student desktops using fully integrated voice-over-IP technology. This is used to present theoretic concepts related to ERP Systems and practical demonstrations related to SAP software. Lesson delivery includes integrated full-duplex audio, interactive whiteboards, application sharing, breakout rooms and

online surveys and evaluations. The technology allows lessons to be recorded for editing and playback. Centra Symposium is very powerful as it integrates many interactive tools that can be used in the live delivery. Of particular note is the "Application Sharing" tool that allows an application stored on the presenter's PC to be viewed on the students PCs. The presenter can demonstrate features of the application to students in the session and also give control of the application to individual students and allow them to utilise and manipulate the application. This is a very powerful feature and quite unique.

If a student has a query, they can "summon" the lecturer via the Virtual Classroom and the lecturer can then appropriately respond to the query. This two-way communication facilitates the interaction between the lecturer and student thus enhancing the learning process. This has been lacking in many of the online solutions up-to-date.

5. Conclusion and Future Directions

The four e-learning technologies that blend synchronous and asynchronous content are not unique but combining these technologies to present ERP education is unique. They provide an avenue for ERP e-learning using a variety of methods to cater for students' differing needs and learning styles. The e-learning model has become increasingly relevant in light of recent issues such as SARS and terrorism that have acted to inhibit and disrupt offshore education.

We are using the ERP e-learning model with our partners in Singapore and Hong Kong. We are still in the early implementation stage. Once fully implemented we will carefully analyse the effectiveness of the model. If we find it successful we plan to extend our ERP e-learning model to include our other partnering universities throughout the Asian region. Beyond this we would explore the possibility of offering ERP education to anybody who enrolls online into any of the subjects on offer. This would be true e-learning as it provides the accessibility and flexibility to overcome the geographical barriers, ideologies, work commitments and traditional course structures that have prevented people from acquiring ERP knowledge and skills.

Abstract

This paper presents preliminary findings from work-in-progress that examines the attitudes of young Singaporeans toward mobile data services (MDS), focusing on the factors influencing their adoption of these emerging services. In-depth focus group interviews provided data for qualitative analysis. The analysis reveals that participants are generally receptive towards these technological services, based on their perceptions of the benefits of MDS and their expectation that MDS will deliver functional utility and satisfy hedonic influences. However, potential barriers to adoption include insecurity regarding MDS service providers, the reliability and security of MDS applications, their costs, loss of human touch, difficulty of use and a lack of social support. The authors conclude by discussing the contributions of their research to knowledge of technology acceptance and managerial practice.

1. Introduction

The surge in adoption of mobile digital devices worldwide [31] generates a keen interest by industry players to expand their profitability by offering mobile data services (MDS) to supplement voice telephony. To date, huge investments in Third Generation (3G) networks show disappointing results largely because network operators are unsure which 3G services consumers want and will pay for [12]. From the supply perspective, operators are reluctant to commit the fixed costs needed to develop new MDS unless they are certain that demand exists. From the demand perspective, wary Singapore consumers accept services such as text messaging and downloading ringtones and pictures, but do not actively seek new MDS [17].

Further, the demand for MDS is a moving target: each new MDS technology creates new possibilities to create consumer value, while consumer awareness of and preferences for MDS evolve. This dynamism in the MDS environment underscores a need of extending the scope of traditional adoption theories. From the practical

perspective, operators need to understand the drivers and inhibitors of MDS adoption.

This paper presents work-in-progress, focusing on our preliminary findings as we seek to understand the factors influencing adoption of mobile applications. The paper first reviews literature on adoption behavior, and discusses our methodology. Next, the paper reports the insights gained from in-depth focus group sessions conducted with young Singaporeans. The last section discusses the implications of these preliminary findings and presents recommendations for industry players.

2. Literature Review

Research on innovation diffusion and technology acceptance has examined various variables influencing the adoption of new innovations and technologies. These variables include activities of industry players, beliefs about using the new technology, perceived needs and past experience.

2.1 Activities of Industry Players

Gatignon and Robertson [14] posited that the actions of industry players, including their competitive activities, play a role in affecting the pattern of adoption and rate of diffusion. However, few studies have explained or empirically examined this role.

2.2 Beliefs about Using a New Technology

Based on the theory of reasoned action (TRA) [13], the technology acceptance model (TAM) [7] posits that two specific beliefs of using a new technology, namely, perceived ease of use and usefulness, affect people's acceptance of technology. Perceived ease of use is an indicator of the cognitive effort needed to learn and to utilize a technology whereas perceived usefulness is a measure of an individual's subjective assessment of the utility offered by a technology in a specific task-specific context [15]. The effect of these two variables on technology acceptance is supported by many empirical studies (e.g., [8] [24] [27]).

Most existing studies on technology acceptance focus their investigation on the functional utility of a new technology. Few studies have looked into people's evaluation of the costs and risks of using a new technology. The evaluation of costs and risks could be fairly complex as it may require an assessment of transaction costs, switching costs and opportunity costs. For example, in adopting a new computer software, a user generally must undertake a substantial change in the approach and the procedures involved in performing a task, which represents switching costs [11]. Further, the user must also consider the uncertainty concerning the performance of the new system functioning as advertised. In addition to attitude, subjective norms and perceived behavioral control were posited to influence intention to adopt the new behavior in the extended theory of planned behavior [1] [3] [27]. Researchers concur that beliefs about the normative expectations (normative beliefs) of other people and motivation to comply with these expectations influence a person's intention to adopt a technology.

2.3 Perceived Needs

The advantage that a new behavior creates basically reflects how well it helps satisfy certain innate needs of a user. Researchers studying uses and gratifications of technology postulate that adopters seek different gratifications in technology based upon their individual "needs" [9] [21] [22] [23] [26]. These needs may include social interactive, affective, cognitive, personal integrative and diversion needs [20].

2.4 Past Experiences

In deciding whether to use a new technology, an individual will compare the benefits, effort, costs and risks between adopting the new technology and continuing the use of an existing technology. Even when people are eager to change, there are forces that encourage the maintenance of existing behavior [30]. Although studies in this area have been modest in number, researchers report that past behavior has direct effects on intentions and/or behavior (e.g., [2] [29] [10]). For example, Venkatesh and Davis [29] found that direct experience with the software examined in their experiment affects technology acceptance, and explained this finding by saying that people essentially form self-efficacy beliefs from their own direct experience in a similar situation. Eastlick and Lotz [10] examined the influence of existing behaviors such as consumers' prior experience with computers, cable television and shopping from other non-store retailer categories on the adoption of interactive shopping. Their results showed that respondents with prior experience of similar innovative shopping activity (such as catalog shopping) were more likely to adopt interactive shopping.

In short, our literature review shows that the role of certain variables in the adoption decision process, such as the activity of industry players, perceived risks and past

experience have not been well investigated. Using MDS as an example, our research attempts to uncover various variables affecting technology adoption and the role that they play in the adoption process.

3. Methodology

The research presented in this paper represents the first stage of an ongoing project concerning MDS adoption in Singapore. Focus group interviews, which are beneficial for understanding attitudes and perceptions that are developed through interaction with other people [19], were used for generating insights in this stage. The interviews conducted help us specify the content area of MDS adoption and identify factors affecting the adoption.

The scope of this research is limited to three specific MDS: messaging (short text messaging or SMS and multimedia messaging or MMS), mobile gaming and non-voice mobile transactions. SMS refers to the delivery and receipt of messages that include only text over existing mobile networks, whereas MMS messages also incorporate images, sound or video. Mobile gaming refers to individual play of interactive games over mobile networks, or play of games that have been downloaded onto mobile devices. Non-voice mobile transactions refer to the non-vocal exchange of value between parties over existing mobile network based communication. These range from accessing information and downloading of free pictures and ringtones to payment for online goods and services, making donations, payment of bills, and purchases at the point of sale (such as retail stores, car parks, or cinemas).

The three specific services were selected because these types of applications are often the most profitable [4]; therefore, the work will be of interest to practitioners. Singaporeans are also more likely to be able to relate to these kinds of services because of the widespread adoption of SMS (80 percent), single-user gaming on mobile phones (12 percent) [17] and the Internet (nearly 60 percent in 2000) [18] as well as non-voice transactions (such as ATMs). Finally, some of these applications, especially mobile transactions and mobile gaming are recently launched. Thus, we may be able to gain insights into the reasons for variation in receptiveness towards MDS.

While small, the Singapore market is an interesting research site: at 78 percent, Singapore has one of the highest mobile phone penetrations in the world [5]. As the standard of living and economic condition in Singapore is generally good and the education standard is relatively high [18], subscribers have the digital literacy and disposable income needed to try out new services. Finally, a mix of cultures in Singapore provides a test-market for many innovations which diffuse to regional markets [28]. Thus, our findings will interest industry players.

3.1 Data Collection

The guidelines for the focus group discussions were derived from our literature review and research objectives. Participants were invited from several sources: convenience sampling of friends and acquaintances of the researcher, and invitations posted on online forums (such as Yahoo!) and in the public folder of a local university. The first session included tertiary students from local technical institutes, polytechnics and universities. The second session tapped young working adults in their twenties, who have been working for ten months to three years. Each session took approximately two hours, and began with general discussion of the participants' knowledge and sources of information about mobile technology and MDS. A deeper discussion ensued, focused on factors influencing adoption, past experience with mobile applications (if any), perceived barriers to the adoption and use of existing MDS, and their opinions about service providers. All sessions were videotaped for later analysis.

3.2 Data Analysis

Consistent with the "annotating-the-scripts approach" [16], we read the transcripts of the video-recorded sessions, and then re-watched the tapes, before interpreting the data. This enabled us to view each experience as a whole and to re-experience the group discussion, interpreting not only the transcript, but the body language and the tone of the discussion as well. We then analyzed our interpretations and highlighted the themes that emerged.

4. Findings

This section explores responses to uncover the motivations and barriers for the adoption of MDS. Our findings indicate that the tradeoff between perceived costs, risks and benefits, and subjective norms about the use of MDS influence the intention to adopt. Figure 1 portrays links among the main themes revealed during our research.

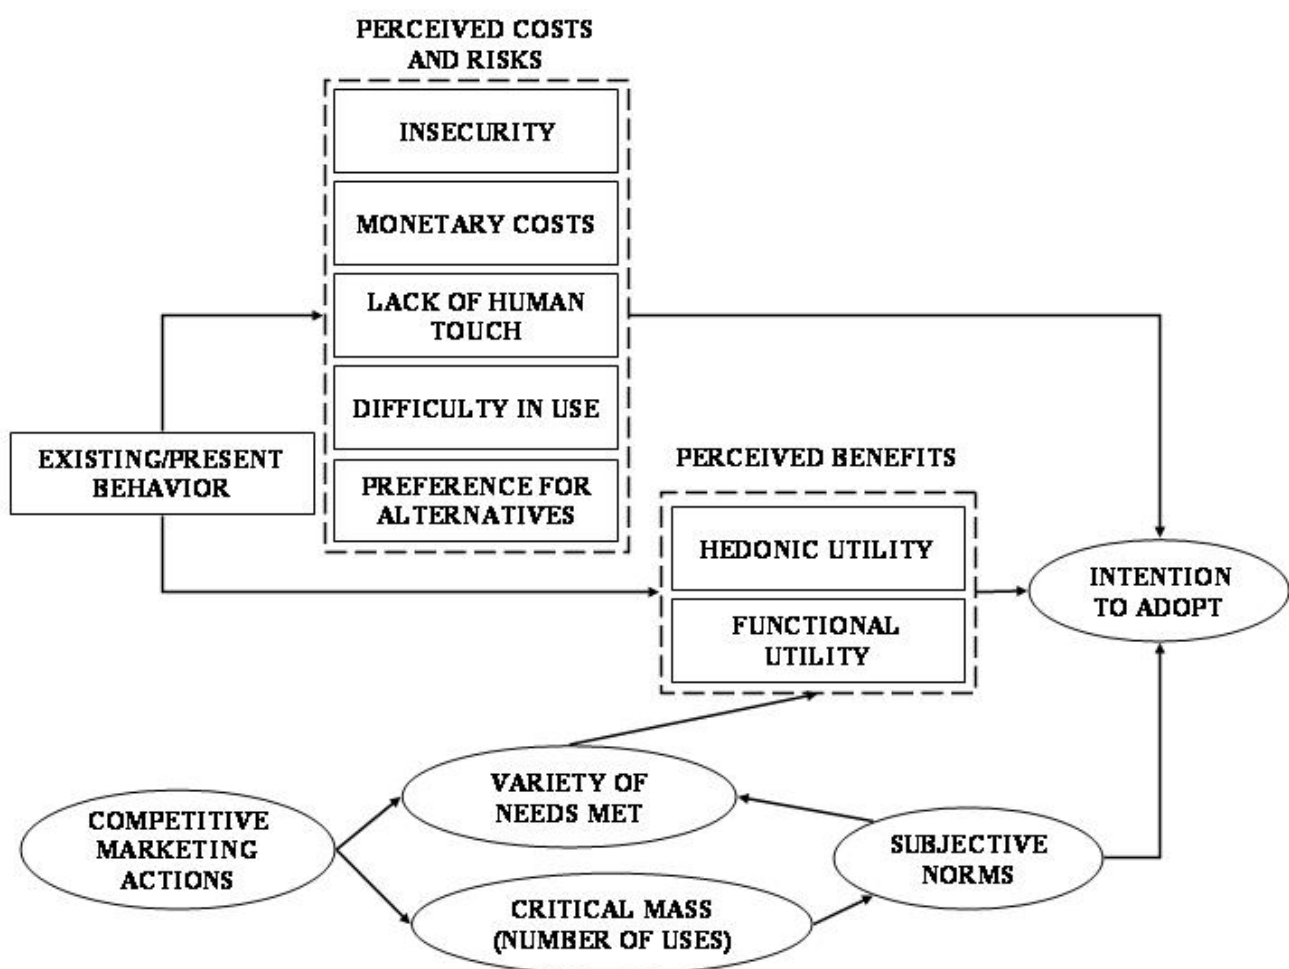

Figure 1 Main themes revealed in the focus group interviews

4.1 Drivers of MDS Adoption

Competitive marketing actions by industry players influence the pervasiveness of use of MDS within the society when they launch new services and improved affiliations. These actions help attract a critical mass of users, which then drives the formation of subjective norms. The norms in turn help generate the variety of needs met by using MDS, which subsequently influences consumers' perceptions of the benefits of using MDS, thereby affecting intention to adopt MDS.

4.1.1 Competitive Marketing Actions

Our findings show that participants rely on the mass media for information. They trust, to some extent, the information provided by the mass media and are attracted to new behaviors because of the media. This is evident from repeated comments by participants about the usefulness of MMS for real estate agents (which was portrayed in advertisements advocating the use of MMS by Nokia and the service providers in Singapore.)

Student E: ... "I find it very useful, let's say if the other party has the phone, then you can message him, the client, no need to go down and see, can get some kind of rough idea, ... You like, you can go down and see..."

4.1.2 Critical Mass

The use of the mobile device in our daily lives, coupled with messaging capabilities and installed games, captivates us and replaces the existing behavior of reading and sleeping while we wait or travel. In fact, this is also one reason for the massive success of SMS, which all our participants confess to be reliant upon.

Participant A¹: ... "there is a very strong expectation when you send a SMS is that you have to reply, everywhere. ... Even if that certain remark doesn't require a reply, you would still expect some kind of response."ⁱ

Student C: "Even when I'm asleep I'll keep my phone on. ... If I come to a state when I forget to bring my phone, I'll feel lacking, handicapped."

The excitement of competing with other people in playing games also helped in creating a critical mass who engaged in the "Snake" game (that is pre-installed in all Nokia handsets) craze at one time. As explained,

Participant F: ... "everybody were playing, then they'll go like ... I got 900 something points, then you'll no shio², so must go play as well."

This is also similar to the phenomenon of network gaming and multi-player gaming via the Internet. Therefore, it is likely that the downloading of games and the capability to play interactive games with other mobile device owners will be a hit if there is a critical mass involved.

4.1.3 Subjective Norms

Subjective norms are significant for three reasons. Firstly, they influence consumer adoption because most people have a need to belong, or conform to predominant behavior, which is usually brought about by the critical mass. For example, one of the reasons for the widespread adoption of Nokia handsets initially was the massive exchange of "picture" messages (using alphabets and symbols, users construct images that will only show up properly as pictures on Nokia handsets). As explained by a participant who related a similar scenario with MMS:

Student B: ... "if a lot of people are already using MMS and you still don't? ... they keep sending you MMS, and you keep cannot receive it. It's very irritating; gradually you would want to see what they actually send to me."

Secondly, as clarified by our student participants, subjective norms also provide a cue for the usefulness of the application. Conformist behavior could be due not only to the need to imitate and "belong", but also normative beliefs that "what others need should be what I need as well".

Student B: ... "if a lot of people have a need, you would also have a need."

Thirdly, subjective norms play an important communication role, as consumers seem to rely on it as a trustworthy source of information and feedback:

Student B: "Sometimes, it depends on what applications, you see. ... for mobile applications, I may wait for people to use it first..."

Interviewer: "Which one will you be more influenced by? Like the media, friends, family, or do you read up about it?"

Participant G: "Friends and media. I wouldn't go read up about such things. Can't be bothered."

Participant A: "Depends on the service."

4.1.4 Variety of Needs Met

The variety of needs the service can meet is a factor affecting attitude toward adoption. An anecdote raised by a participant led to the following discussion about this point:

Participant B: ... “No point they provide a service like pay car park, full stop... but others, like bills, fines, as well, more extensive, every other thing in your life. There’s a higher chance that you try something, and feel maybe it’s not bad, then you’ll try another, and another, then slowly pick up...”

This comment reminds us of the diffusion of stored-value cards in Singapore. The adoption of these cards only took off after the mandatory use in cars for the electronic road-pricing scheme (an automated toll-paying system for entering the business district) in Singapore. Subsequently, the use of these cards became more popular as it was later applied to many car parks, and even the grocer’s and vending machines.

The availability of more variation in the use of MDS affects people’s perceptions of its usefulness and benefits. MDS is not currently useful enough with its limited range of applications, most of which is also unknown to the ordinary mobile phone user.

4.1.5 Perceived Benefits

Two major benefits of MDS identified were functional utility and hedonic utility. Usefulness is the most easily identifiable factor influencing the adoption according to all the responses. The functional value of MDS points to two aspects: convenience and immediacy. These sentiments are shared by both focus groups.

Interviewer: “Would you be interested in shopping with your mobile phone?”

Participant B: “Yes. Why not? Sometimes, if I’m so busy at work, I don’t even have time to go and shop, so it’s very convenient...”

Participant E: “Sometimes when you are just on the streets, and you see something, and you want to check out something, you can check it out immediately... Or if you are out with your friends, and you have to decide where to go for dinner, so you can check it out immediately on the Internet to see what is good. And it’s very fast.”

Student C: ... “for certain kinds of information, you want it at that particular time, you need it ... it’s emergency that kind of thing...I need the information, there right now... even if later I have the information, it’ll be a lost cause.”

Functional utility is not the only advantage that consumers seek; hedonic “usefulness” is also important as consumers buy and consume certain products to make themselves feel good. The participants reveal keen affinity for camera-enabled phones, MMS and the

downloading of ringtones and pictures for reasons such as affection for the application and as a means of self-expression.

Student B: ...“ I like the idea you can take a picture anytime you want...”

Participant E: “...when suddenly everyone can afford a mobile phone. Then like got the same phone, so must make mine different, so download ring tones, and what have you.”

4.1.6 Existing/Present Behavior

Existing behavior serves as a basis to which the perceived benefits and risks of the new behavior is measured upon. Existing behavior can serve as a double-edged sword as it could encourage maintenance of existing behavior, or help reduce the learning curve and thereby encourage new behaviors. The participants relate this with regards to MMS:

Student C: “All I need is the basic functions. Like make and receive calls, and send and receive SMS... The optional functions are more on a case-to-case basis. Some may find that photo taking to be very useful, if they need it... But some don’t need it at all...”

Current use of SMS does not lead to a better opinion of MMS because participants do not view them in the same way. Of the fourteen participants, only about 30% had an MMS-enabled phone, and none used this capability regularly.

However, they also saw the other side of the influence of present behavior. Some are already avid players of pre-installed games on their mobile devices although these are single player games that are played only against the computer program installed in the mobile phone and are relatively simple. There are some who are also network and Internet multi-player gaming enthusiasts. Therefore, participants see these gaming behaviors similar and think that current practices will evolve to the new behavior because people are interested and the learning curve is reduced.

Student B: “People now already play games over their mobile phones. ... Especially when they are traveling, in the buses...”

Student C: “It’s an alternative source of entertainment... like last time I’ll read books, but now got my mobile phone to play with... most of those who are interested in LAN gaming... will play also, ‘cos it’s part of their hobby.

4.2. Barriers to Adoption and Use

There are many reasons for the decision not to adopt MDS, including insecurity, monetary costs, lack of human touch, a preference for alternatives and reliability.

4.2.1 Insecurity

In general, participants were insecure in three aspects: including a lack of confidence in their service providers, doubts about the reliability of the application as well as concerns about the security of mobile technology. Also, perhaps owing to the repercussions from the Internet security hazards, the security of the transaction is still a major deterrence despite people's interest in mobile transaction. These factors may pose major drawbacks especially with regard to mobile transactions.

Participants reveal a lack of trust and a generally poor impression of their service providers. This is a concern, especially with mobile transactions, because consumers may not adopt a service because of predicted difficulty in the usage as well as the lack of support in aid.

Participant E: "It's lousy... You don't hear from them, unless they (service provider) want to tell you that they have some new service, then they'll SMS you, or the next thing will be your next bill. Then you don't hear from them..."

Participant B: "...there's no way other than have complete trust in them that, that's the actual amount that you really used... I feel that there's a lack of consumer protection, they can bill anything they want..."

Interviewer: "...do you think the service providers are giving you enough help or information about MDS, or rather non-voice communications..."

Participant B: "If you are an existing subscriber, press 1. Then after 10, 15 minutes later, maybe you get some voice..."

Both groups of participants are also skeptical about the performance of mobile service applications as there is still little known about them. This is especially a concern when conducting mobile transactions because people will have to face the issue of accountability if the transaction goes awry. This is especially so with the student participants, who prefer cheaper and "just as convenient" alternatives:

Student A: "... I would rather call someone to talk to the person and make a reservation. ... Maybe I'm not good in that, that's why I don't use it."

Student E: "Maybe cock-up or something.... Then don't know who to blame."

The interest in mobile transaction is more prominent among young working adults who are possibly more time-poor. However, their attitudes toward adoption are also less positive, reflecting skepticism about MDS performance and the security of the channel.

Participant F: "... I think it's more feasible to carry around the notebook and the phone separately... You'll always fall back on something that you are comfortable with, like the PowerPoint in my laptop. And to use the phone with the PowerPoint presentation inside, I think I would still be a little afraid whether something will go wrong..."

Interviewer: "But if you are already so twenty-four by seven³ on your phone, you don't have to bring your money out, don't have to bring your cards out. Everywhere you go, just carry your handphone. Is the idea not appealing?"

Participant F: "There should at least be some kind of security code or password that you have to key in, so that at least it wouldn't be a problem if you get robbed..."

Interviewer: "Would you be interested in shopping with your mobile phone?"

Participant A: "Depends on the security."

4.2.2 Money Issues

A common characteristic of both groups is their unwillingness to pay for these services. The students were particularly concerned about cost possibly because of their limited income. Participants also distinguished between the cost of getting the device and the cost of maintaining the use of the service as separate issues. Seemingly, participants are willing to spend the extra money to be able to use the application, but this does not mean that they will actually capitalize on it.

Participant E: "... for example, my phone has GPRS, but I actually don't use it... But if I'm buying a new phone at the shop and the phone with GPRS just costs \$30 more, I will still buy the phone because it's like oh, it's additional benefit although I'm not going to use it..."

4.2.3 Lack of Human Touch

Both groups expressed concern about the lack of human touch. Human touch seemed to be more important for the time-poor young adults, who were less

capable than students of finding time to interact socially.

Participant A: ... "we could be meeting our friends through your phones."

Participant C: "That's so sad..."

Participant A: ... "when the technology is so advanced, and the cost is so cheap, people rather stay at home and have conversations... that's a concern, socially."

Student D: ... "with SMS, you cannot sense the tone of the person; ... it's not professional to use SMS to communicate 'cos there's no human touch to it. So actually calling the person would be more appropriate than SMS."

4.2.4 Difficulty in Use

Another factor hindering the adoption of some services is the ease of use of the application. As explained by a participant:

Participant F: ... "I wanted to use GPRS. I was trying to get it. So I went to the web site and all but two times I keep getting "cannot open file". It's just not easy when it comes to GPRS and that sort of thing."

This is also a major hindrance with mobile gaming because consumers are accustomed to game controls on keyboards and game devices, and not comfortable with the small size of the mobile devices, their low graphic quality and short battery life.

Participant E: "Quite hard, this one is like so small, there's no room for two thumbs to be moving around"

Participant B: "Controls small."

Participant G: "Also because my battery always run out, so I have to charge it, and it might be inconvenient to charge it where I am at that time."

4.2.5 Preference for Alternatives

Participants expressed the view that Singapore is too small a country to require MDS because of the existence of alternatives "which are all faster and cheaper". This point is reiterated several times in both sessions. Also, the use of MDS is just "yet another means of doing it", and so it is not critical that consumers adopt it.

Participant F: ... "Frankly I think it's much cheaper to stay at home and use the Internet. You're out, you use the mobile phone just to call people or send SMS..."

Using the Internet at home, calling the ticket hotline or going down to the cinema, I think that's faster."

Student C: "Actually, looking in the context of Singapore, Singapore is very small... from my place to any cinema is very nearby, so using such technology is not very feasible. There's other ways of doing it."

5. Discussion

Despite the practitioners' excitement in bringing MDS to the market, consumer acceptance is still uncertain. Our research shows that consumers are generally receptive but express several major reservations, mainly insecurity, money issues, and the lack of social motivation.

Although our small sample and qualitative approach make it risky to generalize our focus group findings, future research involving both qualitative and quantitative methodology could illuminate these issues more thoroughly. Recently, we conducted a survey on six hundred undergraduates in Singapore and the preliminary results of the survey corroborate some of the focus group findings. For example, about three out of four respondents (74.9 percent) express distrust in the reliability of the service providers in the billing and 81.9 percent of respondents find the idea of using MMS favorable. Present behavior of using the existing technologies (SMS, pre-installed games and Internet multi-player gaming) also shows significant and positive correlations with intention to use MMS (.217, $p < 0.01$) and mobile gaming (preinstalled games: .401, $p < 0.01$; multi-player gaming: .167, $p < 0.01$). Nearly half of the respondents (46.6 percent) expressed concern over the loss of human touch due to MMS while the majority of them (81.3 percent) regarded the use of MMS expensive.

5.1 Contribution to Knowledge

Consistent with existing literature, our findings suggest that consumers consider a myriad of factors, such as usefulness, normative beliefs and subjective norms before making a technology adoption decision. Most of previous studies, however, have focused on the adoption of technology in organizational contexts and also only concentrated on functional utility. In contrast, our findings corroborate the view that hedonic benefits affect consumers' adoption of technology [6], and highlight the importance of the role that industry players can perform in influencing adoption.

Interestingly, information and communication technology (ICT) which is originally intended for bringing people together could also separate people apart, as indicated by some of our participants' concern about the loss of human touch. This is consistent with

the paradox of assimilation and isolation of technological products that Mick and Fournier [25] proposed, whereby technology cannot only facilitate human togetherness but also lead to human separation. In addition, social influences affect not only normative beliefs about how our significant referents want us to behave, but also perceived beliefs and pervasiveness of use.

Our focus group findings also highlight the influence of present behavior (alternatives of satisfying particular needs) on the consideration of new behaviors, consistent with the studies by Venkatesh and Davis [29] and Eastlick and Lotz [10]. For example, consumers may consider going to the cinema directly or going online instead of booking the tickets over a mobile device.

5.2 Managerial Implications

Our focus group findings suggest that participants have a negative impression of the service providers, viewing them as profit-seeking companies rather than aids to their lifestyle. Thus, service providers could attempt to improve their images by taking an active role in meeting subscriber needs. Improving the image of the service providers will also demand establishing trust among the consumers. This will further help the adoption of MDS, especially with regards to mobile transactions.

Service providers might encourage MDS adoption by first absorbing costs for early adopters and then providing sufficient assistance to the next wave of users, thus ensuring that the perceived benefits of using an application will outweigh the costs of using it. The addition of applications via co-operation with content providers would also persuade trial of MDS. It would be advantageous to persuade consumers that MDS is an extension of alternatives such as self-service transaction machines (e.g. ATM) and cashless modes of transactions (e.g. stored value cards) rather than a new technology so as to reduce consumer perceived costs, risks and learning curve. Benefits such as “anytime, anywhere” as well as security and reliability issues should also be emphasized.

In order to reap the potential profits that MDS offers, a critical mass must be achieved. Our findings indicate that there are two major communication channels that consumers use – the mass media and word-of-mouth. As shown by the participants’ recollection of and interest in advertisements illustrating the usefulness and ease of use of MMS, industry players can consider making more use of the media in demonstrating new uses and MDS applications. The other main source of information for consumers is from word-of-mouth feedback. Thus service providers can also utilize this avenue for promotion of new services as well as encouraging adoption. For example, service providers can, based on their databases, find out users who are using or prone to using new applications. By communicating to these users or providing “exclusive

personalized promotions”, service providers can encourage them to recommend such services to their friends. For example, service providers can promote the formation of mobile communities for playing interactive gaming by offering discounts on each individual’s subscription.

5.3 Future Research

Consistent with traditional scale development methods, we used the findings from the focus group to refine a questionnaire that we recently employed in a survey. We conducted this survey for testing some of the relationships portrayed in Figure 1, and are currently analyzing the survey data. Future research examining the role of industry players on consumer adoption patterns is particularly valuable as little research has been done on the role. Future research examining how consumers cope with their present concerns with regards to an existing technology will also be useful in predicting and overcoming concerns about a new technology.

To conclude, we believe that in this dynamically changing environment, it is necessary to obtain a more thorough understanding of the adoption behavior of the consumers. This will aid the design and the marketing of the applications, thereby avoiding the lame adoption of some MDS applications, such as WAP.

6. Notes

¹ Student participants are labeled as “Student”. Young working adults are labeled as “Participant”.

² Shiok: lingo used in Singapore, synonymous with kick, high or feeling of excitement and happiness.

³ Twenty by seven means twenty-four hours by seven days a week.

Abstract

Employees generally need to solve various situations of problems occurred during task-executions in e-business. Such problem-solving behaviors contain rich information helpful to provide effective knowledge support. This work proposes a mining framework to discover problem-solving knowledge by analyzing problem-solving behaviors recorded in an intranet portal log file. The discovered knowledge can provide guidance and support to assist employees handle various situations of problems.

1. Introduction

The intranet became a platform for enterprises to deliver inner services to employees. Companies adopt Internet-based electronic services (e-services) conducting business process and sharing of process information. Database and knowledge-based system are set up as corporate knowledge repositories to manage corporate knowledge. Intranet portal provides the e-service to facilitate employees getting desire process knowledge in corporate knowledge repositories.

Providing task-relevant information to support effective task-executions in business processes has recently been investigated [1, 2, 4, 11, 16]. However, discovering task-relevant knowledge, in particular problem-solving knowledge has not been addressed. Employees generally need to solve various situations of problems occurred during task-executions in e-business. This work develops a mining framework to discover employee problem-solving knowledge from intranet access log file. The discovered problem-solving knowledge can assist employees search for solutions to provide effective task executions.

2. Related work

Kaula [8] outlined the necessary strategies for problem-solving. Wooldridge and Jennings [12, 13, 14] proposed a preliminary problem-solving model of team action. Heh [7] proposed a graphic-based evaluation model of problem-solving. Nair and Ramnarayan [10] investigated the relationship between cognitive needs of individuals and their effectiveness in solving complex problems. Gregor [5] investigated the role of explanations in knowledge-based systems to solve cooperative problems. Zhuge et al. [17] presented a cognitive-based problem-solving framework consisting of a problem-solving space, a category-based representation,

and a set of problem-solving control strategies. Zhuge [16] designed an approach integrating workflow and agent concept to cooperate problem-solving process.

Synonymy and polysemy issues have created limitations in information retrieval (IR). A high level, uniform knowledge framework is needed to better enable effective solution searching. Zhuge [15] proposed an active document framework (ADF) to make knowledge documents self-representable, self-explainable and self-executable. Moreover, Liu et al. [9] proposed a semantic topic method to assist user in self-learning.

Various techniques are necessary to support the discovery of hidden knowledge in problem-solving process. Data mining is a useful tool for discovering useful information from a large amount of data. The association rule technique is a marvelous method for discovering relationships between knowledge items. Well-known mining algorithms are *Apriori* and *Apriori-like* methods [3, 6].

3. Framework overview

A mining framework to support problem-solving process is illustrated in Figure 1. This framework is designed for e-business workflow environments. When employees encounter problems, they rely on problem-solving knowledge, e.g. user guides and experiential reports. Problem-solving knowledge is stored in corporate knowledge repositories. Companies provide Intranet portal to facilitate the tracking of employees' problem-solving behaviors, e.g. relevant documents accessed during the problem solving process. The employees' access to corporate knowledge repositories is an important resource for mining problem-solving knowledge. The intranet portal log file records the relevant documents accessed by employees. Problem-solving knowledge can be discovered from the access log file. The proposed framework contains three phases, including data preprocessing, knowledge discovery and knowledge support. In the data-preprocessing phase, a formalization engine is employed to unify the representations of various kinds of knowledge document forms. A knowledge-node format is defined to uniform the knowledge representations. Moreover, an inference engine is used to identify uncertain access behavior of employees. On the basis of uniform knowledge representations, the knowledge-discovery phase employs a mining engine to discover the problem-solving knowledge. The discovered

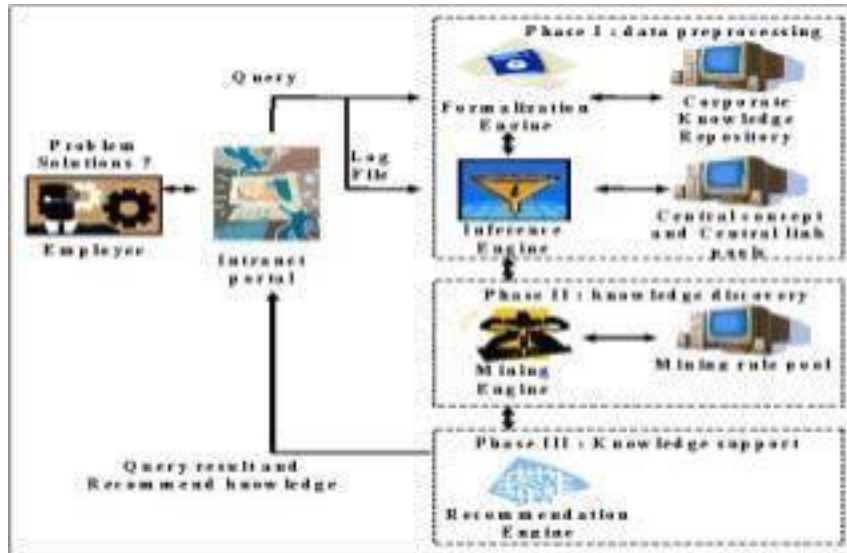

Figure 1: A mining framework to support problem-solving process

knowledge will be stored in knowledge support pools. Finally, the knowledge-support phase utilizes a recommendation engine to recommend relevant problem-solving documents to employees according to employee profiles. The recommendations assist employees solve further problems and provide effective support for task executions in e-business.

4. Proposed framework

4.1 Formalization Engine

The presentation formats of documents are varied. These can include letters, faxes, order forms, notifications, receipts, memos, etc. Although the knowledge documents are digitalized, it is hardly to search information among various types, we need a uniform format to formalize the knowledge document presentation. Knowledge document with uniform format will be the best knowledge support to solve problem occurred in e-business. In data preprocessing phase, formalization engine uses node format to provide such function.

The main function of formalization engine is to construct knowledge document profile. Semantic-based method is used to define related knowledge representation format for e-business. In order to make it easy to modularize corporate knowledge documents, we define the business knowledge document as level-wise node type:

Definition 1: *Knowledge Node (KN)*: Each corporate knowledge document is considered as a knowledge node. KN is the first level.

Definition 2: *Abstract Conceptual Node (ACN)*: Abstract conception means that expert uses a knowledge representation to abstract the concepts behind KN. Each knowledge document may contain one or many abstract conceptions. Each abstract conception is presented as an abstract conceptual node. ACN is the second level.

Definition 3: *Semantic link (SL)*: After analyzing ACNs' contents, if a semantic relation is existed, a semantic link will be constructed to connect two ACNs.

4.2 Inference Engine

The inference engine transforms the employees' sequential access behaviors recorded in the log file into KN representations, which corresponds to a KN sequence. Notably, the information of specific problem in the KN level may be sparse. To gain more information for mining process, we pay attention to the ACN level. From ACN level, a KN sequence corresponds to an ACN network. In addition to ACNs, SLs, semantic relations exist in ACN network. We define these relations as inference links.

Definition 4: *Inference link (IL)*: In sequential access behavior, KNs form a banding status. If no semantic relation exists between ACNs, an inference link may be constructed to connect them. Inference link is inferred as a candidate of human cognitive behavior.

For each problem, ACNs network is considered as a *Conceptual Knowledge Access Network (CKAN)*. Because of various situations, specific problem may own one or many CKANs. By analyzing each CKAN, we get weight and frequency of ACNs, SLs, and ILs. From knowledge document profile, we get weight of ACNs. ACNs' information used to construct each CKAN's concept profile. Links' information is used to construct each CKAN's link profile. Proposed framework uses two pool mechanisms to store profile information. *Central concept pool (CCP)* is used to store all CKAN's concept profiles of specific problem. Higher weight or frequent ACN is considered as central concept. The filtering criterion is based on threshold setting. *Central link pool (CLP)* is used to store all CKAN's link profiles of specific problem. Higher weight or frequent link is considered as central link. The filtering criterion is also based on threshold setting.

Inference engine carries out inferring process during *CKAN*'s concept and link profile construction. Working steps of process are illustrated as the following:

- (1) Read employee access behavior in intranet portal's log file.
- (2) Identify each knowledge document in access sequential patterns and search for its profile in knowledge repository.
- (3) Identify *KNs* and *ACNs* to construct *CKAN* according to knowledge document profiles.
- (4) Construct connecting links and identify link types of each pair of *ACNs*.
- (5) Record weight and frequency information of each *ACN*, *SL*, and *IL* in *CKAN*'s concept profile and link profile.

4.3 Mining engine

Data preprocessing phase provides information support for problem-solving process in e-business. In knowledge discovery phase, a mining engine is employed to discover the problem-solving knowledge. A specific problem may have more than one *CKAN* concept profile. We consider each *CKAN* concept profile as a transaction of specific problem. Concepts in *CKAN* concept profiles are considered as item in transaction. Mining engine uses mini-conf and mini-support as the thresholds of executing *Apriori* algorithm. A knowledge support pool (*KSP*) is used to store association rules of specific e-business problem. Discovered rules are considered as a specific problem's solving knowledge. The steps of mining process are illustrated as follows:

- (1) Select all *CKANs*' concept profiles of specific problem in *CCP*.
- (2) Consider each specific problem's *CKAN* concept profile as a transaction and central conceptual nodes as the knowledge items of the transaction.
- (3) Use *Apriori* algorithm to discover association rule.
- (4) Mining results stored in *KSP* are specific problem's support knowledge.

4.4 Recommendation Engine

In e-business, knowledge support plays a key role to provide effective problem-solving process. In the knowledge-support phase, a recommendation engine is designed to suggest key steps and documents for problem-solving process. A *Guiding Problem-Solving Process* (*GPSP*) is supported to assist the problem-solving process. Association among central concept nodes is used to predict empirical behavior in problem-solving process. *SL* and *IL* in specific *CKAN*'s link profile will be used to connect relevant central concept nodes to construct *GPSP*. *GPSP* shows employee the empirical problem-solving steps and key knowledge documents. Two modules are designed to provide recommendations.

Identification module

ò Problem identification function

- (1) Accumulate and gather statistics of nodes occurring frequency in all *CKANs*' concept profiles of specific problem in e-business.
- (2) Use threshold methods to filter *ACNs*. Nodes with weight or frequency higher than some thresholds are considered as central concepts of specific problem solution. Central concepts will be constructed in specific problem description stored in *CCP*.

ò Problem feature matching function

- (1) Real time to catch employee access behavior in intranet portal.
- (2) Accumulate and gather statistics of *ACNs* occurring frequency.
- (3) Identify central concepts of current problem and use clustering method to search for matching problem descriptions in *CCP*.
- (4) According to match process, it classifies current problem into specific problem or produce new problem identification.

Selection module

- (1) Get the central concept nodes and mining profile of specific problem description stored in *CCP*.
- (2) Get the mining profile of specific problem stored in *KSP*.
- (3) Use mining profile of specific problem to identify the relations between central concept nodes.
- (4) According to central concept nodes and their relations, select higher weight and frequent *SLs* and *ILs* in specific *CKAN*'s link profile to construct *GPSP* for knowledge recommendation.

5. Conclusions

Problem-solving knowledge plays a key role in supporting effective e-business services. In problem-solving process, employee access behavior contains rich knowledge. This study enforces practical knowledge discovery in problem-solving process. Proposed mining framework discovers hidden knowledge of employee access behavior. It divides knowledge discovery process into three phases. In data-preprocessing phase, a well-defined format of knowledge representation is defined to support mining and information search. In knowledge-discovery phase, mining mechanism discovers context-aware problem-solving knowledge of e-business. Knowledge-support phase provides employees guidance and documents relevant to problem-solving. The guiding process shows employee the experiential problem-solving steps and important knowledge documents.

Pomona, CA 91768

Abstract

Mong Reththy is an agribusiness industrial group of companies headquartered in Phnom Penh, Cambodia with total revenue of approximately US\$48 million from 9 divisions. The purpose of the project is to describe background of this company and the Camerica consulting group working with them. Further, to illustrate the index of the Mong Reththy website and examine the English language narrative used. The purposes of the website both locally and globally are examined and sample narrative for improvement is presented.

Introduction and Background

Cambodia struggles to rebuild itself after 30 years of civil strife and warfare, including the genocidal Khmer Rouge period and the isolation and neglect by the international community. Life expectancy is only in the mid – 50s. Infant mortality stands at 95 per 1,000 childbirths. 85% of Cambodians live in rural areas where life is harsh and access to basic services is difficult. They depend largely on agriculture for their livelihoods. The agriculture sector accounts for 32% of the total economy. For the most part, agricultural products are exported as raw materials with limited value added. (USAID and Cambodia: Retrieved on March 1, 2002 at http://www.usaid.gov/regions/ane/newpages/one_pagers/cambodia01a.htm)

Most value added manufacturing of these raw materials takes place after export to Malaysia, Singapore and Thailand. Mong Reththy is vitally interested in the feasibility of manufacturing facilities in Cambodia in order to export more valuable agricultural products at substantially higher prices. In effect, managing more of the supply chain before exports leaves Cambodia, increasing overall revenues and strengthening the young developing Cambodian economy. Mong Reththy manages logistics of the supply chains of four specific agricultural commodity products: palm oil, tapioca, rubber and grapes.

CAMERICA Consulting Group, 848 West Cesar E.

Chavez Ave., 2nd Floor, Los Angeles, CA 90012-2131, U.S.A. is a non-profit association of research consultants specializing in providing services to Cambodian agricultural and industrial raw materials producers. Mr. Phillip T. Thong, C.P.A. is the principal of CAMERICA. Mr. Thong is a successful Cambodian American partner in Thong and Yu C.P.A. firm, and leader in the Cambodian American community of southern California. It is his goal to make a significant contribution to his community both in Los Angeles and his Cambodian motherland.

Camerica -- on behalf of His Excellency Mr. Chan Sarun, Senior Minister and Minister of Agriculture, Forestry and Fishery, Phnom Penh, Cambodia, and the Mong Reththy Group, 130 Vithei Preashy Sihanouk, Phnom Penh, Cambodia, Principal: Oknha (Royal Title) Mong Reththy to examine and research global business communications and website development.

Camerica Objectives for Contribution

1. To examine the global business of Mong Reththy Group, Ltd., Cambodia to identify international markets of four commodity products: palm oil, tapioca, rubber and grapes in Cambodia.
2. To examine alternatives for Global business communications.
3. To work with Cambodian website developers who created <http://www.mongreththy.com/> to enhance website content. Specifically, rewrite extensive awkward and incorrect English text.
4. To make a personal and professional contribution to a real SME. in a newly democratized nation struggling to be recognized by the international community.

Visits were made to agricultural plantations of Mong Reththy in Southwestern Cambodia around Kampot and Phnom Bokor Mountain. Trips to Malaysia and Singapore to investigate current Mong Reththy brokers and business partners/alliances will be necessary. Numerous interviews with local experts were conducted to fully investigate market distribution and various value added manufacturing alternatives.

Mong Reththy Group of Companies

This agro industrial group of companies is headquartered

at 152S, Preah Norodom Boulevard, Phnom Penh 12301, Cambodia and enjoys total revenue of approximately US\$48 million from 9 divisions:

1. Mong Reththy Group Company Limited
2. Mong Reththy Investment Cambodia Oil Palm Company Limited (MRICOP), an International Joint Venture Agro industrial Company, whose partners are Cambodian, and Korean, established in March 23, 1996.
3. Mong Reththy Investment and Cambodia Tapioca Flour Company Limited was established in 1999.
4. MRT-RML Livestock Corporation (Cambodia) Private, Limited was established in 2001 mainly for cattle breeding and ranching for export to Malaysia.
5. Mong Reththy Group - Tiwanon Construction Joint Venture Company Limited.
6. Mong Reththy Steel Industries Company Limited
7. Samnang Khmeng Wat Construction Company Limited was named by the then Prime Minister Samdech Hun Sen, and established in October 1997.
8. Joint venture with three government owned rubber plantations: Chou Kroc, Boeung Ket and Chamcar Andong, in new infrastructure and machinery.
9. Oknha Mong Port Co., Ltd.

They own 48 pieces of heavy equipment with 12 hauling sets which puts them in a good position to play a major role in the rebuilding of the infrastructure of Cambodia.

Need - Cambodia is a post-conflict country, having suffered a protracted period of war, social upheaval and political turmoil for more than 20 years, starting first under the Lon Nol regime and then Democratic Kampuchea. During this period of upheaval, the administration system for policy formulation and implementation was destroyed. The socio-economic infrastructure such as roads, bridges, irrigation facilities among others were damaged and left in a badly neglected state. Human capital, which could have contributed to the development of the country, was decimated by massive purges, forced labor, disease, and bombing. Cambodia has a wartime legacy of millions of landmines still buried and new victims are being claimed even today. With regards to poverty, 35.9 percent of the population lives below the national poverty line and socio-economic indicators such as literacy, infant mortality rate and others are among the worst in the region.

Since Cambodia's admission to ASEAN in April 1999, the country has been enjoying an opportunity as well as facing the challenge of regional economic integration and competition at an increasingly intense pace. (The Japan International Cooperation Agency (JICA), Retrieved October 1, 2003 at <http://www.jica.org.kh>)

Website

A website such as that for Mong Reththy Group (See index page below) serves several purposes. Primarily it serves as a window to the world. An important public relations vehicle which the company can point to as pride to illustrate to potential suppliers, customers and other stakeholders – “here we are.” This company was eager to introduce themselves to a global audience with this device. It is not intended to manage the logistics of a supply chain or for transactory purposes of any type. Perhaps some day the economic need for such sophisticated utilization of software will be merited.

Two problems seem to show most significantly in this first attempt at a website. First, the company is Cambodian with predominantly Cambodian stakeholders and as such the website should speak to this local audience. The narrative seen on the index or “front page” was conceived in the Khmer language and subsequently translated into English. This English doesn’t speak so well to the local Cambodian audience. Agreed, the audience is not a group of home Internet users, but larger companies and government agencies that are much business cooperating partners. Versions of the narrative in several languages are recommended, but not the existing narrative. The entire website needs to be rewritten in say three languages: Chinese, Japanese and English; and completely redesigned and rewritten. The desired business communications or “impact message” is completely different in each language.

The second problem focuses on the website narrative intended for the global audience. The website originates from Cambodia whose language is not known much outside home borders, therefore English was chosen as a global website language. Unfortunately the translated Cambodian thought, which indeed comes from the heart, and speaks so very beautifully to the Cambodian people – does not “read” very well in English. The beauty of the narrative in native Khmer is somewhat like poetry. When translated directly into global English these thoughts from the heart give the reader a mixed reaction of quaint, odd and confusing.

The lesson is simple and important. When building a website for a local audience, and another one for the world. What the reader sees, reads, perceives and the resulting impressions are everything. When communicating meaningful values to a local audience, present them in the most meaningful way possible. When seeking commercial impact from a global audience, communicate as the global world of business communicates, in whatever language chosen for whatever audience.

Original Text from Index Webpage

As an example, compare the original text of the front page of the current Mong Reththy website (<http://www.mongreththy.com/>) (See “print screen” picture of index page below)

Introduction

Reflecting undaunted will of Oknha Mong Reththy and those of the Cambodian people in the immediate on going negotiation of the Paris Treaty: To end h decades of civil war and elevate the plight of the people and give hope for the reunification of all factional parties.

Oknha Mong Reththy Chairman and founder of the Mong Reththy Import Export & Construction Company Limited, contributed a great deal to the ashes after the so called Cambodian Year Zero which destroy the country infrastructures, economic, morality and mentality well-being of the Cambodian people. We strongly believed that our hard working years and 3 years of on going efforts to accomplish the first of it kind Agro Industrial of Oil Palm Estate, will definitely pave the ways for Cambodian and put her one famous image back on the world map.

Oknha is the noble title has granted by His Majesty Preah Bath Norodom Sihanouk Varaman, the King of Cambodia, in 1996 for the charity works he has devoted and participate in rebuilding the country. Mong Reththy Import Export and Construction Company Limited (MRIEC) was established in 1991 as a form of family business. Today MRIEC does not merely operate as a family business but has expanded to include various associated and investment companies in the country.

Back in 1991 the company main activities were exporting of Processed Cambodian Natural Rubber to Asia Countries: Singapore, Malaysia, Hong Kong, and China etc. Apart from rubber trade, we are also importing Steel Bars, Cement, and other needed Building Materials, as well as Machinery & Heavy Equipment etc. By late 1996, Oknha Mong Reththy has inaugurated its other associated companies:

Edited Text for Index Webpage

The following edited version was presented to eliminate the English writing grammatical errors, but intended to preserve the original meaning.

Introduction

*Our mission reflects the undaunted will of **Oknha Mong Reththy**, as well as the Cambodian people: To end the decades of civil war, to elevate the plight of the Cambodian people, and to give hope for the reunification of all factional parties.*

*Oknha Mong Reththy, Chairman and founder of the **Mong Reththy Import Export & Construction Company, Limited** has contributed enormously to the reconstruction of ruin after the so-called “Cambodian Year Zero” which destroyed the country’s infrastructure, economy, morality and mentality; along with the well being of the Cambodian people. We strongly believe that our three years of hard work and diligence have resulted in the first of its kind Agro-Industrial Oil Palm Estate, which will pave the way to a proud future and reestablish Cambodia’s once famous image on the world map.*

*“Oknha” is the noble and royal title that has been granted by **His Majesty Preah Bath Norodom Sihanouk Varaman**, King of Cambodia, in 1996 to Mong Reththy for his charitable works, as well as his devotion and participation in the rebuilding of Cambodia. **Mong Reththy Import Export and Construction Company Limited (MRIEC)** was established in 1991 as a small family business. Today MRIEC has expanded into a major Cambodian agro-industrial conglomerate of associated and investment companies making a significant contribution to the Cambodian economy, and employing thousands of hard working citizens.*

*Initially, in 1991, the company’s main activities were exporting processed Cambodian Natural Rubber to Asian countries such as **Singapore, Malaysia, Hong Kong, China**, and others. Since then, importation of steel bars, cement and other critical building materials, as well as machinery and heavy equipment has been added. By late 1996, **Oknha Mong Reththy** has inaugurated the following associated companies:*

Example of Text Rewritten for Global Market

Here is an example of a complete rewrite in English for a global market. We do not propose that this is the best possible rewrite and other issues and key success factors may need to be emphasized on this index or “front page” – the opening window to this company. Obviously it was

necessary to change the tone, and meaning of the opening text.

Introduction

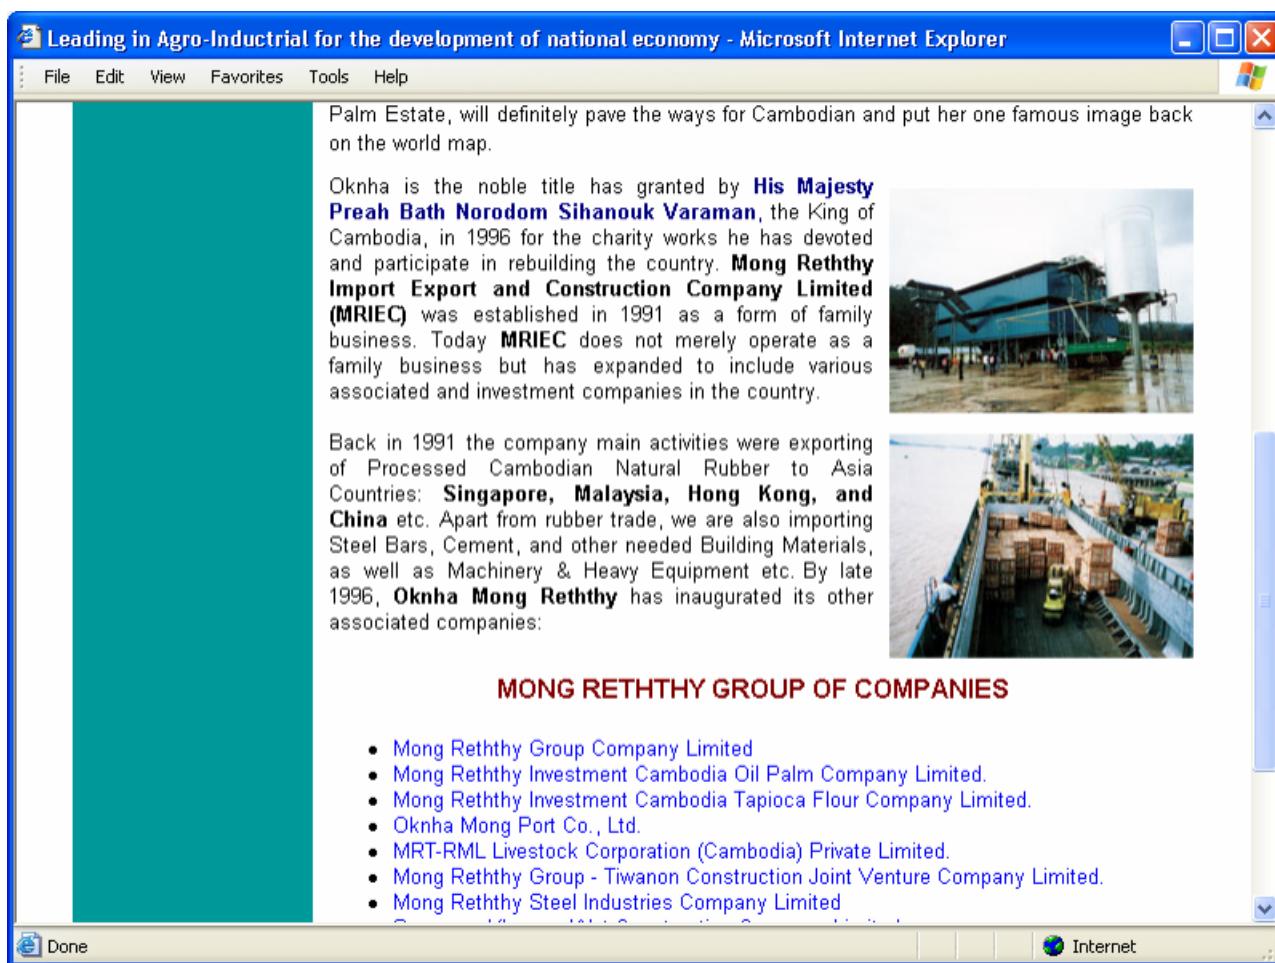

Our mission is to rebuild the infrastructure of Cambodia. We are building the finest roads, bridges, schools, temples and infrastructure systems with a traditional Khmer dedication to quality and excellence. We are dedicated to a new and prosperous Cambodia. We are a growing major player in agribusiness and construction in Southeast Asia and a loyal partner to our neighbors. Cambodia is back in business and ready to show the world her best stuff and Mong Reththy is leading the parade of key competitive strengths.

We are Mong Reththy Group -- a company big enough to rebuild Cambodia. A company with a reputation as solid as the Great Angkor Wat and a vision for the future as vast as the globe itself. We remain truly dedicated to the progress of all ASEAN economies.

We are nine solid divisions ready to provide the global market with Tapioca, Palm Oil, Industrial construction and a host of other resource based products and services.

Please contact us and let us provide a demonstration of what we can do for your company or your project. We are the project experts rebuilding Cambodia.

Abstract

By Internet age arrived, collaborative commerce has completely changed business environment and model. Collaborative Marketing (CM) has continuously growing in a seemingly unabated fashion worldwide. The enterprise competitive condition has completely changed into global competitive environment within supply chain. In addition, this study provides an appreciation of the emergence and content of Integrated Marketing Communications (IMC) that widely used by industry and commerce in the US and UK. Systems intervention is one main stream of systems thinking in England. In order to build a systemic approach of IMC, this research examines systems intervention to see what it can contribute to CM and IMC for enterprises. This study examines how CM can help IMC through identifying key customer knowledge sources, hence, marketing and advertising would be based on a single global campaign, with only minor adjustments for local markets. The aims of this paper are to explore the role of customer knowledge sources within collaborative IMC and develop a conceptual framework to further suggest better solution for IMC collaboration.

Taking beauty enterprise as an example, this research focuses on CKM (Customer Knowledge Management), CM, IMC and systems intervention to design the questionnaire for 120 companies. There were 8 available responses from 60 collaborative partners in Taiwan and 19 available responses from 60 collaborative partners in China (Return rate 22.5%). This paper identifies the difference of knowledge sources, CM, IMC

and systems intervention between Taiwan and China in a leading beauty enterprise and finds out that CM has significant effect on IMC that could be used for IMC planning in the future.

1. Introduction

Although collaboration maximizes the combined competencies of the partners to achieve each partner's strategic goals and to provide solutions to meet customers and stakeholder needs, the processes and procedures of collaboration required for success are a little less clear [12]. Actually, the processes for integrating customer knowledge sources are complicated. The best way to avoid the problem is to define a joint process and implementation plan for collaboration. Actually, it is difficult for enterprises to manage and balance value chain processes and further associate communications. However collaboration provides the functionality to access and utilize the information that is being communicated.

There are a number of specialists who have suggested models of IMC (IMC), including some who set out specific aspects towards achieving successful IMC [10]. The Caywood et al. [1] study introduced a new conceptual debate concerning integrated approaches to marketing communications. It is known that buyers and suppliers have high hopes for utilizing the Internet to streamline trading partner relationships. Recently, Corelissen and Lock [3] have examined IMC as a body of theory and hypothesized its influence upon practice. Low [7] identified factors that are significantly related to the

degree of integration of a company's marketing communications activities. Cornelissen [2] further collated the available evidence on the US and UK marketing communications practices.

Collaboration in IMC with enterprises from similar or competing product sectors may offer significant advantages. For example, collaboration with European firms has been a popular market entry route for Japanese firms. Perks [11] presented four major Euro/ Japanese cases of new product development collaboration. Michael [9] examined whether one hybrid form, the franchise chain, can coordinate elements of the marketing mix.

Lin [8] presented the IMC Model and it provides a framework to review, operationalize and evaluate the process and effectiveness of IMC. Based on this model, we further examine how CM can help IMC, hence, marketing and advertising would be based on a single global campaign, with only minor adjustments for local markets.

By emphasizing on knowledge in the global economy, the collaborative partners start to overlook major customer knowledge. Gibbert et al. [5] think that CKM can provide a significant competitive advantage for companies, but its possible stumbling blocks have to be appreciated. They identified two major stumbling blocks, first the cultural challenge (in terms of re-thinking the role of the customer and the far-reaching implications this has for the mindset of employees within the organization), and second the competency challenge (in terms of the skills and processes needed to take full advantage of participative techniques). There is an important issue existed CM to understand what kinds of customer knowledge sources they can share with each other. So, it would be interesting to find out the answer for collaborative partnerships.

This paper is not only focusing on organizational process improvement of IMC and CM, but also trying to tackle the issues in the dimensions of organizational

design, organizational culture and organizational politics. These four dimensions [4] must be considered in order to help to achieve the ideal dynamically balanced organization for IMC and CM. Schultz and Kitchen [13] do not believe IMC is a theory but believe the general idea of integration, processes, and systems thinking must prevail in the 21st century. However, in order to build an effective systemic approach and to avoid introducing other weaknesses, it is now necessary to carry out an in-depth consideration of systems intervention and make the IMC and CM model even more effective.

The aims of this paper are:

1. Develop a conceptual framework that identifies the customer knowledge sources and further finds out systems intervention for CM and IMC.
2. Identify the difference of knowledge sources, CM, IMC and systems intervention between Taiwan and China in a leading beauty enterprise.
3. Find out the key knowledge sources for CM and IMC.
4. Use systems intervention to choose suitable method for CM and IMC strategies.
5. See how CM can help IMC.

2. Theoretical Background

Although collaboration maximizes the combined competencies of the partners to achieve each partner's strategic goals and to provide solutions to meet customers and stakeholder needs, the processes and procedures of collaboration required for success are a little less clear (Rabin, 2002). The best way to avoid the problem is to define a joint process and implementation plan for collaboration. Actually, it is difficult for enterprises to manage and balance value chain processes and further associate communications. However collaboration provides the functionality to access and utilize the information that is being communicated. For example, collaboration with European firms has been a popular

market entry route for Japanese firms. Perks (2000) presented four major Euro/ Japanese cases of new product development collaboration. Michael (2002) examined whether one hybrid form, the franchise chain, can coordinate elements of the marketing mix.

IMC research had its beginnings with the Medill School of Journalism at Northwestern University (Duncan and Moriarty, 1997). American Association of Advertising Agencies (4As) (1989) defined IMC is a concept of marketing communications planning that recognizes the added value of a comprehensive plan that evaluates the strategic roles of a variety of communication disciplines- general advertising, direct response, sales promotion, and public relation- and combines these disciplines to provide clarity, consistency, and maximum communication impact [1]. The combination of marketing and public relations communications disciplines has a number of labels. In the late 1980s, advertising agencies attempted to co-opt the concept by calling it 'the new advertising' (Hume, 1991), but other labels were also suggested: 'the new PR' (Harris, 1991), 'integrated marketing' (Wilcox, Ault and Agee, 1992), 'integrated corporate communications' (name of a master's program at Duke University), or 'integrated marketing communications' (Schultz, Tannenbaum, and Lauterborn, 1993). Recently, Reid et al. (2001) have employed Duncan and Moriarty's (1997) Integrated Marketing Audit to examine key communications issues and demonstrated that a higher level of integration is associated with better brand-related performance. Schultz and Bailey (2000) have defined a new approach for the 21st century marketplace because the new electronic communication and marketing alternatives and opportunities explored the alternatives available to communications around the world. Bush and Bush (2000) have proposed that the explosive growth of the Internet has the potential to change agency-advertiser relationships and blur the functions performed by each.

This paper carries out a comparison of current IMC approaches using six aspects: awareness integration, unified image, database integration, customer-based integration, stakeholders-based integration, and evaluation integration.

Since the 1930s, there have been three competing models of management in organization theory- the traditional approaches, human relations theory, and systems theory. However, with the recognition of the deficiencies of both the traditional approaches and human relations theory, the systems theory has now grown to a position of prominence in management theory. Flood and Jackson (1991) mentioned: "Systems thinking developed, therefore, as an alternative to mechanistic thinking, and proved itself more satisfactory for explaining not only complex biological but also social phenomena." Systems thinking draws a blue print to tackle the main issues of IMC and help to build a systemic approach of IMC. Some approaches in systems thinking could be used to improve IMC program such as Total Systems Intervention (TSI), system of evaluation methodologies, triple loop learning and critical appreciation. TSI is presented by Flood and Jackson (1991), which provides direction to systems practitioners wishing to choose relate and choose between methodologies in a theoretically informed manner. TSI's principles and philosophy can enhance IMC approach to set up effective communication in organizations. Flood (1995) identified that unless all four key dimensions of organization (organizational process, organizational design, organizational culture and organizational politics) are taken into account, i.e., a whole system view is developed, then problem solving is bound to be ineffective. Thus, TSI provides principles, processes and methods for problem solving which enable effective intervention in these four dimensions of organization to bring about improvement, which should help IC problem solving.

Organizational process means 'rules about efficiency

of flows and control over flows' and aims to achieve efficiency in terms of no unnecessary waste of time or resources (Flood and Romm, 1996). Flood (1995a) recommended Quality Management and Business Process Reengineering to make the processes more efficient. Organizational design concentrates on 'rules about effectiveness of functions and their organization' and here effectiveness refers to achieving chosen tasks of functions (Flood and Romm, 1996). Flood (1995) recommended using the Viable System Model (VSM) which brings together five main management functions (operations, co-ordination, control, intelligence, and policy) and organizes them according to a carefully worked-out series of information flows. Organizational culture means 'mediation of behavior in terms of people's relationship to social rules and practices' (Flood, 1995). This is recognition that different people need different things, understand things differently and respond to things in different ways. Flood (1995) has found that debating methodologies such as Testing Polarized Viewpoints, Exploring and Choosing Designs, and Exploring and Making Decisions could help to resolve the human problems of organizational culture and organizational misunderstanding. Organizational politics means 'power and potency to influence the flow of events' (Flood, 1995a). It is important to understand who holds power, and how this power can be used to serve certain interests. Flood (1995) points out that Critically Evaluating Designs and Decisions could help managers to think about whose interests are being served in design work and decision making.

Basically, if the organizations can look at their IMC approach through these four dimensions of organizations, they satisfy TSI's philosophy. If all four key dimensions of organizations are fully taken into account, then effective IMC approach can be achieved. Gould, Lerman and Grein (1999) indicated the importance of globally integrated marketing communications and adopt three

emergent themes: 'the evolving nature of the globalization process, its contingency element and its cultural dimensions of client and agency.' Be considered seriously, issues of IMC can be tackled and communications can be effectively integrated under the four dimensions of organizations. Lin (2000, 2001) developed a new integrated communications model which uses a systemic view for assessing the applicability of IMC. Furthermore, systems thinking and the pluralist approach from the Center for Systems Studies at the University of Hull (U.K.) can enhance the IMC approaches [8].

Gibbert et al. (2002) have presented the concept of Customer Knowledge Management (CKM) that refers to the management of knowledge from customers, i.e., knowledge resident in customers. Moreover, five styles of CKM were also proposed and illustrated by way of corporate examples. Park et al. (2001) have focused on knowledge refinement that is a necessary process to obtain and maintain current knowledge in the domain of interest. Shaw et al. (2001) have presented a systematic methodology that uses data mining and knowledge management techniques to manage the marketing knowledge and support marketing decisions. Lesser et al. (2000) have identified four approaches (customer knowledge development dialogues, facilitating the capture of knowledge relevant data, demonstrating enterprise leadership commitment to customer knowledge) that can expand the availability and use of customer knowledge. Lin and Su (2003) mentioned a systemic integrated communications model which can help enterprises identify the potential issues of CRM. Tiwana [14] provided knowledge sources and categories such as markets, competitions, customers, orders, contracts, products and services, customer complaint and best practices. Basically, knowledge about these sources and categories must be integrated into a knowledge-enabled CRM strategy.

3. Research Design and Method

3.1 Research Framework

This paper aims to explore the relationship among customer knowledge sources, CM, IMC and systems intervention. The conceptual model is displayed in Figure 1. The problems of organizational process, design, culture and politics in each aspect of IMC must first be identified. These problems will be reflected to the three modes in order to get the best solution in a systemic view. Tiwana (2000) provided knowledge source and categories such as markets, competitions, customers, orders, contracts, products and services, customer complaint and best practices. The conceptual model is displayed in Figure 1.

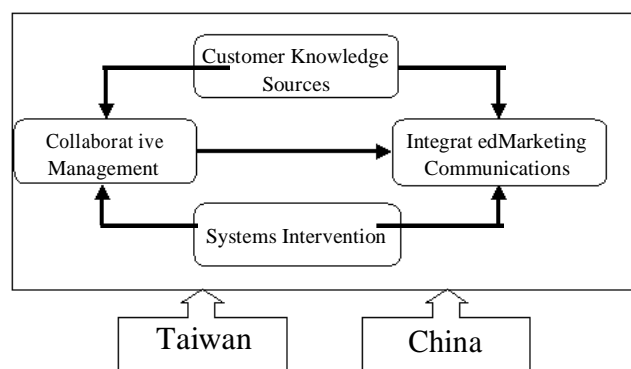

Figure 1. Research framework

3.2 Research Hypothesis

This paper aims to explore the relationship among customer knowledge sources, CM, IMC and systems intervention. Further to explore the effect of the dimensions of customer knowledge sources and systems intervention on the dimensions of CM and IMC. According to the purpose of the research and the literature surveyed, the hypothesis is identified as follows.

H₁₁: There is significant difference between Taiwan and China in the dimension of customer knowledge sources.

H₁₂: There is significant difference between Taiwan and China in the dimension of CM.

H₁₃: There is significant difference between Taiwan and China in the dimension of IMC.

H₁₄: There is significant difference between Taiwan and China in the dimension of systems intervention.

3.3 Sampling

There were 8 available responses from 60 collaborative partners in Taiwan and 19 available responses from 60 collaborative partners in China (Return rate 22.5%).

4. Research Findings and Discussion

4.1 Descriptive Statistics Analysis

As shown in Table 1, in the dimension of customer knowledge sources, the mean of market information is higher than the other factors. So it seems that market information plays the most important role in this dimension. In the dimension of CM, the mean of collaborative relationships is higher than the other factors. So it seems that collaborative relationships plays the most important role in this dimension.

As shown in Table 2, in the dimension of IMC, the mean of customer-based integration is higher than the other factors. So it seems that customer-based integration plays the most important role in this dimension. In the dimension of IMC, the mean of organizational processes is higher than the other factors. So it seems that organizational processes plays the most important role in this dimension.

Table 1. The mean of customer knowledge sources and CM

Customer Knowledge Sources		CM	
Factor	Mean	Factor	Mean
Market Information	4.443	Collaborative Relationships	4.145
Competition Information	4.128	Core Capability	4.012
Customer Information	3.898	Customer Focus	3.92
Order Information	3.66	Legal and Financial Facilitators	4.018

Product and Service Information	4.123	Business Systems	3.954
Customer Complaint Information	4.167	Common Views	3.948
Best Practice Information	4.045	Attitude	3.953

Table 2. The mean of IMC and systems intervention

IMC		Systems Intervention	
Factor	Mean	Factor	Mean
Awareness Integration	4.134	Organizational Culture	3.977
Image Integration	4.054	Organizational Politics	4.083
Database Integration	3.958	Organizational Design	4.174
Customer-based Integration	4.149	Organizational Processes	4.284
Stakeholders-based Integration	4.094		
Evaluation Integration	3.973		

4.2 Reliability Analysis

The analysis of scale reliability was performed using Item to total correlation, Cronbach's alpha coefficient and the cluster effects among variables. In the dimension of customer knowledge source, the value of Cronbach's alpha of the factor of market information, customer information, order information, product and service information, customer complaint information and best practice information are all great than 0.6. In the dimension of CM, the value of Cronbach's alpha of the core capability is less than 0.6 so we cancel this factor and the value of Cronbach's alpha of the others factors are greater than 0.75. In the dimension of IMC, the value of Cronbach's alpha of the factors of awareness integration, database integration, customer-based integration, stakeholder-based integration and evaluation

integration are greater than 0.65. In the dimension of systems intervention, the value of Cronbach's alpha of the factor of organizational culture, organizational politics, organizational design and organizational process are 0.7248, 0.6975, 0.75 and 0.7609 respectively, those values are greater than 0.6.

4.3 The difference between Taiwan and China

This research adopts t test to examine the difference between Taiwan and China regarding the dimension of customer knowledge sources, CM, IMC and systems intervention. The result of the analysis is shown as Table 3. Although there is no significant difference in both customer knowledge sources and CM dimensions, there is significant difference with the factors of awareness integration and evaluation integration in both IMC and systems intervention dimensions. So, findings provide no support for H11 and H12 and also provide partial support for H13 and H14.

Taiwan's collaborative partnerships focus on marketing information and product and service information for customer knowledge sources; collaborative relationships and legal and financial facilitators for CM; awareness integration and customer-based integration for IMC and need the solution about organizational design to get CM relationship improved. China's collaborative partnerships focus on marketing information and customer complaint information for customer knowledge sources; collaborative relationships and common views for CM; customer-based integration and stakeholders-based integration for IMC and need the solution about organizational processes to get collaborative marketing relationship improved.

Table 3. The different analysis of every dimension between Taiwan and China

Dimension		Mean Taiwan	Mean China	T-value	P-value	Significant difference
Customer Knowledge Sources	Market information	4.656	4.224	1.803	0.084	No
	Customer information	3.875	3.921	-0.192	0.85	No

4.4 The regression analysis of the effects of customer knowledge sources and systems intervention on CM

As shown in Table 4, the dimension of customer knowledge sources has significant difference in the factors of collaborative relationships, customer focus, business systems, common views and attitude. The dimension of systems invention also has significant difference in the factors of legal & financial relationships, common views and attitude.

According to statistic outcome in the dimension of

customer knowledge sources, the factors of marketing information and product and service information directly affect collaborative relationships, the factor of customer information directly affects customer focus and the factor of order information directly affects business system, common views and attitude.

In the dimension of systems intervention, the factors of organization culture and organization design directly affect legal & financial relationships and the factor of organization process directly affects business systems, common views and attitude.

Table 4. The analysis of regression of the effects of customer knowledge and systems intervention on CM

Model	CM					
	Collaborative	Customer	Legal & financial	Business	Common	Attitude

	relationships	focus	relationships	systems	views	
Market information	0.54***					
Customer information		0.507**				
Order information				0.42**	0.356*	0.513***
Product and service information	0.423**

P value	0.000***	0.007**	0.000***	0.000***	0.000***	0.000***

* P<0.05; ** P<0.01; *** P<0.001

4.5 The regression analysis of the effects of customer knowledge sources and systems intervention on IMC

As shown in Table 5, the dimension of customer knowledge sources has significant difference in the factors of database integration, customer-based integration, stakeholders-based integration and evaluation integration. Besides, the dimension of systems intervention has significant difference in the factors of awareness integration, database integration, customer-based integration and stakeholders-based integration.

In the dimension of customer knowledge sources, the factor of customer information affects database integration, the factor of order information affects customer-based integration, the factor of customer complaint information affects stakeholders-based integration and the factor of product and service information affects customer-based integration and evaluation integration.

In the dimension of systems intervention, the factor

of organization culture affects customer-based integration, the factor of organization leadership affects database integration and stakeholders-based integration, the factor of organization design affects awareness integration, database integration and stakeholders-based integration and the factor of organization process affects database integration.

4.6 The regression analysis of the effects of CM on IMC

As shown in Table 6, the dimension of CM has significant difference in the factors of customer-based integration, stakeholders-based integration and evaluation integration. In the dimension of CM, the factor of legal & financial relationship affects customer-based integration, stakeholders-based integration and evaluation integration; the factor of common views affects evaluation integration and the factor of attitude affects stakeholder-based integration.

Table 5. The analysis of regression of the effects of customer knowledge sources and systems intervention on IMC

5. Conclusion

The findings of this research are as follows:

1. Although there is no significant difference in both customer knowledge sources and CM dimensions between Taiwan and China, there is significant difference with the factors of awareness integration and evaluation integration in both IMC and systems intervention dimensions.
2. Collaborative partners consider that more market information, and product and service information can build collaboration and trust relation between collaborative partners. Solving methods of organizational culture and organizational design can help to clarify with the legal and financial relation between collaborative partners. In addition, gathering order information and the solving methods of organizational process will help to build up business IT system, common view and positive attitude.
3. In IMC dimension, gathering customer information

and solving methods of organizational design, organizational politics and organizational process will help to database integration. Gathering order, product and service information and solving methods of organizational culture will help to customer integration. In addition, gathering best practice information and solving methods of organizational design and organizational politics will help to stakeholders-based integration.

4. CM has significant effect on IMC that could be used for IMC planning in the future.

Moreover, this study presented a conceptual model of Collaborative-CKM to see how CM can help IMC implementation. The result of the research could be consulted by the other industry to create their Collaborative-CKM framework and IMC implementation.

Abstract

In terms of transforming supply chain into integrated value systems, the benefits of Early Supplier Involvement (ESI) in product development have been widely accepted. Despite past advancements in ESI, some unique issues have not been addressed for ESI in e-product configuration for mass customization. As far as variety management and online configuration are concerned, the difficulties of ESI in online mass customization manifest themselves through two main aspects: (1) Support the seamless information integration with respect to its high variety and large volume not only among internal functions but also with external suppliers; (2) Support real-time online configuration for product configuration generation and optimization based on customer requirements and supplier capabilities. Accordingly, this work proposes two potential solutions. PFA-based integrated information model is established to synchronize the PFA generic structure and supplier product information. Meanwhile, the mechanism of real-time bidding is explored to back up online configuration with the rapid RFQ requirements.

1. Introduction

e-commerce and mass customization have been foreseen as a primary style of manufacturing in the coming decade and beyond. With respect to new capabilities implied by e-commerce, customers will be able to input and interact directly with design, manufacturing and service providers. The providers will have to respond to a high variety of requirements and orders within the constraints of cost, schedule and quality. With the advent of information technology, electronic product configuration (ePC) for mass customization is being recognized as a potential dimension to enhance company profitability through a synergy of increasing customer-perceived value while reducing customization cost and improving product realization efficiency.

The implementation of ePC for mass customization mainly involves two critical issues: (1) Electronic catalogs have to be properly constructed to organize unstructured product information, achieve effective variety management, and enable reengineering companies' supply chain relationships. (2) The basic mechanism of online configuration needs to be explored through modeling product configuration process, formulating intelligent configuration systems, and developing approaches to the

rapid request-to-quotations (RFQs) processing

In terms of transforming supply chain into integrated value systems, the benefits of Early Supplier Involvement (ESI) in product development have been widely accepted. As stated by [1], ESI is advocated as a means of integrating suppliers' capabilities in the buying firm's supply chain system and operation. Partnerships are formed with suppliers to take advantage of their technological expertise in design and manufacturing. A number of empirical studies reveal both strategic and tactical benefits of ESI. Dowlatsahi [2] develops a most comprehensive ESI framework. It is an initial conceptual ESI framework and can be used by companies. Bidault et al. [3] report the results of an empirical study that explores the drivers of the adoption of ESI in the product development process. Hartley et al. [4] conduct a study that empirically tests whether management of the buyer-supplier interface affects supplier-related delays. LaBahn et al. [5] develop a contingency model of component supplier intentions. Wynstra et al. [6] propose a coherent framework of specific activities across a number of different management areas within purchasing involvement in product development. Dowst [7] outlines nine areas in which suppliers can be involved in the buyer's design process. Huang et al. [8]~[9] identify that major ESI issues include make or buy decisions and supplier selection. Research literature on ESI in online mass customization is relatively scarce. Ghiassi et al. [10] describe a software system that supports electronic business operations in mass customized markets with synchronized supply chain required.

In spite of past progress in ESI, some unique issues have not been addressed for ESI in ePC for mass customization. As far as variety management and online configuration are concerned for ePC, the difficulties of ESI in online mass customization manifest themselves through two aspects.

Firstly, mass customization is facing a variety dilemma resulting from the continuous generation of product variants to meet diverse customer needs. To achieve effective variety management, a promising strategy is to shift the practice from designing and managing individual product instances to establishing product families. Although many research efforts have been put on supply chain management issues such as improving the process efficiency and integrating manufactures' systems with suppliers', there is a remarkable lack of clarifying the underlying mechanism of such integration in mass

customization context, where product information is normally organized as product family architectures (PFA).

Furthermore, online configuration is another crucial factor to a success of ePC. Since mass customization involves understanding accurately customer needs and subsequently creating a complete description of a product variant that meets those needs, this is typically a sales order configuration process. Such a configure-to-order process assumes that a valid design is assembled from instances of a fixed set of well-defined component types (e.g., part catalogs), in which components are interconnected in a predefined way to meet a set of customer requirements and certain design constraints. ESI in online configuration is mainly embodied on supply development based on competitive bidding among suppliers. The bidding process is time consuming and often conducted offline. Thus, the traditional bidding is not applicable for real-time product configuration design with the rapid RFQ processing.

To overcome the two key hindrances of implementing ESI in ePC, this work emphasizes two potential solutions accordingly. PFA-based information integration between various business entities across a supply chain enables incorporation of ESI in online mass customization. Meanwhile, real-time bidding is proposed to accommodate the demands of online configuration.

2. Framework of ePC for mass customization

With the utmost concerns on the fundamental issues of ePC, an ePC system is characterized by two basic properties: (1) Supporting the information management and integration in terms of its high variety and large volume not only within internal functions but also with external suppliers. (2) Supporting real-time online configuration for product configuration generation and optimization based on customer requirements and supplier capabilities.

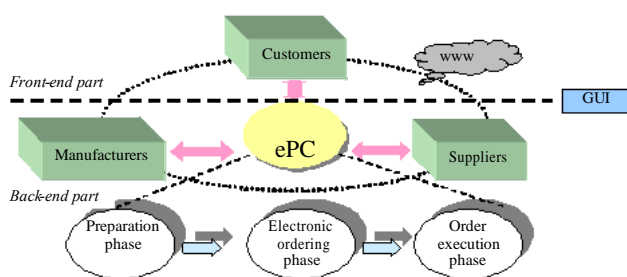

Figure 1. A simplified framework of ePC for mass customization

Electronic linkages enable better communication and coordination among distinctive entities across a supply chain and necessitate the redesign of the traditional supply chain relationships. A framework of ePC can be constructed to introduce the concept of integrated “value chains” into the online mass customization process. The whole ePC process is separated into three major phases including the preparation phase, the electronic ordering phase and the order execution phase. Once the management adopts online mass customization as its

business strategy, the general procedure will start. Figure 1 illustrates the simplified framework.

Along the overall procedure, the task of the preparation phase is the construction of product family architecture (PFA), which represents product knowledge needed in the online configuration process. It defines the generic product model and classification (assortment) of products and component parts by means of modules, variety parameters, and constraints. During the electronic ordering phase, PFA is applied to product configuration. It creates a specific product instance or variant based on the generic model. This configuration solution can be represented as a product specification, a sales order, or a part list or a BOM. In this sense, PFA-based product configuration becomes the derivation of product variants through instantiating the generic product structure according to customer-specified variety parameters [11]. The order execution phase encompasses a number of sub-activities such as order entry, production scheduling, material planning, capacity planning, shop floor control, and so on. Research and applications in this area have been under their relatively strong status.

3. ESI in ePC for mass customization

Online mass customization implies an advantage over traditional supply chain intermediaries, that is, the direct interaction among customers, manufacturers and suppliers for every single transaction, which involves coordination about the customer-specific product design. The costs rising from customization consist largely of information costs resulting from the transfer of individual configurations to manufacturing, the increased complexity in production planning and control, the coordination of external suppliers involved in individual assembly, and individual distributions of customer-specific products. Electronic linkages enable companies to reengineer supply chain relationships fundamentally in reducing transaction costs through electronic handling of orders, invoices, and payments. These will facilitate reduced inventory requirements and vendor managed inventory programs. In particular, online product configuration results in an increasing number of supplier-customer relationships and an increasing use of supplier parts. Design-stage sourcing, if accomplished properly, is particularly effective at the downstream assembly-to-order stage of order fulfillment. Therefore, the involvement of suppliers in online product configuration becomes an important issue for web-based sales support. Furthermore, suppliers should be involved earlier than they must be actually involved. During online configuration, decisions regarding supplier parts, such as make or buy decisions, bid preparation, and supplier selection, must be determined with real-time interactions with customers, marketing personnel, and designers. Traditionally, however, suppliers are often involved offline after design is over.

3.1 PFA-based integrated information model

As the front-end of the company’s interactive interface

to online customers, electronic catalogs work as a virtual gateway by providing customers with an immediate access for obtaining product information, ordering goods, making payment, providing feedback and participating in other corporate activities. Good electronic catalogs should be built upon a thorough understanding of the coherence of product information. This research extends our previous work on the product family architecture (PFA) for mass customization [11] [12]. PFA is the conceptual structure and overall logical organization of generating a family of products, which provide a generic umbrella to capture and utilize commonality, within which each new product is instantiated and extended so as to anchor future designs to a common product line structure. The rationale of such a PFA lies in not only unburdening the knowledge base from keeping variant forms of the same solution, but also with modeling the design process of a class of products that can widely variegate designs based on individual customization requirements within a coherent framework. For each view of PFA, such as functional features (FFs), technical parameters (TPs) and components / assemblies (CAs), a generic structure can be established to understand variety and its impact on product differentiation [13]. There are basically three aspects underlying a genetic variety structure (GVS), which are product structure, variety parameters and configuration constraints.

(1) Product structure: All product variants of a family share a common structure. It can be described as a hierarchy comprising parts (P_i) at different levels of abstraction, where $\{P_i\}$ can be either abstract or physical items. Such a breakdown structure (AND tree) of $\{P_i\}$ reveals the topology for end-product configuration.

(2) Variety parameters: Usually, there is a set of attributes (characteristics variables), A_i , associated with each P_i . Among them, some variables are relevant to

variety and thus are defined as variety parameters, $\{V_{ij}\} \subset A_i$. Like attribute variables, parameters can be inherited by child node(s) from a parent node. The instances, $\{P_{ijk}\}$, of a particular P_i in relation to a certain V_{ij} embody the difference among product variants.

(3) Configuration constraints: Configuration constraints manifest themselves through restrictions on the combinations variety parameter values, $\{P_{ijk}\}$. For the player example in Figure 2, there is a color compatible constraint among $\{P_{33k}\}$ and $\{P_{51k}\}$. The instantiation of a part, P_i is achieved by specifying one and only one value for each variety parameter related to P_i that is,

$$P_i \xrightarrow{\{V_{ij} \rightarrow V_{ij}^*\}} \{P_{ijk}^*\}, \forall k \in [1, N].$$

This can be expressed as a XOR (i.e., exclusive OR) relationship in Figure 2, meaning only one of $\{P_{ijk}\}$ can be selected for a product variant. For example,

$$\begin{aligned} V_{31} &\rightarrow V_{31}^* \\ V_{32} &\rightarrow V_{32}^* \\ V_{33} &\rightarrow V_{33}^* \\ P_3 &\xrightarrow{V_{34} \rightarrow V_{34}^*} \{P_{31k}^*, P_{32k}^*, P_{33k}^*, P_{34k}^*\}, \forall k \in [1, N] \end{aligned}$$

As far as variant handling is concerned, the rationale for the generic variety structure lies in the recognition of the origin and subsequent propagation of variety. Three levels of variations have been indicated, i.e., at the structure, variety parameter and instance levels. Different variation levels have different variety implications. Accordingly, a generic representation can be introduced to represent variety with minimum data redundancy. There are two basic concepts as described below.

(1) Generic product: A generic product represents a set

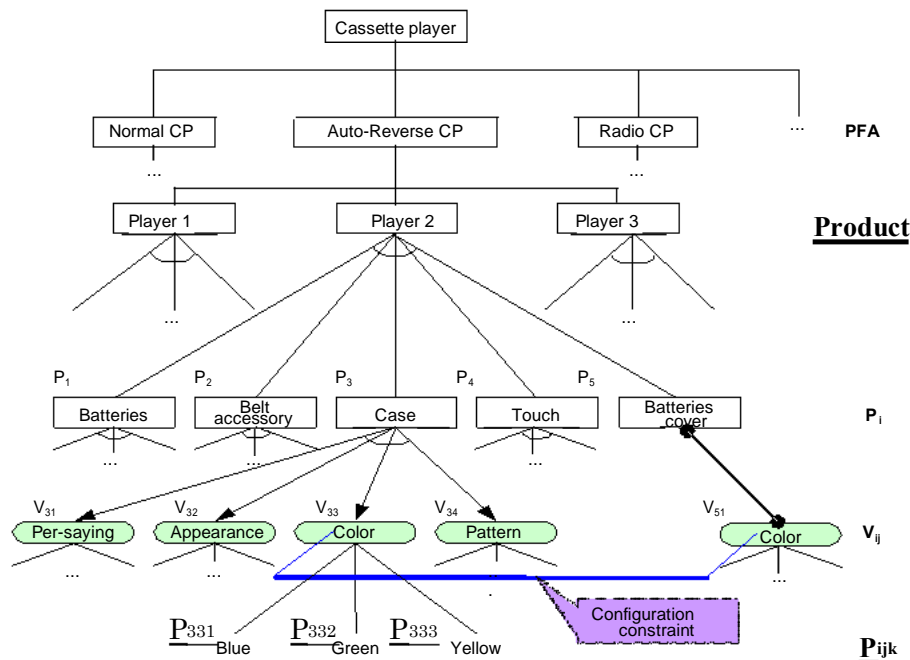

Figure 2 Generic variety representation for CP products

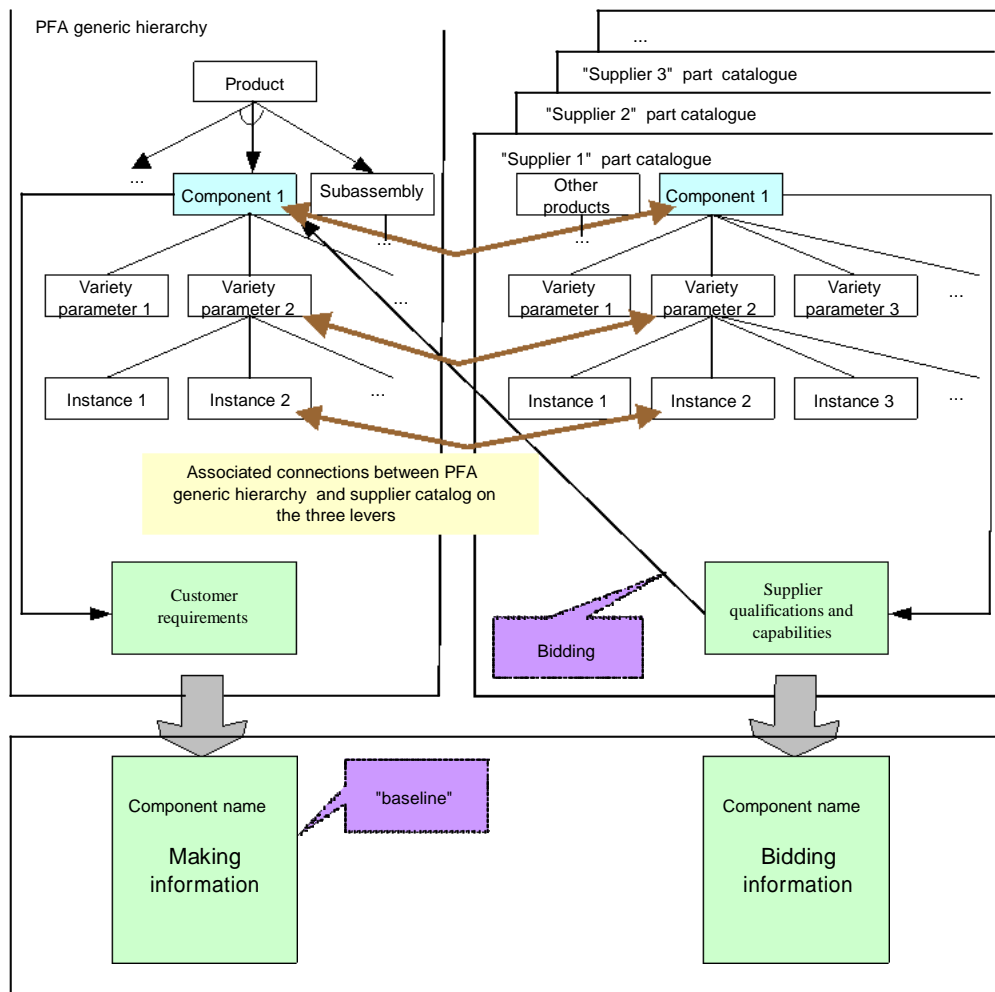

Figure 3. Integrated information model for ESI in online configuration under the umbrella of PFA

of similar products (called variants) of the same type (namely a family). A product may refer to an end product, a subassembly, an intermediate part, or a component part. For the player example in Figure 2, a blue case (P_{331}^*), a green case (P_{332}^*) and a yellow case (P_{333}^*) are three individual variants, whilst a generic product, $P_3|v_{33}$, represents such a set of variants (a family of player cases), that is, $P_3|v_{33} \rightarrow \{P_{331}^*, P_{332}^*, P_{333}^*\}$. Nonetheless, these variants are similar in that they share a common structure (Figure 2) in configuring a player.

(2) Indirect identification: Instead of using part numbers (referred to as direct identification), the identification of individual variants from a generic product (within a family) is based on variety parameters and their instances (a list of parameter values). Such identification is called indirect identification. In the above example, a variety parameter, color (v_{33}), and its value list, {"blue", "green", "yellow"}, can be used for an indirect identification of a particular variant, e.g., $P_{331}^* \sim P_3|v_{33} = \text{"blue"}$. On the other hand, the identification of product family (generic product) "player case" is described as P_3 .

The electronic catalog works not only as the front-end of the company's interactive interface to on-line customers, but also integrates the back-end product operation capability of manufacturers and suppliers. The online sales order configuration coupled with supply chain planning is an important strategy in order to synchronize design and production planning functions by considering materials and capacity availability associated with suggested configurations.

Figure 3 illustrates how to incorporate ESI into online mass customization under the umbrella of PFA. Suppliers to certain component parts can be organized in a similar way to the GVS, in which attributes of the suppliers can be retrieved and evaluated according to their relevance to and satisfaction of those variety parameters required by certain component parts in a particular configuration. In this sense, variety parameters play an important role to link suppliers to the PFA.

Such issues as "Make" or "Buy" decisions and supplier selection can be dealt with according to the justification of the values of relevant variety parameters between a specific supplier and a particular instantiation of the PFA. Figure 3 shows the elaboration of the supplier product model and its information exchanges with the PFA, through which PFA information and supplier part

information can be synchronized.

3.2 Real-time bidding

ESI in online mass customization differentiates itself from traditional ESI in product development through real-time bidding. Traditionally, the process of inviting and submitting bids is somehow time-consuming and often conducted off-line. With online mass customization performed, customers highly desire real-time online configuration, which aims at producing rapidly product configuration design with estimated price and delivery time subject to customer requirements and engineering or physical constraints. As such, it is really imperative to redesign the way in which a bidding process is incorporated in online configuration under mass customization environments. Real-time interactions between various entities are required as illustrated in Figure 4.

Figure 4. Real-time interactions

3.2.1 Static real-time bidding

Figure 5 shows an overview of the static real-time bidding process. A core of implementing static real-time bidding is to set up a centralized database for integration and management of supplier bidding information. The whole process starts with capturing customer functional requirements and ends at order entry. It is divided into three main stages including bidding preparation, bidding implementation as well as configuration generation and optimization.

In the bidding preparation stage, customer needs are captured as a set of functional requirements to certain components parts taking advantage of the electronic catalogs of ePC systems. As the electronic catalogs are organized based on PFA, customer requirements are actually reflected onto corresponding variety parameter instances within the generic structure of PFA. Subsequently the particular instantiation of the PFA is linked to product information systems of both manufacturers and suppliers, which are constructed in a similar way to the GVS of PFA. As a result, attributes of manufacturers and suppliers can be retrieved and evaluated according to their relevance to and satisfaction of those variety parameters in terms of customer functional requirements. In this sense, variety parameters work as a bridge to connect customers, manufacturers and suppliers together under the umbrella of PFA. While the mapping relationships among the triple entities are straightforward by using the PFA generic structure, it is critical to establish such linkages so as to enable downstream tasks such as “Make” or “Buy” decision and best supplier selection.

In respect of static real-time bidding, supplier bidding information must have already existed, that is, a number of potential suppliers are selected to put into an initial database based on last experience. In this case, ePC invites suppliers to provide the entire PFA-based product information instead of inviting bids for individual component parts. The bidding information is constantly updated in terms of suppliers’ current capabilities. Towards this end, it is essential to integrate the centralized supplier database into their MRP or ERP systems. Moreover, the suppliers in the database may keep changing. New suppliers are added with new partnerships built whereas unqualified suppliers are deleted.

Based on customer requirements, supplier bidding content is primarily comprised by two parts, supplier

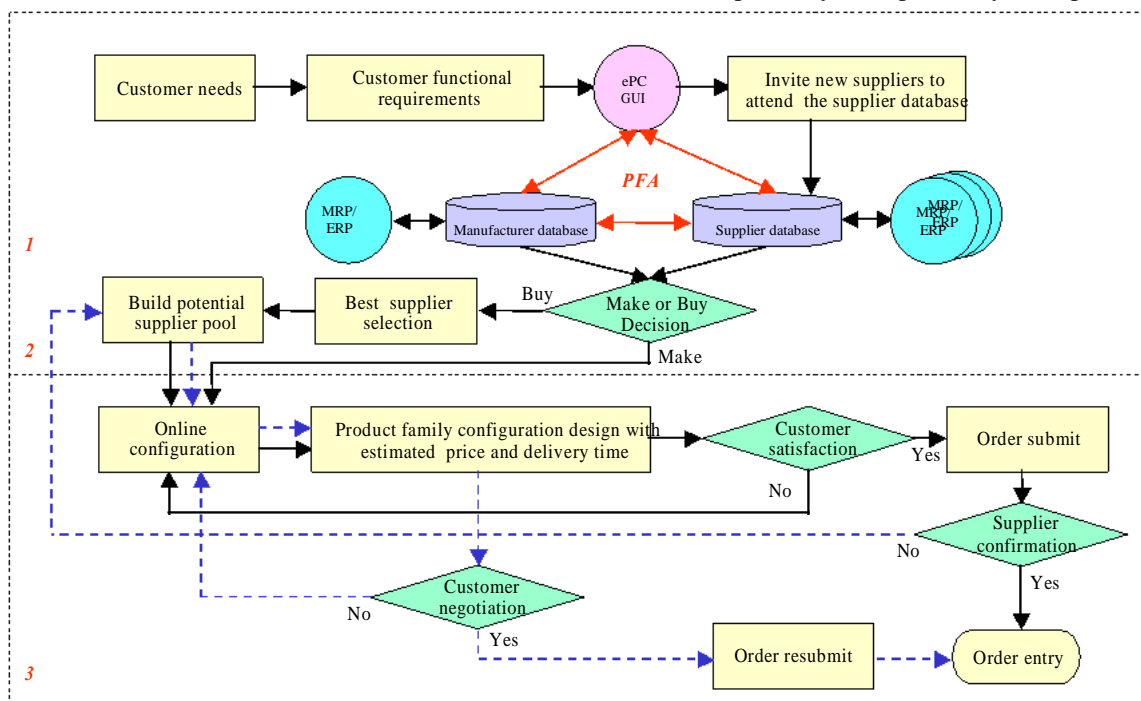

Figure 5. Static real-time bidding

qualification information and supplier production capability. Supplier qualification information is related to a set of fundamental non-technical requirements such as financial status, quality management systems and after sales customer service. On the other hand, supplier production capability is mainly concerned with technical requirements consisting of PFA-based part catalogs as well as component price and delivery time.

According to supplier bidding information, “Make” or “Buy” decision and best supplier selection can be carried out to achieve real-time bidding.

“Make” or “Buy” decision making is embedded in the

ePC system. Manufacturers who are capable of providing customers with the expected functional features first publish their “Making” information of specific component parts as a baseline for all suitable suppliers who are automatically authorized to participate in the bidding process. Through comparing with supplier bidding information, ePC can draw conclusions whether or not “Buy” has advantages over “Make”. Outsourcing only occurs when supplier bidding information surpasses the baseline. A Make/Buy index (MBI) is introduced to express the outcomes of comparisons between the suppliers and the baseline. Initially, MBI is 0 for both

Figure 6. A multi-agent system supporting dynamic real-time bidding

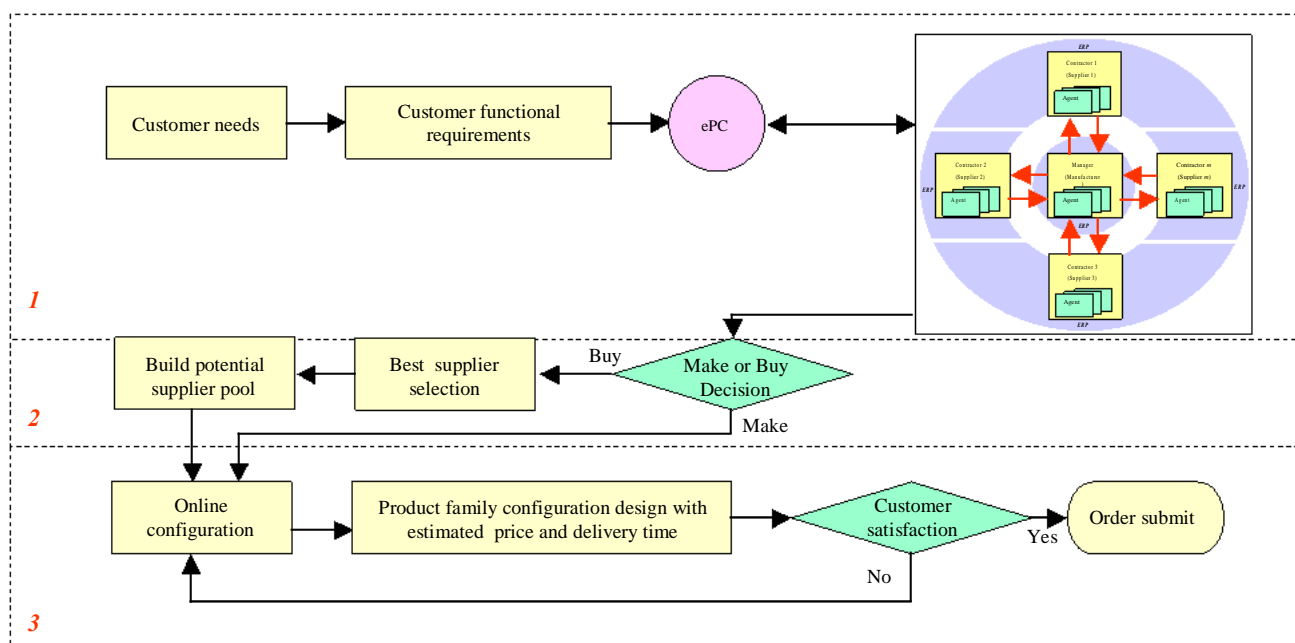

Figure 7. Dynamic real-time bidding

Qualified suppliers with MBI equal to 1 are under further consideration for best supplier selection. Supplier selection is a multi-criteria decision making problem, which contains both qualitative and quantitative factors. In order to select the best suppliers, it is necessary to make a tradeoff between the tangible and intangible criteria, some of which may be in conflict with each other. Besides the Make/Buy index (MBI), other indices can be introduced to measure the extent to which supplier capabilities match customer requirements.

It is notable that a customer-satisfied configuration design needs to obtain the confirmation from the relative suppliers when taking into account possible variations of supplier capabilities. In other words, the selected suppliers have to make sure their bidding information once more in present scenario. Next, the contracts can be awarded to them. If the suppliers cannot offer overall production capabilities as promised in bidding information, they are referred to as unqualified suppliers, and a reconfiguration is done without the consideration of the unqualified suppliers in the potential supplier pool. The results of reconfiguration are then negotiated with customers.

3.3 Configuration generation and optimization

With product design practice shifted from designing an individual product to designing a product family for mass customization, product configuration design is also referred to as product family configuration design, which always contains two fundamental tasks, generation of a family of configuration design alternatives and evaluation for the optimal one. In response to them, an intelligent system is desired to achieve the following three targets simultaneously for product family configuration design: (1) Automatically produce a family of feasible configuration design alternatives according to all the requirements and constraints. (2) Subsequently select the optimal configuration design from the family in terms of multiple rational design objectives. (3) Reusable and robust to varying configuration spaces in various customization cases.

Product configuration design and optimization start with creating a PFA generic variety structure (GVS) representation. After that, customers propose functional requirements according to customizable features represented in the GVS. A configuration space is then derived from the synthesized information provided by a set of predefined modules and the customers' requirements. All configuration alternatives can be generated from the configuration space. After formulating a mathematical model with respect to the configuration space, an optimization algorithm is employed to produce the optimal configuration alternatives. A class diagram describes the underlying mechanism of product configuration design and

optimization in Figure 8.

Customer value comes from a balance of quality, cost, and delivery time. Cost, quality, and time are three commonly used parameters in expressing customer value. To assist customers in dealing with customization options, customer-perceived quality is differentiated from engineering quality, which is not what customers really care about. In this case, utility is taken advantage of to measure customer-perceived quality. As such, Utility of quality, customization cost and delivery time are proposed as three critical performance criteria for product family configuration design optimization. Solutions resulting from such multiobjective optimization are expected to comprehensively express customer value and desirability. In addition of consideration from customer perspectives, selection for the "best" configuration design may involve more optimization objectives from the perspectives of manufacturers, suppliers, distributors, retailers and so on. In essence, it reveals the importance of product family configuration design carried out under the umbrella of the whole supply chain. For instance, from the manufacturer or supplier perspective, customizability is recognized as a potential index to fully measure the capability of design and manufacturing in terms of the nature of product family design. This direction is under an active exploration.

4. Implementation consideration

A computer-integrated system is necessary to develop the ePC for mass customization with static real-time bidding. Figure 9 shows an example of a system architecture. Customization by customers is enabled

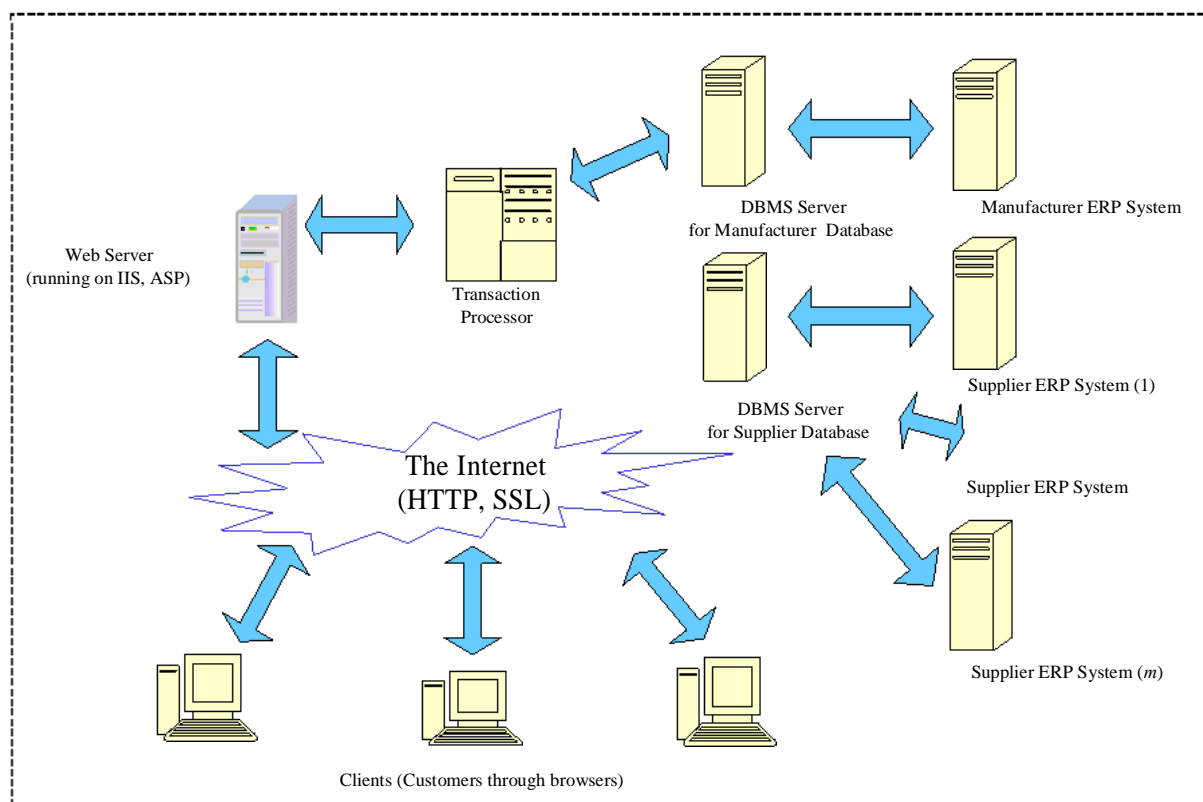

Figure 9. System architecture

through any Internet browsers. All information flow from the Internet is handled by the web server, in this case, running on an Internet Information Server (IIS) and using Active Server Pages (ASP) technology. The transaction processor acts as a connection module to process customers' data, real-time bidding and online configuration. Part of data that the transaction processor handles is retrieved from and updated into the database management system (DBMS) servers. Different DBMS servers could be assigned to deal with different tasks.

Two DBMS servers work as the manufacturer database and the supplier database respectively. Moreover, they are integrated with the ERP systems of both manufacturers and suppliers.

5. Conclusions

This research tried to investigate fundamental issues on ESI in online mass customization. PFA-based integrated information model is established across a supply chain to achieve effective variety management. Furthermore, the underlying mechanism of real-time bidding is explored to support online configuration. Two categories of methodologies are proposed as static and dynamic real-time bidding. A system architecture has been demonstrated for the ePC system with static real-time bidding.

Abstract

The current business environment is very competitive and complex that organisations need to understand new possibilities and opportunities in order to survive, sustain and grow. This requires creation of strategic partnerships based on new eBusiness models. To implement these models organisations need to IT enable its business process by undergoing an eTransformation process. We conducted a study using Porter's five competitive forces and new business models in order to give a new meaning to eBusiness strategies. This study also describes the decision making process in arriving at the business strategies and appropriate eBusiness models and the competitive advantage it gives to the organisations

Keywords: eBusiness Strategy, 7E's in eTransformation, Porters Forces, eBusiness Models, Competitive Advantage

1. Introduction

The digital revolution is changing the way buying and selling is being done creating new business cultures, new business strategies and new business models. There are many force working on organisations forcing them to revolutionise the way they do business. These forces effect the organisation so much that a need is created for business organisations to transform in order to Survive, Sustain or Grow [6]. There are five competitive forces described by Porter that effect organisations and impact on their position in the market. They are the threat of new entrants, rivalry among existing firms, threat of substitutes, bargaining power of suppliers and bargaining power of buyers [10].

In addition to the forces affecting the competitiveness of the organisation, ETransformation also has had a major impact on the way business is being done in the world. Many businesses such as Amazon.com, ebay.com and DELL have completely changed the way business is being done introducing new strategies and new business models to gain competitive advantage.

This study looks at Porters five competitive forces and discusses what strategies should be adopted to minimise the negative impact of the forces and to capitalise on the forces that can be used for the business's advantage. It also looks at eBusiness models and proposes the most effective models for different combination of forces.

2. Theoretical Background

2.1 Michael Porter's Five Competitive Forces

Micheal Porter has identified five competitive forces that determine the attractiveness of a market [10]. They are described in Figure 1.

Figure 1: Micheal Porter's Five Forces [10]

The competitive forces are as follows:

- (i) Threat of New Entrants: This deals with the attractiveness of the industry sector and the height of it's entry and exit barriers [14].
- (ii) Rivalry among existing Firms: This discusses the strength and aggressiveness of the competitors in the industry sector. An industry is considered to be unattractive if there are many aggressive competitors thereby resulting in price wars, advertising battles, new and competitive product introductions, etc.
- (iii) Threat of Substitutes: Some products/services have substitute products eating in to the market share which is very difficult to manage. Substitutes generally place a limit on prices and profits, making the industry unattractive and unprofitable to work in.
- (iv) Bargaining Power of Suppliers: Suppliers can impact the price of products and limit the quantities as well if they are few in the market and if they are concentrated or organised.
- (v) Bargaining Power of Buyers: Buyers become powerful when the switching costs are low, when products are undifferentiated and when they are price sensitive. The customers are very powerful in the online economy as there are so much of information about companies for comparisons and switching costs being low.

The study proposes business strategies and eBusiness models by looking at which force is high and which force is low at a given time.

2.2 eBusiness Models:

The industry sectors are changing the way they do business by using many different collaborations with customers (B2C), service providers (B2B), financial organizations (ePayments), government (B2G), and even competitors (B2B). There are many eBusiness Models that organizations can use effectively to get benefits such as group marketing, group ordering, product bundling, direct-to-consumer access, etc. As mentioned by Rappa [11] and Burn [4] Internet commerce has given rise to new kinds of business models.

The models described by Rappa and Burn have been categorized in to a few main eBusiness models with a fare amount of differences and advantages. Few models have been added by the authors to complete the existing and new eBusiness Models. It is important to evaluate which model gives the optimum advantage for the business being considered. Some of the emerging and existing eBusiness Models are described below.

- The linear Model (Traditional)

Figure 2: The Linear Model

- The Digital Value Hub (eEconomy)

Figure 3: The Digital Value Hub

- Direct-to-Customer eBusiness Model

Figure 4: Direct-to-customer Model

The approach adopted by DELL increased their sales from \$7M per day in 1997 to \$40M per day in 2000 [14]. This model which bypasses certain nodes in the supply chain gives the manufacturer the competitive advantages to sell at a lower price reducing intermediaries, faster delivery of goods, build according to customised orders, earlier receipt of payments, speeds up new product

release cycles, uses customer data to provide value added service and helps proactive decision making [14].

- Supply chain eBusiness Model (Horizontal Marketplace):

Figure 5: Supply chain eBusiness Model

This model creates a virtual value chain and an information flows across the supply chain. All parties have a strong electronic link among backend systems. This enables very effective order processing, product tracking and fast resolution of SCM issues.

- Full service provider eBusiness Model (Vertical Marketplace):

Figure6: Full service provider eBusiness Model

This is a very effective portal where the manufacturer sells their own products or services bundled with third party products or services. This offers a wider range of products/services to the customer at a reasonable or lower price as the products are bundled and therefore, concessions can be introduced. This is a very effective strategy to achieve economies of scale in delivery/distribution, channel usage and promotion which takes care of the threat of new entrants to the market.

- eAuctioneer eBusiness Model:

Figure 7: eAuctioneer eBusiness Model

The eAuctioneer model is very successfully used by eBay. Here the intermediary does not take responsibility

for the sale or the payment and the eAuctioneer owns the valuable customer relationship and data but not the transaction.

- Revenue sharing eBusiness Model

Figure 8: Revenue sharing eBusiness Model

This model uses the synergy of a collection of SMEs to get the competitive advantage. The eHub or the ePortal is the front-end for a collection of SMEs in the same industry using the portal to either market/promote each other's products collectively, pose as a larger company with a wider product range/capacity to get larger projects or use bulk ordering with suppliers to get economies of scale. Either way, the collective synergy is a much greater strength for the SMEs involved than trying to market or buy separately.

3. The Environmental Analysis and the Development of eBusiness Strategies

The study describes the business strategies adopted and eBusiness models that can be used after analyzing the business environment of an organization. This is used in linking environmental analysis to eBusiness Goals/Strategy development in the strategic eTransformation Model: Seven E's in eTransformation [2]. The 7E Model is developed by the researchers at the University of Western Sydney, Australia and currently, it is successfully being used to eTransform SMEs in the manufacturing sector in Western Sydney Region [3]. The Model is described in Appendix 1. The first two stages of the model deal with analyzing the strategic position of the company in the competitive environment it works in order to develop business strategies, eBusiness models and strategic alliances for the benefit of the company.

4. The Market Forces, Development of Strategies and eBusiness Models

As expressed earlier, Porter explains why strategies need to be developed according to the market forces working on a company in a given industry. As Porter explains, strategic positioning is "performing different activities from rivals or performing similar activities in different ways"[9], where competition is minimized by the adoption of proper differentiation strategies. The following section will explain how business strategies

and the appropriate eBusiness models should be linked to a company to get the competitive advantage depending on what forces work on that company. There are other factors such as the market economics (monopoly, oligopoly, perfect competition), company strengths/weaknesses and external opportunities/threats that will effect the final decision to adopt a particular strategy and a specific eBusiness model for the company.

According to Porter [10] the five forces working on a company at a given time are (i) Threat of New Entrants, (ii) Rivalry among competitors, (iii) Threat of Substitutes, (iv) Bargaining Power of Suppliers and (v) Bargaining Power of Buyers. When the forces are high, the strategy is mainly to position the company in the least vulnerable position or in other words, in a position where the company is least effected by the competitive forces. When a certain force is high, the business strategy should be to either minimize the force or diversify in to an area that will have a minimal effect from that force. When a force is low, the strategy should be to capitalize on the force or to use it to get more competitive advantage.

4.1 Threat of New Entrants

The best way to achieve the competitive advantage when there is a major threat from new entrants is to either differentiate or to strengthen the barriers of entry. This could be done by either adding value to the product/service by product differentiation strategy or product bundling. Another strategy would be to form strategic partnerships or alliances to strengthen the company's position in the market. Customer Relationship Management (CRM) [1] or in other words, providing a better, convenient, less costly customized service to the customer is also another strategy. Cost leadership is also an effective strategy where the company is in a position to reduce the price of the product/service to an extent that newcomers cannot even come close to the pricing structure.

The most suitable business models would be

- The Full-Service-Provider Model for value added service providing or product bundling where the new comers find it difficult to compete with
- Direct-to-Customer Model for Customer Relationship Management (CRM) [1] strengthening the B2B partnerships with suppliers to give the customer a customised product according to customer requirements
- EPortal Model where existitng competitors get together for joint marketing, bulk buying of raw materials to get the competitive advantage through economies of scale and use the synergy to increase the product line making it difficult for new entrants to survice in the market
- Digital Value Hub Model to have strong B2B strategic partnerships with existing nodes in the supply chain such as suppliers, manufacturers, dealers and customers.

These strategies and eBusiness Models make sure that there are major barriers for the new entrants making their entry full of obstacles there by getting the advantage to the company.

4.2 Rivalry Among Existing Firms

When there is a very high (perfect) competition in the industry, customers are given a wide choice of companies to select the service/product from. With the Internet, the customers can compare prices/products/services, company's profiles, other products/services offered, after sales services, etc. very easily and conveniently. The main strategy would be to differentiate, integrate, promote, manage customer relationships and have strategic partnerships.

Value addition or Product differentiation will move the product from a very competitive market to a market segment which would not be that competitive. Product bundling will provide a total solution to the customer which many competitors would not be able to provide. This is practiced a great deal in the tourist industry where they deal with ticketing, hotel bookings, car rentals, etc.

With internet technologies, it is very easy to link up with partners to form strategic alliances. Organisations can link up horizontally with the supply chain to provide a value added better service to the customer increasing CRM. Target marketing or niche marketing are effective marketing strategies which will make a major difference in creating awareness of the company and its products/services.

Another effective strategy would be the price discrimination strategy as proposed by Shin [13]. There are many Internet shopping agents such as pricescan.com and mySimon.com [8] offering price comparisons and a lot of other information to customers to compare products/features and prices. Companies can change different prices for different market segments or different combinations of product/service offerings for different prices. Discounted pricing can also be offered depending on quantities as well. This makes it difficult for customers to compare prices of alternate products offerings [13].

The most suitable eBusiness Models would be

- Direct-to-Customer Model for better CRM and to provide a quicker convenient service to any customer anywhere in the world
- The Full-Service-Provider Model to provide the supporting services using the concept 'product bundling'
- EPortal Model for a few competitors to get together for joint marketing, bulk ordering (to get economies of scale) and taking large orders using the revenue-sharing concept.

- Supply Chain Model to provide a better service to the customer including order tracking, customised products/services, etc.
- eAuction Model to market the products in a new C2C market place attracting new customers from a different market segment.

4.3 Threat of Substitutes

This threat is often ignored or neglected till it becomes too big a threat to handle. The plastic bag manufacturers face the substitute force coming from the paper bag manufacturers and promoters such as the environmental groups. The best strategies for such a situation would be product diversification, market diversification, product bundling, effective pricing strategies or strategic alliances.

Diversifying in to a new product or market is a permanent solution of avoiding the pressure of dealing effectively with substitute products/services, but, is not always possible. Strategic alliances and product bundling can add value to the basic product/service taking it away from direct competition from substitutes. One good example would be how soft drink producers link up with major food chains such as McDonalds, Hungry Jacks and KFC to beat the competition coming from ready-to-drink fresh juice producers and dairy drink producers. In certain markets, with price-sensitive customers, cost effective pricing strategies would negate the force coming from substitute products.

The most suitable eBusiness Models would be

- The Full-Service-Provider Model mainly for Product bundling and Strategic Alliances. This can also be used effectively for discounted or low pricing strategies.
- The ePortal Model can also be used for many competitors to get together and act as a Market Force using the synergy mainly to market or promote the products/services.

4.4 Bargaining Power of Suppliers

In an industry where there are limited or powerful suppliers of raw materials, a company can face major problems not being able to produce the products on time or to the expected quality and quantity. The suppliers can also monopolise on the prices for raw material thereby affecting the pricing strategies of the manufacturer. The best strategies for such situations are backward integration, Supply Chain Management (SCM), strategic alliances and bulk ordering strategies.

Backward integration will allow a company to become a component manufacturer or a raw material dealer reducing or eliminating the barrier of dealing with the bargaining power of suppliers. Supply Chain Management will definitely improve the relationships with the nodes of the value chain where the raw material ordering, manufacturing, buying from suppliers and

tracking rawmaterial orders will result in lowering the bargaining power of the suppliers. Electronic links will help the transfer of valuable information w.r.t. raw material which will ease the situation. Bulk ordering is also a good strategy where few companies who are in need of the same material get the pricing advantage by ordering in larger quantities (getting economies of scale).

The proposed eBusiness Models for such a situation would be

- The Supply-Chain Model which will increase the relationships with the companies in the manufacturing process tremendously. It can also deal with backward integration effectively.
- The ePortal Model which could be used to get the advantage in bulk ordering which could lower the cost of raw material and the dependence on the suppliers.

4.5 Bargaining Power of Buyers

One of the most important dynamics driving the expansion of the global online environment is the shift or power in the business relationship from seller to buyer [7]. As predicted by Alwin Toffer in 1990s, the buyer is becoming more and more powerful making the seller's job more and more difficult to survive in the competitive business world. In some instances, the buyers or customers are getting together in ordering in bulk to get products for the minimum prices. With the Internet, the services offered have impacted the buyer more than ever demanding convenience, 24/7 service, best bargains, best discounts, services with no geographical boundaries and more than ever, excellent Customer Relationship Management (CRM).

The best strategies proposed are Product differentiation (with value addition), Customer Relationship Management (CRM), Marketing Strategies, Pricing Strategies, Expanding Product lines, etc.

Product differentiation is improving the product and adding value to it to be different from the competitors. Porter's differentiation strategy [9] is very effective in such instances. CRM will let the company focus on high value customers [1] and have a customised approach rather than a mass-production approach. This will create brand loyalty and trust among customers.

Online and offline marketing strategies [7] and Customer Relationship Marketing [8] are another important ways of promoting the company and products to reach the customers. There can be so many other mechanisms that can be used such as product based marketing, customer based marketing, segmented and behaviour oriented marketing [12]

Traditionally, the price of a product/service depends on quality, features, quantity, type of customer, etc. On the Internet, there are many more strategies used and one such technique is customised negotiated pricing, used by

priceline.com. Here, the customer sets the price and allows the sellers to bid and the lowest bidder gets the sale [7]. Another pricing strategy would be to camouflage the real price by bundling or unbundling the product/service related components or features thereby making it difficult for customers to compare the pricing with similar products/services. eAuctions such as eBay.com and reverse auctions are also ways of reaching the cyber customers in the e-marketplace. [12]. Expanding the product line can also give the customer a wider variety and choice creating a customised approach to selling products/services.

The most suitable eBusiness models for that category are described below.

- Direct-to-Customer Model has many advantages such as good CRM, understanding the customer better, customised product/service offering, being able to sell at a lower price, rapid offering of the latest or the newest products/services, etc.
- The Full-Service-Provider Model offering a bundled product making it convenient for the customer to get all the services needed from one company.
- EPortal Model where many competitors getting together in order to cater to large orders or to increase the collective product line to show that the company is larger than in reality.
- EAuctions Models that can be used to market, advertise and sell products with different client market segments dealing with brand loyal and other customers effectively.

Depending on which force is working on the company, the strategies are developed and the suitable eBusiness models are being used. Table 1 describes the summary of all the strategies described in this section.

Porter's Force	Business Strategies for Competitive Advantage	Suitable eBusiness Models
Threat of New Entrants	Product Differentiation / Product Bundling / Customer Relationship Mgt (CRM)/Strategic Alliances / Cost Leadership	Direct-to-Customer Full Service Provider EPortal Digital Value Hub
Rivalry among existing Firms	Product (Value-added) Differentiation / Strategic Alliances /Product Bundling / Horizontal integration / Marketing / Price discrimination strategies/ Pricing Strategies / Targeting Niche markets/ Customer Relationship Management (CRM)/Expand Product Line	eAuction Model Full Service Provider EPortal Supply Chain Model Direct-to-customer Model
Threat of Substitutes	Product diversification / Market diversification / Product bundling / Strategic Alliances / Pricing Strategies	Full Service Provider ePortal / eRegion

Bargaining Power of Suppliers	Product differentiation / Backward Integration / Supply Chain Management (SCM) / Strategic Alliances / ePortal for bulk ordering	Supply Chain Model EPortal / eRegion
Bargaining Power of Buyers	Product (Value Added) Differentiation / Forward Integration / Marketing / Product bundling / Product Development / Strategic Alliances / Customer Relationship Management (CRM) / Cost Leadership / Pricing Strategies / Expand Product line	Direct-to-customer Full-Service-Provider EPortal eAuctioneer

Table 1 : Development of Business Strategies/eBusiness Models using Porter's forces

The effectiveness of the appropriate strategies and eBusiness models described above can only be measured by actually applying them to businesses and measuring its success. The researches at University of Western Sydney is applying these strategies to the businesses [5] in the industrial sector validating and refining the models, methodologies and strategies through a process of Action Research.

5. Conclusion

eTransformation is actually a business transformation to get the competitive advantage. The Internet makes it so easy to link up with strategic partners, but, the proper business strategies and business models should be adopted looking at the environmental forces and competitive forces working on the company. The mix of using a strategic eTransformation model along with a strong environmental analysis using some of the best models available such as the Porters Five forces model and the SWOT analysis and linking up with emerging eBusiness models definitely give the competitive advantage to any company working in any industry sector.

Appendix 1

The Seven E's in eTransformation – A Strategic eTransformation Model

The Seven E Model [2] was developed by the researches in the University of Western Sydney after carefully analysing the existing eTransformation methodologies and Models. This Seven E model is being currently used to eTransform SMEs in the Western Sydney region [3].

This model consists of seven very important aspects of eTransformation (Figure A). Each stage is important in its own right and as a part of the whole process. The seven steps, out of which six steps could be achieved one after the other are linked to the seventh step 'Evolution', which deals with the crucial issues related to change management. After each stage, the organization can go

through the changes to the evolution stage and through that, go to the next stage, after the required evolutionary change management issues are done.

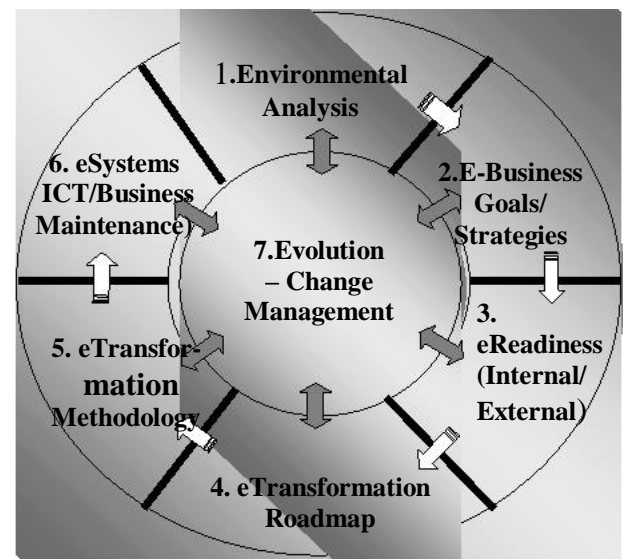

Figure A : The Seven E's in eTransformation (Arunatileka, 2003a).

The significance of each stage of the 7E model (Table A)

Stage	Significance	Methodology used
1. Environmental Analysis	To understand the Global IT and Business Trends and the Sector's Strategic Situation	Understanding of Global Trends in Business and IT SWOT Analysis Industry Analysis (Porter's Forces)
2. eBusiness goals and Strategies	Develop eBusiness goals and strategies to gain competitive advantage	Develop eBusiness, Strategies & Adopt eBusiness Models
3. eReadiness	E-Readiness of the industry and the enterprise under consideration	Questionnaires to measure eReadiness of the Internal and External entities
4. eTransformation Roadmap	To develop a specific path to proceed for the organisation	eTransformation Roadmap and the Convergence Model
5. eTrans. Methodology	eTransform the organization in an incremental way	The Evolutionary eTransformation methodology
6. E-Systems	Provide support and maintenance of the implemented systems	Develop IT Policies, Security, Support, Maintenance mechanisms
7. Evolution - Change Mngmnt.	Management of the proposed changes in an evolutionary manner	McKensy's 7S Model for Organisational Change

The significance of each stage of the 7E model and the methodologies used (Table A).

Abstract

As segmentation has been one of the central marketing tasks for decades and customer profitability valuation has seen wide study during the past few years, surprisingly, up to this date, there is a gap in marketing research that await a bridge to link up of these two important and closely related dimensions. In this paper, we introduce a decision support system with the goal of maximizing customer equity by segmentation. The decision support system introduced here is unique in that it accommodates the essence of customer profitability valuation into a segmentation scheme in a sensible and flexible manner, that it suggests the number of segments to be determined by the goal of profit maximization instead of some arbitrary numerical criterion, and that central to its technical core the outlier problem which is pervasive in cluster analysis has been addressed by a modified K-Means algorithm so that clustering can reflect the pattern of the majority of ordinary observations in a data set instead of being influenced by a handful of outliers. It followed by a number of test datasets from a public data source and a conclusion remark was made at the end.

1. Introduction

Central to the current Customer Relationship Management (CRM) thinking is the idea that a firm's customer base is the key to the business' profitability. Just as Blattberg and Deighton [1] put it, the essence of CRM emphasizes that "growing a business can be framed as a matter of getting customers and keeping them so as to grow the value of the customer base to its fullest potential". In this light, there are two stepping stones to successful CRM implementation: customer profitability valuation and customer segmentation.

What underlines the importance of customer profitability valuation is the recent emphasis on the concept of customer equity which, for a firm, can be defined as the total of the discounted lifetime values of its customer base [13]. At the individual level, therefore, an

array of studies has aligned "lifetime value" with the revenue and cost associated with a customer over time [2], [6], [8], [12]. The essential assumption implied in this type of models is that managers can predict, at least with tolerable errors, *both* a customer's expected contribution to a firm's revenue over time *and* the costs that will incur for the acquisition, maintenance, and retention of this customer, again, over time. As a manager is likely to point out, this assumption may not be realistic for marketing decisions (in which costs are usually determined by marketing mix strategy and strategy in turn follows segment definition) in any marketplace that sees competition and undergoes structural change, which most industries do nowadays. That is, except for the role to play in long range planning, current customer profitability valuation models neither fit in nor provide practical guidance for manager's actual decision making.

The other stepping stone to CRM is customer segmentation. Having seen limelight in marketing for at least half a century, segmentation mainly "involves viewing a heterogeneous market as a number of smaller homogeneous markets, in response to differing preferences, attributable to the desires of consumers for more precise satisfaction of their varying wants" [16]. Technically, segmentation issues that usually puzzle researchers and practitioners include the "optimal" number of segments and the bias of segmentation caused by outliers in a dataset. Yet more importantly, though various models have been proposed for segmentation in the marketing research literature (for a comprehensive review, see Wedel and Kamakura [17]), the relationships between most established quantitative segmentation models and marketing decision making, as implied managerial relevance in which should be the *raison d'être* of developing a model, are mostly neglected.

Meanwhile, to follow the CRM principles, a profit-maximizing firm will seek to maximize the profit to which its customer base can contribute. In terms of implementation, customer segmentation is likely to play a central role. Surprisingly, however, except for a few superficial discussions on the importance of market segmentation on customer profitability [11], [12] to the

best of our knowledge, there seems to be a vacuum in marketing research that clarifies the relationship between customer profitability and segmentation, not to say attempts that formally links up these two important issues in a model.

This paper, therefore, aims to present a managerially relevant and easy-to-implement model in the form of a decision support system (DSS), to which we give the name of MCES (Maximizing Customer Equity by Segmentation), that addresses the several issues mentioned above. In the following sections, we will first discuss the relationship between customer profitability and segmentation, and then propose a segmentation decision framework for the maximization of customer profit—the backbone of our proposed DSS. Next, on the more technical front, we will introduce a modified K-means cluster algorithm that serves as the quantitative core of the DSS. Finally, we will discuss the implication of such a DSS as well as directions for future research.

2. Assumptions of MCES

Current customer profit valuation techniques are developed upon the assumption that managers can reasonably predict the revenue a customer will contribute to the firm *as well as* the costs necessary for generating them. What is implied in models thus developed [2], [6] [8] then is that the revenue side and the cost side can be determined *simultaneously*. Arguably, though sound in terms of strategic thinking, of accounting, and perhaps of financial performance projection, current customer profitability valuation models thus developed seem distant from managers' daily marketing decision making. It needs not be so. The value of customer valuation and its accompanying CRM implications, we propose here, can be fully unleashed so that it can fit neatly in marketing decision making process if a more realistic view of customer profitability is taken. The key to managerial relevance for customer valuation in the context of marketing decision making, however, is the important but long neglected link (in terms of implementation) between segmentation and customer valuation. Just like Wedel and Kamakura [17] mentioned, traditionally, segmentation models put emphasis on goodness of fit and neglect the importance of relating marketing research with marketing strategy within a single model. The proposed MCES model in the form of a DSS, that will be introduced below, is a formal attempt to develop a managerially relevant framework which aims to combine inference and profit maximization and in which, in the words of Wedel and Kamakura ([17], p.340), "decisions on the proper number of segments would be based on managerial criteria (expected profits)

rather than goodness of fit; inferences would be made directly in terms of the optimal marketing effort rather than mere descriptions of the segments."

The first task in actually bridging customer profitability and segmentation, given the essence of customer valuation and that profit is the difference between revenue generated and costs incurred, then, is to make more realistic assumptions than what current customer valuation models assume. In this light, the tenet of the decision support system proposed here is that for a manager with bounded rationality, certain experiences with the customer base to be managed, and perhaps some familiarity with established probabilistic models (not a necessary condition, though), the revenue a customer can generate in a reasonable period of time can be roughly predicted *a priori*, whereas the cost side can only be managerially estimated *after* marketing decision relating to segmentation is made. In the marketing research literature, the array of well-established models based on NBD has demonstrated that even without marketing mix information in the form of covariate, an NBD-based model performs well in a wide range of applications for the description of customer's repeat behaviors, which in our context can be directly translated into revenue generated by a customer base [10], [14]. A single customer's future contribution to a firm's revenue, then, can be easily derived by, say, empirical Bayesian method. For a nonstationary customer base, inferences can also be made by modified models with a nested NBD core [15]. Even without resorting to these formal probabilistic models, current practice has various heuristics for the prediction of customers' revenue generation potentials built in a wide range of CRM systems. Therefore, it can be reasonably expected that for a single customer, a firm can get a rough but useful estimate as to his/her future contribution to revenue stream, which can serve at least as a baseline in our model. On the other hand, the cost side in the profit equation is more subtle. In fact, in the segmentation context, it is only after the segments and the respective marketing strategy set are defined that the cost to maintain a specific customer can be reasonably calculated. Therefore, in our MCES DSS, we assume that:

1. Each customer's expected contribution to a firm's revenue, given the context, can be roughly calculated by certain heuristic or a formal probabilistic model.
2. Managers cannot figure out the cost to maintain any segment *a priori* (i.e., before a segment is defined), but are able to do it given the defined segments.
- 3.

3. MCES as a Decision Support System

Given the above-mentioned assumptions, here we propose a model to maximize customer equity by segmentation (MCES) in the form of a decision support system. Suppose that each customer's expected contribution to the firm's revenue stream in a period of time is given (either calculated by certain heuristic or estimated by a probabilistic model), the decision framework, which combines managerial judgment and a modified clustering method, can be summarized in the following steps:

1. Managerially define a desirable range of number of segments $[S_i, S]$, $S, S_i \in \mathbb{N}$ and $S_i < S$
2. Setting $m = S_i$
3. Assigning observations into m segments by modified K-means (to be introduced in the next section)
4. For $j=1$ to m , (managerially) judge the cost to maintain each segment thus derived, C_j . Meanwhile, calculate the sum of expected revenue to be generated by the segment members, R_j . Then calculate expected profit (loss) from each segment, $P_j = R_j - C_j$.
5. Summing up expected profits (losses) across the m segments, get gross expected profit E_m , $E_m = \sum_{j=1}^m P_j$.
6. If $m < S$ then $m = m + 1$ and go to step 3; otherwise go to step 8
7. Compare the E_m , $m = S_i, \dots, S$, choose the solution among the $S - S_i + 1$ choices which maximizes E_m .
8. End

For a fictitious example, let's assume that the expected contributions to revenue in the coming year of a small bank's 500,000 customers (by whatever heuristic/model on which its CRM system may rely) are given. The manager, upon making the annual strategic marketing plan, applies MCES for customer segmentation. Taking the resources available and past experiences into consideration, she first decides that the number of segments with managerial meaning as well as operational efficiency/effectiveness should fall between 2 and 5. Therefore, MCES guides her through scenarios with 2, 3, 4 and 5 segments, respectively. For each scenario, once the segments are objectively defined (to be elaborated in the next section), the manager judges the appropriate cost for the maintenance of each segment depending on segment characteristics that can be easily summarized in the form of descriptive statistics (e.g., segmental means). The system then calculates the expected profit of each segment. The total expected profit

for the scenario is then derived by summing over the segments. Having done this for the four scenarios with different number of segments, the system list all the scenarios' expected profit in descending order. The "best" segmentation scheme is now obvious.

Simple as it seems, though, this proposed MCES framework has several features that positively distinguish it from established segmentation schemes:

1. It accommodates the essence of customer profitability valuation into a segmentation scheme in a sensible and flexible manner.
2. Unlike most segmentation approaches that make the defined segments *independent* of strategic considerations, MCES allows for, actually depends on, managerial judgment as an important input in finding the "best" definition of segments. In this way, a segment is no longer the end *per se* (as most segmentation models imply), but the means used by managers for the attainment of managerially desirable goal—which is what segmentation is managerially meant for.
3. The application of MCES addresses the issue that usually puzzles modelers as well as managers, namely: how many segments is the *most appropriate*? As Milligan and Cooper [9] concluded from their empirical comparisons among 30 stopping rules for the determination of number of clusters in cluster analysis, lacking a universal theoretical criterion and susceptible to data dependency in empirical settings, it is almost impossible for any numerical rule to claim as the "most appropriate" for the number of segments. Under MCES, however, the thorny problem of number of segments is solved, no longer by an arbitrary rule, but by the interplay of cluster analysis and managerial judgment (it should be highlighted here that it is not the number of segments a priori, but the costs associated with segments post-hoc to be judged by managers).

4. Modified K-Means as the Technical Core of MCES

Given a set of relevant individual level customer information, be it behavioral and/or demographic, cluster analysis is the dominant approach to segmenting a customer base. Among various cluster analysis methods, K-means is the most popular one. As Green et al. [5] and Huang [7] indicated, K-means is capable of handling large database that the business uses for their marketing efforts. Therefore, we have K-means as the technical core of the above-proposed MCES (Step 3). However, K-Means is highly susceptible to out-of-proportion

influences of outliers [4]. Therefore, here we propose a modified K-Means algorithm by temporarily skipping outliers in the step of cluster formation. To implement this approach, the mean and standard deviation of the whole data set is first calculated. Data points whose distance to this mean going over some multiple z of the standard deviation are then temporarily skipped. Once the cluster analysis of the remaining, “ordinary”, data points is done, the extreme-value points are then ascribed to the nearest group according to the distances calculated between the extreme-value point and group means.

Algorithm

Program Initiated

Step 1. Calculate the mean and standard deviation of the data set. Skip the points whose distance to this mean is beyond z standard deviation.

Step 2. Randomly generate seeds for non-extreme-value points.

Step 3. Following traditional K-Means, start grouping.

Step 4. Check the grouping by MSE. For example, in Figure , calculate the MSE from point C to group A and the MSE from point C to group B, respectively. If $MSE(C, \text{group B}) < MSE(C, \text{group A})$, then accept that C belongs to B. Otherwise, regroup point C into group A.

Step 5 After all non-extreme-valued points are segmented, assign extreme-valued points into groups whose group means are nearest to these points.

End of program

The Network Data Examples

We use four data sets that have been previously analyzed and published that are available in the public domain for an empirical test of this modified K-means. According to the requirement stated above, we first set the criterion of extreme value, z , equal 2. That is, those data points that are more than 2 standard deviations away from the data mean are treated as outliers. The model results, both from traditional K-Means and from the modified K-means are compared in Table 1.

Judging by Table 1, the modified K-means we propose here leads to more appropriate segmentation in terms of segment membership identification. The within-group SE criterion also indicates that our model outperforms the traditional one in most cases. The exception, however, has some interesting implication. An intuitive explanation of the exception is that by traditional K-Means, outliers are accounted for in the grouping process simultaneously with other points. Our two-stage modified K-means, instead, defines group boundaries solely on non-outlier points. As Figures 1

illustrated, in cases where outliers are really “extreme”, traditional K-means are likely to be heavily biased by these extreme points. In that case, traditional K-Means may lead to better SE comparing with our method. However, managerially, the segmentation which is less susceptible to the influences of extreme-valued points are more relevant if the majority of “normal” data points are of central concern in a segmentation scheme.

5. An application of on line customer behavior survey

Since the MCES decision framework has not been introduced into practice, to demonstrate how it will actually work, here for mainly pedagogic purpose we simulate a project to exposit how managerial judgment would be fused with a decision support system under MCES. This simulated project aims to segment a bank’s potential customers for the purpose of launching the bank’s online transaction platform. That is, given a base of prospects, we, playing the role of the bank’s marketing manager, would like to segment potential customers by their online behaviors so that various marketing mixes can be offered to different segments for the purpose of maximizing the transaction platform’s expected profit. The data comes from the online survey from GUV’s WWW user Survey Team. It includes 103 items and result in 9147 observations.

As the data consists of prospects instead of customers, expected size of customer base as well as expected contribution to online transaction revenue by future customers can only be predicted by heuristics concerning penetration, pattern of transaction amount and frequency, rate of retention, and so on. Therefore, in this simulation, the manager is able to assign an expected value to each observation with the aid of a heuristic based purely on demographic profile. Before the implementation of cluster analysis, the manager looks at the discriminating power of the 103 items in the survey by using a heuristic criterion of max-min difference. That is, for each attribute (item), the manager calculates the difference between the biggest and the smallest value among the 9147 observations. Only attributes whose max-min differences are larger than 0.2 are then included for the following cluster analysis. 21 attributes are therefore retained for analysis.

Initiating MCES, the manager first sets up the range of number of segments between 2 and 5. Here we only illustrate how the system works for the situation when it comes to the scenario of 4 segments. In this case, the technical core of MCES, the modified K-Means ascribed the 9147 data points into 4 segments. The result is summarized, in the form of descriptive statistics, which

is presented to the manager for human input. The system then sums up expected contribution to revenue of each segment member to derive expected contribution to revenue by each segment.

Apparently, segments 1 and 3 are heavy Internet users. Between them, segment 1 users reflect a relative functional orientation that uses Internet mainly for information search, while segment 3 users in comparison reflect a relative leisure orientation that uses Internet mainly as the substitute for entertainment and interpersonal communications. On the other hand, segments 2 and 4 consist of light users. In terms of orientation, segment 4 is similar to segment 1, whereas segment 2 is close to segment 3.

Given the analysis (table 2), the four segments found are different in orientations and/or degree of usage. The manager therefore initiates a set of strategies for the four segments found.

1. Hard-core penetration

For segment 1, the heavy and functionally-oriented Internet users, direct benefits of online transaction with the bank should be intensely communicated through multiple online communication channels to reach rapid penetration.

2. Soft-core penetration

For the heavy and leisure-oriented Internet users of segment 3, another set of online marketing communication mixes should be initiated based on a tune with hedonic appeal. Rapid penetration is also the goal.

3. Functional communications

To segment 4, the light and functionally-oriented Internet users, well-designed and user-friendly online transaction platform should be explained via both online and offline channels. The short-term goal is not necessarily to attract these customers to directly apply for the service, but instead on lowering their psychological barrier to the Internet environment and on developing the trust of the bank's system from these customers.

4. Leisure communications

A soft-soft communication plan should be initiated for segment 2 which consists of light and leisure-oriented customers. Hedonic appeals should be stressed in design, and the goal is to attract these customers by, for example, word of mouth, in a longer run.

Given the strategic outline and the information of expected segment contribution to revenue, the manager then allocates resources for the management of these four segments. The cost associated with each segment can then be estimated. Therefore, expected profit in the four-segment scenario can be derived. Repeating the same procedure over the scenarios of 2, 3, 4, 5 segments, respectively, the segmentation scheme that maximize the expected profit of the online transaction platform is then

decided. The beauty of MCES is that upon the final definition of segments, the manager has already considered feasible alternatives and objectively chosen the best option among them. Meanwhile, once the segments are defined, the manager already has a set of strategic map as well as profitability projections.

6. Conclusions

As segmentation has been one of the central marketing tasks for decades and customer profitability valuation has seen wide study during the past few years, surprisingly, up to this date, there is a gap in marketing research that await a bridge to link up of these two important and closely related dimensions. By the introduction of a decision support system (MCES) with the goal of maximizing customer equity by segmentation, this paper attempts to fill the gap. We take the view that for a segmentation scheme to be managerially relevant, segments should not be the end of a one-shot model which is independent or antecedent of strategic decision making. Instead, managers should be provided with a set of possible segment alternatives as the means for them to initiate relevant strategies so that profit maximization, or customer equity maximization if one likes, can be objectively approached through the interplay of numerical classification rules and managerial judgment. The MCES decision support system introduced here is unique in that it accommodates the essence of customer profitability valuation into a segmentation scheme in a sensible and flexible manner, that it suggests the number of segments to be determined by the goal of profit maximization instead of some arbitrary numerical criterion, and that central to its technical core the outlier problem which is pervasive in cluster analysis has been addressed by a modified K-Means algorithm so that clustering can reflect the pattern of the majority of ordinary observations in a data set instead of being influenced by a handful of outliers. More managerially relevant segmentation, therefore, is expected from the adoption of this decision support system. We also resort to fictitious case as well as real-world data to exposit and demonstrate, at least partially, the performance of the proposed framework. In a word, the system reflects our argument that it should be managers, rather than numerical methods, that should have a final say on the definition of customer segments.

Common sense MCES may seem if one buys in the popular CRM rhetoric. However, to the best of our knowledge, segmentation techniques, no matter how complicated and/or refined they are, have never been fused into the customer profitability valuation framework which we think to be of ultimate importance if a firm

really aspires to leverage its expensive CRM system. And to actually achieve this goal, managerial judgment should play no lesser role than complicated numerical rules in segmentation tasks. Admittedly, being a pioneering research that attempts to fuse two important CRM dimensions together, this paper puts more emphasis on the principle side rather than details. Given the foundation we lay here, a few important aspects should be attacked in the future. For example, quoting various references, this paper takes each customer's expected contribution as exogenously given. One direction of future research is to handle this aspect within the system. Meanwhile, though a series of research based on probability models has shown that marketing covariates are not necessarily crucial for the prediction of customer's repeat behavior, a further refined MCES may allow for expected customer contributions to be changed given a set of marketing mix for a specific segmentation definition. Meanwhile, for some reasons that cannot be expected a priori, there may be cases that a firm decides to discard certain segment(s). It is therefore of interest for future research to take this possibility into account.

To sum up, guided by the principle of profit maximization, this study adds to managers' decision making toolbox an objective and easy-to-implement framework for segmentation. Also, upon segmenting a customer database, the modified cluster algorithm proposed in this study will serve to lessen biases caused by outliers in a database as is frequent in segmentation practice. We believe that a decision support system thus developed will improve a business' efficiency and effectiveness in segmentation so that the potential of its CRM system can be tapped.

Barriers to Uptake of Wireless Healthcare Applications – A Review

Raj GURURAJAN, Joshua LAST & Shri RAI

School of Information Technology

Murdoch University

Perth, Western Australia

ABSTRACT

Wireless technology is growing and a number of vendors are providing solutions in the area of healthcare. These solutions include electronic prescriptions using handheld devices, data capturing at point of entry using wireless devices, communication of patient information and accessing patient databases using handheld devices. While these new systems appear to be providing solutions to some of the problems encountered by the healthcare industries, there are a number of barriers associated with the wireless technology itself, prohibiting the uptake of this technology in healthcare settings. This paper provides a review of such barriers.

INTRODUCTION

Recent advances in wireless and mobile technology have enabled healthcare industries to provide more responsive service to their customers. Wireless applications that are emerging in the market address some of the problems of the healthcare industries such as data management. This development has prompted renewed interest in technological issues associated with healthcare industry and how the emergence of wireless technology can be applied to the healthcare settings. Current research and development in the area of healthcare includes prescriptions, pharmacy and billing applications. According to a report released in the Wireless News in 2003, it appears that the hospital systems are the fastest growing market for wireless technology. According to [1], wireless technology sector is expected to become a \$2 billion industry within five years. According to GE Medical, the number of clinicians using wireless tools will increase from 1 in 100 today to 1 in five by 2004. Therefore, hospitals are investing money into wireless technology that will augment the management of hospital operation.

However, there is still doubt as to whether wireless mobile technology would provide anticipated benefits as the introduction of such technology in hospital environment is still in its infant stages. A number of barriers associated with the performance of wireless technology are yet to be answered in the literature as the applicability of wireless technology to healthcare is just emerging [2]. The objective of this paper is to identify some barriers to wireless technology in a healthcare setting.

WIRELESS MOBILE TECHNOLOGY

Wireless technology includes the concept of mobile computing, which consists of portable devices that can connect to traditional networks without the utilisation of cables [3]. In a wireless network, computers in an office are linked to one another. These computers communicate using radio signals. The network itself is built around an access point and this point may have a wired connection to another network. This access point can receive data and transmit the same to wireless adapters found in the base computers [4]. In healthcare settings, this technology can be used to access data about a patient, to enter certain predefined terms in order to process billing details or to capture patient data at the point of entry.

The need for wireless technology in healthcare is justified by many studies. For example, [5] provides initial thoughts of applicability of wireless technology in addressing the financial crisis encountered in many healthcare systems. [6] elaborates how wireless technology can be utilised to address the increasingly complex information challenges currently encountered by healthcare information systems. [4] mentions the role of wireless technology and hence the mobility of data using wireless devices in order to comply with the rigorous regulatory framework. [7]'s study provides insights into how wireless technology could be used to reduce medication errors and to generate affordable healthcare applications that allow for

greater mobility and ease of use in entering, sending and retrieving data. Similar views can be found in [8].

While these studies provide justification to the use of wireless technology in healthcare settings, [1] raise warnings as to the infancy stages of the devices in the area of wireless technology that are used for data management. [9] warns of the slower speed of wireless devices compared with the desktop computers. [10] points out the high costs to initially set up these wireless networks and their impact on the financial resources of already struggling healthcare industry. [11] is concerned with the lack of real time connectivity due to the mobility of the wireless devices and their adverse influence at critical times. [12] discusses the limited size of screens found on many mobile devices such as PDAs and argues on their lack of suitability in displaying critical data – especially in medical imaging. [13] provides a discussion on the hard-to-see display screens of current mobile devices and the potential difficulty that these screens can introduce for medical professionals. [14] points out the adverse effects of wireless devices on healthcare industry in terms of the need for high quality graphic displays in specific healthcare settings such as operating theatres. While there is general agreement that wireless technology would provide solutions to some of the problems encountered by healthcare industries, it appears that there are some barriers to the uptake of this technology in the healthcare industry.

Further literature review indicated that it is possible to construct a taxonomy for these barriers. We have grouped these barriers into hardware barriers, software barriers, protocol barriers, cost barriers, logistics barriers, interfaces barriers, wireless coverage barriers, security issues, patient care specific to healthcare settings, efficiency of wireless systems, performance barriers and perhaps workforce issues. Some of these are reviewed in the following sections.

HARDWARE BARRIERS

The hardware barriers of wireless technology applicable to healthcare include the demand for more processing power, potential interference to other existing medical devices, range issues, problems associated with bandwidth and energy consumption by current devices [15-17]. Current healthcare applications process a lot of data and hence the information storage at main memory level is crucial for this processing. Due to their sizes, mobile devices have limited memory power (compared with desktop computers) and this appears to be a barrier in implementing major applications with voluminous data on mobile devices. The size of

the devices also place some constraint on the Central Processing Unit (CPU). Increasing the power of the CPU adversely affects battery life. Battery life is very important for mobility. Due to the limited power possessed by batteries in mobile devices, frequent charging becomes necessary. This introduces usage limitations. When the hardware is not robust enough, various user settings may be erased by weaker battery and the device may need to be reset. This is a source of major concern and seen as a barrier as this restricts long period of mobility without charging.

The hardware devices also cause problems with other existing medical devices by interfering with them. For instance, mobile telephones are not allowed in a number of hospital environments. These interference problems appear to be limiting the usage of certain mobile devices and is considered a barrier. Due to their nature, current mobile devices used for data processing can communicate only up to certain physical distances and this physical range appears to be a major barrier in hospital environments as these environments, can for some very large hospitals, span over a few square kilometers. As the devices move away from their wireless nodes, the communication signal strength becomes weaker and this may introduce unforeseen problems in terms of data management and communication. This is seen as a hardware barrier and healthcare industries are wary of this problem.

Current research in the area of hardware for wireless technology includes the combination of electronic and mechanical components to reduce interference, improved processing power, long battery life, devices going to 'sleep' mode automatically when they are not in use in order to conserve battery life and higher bandwidth [16]. While the comparative analysis of wired and wireless costs has been extensively covered by [16], it is only within the last five years that wireless hardware has become cost effective and hence a cheaper alternative to wired systems. [18] highlights that 'many healthcare providers are extremely adverse to risks associated with adoption of new information technologies' (p.80). In essence, the hardware barriers include the slower information-transfer speeds due to device restrictions, lack of real time connectivity due to device compatibility, small, hard to see display screens due to size restrictions and limited graphic capabilities due to processing power restrictions.

SOFTWARE BARRIERS

A major barrier in terms of software products for the healthcare industry appears to be the incompatibility of off-the-shelf products with specific environments. An area of common

agreement found in the literature is that hospital systems are custom applications that may seldom be applied to other hospitals [19, 20]. Research into this problem includes the design of generic wireless hospital toolsets that can be applied and customised to any hospital [21] and the abstraction of network connection components within the software that will allow for adaptation to either wireless or wired environments [22]. Further, due to lack of technical expertise and costs associated with software training, the healthcare industry is not in a position to attempt new wireless applications. This appears to be a major barrier in the area of wireless software solutions.

In terms of software, research into wireless mobile software is currently scattered in terms of issues ranging from use of web technology [23] to computing language and protocol support [24]. There is also a significant rivalry between proprietary languages for dominance over the wireless market [25]. [26] question the capability of wireless applications in the area of data management. One specific problem raised was the problems encountered due to the mobility offered by wireless. This mobility has created software technical issues of resolving a user based on the location details due to mobility. [26] also question the software issues associated with security and privacy as users move from one service provider to another. The security issues have been highlighted as major barriers in the uptake of mobile devices by many researchers.

PROTOCOLS BARRIERS

The emergence of wireless technology at the user level is attributed to the publicity of the Bluetooth protocol. About 5 years ago, this protocol was publicised by vendors such as IBM and Microsoft. However, since then other protocols such as those by the IEEE have emerged in the market. Current trend appears to be a move towards the use of non-proprietary protocols such as the IEEE 802.11 series [24, 27, 28]. Due to the variety of protocols available, organisations find it difficult to choose a protocol suit that would meet the needs of all the organisations' applications. This has resulted in confusion. This appears to be a barrier.

[29] points out that there is a lack of benchmarking statistics in the area of performance of protocols. While there have been implementations of wireless mobile technology within the health care system, much of the research conducted into wireless implementations have been descriptive in nature and describes the advantages of using the wireless system using single qualitative opinions [30-32]. Therefore, it appears that there is an overall lack of quantitative data collection to prove the claimed wireless advantages. This has resulted in lack of

confidence in using such a technology in a healthcare setting. This is seen as a barrier.

While the hardware devices are useful in the total picture of wireless technology, they need to communicate and a set of agreed upon rules for communication is used to ensure uniformity and device neutrality. These set of rules are called protocols. An area of controversy within the literature and the IT industry is the support for wireless protocols [29] as multiple vendors provide multiple protocols. For instance, to communicate using wireless technology different sets of protocols are available such as Bluetooth and IEEE. On one hand the hardware manufacturers are imbedding support for as many wireless protocols as possible, allowing for integration of new and existing wireless systems in order to maintain healthcare applications developed so far. On the other hand, support for multiple non-standard wireless protocols increases hardware prices and encourages non-compliance with standards. This is seen as a barrier to the uptake of wireless technology in healthcare industries.

COST BARRIER

There are competing views within the literature as to whether wireless systems are worth the cost of development and implementation [33, 34]. Few studies have expressed concerns regarding the viability of wireless technology because of the unjustified benefits. It appears that these feelings stem from the fact that most studies have looked into the cost advantages of new wireless systems with existing systems from a technical point of view and compared the technical cost factors alone. However, studies that have investigated a number of other intangible factors indicate that wireless implementation may provide enormous benefits such as quality of healthcare services to wider community. What appears to be a major barrier is the cost of installation of the new system when a working wired system is already available and the lack of immediate return on the investment.

For the majority of research into wireless implementations, wireless technology is portrayed as the next revolution in hospital care [28, 35, 36]. "Wireless" would seem to indicate that there is no need for wires, but wireless systems need to connect to the main wired infrastructure at some point. This has been indicated in our opening paragraphs. The age of the available physical infrastructure may become a barrier when buildings classified under the 'historical structures' are considered for wireless implementation, as any work on the infrastructure needs permission from relevant authorities. Therefore, cost issues become a concern to organisations because the existing physical infrastructure needs to be maintained as it is or needs

to be upgraded to accommodate various wireless access points.

Return on investment is what businesses are aiming for when investing in a system. This area has also been covered extensively within the literature, and most seem to highlight the reduced occurrence and therefore cost of recovery from medical inaccuracies [36, 37]. Studies have explored the issues of savings from billing errors and any associated legal costs [36, 37]. Cost appears to be a major barrier to the wireless uptake in healthcare.

USER INTERFACE

User interfaces are identified as a crucial link between wireless devices and end users and the issue of user interfaces is emerging in the literature due to the significance associated with the cognitive ability of users in understanding various interaction techniques using these interfaces. While user interface design is an established research area for wired systems, research in the area of interfaces associated with wireless technology is improving in the recent years. Surprisingly, hospital wireless information systems research is not at the forefront of mobile interface design despite the fact there are many wireless healthcare devices already available in the market place such as blood pressure monitors [38, 39]. One reason may be due to the special conditions under which the wireless systems are being utilised in healthcare and the sensitivity of these devices and the information packets passed through these devices. An emerging area of interest is voice recognition for medical command transcription as this may avoid transcription errors and delay in transcribing manual records from source to a computer based records [38]. While traditional computing has evolved in the past three years with various software applications to recognise voice samples, the wireless technology is still struggling due to the hardware limitations of the wireless devices. Further, due to the sensitivity of the patient information, there is some form of reluctance by physicians to adopt this concept. This appears to be a major barrier for the uptake of wireless technology in healthcare. While the voice recognition will mimic data entry operations, a problem that is being investigated is the elimination of background voices and unauthorised command entries so as to arrive at accurate translation of voice commands into data fields. It is hoped that research into speaker recognition will help to eliminate commands from unauthorised personnel and background voices, by authenticating the users voice, and determining the users authority [38]. It is widely accepted that the choice of mobile devices is an important consideration for wireless implementation and this choice is dictated by the ease of use provided by the interface. This appears to be a barrier because

healthcare industry is reluctant to commit on a type of device due to the infant stages of development in this area [36, 40].

COVERAGE

Coverage is not only a technical wireless issue, but also an issue within the hospital setting. By nature, mobile devices may be used to roam around and it is important that connection to the network is retained so that collected data is not lost and information is accessible when and where it is needed. Previous studies provide details of wireless coverage in healthcare settings [36, 41].

Of particular interest to a healthcare setting is the range of the Wireless Local Area Network (WLAN) because of the scale and dispersion of physical buildings [27, 42]. This has lead to research into how range can be maximised through optimising bandwidth and signal strength in a healthcare setting [43]. [44] suggests that wireless range should be limited for security reasons because by having a wider range for wireless devices, the geographical area for network hacking is increased, making these attempts more difficult to monitor and prohibit. It appears that Baylor's theory is purely hypothetical and there is no concrete evidence available to support such a theory. Further, current wireless devices are capable of handling Wireless Encryption Protocols (WEP) and the adverse effect arising out of hacking can be minimised. While studies have compared the wireless range available for various wireless technologies, there appears to be no conclusive agreement as to the security issues associated with the wireless coverage [45]. Issues associated with wireless range appear to a major barrier in the uptake of wireless technology in healthcare settings.

The issues of unexpected problems in connection due to coverage have been studied in prior research [41]. These connection losses are not only inconvenient, but may also risk data access to ensure patient well being by not having important patient data available when it is required for the administration of medication. Prior studies attribute these problems to network range, lead walls and wireless interference [27]. Furthermore, it appears that fundamental problems in coverage may result in denial of service when patient information is most needed. In certain cases, denial of service can result in legal prosecution and healthcare industries are aware of this issue. This has resulted in a barrier adversely influencing the uptake of wireless technology in healthcare settings.

In the past two years, research studies focus particularly on the load-testing of WLAN's [46] and whether implementations are capable of handling the

wireless needs of the hospital environment. Prior studies into interference have covered aspects of technical issues and is of particular concern to hospitals due to the importance of medical data integrity [47] and disruption of sensitive medical equipment, which could put patient's lives at risk. Due to the importance of medical data for health, billing and medical reasons, data integrity needs to be ensured. Interference from walls [45], other RF equipment and coverage holes may diminish or corrupt data integrity leading to losses in patient health data, billing revenue, and legal recovery costs [41]. These are potential barriers to the uptake of wireless technology in healthcare settings.

In terms of radio interference, there exist two dominant competing views within wireless hospital literature; one suggests that interference with medical equipment is non-existent [47], and the other portrays interference as life threatening [36, 48, 49]. According to the first group of literature "Wi-Fi-enabled handhelds or laptops generate about 5 percent of the radiofrequency power that cellular or PCS phones emit". Medical treatment and diagnostic equipment manufacturers have even gone as far as embedding wireless systems into their equipment [47]. However studies have investigated the issues of interference with sensitive equipment and have deployed measures such as frequency modulation to attempt to remove this interference. Interference has been noted ranging from pace maker disruption which, are possibly life threatening to wheel chair malfunctions [50]. These equipment malfunctions have been put down to the lack of medical device immunity to Radiofrequencies (RF) and the increased number of RF emitting devices such as mobile phones and mobile computers. Standards for medical equipment immunity were established in 1993, and these standards must be tightened to allow for increased number and power of RF and their close proximity to sensitive equipment. These conflicting outcomes from prior studies demonstrate that there exists competing views on the issues of interference in the hospital setting, ranging from total acceptance to the banning of wireless technology neither of which seems appropriate [51], resulting in perceived barriers.

SECURITY

Security appears to be a major barrier to the uptake of wireless technology in many areas, including healthcare. The management of security issues in a hospital is an established area, but is challenged through the introduction of wireless technology. Research has been undertaken to specifically lay down foundations for wireless security management [44]. The main concerns for security management within a hospital setting are confidentiality of billing and medical information

[19, 41, 51] and privacy of patient information [19, 41]. Of particular concern to the protection of private and confidential information is the monitoring of network accesses [43] and the tracking of mobile devices [47].

Security threats in wireless environment can range from passively eavesdropping into others' message to actively stealing user's data [52]. In a radio frequency operated mobile commerce, it is possible to listen to one's communication with minimum difficulty. This has an impact on healthcare because of the concern about data and voice messages from unauthorised access. On the other end of the problem is the inherent security risk involved in transferring information over the networks. This problem consists of two components: *identification integrity*, and *message integrity*. The identification integrity refers to the signature elements found in the messages in order to establish where the message is originating. The message integrity refers to details to establish that the message is received as sent and no third party has attempted to open, modify or alter the contents. According to [53], these two items appear to cause a lot of concern to both sender and receiver. While the sender risks theft or misuse of their personnel information such as account and bank details, the receiver (a healthcare provider) risks repudiation of the transaction and resultant non-payment.

In addition to the above two, additional security concerns in wireless technology arise due to the new development in technology itself [53]. The mobile technology is envisaged in such a way that the services offered will eventually warrant payment for the type of services offered. This is already emerging in the domain of mobile telephones. For instance, when mobile telephone users access other network carriers, a special charge is levied on the users. Therefore, it is safe to assume that there will not be any "free services" in the future. The technology is developing in such a way that the payment for such services will be through some form of "smart cards". The details stored in the smart cards need to be transmitted via the networks for validation and verification in order to determine service levels. If these networks are not fully secure, there are possibilities for security breaches to happen.

One major security breach that can happen in wireless networks is when the user details are transformed from one mobile network to another [54]. When this transformation occurs, any encrypted data needs to be decrypted for transparency. In wireless technology, when mobile devices make requests to web pages of a network server, a four-stage process is followed. First, the requests arise from the originating Wireless

Transport Security Layer (WTSL) protocol. Second, the requests are translated at the originating Wireless Application Protocol (WAP) gateway. Third, they are sent to the standard Session Security Layer (SSL) protocol of the destination network. Fourth, the translated information reaches the Hyper Text Transfer Protocol (HTTP) modules in the new network in order for the requests to be processed. In the process of translating one protocol to another, the data is decrypted and then re-encrypted. This process is commonly known as the "WAP Gap". If an attacker is able to have access to the mobile network at this point, then simply capturing the data when it is decrypted can compromise the security of the session.

Data in the Mobile environment is secured using encryption technology. According to [55], it has already been proven that the technology is vulnerable to attacks. Hackers have broken some of the existing algorithms for encryption. So, there is nothing like a complete security. Further, there is no international regulatory framework available to fix certain security related problems. For example, in the current climate, no individual organisation or government can guarantee security to consumers. When the security breach appears in an international transaction, no one country will be able to assume responsibility to prosecute the vandals. While these problems have been recognised and solutions are being proposed, organisations tend to lose consumer confidence. This will potentially impact organisation's revenue.

Trust is central to any commercial transaction and more so in the case of healthcare [56]. Trust is normally generated through relationships between transacting parties, familiarity with procedures, or redress mechanisms. In the case of healthcare, the need for creating the trust in the consumer assumes extreme importance because of its virtual nature. It hinges on assuring consumers and associated businesses that their use of network services is secure and reliable, that their transactions are safe, that they will be able to verify important information about transactions and transacting parties such as origin, receipt and integrity of information, and identification of parties dealt with. Therefore the challenge is not to make mobile Commerce fool proof but to make the system reliable enough so that the value greatly exceeds the risk.

Any new development in technology in today's consumer minds creates both curiosity as well as reluctance. The informality and lack of overall control creates the perception that the Internet is inherently insecure [57]. This inherent perception can trigger business risks and technological risks [10]. Business risks involve products and services, inadequate legal provisions,

reliability of trading partners, behaviour of staff and demise of Internet service provider. Technological risks involve hacker attacks, computer viruses, data interception and misrepresentation all arise. To achieve satisfactory levels of trust, organisations have to think about managing both business and technological risks. Currently healthcare relies mostly on knowledge-based trust that is useful for Business-to-Business commerce [56]. However, there is a big surge in the identification-based trust to satisfy consumer concerns about their transaction details. In addition, current architectures for mobile communications do not provide full security measures in terms of transaction integrity. Some of the models envisaged for mobile communication are based on smart cards oriented approach and hence the issue of transaction security needs greater examination in healthcare.

WORKFORCE ISSUES

The impact of changing work practices due to the advancement of the information technology is a major concern in many organisations, including healthcare organisations. The changing work practices include an increased reliance on computing technology and a move towards a more flexible workforce [58]. While the increased reliance on computing leads to technical errors that may go unnoticed by healthcare operators at the time of capturing patient data, the move towards a more flexible workforce may introduce health related issues. While these two major issues are only concerns at the moment, they may become a major barrier for the uptake of the mobile devices in the healthcare because only a selected few people may be offered training due to cost implications. According to [58], the huge expansion of the use of IT would further result in information overload, causing increases in working time, leading to problems in scheduling the available workforce and work coordination. In the healthcare industry, when these problems are applied to the existing workforce, it would result in a shortage of manpower with the right levels of training. This will adversely impact the healthcare industry resulting in some form of barrier.

CONCLUSION

This paper provided some barriers to the uptake of wireless technology in a healthcare domain. While these barriers appear to be dominating the industry in the current time, a number of solutions are also emerging to address these barriers. In recent months healthcare solutions started appearing using handheld devices and these solutions appear to provide promising signs.

eTransactions in the Australian Supply Chain Setting

Lynn Batten and Ron Savage

School of Information Technology

Deakin University

Melbourne, Australia

lbatten@deakin.edu.au, rons@deakin.edu.au

Abstract

Many sectors of the Australian economy have, in recent years, undertaken an analysis of their supply chain structures. Each sector has determined the underlying technologies to be recommended for use on the basis of past practice in that sector and, in some cases, international practice in the sector. In this article, the authors examine the current role of e-transactions within the context of Australian supply chains.

Our analysis indicates that there is a bifurcation of technical choices along the demarcations of XML and EDI business solutions. For instance, while Mining and Finance have gone the XML route, Wholesale and Retail Trade, along with Transport and Storage have chosen EDI. Moreover, the Health sector appears to be leaning towards keeping both options open to its organizations.

We argue that two factors will need to be considered which will be affected greatly by this parting of the ways on the technology issue. One is the concept of 'design for supply chain' which involves demand generation through joint development of new products and the flow of material across different supply chain entities. The second is the impact of the growth of global trade within international economic blocs.

A natural conclusion is that Australian industry must support a merging of EDI and XML standards.

1. Supply Chains – The Background

Many sectors of the Australian economy have, in recent years, taken on an analysis of their supply chain structures. Although this analysis has taken various forms, a common approach has been for several large organizations, stake-holders in the sector, to band together to fund and support study and development.

Reasons for initiating such projects vary. Faced with cut-backs and down-sizing, some companies have focused on core competencies and attempt to achieve competitive advantage by leveraging their suppliers' capabilities and technologies. Exploitation of these capabilities is expected to result in 'improvements in product quality, quicker integration of technological

breakthroughs, and shorter new product development lead times' [16], thus also providing a competitive edge over competitors.

There is also an expectation of lower transaction costs to the organizations involved as a result of improved trading processes [12]. This is particularly true where businesses at the lower end of the supply chain are not currently trading electronically, but might be encouraged to do so in order to achieve lower costs. However, there are many challenges to integrating businesses' electronic systems through a supply chain, and advice on how to go about it is difficult to come by. A recent study [8] indicates that SMEs greatly underestimate the critical success factors.

Kannan and Tan [9] state that '...no evidence exists on the impact of supplier management on a buying firm's business performance.' In their study, they 'examine relationships between the perceived importance of supplier selection and assessment criteria for items being used in production, and business performance.' Included in the study are several 'hard' criteria such as price and quality, as well as a number of 'soft' criteria such as management compatibility, integrity and buyer-supplier fit. The one supplier assessment factor to correlate positively with all performance measures was also considered to be least important by the group of respondents – all large U.S. firms. This factor was *information sharing*. The authors conclude that 'the results suggest the need for further study of buyer-supplier communication processes. They also suggest a need to develop metrics that allow the effectiveness of buyer-supplier relationships to be assessed.'

In this paper, we consider and compare the approaches to the information sharing mechanisms, integral to the conduct of business within the supply chain, which have been recommended in a number of Australian economic sector projects. The recommendations appear to be essentially one of two choices, resulting in an apparent divergence in solutions adopted by inter-industry sectors.

For this analysis, we have chosen only those sectors in which supply chain management has been undertaken in an attempt to involve the entire sector. Thus, nine out of the seventeen designations of the Australian Bureau of Statistics ANZSIC listing are included here:

- B. Mining
- C. Manufacturing
- E. Construction
- F. Wholesale Trade
- G. Retail Trade
- I. Transport and Storage
- J. Communication Services
- K. Finance and Insurance
- O. Health and Community Services

We discuss the various supply chain management projects undertaken within the last five years or so, particularly in Australia, and provide a description of the information sharing mechanisms chosen. We then consider the implications of these decisions in terms of cross-sector compatibility.

2. The Projects

In this section, we consider supply chain management projects in recent years for nine of the Australian economic sectors and, in particular, focus on eTransaction recommendations arising from those projects.

2.1 Mining

Quadrem was conceived in mid-2000 by 14 of the world's largest mining, minerals and metals companies. Quadrem is a global, internet-based electronic marketplace designed to revolutionize the procurement process in the industry. The marketplace functions are expected to permit participating buyers and suppliers to capture cost reductions and new efficiencies throughout the procurement process. All mining, metals, minerals and mineral processing companies and all suppliers are encouraged to participate. The goals of Quadrem (<http://www.quadrem.com>) as stated on their website are:

- Generate sustainable value for all participants through streamlined transaction and business processes,
- Drive the application of standards in documentation and business processes, and
- Provide many-to-many connectivity for mining buyers and suppliers.

The main areas of focus for Quadrem are on eCatalogues and document exchange.

Quadrem recently signed an agreement with Elemica, the technology infrastructure provider to the chemical industry to create a hub-to-hub connection. Accomplishments and aims of Elemica (<http://www.elemica.com>) are:

- Develop a set of industry-specific transactions.
- Format their transactions using XML.

Quadrem offers a package based on two XML-based standards which, they state, 'provides the infrastructure

that supports the automation of transactions between buyers and sellers and assists with the full integration of these processes into their own systems'. We can say, then, that Quadrem have 2 goals:

- Standardize on XML
- Offer interoperability

These items, taken together, indicate that Quadrem understand the value of adhering to standards, and yet they realize they cannot unilaterally impose a software technology on their customers. Since they are constrained by the investment their potential customers have in packages such as SAP, they aim to provide an interface to such packages.

2.2 Manufacturing

Here, we discuss only two areas, automotive and semiconductor, both of which fall under the 'Manufacturing' heading.

While automotive suppliers vary in their adoption of e-business procedures as a supply chain tool, a recent survey by The Center for Automotive Research [4] indicates that 47% expect it to be a requirement for doing business with the automotive industry within two to three years. Additionally, the survey showed that a majority (81%) of suppliers anticipate a consolidation of the automotive supply chain in the near future, and that, in consequence, customers will reduce their supply chain base all the way along the chain.

The authors of the White Paper on Manufacturing Event Management [2] point out that for automotive suppliers 'the ability to sustain competitive advantage lies in the agility to profitably respond to customers requests'. The White Paper also notes that a move in the industry to 'built-to-order' puts even greater pressure on suppliers to have short lead times, resulting often in high inventory costs.

Tight supply chain structures over many years in the automotive industry have been more conducive to supply chain management strategies than in other sectors, and as a result, a number of off-the-shelf management systems are available. Some of these are PowerB2O, Lean Manufacturing and Supply Chain Execution.

We now turn to the semiconductor section of manufacturing. In many ways, this is similar to the automotive industry because of global coverage and competition alongside a narrow supply chain structure. In 2001, although semiconductor industry capital expenditures fell by more than 35%, companies increased their supply chain management tools budget by 12% [19]. Reasons for the push in this direction include over-inventory and mismanaged inventory situations as well as corporate consolidation. Comparable to 'built-to-order' requirements in the automotive industry are requirements for the handling of 'exceptional' situations for

semiconductor design. Thus software designed for this kind of problem, such as PowerB2O, is popular.

The Semiconductor Research Corporation, which was established in 1982 by the Semiconductor Industry Association, is an international consortium of companies and universities, and as one of its four goals, cites: 'networking among peers up and down the supply chain'. This organization, therefore, ensures that supply chain management issues in the semiconductor industry are acknowledged and addressed.

2.3 Construction

A report of the Australian Construction Industry Forum [15] indicated that 30% of a construction project's total cost is the result of poor information management. Much of the problem is blamed on the failure of hardware and software solutions to meet operational requirements that include mobility of the workforce, diverse working conditions and lack of a fixed infrastructure.

In January 2000, the Construction Industry Advisory Group BSITE (<http://www.bsite.com.au>) was formed. This was an amalgamation of twenty industry leaders from throughout the industry supply chain in both Australia and New Zealand.

BSITE uses technology already prevalent on construction sites, such as mobile phones and fax machines, to perform core functions including job scheduling, time sheeting, activity logging and reporting, contract management, project workflow and document revision.

Thus, rather than being specifically a supply chain management consortium, BSITE focuses on workforce management and project collaboration. They have adopted various global standards for communication between the user and BSITE's software, and have simultaneously used this arrangement to shield the customer completely from the implementation of that software.

Aconex is another Australian business with international customers which targets the same market as BSITE. Their web site (<http://www.aconex.com.au>) says Aconex 'delivers project collaboration software to the global construction and property management industry'. Aconex offer applications which are 'secure, based on 128-bit SSL encryption, and are accessed through standard Internet browsers from anywhere in the world.'

Aconex, then, have taken a different view of the concept of standardization than have BSITE. Rather than target mobile phones, Aconex target customers using standard PCs and provide a single mechanism to access their software.

2.4 Wholesale Trade

The wholesale and retail trade industries must deal with thousands of items, which are bought and sold in numerous locations. The most pressing issue for these industries has been to systematically number products, services, assets and locations, which is precisely what a barcode system is designed to achieve.

The most prevalent bar coding system in Australia is the international EAN system.

EAN has recently joined forces with the Uniform Code Council (UCC) which takes a global leadership role in establishing and promoting multi-industry standards for product identification and related electronic communication with the goal of enhancing supply chain management. The UCC was established in the early 1970's and currently has over 200,000 members worldwide spanning a number of industry sectors including Agriculture, Manufacturing, Utilities, Wholesale and Retail Trade, Communication Services, Property Services, Government, Health and Recreation.

The meat and wool industries form significant components of the wholesale trade industry. Both of these sectors have implemented EAN bar code technology and have developed guidelines for the use of bar codes. For the wool industry, this was completed in 1999 with a committee including both Australian and European wool wholesalers along with CSIRO and EAN [5]. The meat industry's final guidelines were developed jointly between the Australian Meat Industry and EAN and were released in January 2002 [6].

Despite the huge and disparate nature of the wholesale and retail trade industries, much standardization has been achieved by adopting the EAN•UCC numbering and bar coding system (<http://www.ean.com.au>). EAN sees XML as an alternative to UN/EDIFACT in that either one could be adopted as the EDI syntax of choice. Indeed, they understand that it may be necessary for an organization wishing to adopt such a standard to use both in order to achieve interoperability.

2.5 Retail Trade

The grocery segment of the retail industry has implemented an electronic tracking system which is more progressive than those used elsewhere.

The Food Marketing Institute is a U.S. based, but international, professionally staffed organization with close to 2,500 member companies around the world. Although not designed to be a marketplace for the industry, the Food Marketing Institute supports networking between its members and provides relevant, up-to-date information for those working in the sector.

The introduction of ECR (<http://www.ecraustralasia.org.au/index.htm>) in Australia and New Zealand through Efficient Consumer Response Australasia reflects a commitment to take costs out of the grocery supply chain and better satisfy consumer demands through the adoption of world's best practices. Launched in November 1999, ECR Australasia is an informally constituted joint industry body that is supported by the Boards of the Australian Food and Grocery Council (AFGC), Australian Retailers Association, National Association of Retail Grocers of Australia, New Zealand Grocery Marketers' Association, New Zealand Retail Merchants Association and Foodstuffs (NZ) Ltd. The secretariat is located within the AFGC and not as a separate legal entity as in many European countries. Member companies of all supporting organisations are eligible to participate in, provide input to, and access the outputs of ECR Australasia.

ECR Australasia was created with the objectives of:

- delivering benefits to grocery industry trading partners by working together to better meet consumer needs and add consumer value through the establishment of standard industry practices and the development of successful business approaches;
- educating industry participants about the benefits of ECR, through pilots, case studies, seminars and reports; and
- liaising with other industries and organisations, both in Australia and overseas, to ensure common solutions to common problems.

The Uniform Code Council (UCC) is planning some technical innovations specifically for the Retail industry. These include an extension to barcodes called Reduced Space Symbolologies (RSS), expressly for perishables such as produce and meat.

UCC is also promoting Radio Frequency Identification (RFID) tags as a new technology for product labelling. However, RFID is also being promoted as leading to another, albeit unusual, type of interoperability – the fusion of 'physical product flows with the corresponding information flows' (http://www.fmi.org/technology/FMI_it_rfid.pdf). What is new here is the application of RF tag technology to retail products.

Another organization advocating standards for the retail industry is Voluntary Interindustry Commerce Standards (VICS) (<http://www.vics.org>). Their focus is the VICS Standard Bill of Lading (BOL) and 2003 is the target year for the mandatory adoption of the 17-digit VICS BOL number. An interesting point is that they say bar code printing of this BOL number is optional but, if printed, must be done using EAN•UCC-128 symbology.

We note that EAN•UCC appears under various industry sectors in this paper, and so is clearly a standard which can claim to be 'cross-sector'. This can also be

interpreted as meaning that retail trade is not trying to develop standards in isolation to other components of a complex, technology-based society.

2.6 Transport and Storage

In a presentation to the Working Party for the Information Economy Group of the OECD, Malone [11] states that 'The transport industry provides the logistical operations for Australian business through the movement of goods in the supply chain and to market. These key horizontal linkages mean that transport makes a significant contribution to the Gross Domestic Product...Transport activities underpin the effectiveness of hundreds of thousands of small businesses in Australia

- it is a sector that cannot be disintermediated in the supply chain for goods;
- it accounts for a high proportion of transaction costs; and
- its adoption of e-commerce is likely to drive e-commerce uptake in the many sectors it services...with consequent benefits for those services.'

The Australian government has therefore undertaken, in partnership with industry, to facilitate and support e-commerce uptake specifically in the transport and logistics sector. The government-sponsored 'Trucks Online' project was completed in 1998 and proposed an EDI solution.

Tradegate-ECA is a not-for-profit, non-government, Australian user organisation, headquartered in Sydney, Australia. Its role is to facilitate the use of electronic commerce techniques for the exchange of information between customers and their suppliers, with a focus on exporting and importing. It does this by bringing together many different types of organisations involved in several supply chains so that a common agreed strategy can be developed and implemented using the relevant international standards. Thus, in many ways, it is a cross sector approach to trading.

The Tradegate 'community' has 850 members across Australia, including air and shipping lines, freight forwarders, railway operators, customs brokers, trucking companies, importers and exporters, banks and insurance companies.

Tradegate's Domestic Transport Project, DOMEDI, has implemented the following:

- Adopt the global EAN•UCC numbering and bar coding system
- Standardize message types rather than (product-specific) messages
- Standardize at federal government level
- Encourage industry-wide adoption, i.e. interoperability between companies

- Incorporate overseas work, i.e. encourage interoperability between countries.

These days, transport is more often referred to as Logistics Chain Management since it is viewed as being an integral part of Supply Chain Management.

An Australian company specializing in software for this field is Logistics Systems International (<http://www.lsi.net.au>) which targets interoperability between the sending, transport and receiving systems using standard barcode technology for tracking purposes.

2.7 Communication Services

Despite the fact that the telecommunications industry is the provider of the means of electronic invoicing to all other industries, it itself is so highly competitive that it has not reached the point at which a group of major players in the industry has seen the imperative to form a consortium.

A large number of organizations (Deloitte Touche and Tohmatsu, Canopy International) provide professional services such as supply chain assessment, strategic and financial consulting specifically targeting the telecommunications industry.

In Australia, SETEL – Small Enterprise Telecommunications Centre Limited – has sought to replicate the Business Council of Australia e-Commerce Roundtable in pulling SMEs in the industry into a forum to ensure that:

- Carriers and providers give out accurate and timely information about products and services, and that
- Small businesses take steps to inform themselves about products and services as part of responsible business decision making.

SETEL was established in 1992 to service the research, policy and information needs of the small business members of the Telstra Small Enterprise Policy Panel, plus the wider small business community, and to provide research material from the Small Business sector perspective. SETEL [17] has an important document available for people who want a gentle introduction to reasons for the adoption of eCommerce, and which discusses the influence this adoption will have on a business's supply chain.

2.8 Finance and Insurance

In the banking industry, the SWIFT consortium has been around since 1977. SWIFT (<http://www.swift.com>) is an industry-owned, international cooperative (under Belgian law) supplying secure messaging services and interface software to 7,000 financial institutions in 200 countries, and it employs about 1,500 people. SWIFT provides messaging services to banks, broker/dealers and investment managers, as well as to market infrastructures

in payments, treasury, securities and trade. These services are designed to help customers reduce costs, improve automation and manage risk. The guiding principles of SWIFT are: to offer the financial services industry a common platform of advanced technology and access to shared solutions through which each member can build its competitive edge. The solutions developed are based on XML.

In order to join SWIFT a minimum level of infrastructure must be in place, and so small business is to a large extent excluded from membership. In early 2002, SWIFT migrated from X.25 connectivity to IP connectivity and has established SWIFTNet and SWIFTNet FIN to assist with the move.

Considering that 'SWIFT is the industry-owned cooperative supplying secure messaging services and interface software to 7,000 financial institutions in 198 countries', this indicates that:

- the financial sector is capable of being intensely focused
- intercontinental interoperability can be achieved
- in this, admittedly unique, sector, convergence on a single standard is possible.

SWIFT standards are based on, but not limited to, ISO 15022, XML and XML schemas.

In the Australian health insurance area, SuperEC (<http://www.superec.org>) got off the ground in 2000. It has three levels of membership with over two dozen members. The governing council is comprised of four key bodies: the Association of Superannuation Funds of Australia Limited, the Australian Taxation Office, the Investment and Financial Services Association, and the Association of Payroll Specialists. An early policy decision for SuperEC was to ensure that the standards would be written in a manner that is neutral to the technical transport mechanism. Another decision was to choose technologies that would allow participation at a low cost. Technically, the standards are a set of XML message packets that may be sent as attached, encrypted email. This set of technologies is available on all platforms and at a relatively low cost of implementation. SuperEC has also developed messaging standards for the industry. SuperEC itself is based on ebXML [3].

A recent move in this sector has been to a business reporting standard with the introduction of XBRL (See <http://docs.hr-xml.org/20010419/XBRL-ExecSummaryGeneral%20Ledger.pdf> for a summary provided by XBRL.org). This is an open specification standard for software, developed by almost 200 companies, professional organizations and governments world-wide, which is designed to capture, analyze and reuse business information. It is based on XML and is compatible with ebXML.

2.9 Health

An innovative e-commerce project begun in the late nineties in Australia was PeCC, originally 'Pharmaceutical Electronic Commerce and Communication', but later changed to 'Project for Electronic Commerce and Communication'. Quoting from [18], 'PeCC's vision was to link the pharmaceutical supply chain end-to-end, starting with manufacturers and ending with the consumption point – the hospital patient...The vision included a common numbering system and integrated information systems throughout health so that products could be ordered, coded, tracked, delivered, stored, dispensed with barcode-swiping all the way. EDI was successfully implemented for orders and confirmations for manufacturers and distributors, with supply chain reform pilots in some hospitals.' But because of confusion over EDI protocol standards, 'there is a general movement towards a common standard called X12. This, in turn, is part of an international movement towards UN/EDIFACT' [13].

Since UN/EDIFACT is becoming so widespread, it is clear that this drive for interoperability within the health sector should automatically lead to interoperability with players in other industry sectors.

The National Supply Chain Reform Task Force (NSCRTF) was established in 2000 to identify key areas for joint work between governments, the hospital sector and product suppliers to facilitate the adoption of an e-enabled supply chain in hospitals. Their report, (NSCRTF 2003) indicated that there were many weaknesses in the sector. In January 2002, the Australian Health Ministers' Advisory Committee endorsed the NSCRTF national plan covering five key areas. The list of tools identified as needing consideration for use in the industry are: EDI, XML, EAN barcoding, e-marketplaces and e-catalogues, web services, e-mail and fax.

It is unfortunate that, in 1983, the health industry in North America established a barcoding system through its Health Industry Business Communications Council (HIBCC; <http://www.hibcc.org/barcode.htm>) which is formatted differently from the EAN codes. The global health industry tends to have adopted the North American style coding.

A number of related health industry projects have sprung up in Australia over the last few years. One such is the ICTeHealth Project, which includes the PeCC and NSCRTF perspectives, and focuses on determining the data interoperability problems in New South Wales hospitals. This project began in 2002 and is concerned with investigating the flow of information in four key areas of clinical process within a hospital setting – pathology, pharmacy, purchasing and radiology.

At the international level, two projects stand out:

Global Health Exchange (<http://www.ghx.com>) was founded in 2000 by five leading health care suppliers: J&J, GE Medical, Baxter, Abbot Labs and Medtronic. It provides supply chain solutions to bring together hospitals, manufacturers and wholesalers. They have developed a range of product components which connect in various ways to GHX's own AllSource system. For instance, hospital staff can use a web browser to connect to AllSource, or GHX and their partners can provide customized code which links a hospital's existing ERP system to AllSource. AllSource corresponds exactly to HIBCC's Universal Product Number Repository, which means a single converter between the two would serve all users of both systems.

HL7 promotes a set of American National Standards Institute (ANSI)-approved standards, covering clinical documents and the sharing of medical knowledge, as well as administrative documents covering intellectual property, ethics, and so on. The clinical-type documents are XML-based, so as to be both human- and machine-readable, and to be deliverable to devices such as web browsers and mobile phones.

Their Reference Information Model (RIM) is actually expressed in the Unified Modeling Language (UML). RIM is not a product-based approach, but a clinical-activity-based approach, and hence differs significantly from previously mentioned systems.

3. The Cross-Sector Issues

We have seen above that Australian industry sectors have generally taken one of two paths when instituting technical solutions to their cross sector business: a choice between XML and EDI.

The question remains: for those companies who must work cross-sector, and for those who do business on the global scene, how large is the barrier imposed by the use of two separate and very different schemas?

Handfield and Nichols [7] point out that 'Supply chain members will increasingly need to improve coordination not only in the area of demand replenishment, but also in the area of demand generation through joint development of new products. ...An equally important benefit of this collaboration is the increased standardization and simplification of product designs that can lead to a "design for supply chain" approach.... Design for supply chain extends the concept of "design for manufacturability", which refers to the process of simplifying product designs to allow easier manufacture and assembly, to the broader scope of the entire flow of material across different supply chain entities.'

Thus, these authors imply that in order for supply chain management effectiveness to move to 'the next level', the technical ability to work seamlessly across sectors must be in place.

On another level, they note that global trade “is increasingly taking place within blocs, such as the European union, the North American Free Trade Area, and other regional groups. ...the bulk of international trade takes place in materials and intermediate components. Global corporations will ship semi-manufactured products between their own facilities or from suppliers to assembly plants and distribution centers. The trend toward global supply chains has been fueled by needs for centralized research and development, the development of homogeneous markets and global products and global market segments for many products, the need for economies of scale in specific industries, wage differentials between advanced countries and other less developed countries, and political efforts to maintain low tariff barriers.”

They raise a number of important questions about global supply chains and their management, arguing that the crossing of international boundaries must necessarily impact business strategies. One of the specific questions not posed is the issue of technology, and whether it will be *possible* to integrate different business technologies across global supply chains.

It is clear to the present authors that the technology may well be one of the most significant barriers to the development of any economy past national boundaries. The problem of interoperability has already been recognized by several major players. Microsoft, as part of a ‘module map’ for reshaping business software [1], has plans to develop software for small to medium-sized businesses which is ‘fully interoperable and interconnectable’. One of the biggest problems faced by companies who have invested large amounts in expensive software is to get it all to work together. While this sounds as if Microsoft has solved the XML versus EDI problem, this is not the case. Microsoft is using XML to enable web services via their .NET system. Sun and IBM have taken up similar strategies, Sun One and WebSphere, both based on XML.

The UCC was, from its inception, a proponent of EDI and in 1996, at the urging of a number of commercial and industrial sectors, conducted a study to determine the feasibility of merging several different existing implementation guidelines into one. The positive feedback from this feasibility study resulted in the development of an Industrial/Commercial purchase order based on the United States EDI ASC X12 national standard, and in November 1997, the UCC became the management and administrative body for I/C EDI.

The priorities of early EDI standardization were in the areas of customs, commerce and transport. Europe and the United States developed EDI solutions independently. The European version, EDIFACT, included accounting functionality while ASC X12 did not. In contrast, the aims of XML were to be non-proprietary and self-

describing, and flexibility rather than standardization was a main goal.

With the strong push in the business world to the use of XML, the link between EDI and UCC is founded on a set of Business Messaging Standards based on XML, and this is consistent with the move to interoperability of EDI and XML via xCBL and XRBL. The EDI standards committee X12 along with UN/EDIFACT are now working on Next Generation EDI based on XML, which appears to focus only on internal financial and managerial reporting.

4. Conclusions and Recommendations

In choosing technical standards to support supply chain management, a number of Australian industry sectors have chosen to go with XML based standards while others have gone with EDI. While recent developments have seen a significant improvement in interoperability between these two standards, the cost of the interface remains high.

In order for Australian commerce to remain competitive in a global environment, where increased standardization and simplification of product design are expected, the technical ability to work seamlessly across sectors and national boundaries is an imperative.

In addition, the move to trading within and between geographic and political ‘blocs’, resulting in global supply chains, must inevitably lead to an integration of business technologies across large sectors.

To enable Australian business to stay abreast of these global moves, the authors therefore propose the development of a universally and freely available translation scheme between the most recent XML and EDI syntax versions organized by the Uniform Code Council in conjunction with those sectors which would benefit immediately: Wholesale and Retail Trade, Transport and Storage, and Health. Such a translation scheme would be an inexpensive solution to the interoperability problem and, based on experience of the authors [10] could be achieved within two to three years.

Abstract

This paper first compares the definitions for business model in e-commerce given by scholars from all over the world, and then discusses types of business models in the application of e-commerce for China's import and export companies, and points out that three unique types of business models are adopted now in the practice of e-commerce for China's import and export companies. Also, this paper analyses the current state and business models of the largest import and export companies in Jiangsu Province, China as example case, and forwards some suggestions on how to improve the performance of e-commerce of those companies by selecting a suitable business model.

1. Definitions of Business Model in Electronic Commerce

1. 1 Definitions

Different scholars and researchers define *Business Model* in different ways. The most common definitions are as follows:

Rappa (2002) thinks that a business model is the method of doing business by which a company can sustain itself -- that is, generate revenue. The business model spells-out how a company makes money by specifying where it is positioned in the value chain. Rappa also thinks that Internet commerce will give rise to new kinds of business models, for example, the Web

has popularized the auction model and broadened its applicability to a wide array of goods and services [3].

Timmers (1998) gave the definitions of business model as follows:

- z An architecture for the product, service and information flows, including a description of various business actors and their roles; and
- z A description of the potential benefits for the various business actors; and
- z A description of the sources of revenues.

Also, Timmers (1998) listed 11 business models currently in use or being implemented, and they are: (1) E-shop; (2) E-procurement; (3) E-auction; (4) E-mail; (5) Third-party marketplace; (6) Virtual communities; (7) Value-chain service provider; (8) Value-chain integrators; (9) Collaboration platforms; (10) Information brokerage, trust ; (11) other services[4].

Weijun Zhong (2003) defines business model from the perspective of value creation pattern, and his definition can be seen clearly from table 1.

Table 1 Business model defined from the perspective of value creation pattern

Bus iness Model	Buil der of the Web	Users of the Web	Value Creation Patterns
-----------------------	---------------------------	------------------------	-------------------------------

Inc ome-dr iven	Pure e-comm erce dealers	Visitor s of the Web	Acquirin g income directly
Cos t-drive n	Trad itional business dealers	Traditi onal business dealers	Lowerin g cost
Ser vice-dr iven	Thir d-party (brokers)	Traditi onal business dealers or those who need services in traditional business	Acquirin g fees for providing services
Sca les-driv en	Busi nesses seeking growth	Busine sses seeking growth	Enhanci ng the power of the businesses and Expanding market share
Str ategy-d riven	Busi nesses with great insights	Busine sses with great insights	Enhanci ng Competitive advantages

1.2 Comments on the Above Definitions

Although business models are perhaps the most discussed topic, however, they are the least understood aspect of the internet. So we still have no definition for it that can be accepted by everyone. It depends on a lot of factors including what goods or services a company deals with and which line the company is in. Especially when we discuss a specific line or industry, we can find that a certain industry might develop its own way of doing business and thus develops its unique business model, and the import and export companies in China are no exception [1].

2. Types of Business Model in the Application of E-Commerce for China's Import & Export Companies

2.1 The Importance of E-commerce for Import and Export Companies in China

With the reformation in the area of import and export business in China, more and more production companies got the license of dealing with import and export operations by themselves which made the professional import and export companies face even tougher competitive environment. Gone are the days when state-owned professional import and export companies dominate and enjoy the benefits of monopoly. One way of reducing such competition is to improve their efficiency by using internet and implementing e-commerce [2].

Internet can affect the professional import and export companies in the following three ways:

- z Reducing the barriers to import and export business, or in other words lessen the importance of the roles that those professional import and export companies play.
- z Changing the way of doing business for those import and export companies in China, especially when EDI (Electronic Digital Interchange) has become more and more popular in China. Those companies who can integrate resources from both suppliers and buyers may have more opportunities of doing well in the future.
- z Urging the reformations of the trade-related government departments. As we know, e-commerce can not be realized without the basic infrastructure including laws, tax policies, telecommunication constructions and etc. So government departs including customs, taxation bureaus and Ministry of Commerce have done a lot to facilitate the implementation of

e-commerce for import and export companies.

2.2 The Three Main Types of Business Models in the Practice of E-commerce for China's Import and Export Companies

The Chinese import and export companies created their own models in the process of exploiting e-commerce chances. We should not rigidly copy the above-mentioned business models for import and export companies since those business models might be only effective for certain companies in certain industries. The author summarizes three main types of business models as follows:

E-government mode. Like TradeNet in Singapore, the Ministry of Commerce of China has made great efforts in establishing a system which can integrate the whole process of doing business by using internet. One of the achievements of the Ministry of Commerce of China is that it created an identical series of standards that can be used among government departments, import and export companies, banks, transportation companies and so on. Another achievement is that the Ministry of Commerce of China also established the Online Trade Fairs on its own website (www.ec.com.cn/) which enable hundreds of thousands of dealers from both at home and abroad "meet" on internet and thus create potential opportunities for them[5].

Self-established websites. Most of the Chinese import and export companies built their own websites. But up to now those websites can only be used as Yellow Pages, which can only release company information, and most of the websites do not update frequently. This has limited the use of the websites, and those websites can not really be used to fulfill transactions. Another shortcoming of the so-called self-established websites is that it's quite expensive to build and maintain them, and the import and export companies lack professional technicians in computers who can

guarantee the everyday operation of the websites[6].

Third-party marketplace. Due to the expensive maintenance fees and the fact that most of the self-established websites are not well-known by their target audience, most of the companies are members of at least one third-party website. Among the third-party websites the most famous one is Alibaba.com. We can see the popularity of this website by some statistics (see table 2).

Table 2 Some statistics about www.alibaba.com

Item	Statistics	
	Chinese Website www.China. Alibaba.com	International Website www.ali baba.com
number of members	1.5 Million	0.6 Million
new members per day	3000	1000
web pages visited per day	5 Million	1 Million
web pages visited per month	150 Million	3.5 Million
pieces of information for demand and supply per day	11, 000	4, 000

data base for business information	0.9 Million	0.6 Million
enquiries every month	2 Million	1 Million

Source: <http://www.zjol.com.cn>, June 19, 2003

2.3 Some Characteristics of the Business Models of the Import and Export Companies in China

z government departments play a very important role in pushing the development of e-commerce in foreign trade area in China.

z most of the import and export companies use more than one mode of business model in their e-commerce practice.

z Due to the complexity of foreign trade process, the mode of business model for import and export companies should consider more factors and involve more participants including government, banks, telecommunication companies, transportation companies and etc.

3. Case Study—Current State and Business Models of the Largest Import & Export Companies in Jiangsu Province, China

Jiangsu province is a developed province located in east China, and according to the most recent statistics from January through July 2003, the amount of export of Jiangsu province reaches \$29.62 billion, which is 13% of the total export of the whole country. In the meantime, the import and export companies strive to start and implement their e-commerce in doing business with foreign companies. We can have a glance at the current state of those companies in Jiangsu Province, also we can judge the business models

that they adopt from a recent survey made by the author of this paper among the largest import and export companies concerning their e-commerce.

3.1 The Largest Import and Export Companies in China Are Still at the Early Stage of E-commerce.

According to the above-mentioned survey, the largest import and export companies in Jiangsu Province are still at the very early stage of e-commerce. For example, only 10% of the companies established websites where their

Figure 1 How much information the websites can provide

customers can get information of the whole products, another 10% of the websites provide most of the products' information, but 70% of the websites can only provide their customers with very little information about their products, and 10% of the websites provide no information about their products (see Figure 1).

3.2 The Challenges That the Import and Export Companies in China Are Facing.

According to the survey, the largest import and export companies meet with the following difficulties or problems (see table 3). From Table 3 we can see that the 3 biggest problems for those companies in doing e-commerce are lack of credit (55%), lack of cooperation from their

upstream and downstream business partners (45%) and lack of safety or online settlement means (40%).

Table 3 Problems that import and export companies are facing in doing e-commerce

Type of problem	Percentage of the companies that have the problem (%)
No enough technicians to maintain websites	25
Weak information system	35
Lack of laws	35
Lack of Credit	55
Lack of safety	40
Lack of popularity	25
Logistic problem	10
The upstream and downstream partners' cooperation	45
Online settlement problem	40

3.3 Some Tips on How the Import and Export Companies in China Improve Their Performance in the Process of Implementing E-commerce.

(1) The government at all levels should make laws to guarantee the implementation of e-commerce.

(2) The import and export companies should know that e-commerce is a trend in the future and an efficient way of enhancing their competitiveness in doing business.

(3) E-commerce is a gradual process in which every participant can only progress little by little, and the performance of e-commerce can only be seen in a relatively long time.

(4) The companies should attach great

importance in online marketing skills which are quite different from the offline ones.

4. Conclusions

(1) Business model is a different conception for different industries dealing with different products or services, therefore we have different definitions for it from scholars and researchers all over the world.

(2) Business models of e-commerce for China's import and export companies are unique because of the unique circumstances of China in its laws, credit conditions, information system, logistic system and other basic infrastructure.

(3) Although e-commerce for China's import and export companies is still in its inception period, progress has been made and the difficulties will be overcome since more and more parties now get involved to try to create a suitable and efficient business model to improve the performance of e-commerce for those import and export companies in China.

Abstract

This paper formulates and analyzes a model to integrate inventory management and promotion decisions in a multi-product environment. The model assumes that actual demands for the items depend on both item availability and the level of promotion used for the item. A notable feature of the model is that customer demand is partially backordered, where the fraction of demand backordered depends on how long a customer has to wait for delivery. The firm is assumed to have a limited promotion budget. The effect of a promotion is modeled through an increase in the demand rate of the item being promoted. We formulate a general, non-stationary, finite horizon version of the problem. However this problem is very difficult to solve optimally. In order to develop insights into the nature of the solution we formulate a stationary version of the general problem with the additional restriction that only one item can be promoted at a time. An efficient solution approach is developed for this stationary version, and limited numerical results are provided. These numerical results indicate that a coordinated approach to promotions and logistics decisions can lead to significantly higher profit for the firm.

1. Introduction

The emergence of internet based communication channels has enabled new levels of coordination in global manufacturing and logistics. Initiatives such as Collaborative Planning and Forecasting, electronic marketplaces, B2B and retailing over the web allow companies to develop new methods for designing and managing logistics systems. From the operations researcher's perspective, the challenge is in developing models that incorporate the additional data that is available in these environments and in using the data to implement more efficient and effective logistics policies. Since so much more data on customer behavior can be collected, we expect that these models will encompass more and more sophisticated modeling of customer behavior. This will allow a closer integration of marketing decisions with basic logistics decisions such as inventory management.

The goal of this paper is to develop a model to illustrate how marketing and operations decision-making can be integrated. The model we develop assumes that demand for items depends on both item availability and the level of promotion used for the item. We also assume that there is a limit on the amount of promotional activities

that the firm can engage in (this may reflect a limited promotion budget, a limit on the ability of consumers to absorb the promotional message, or a limit on the capacity – space on a web site – of the delivery vehicle for the promotional message). By choosing the promotions carefully and integrating the promotion schedule with inventory management the firm should be able to increase profits compared to a situation where inventory management and promotions are independently managed.

An important aspect of Internet retailing operations is the planning and coordination of advertising and promotions. Critical pages on a web site display featured items and certainly have an effect on the sales for these items. This behavior is similar to point-of-purchase displays in physical retailing, but is much more powerful since it can encompass any items that the retailer sells, not just those that satisfy certain size and selling price constraints.

Building upon the ability of e-commerce to capture more details of a customer's shopping behavior we present a scheme to coordinate customers purchase behavior with promotions and inventory stocking decisions. Our model shows how to coordinate the scarce resource of featured item advertising with inventory decisions in order to maximize the revenue from the assortment of items the retailer sells and to minimize the inventory costs.

Our model can be viewed as a generalization of the classical Economic Order Quantity model [10], and the related literature is vast, see e.g. [9] [23].

There is a small but growing literature that considers the impact of customer behavior on operations decisions. One strand of this body of work focuses on substitution behavior (see [1] [2] [7] [15] [21]).

Another strand focuses on promotion decisions. Cheng and Sethi [5] consider a periodic review model coupled with promotion decisions. Huchzermeier et al. [11] study the effect of consumer decisions when faced with promotions on the supply chain. Iyer and Jianming [12] show that information sharing is important in the context of retail promotions. In contrast to these papers we consider a continuous review model, explicitly consider stockouts as a cost reducing tactics, and consider multiple items in the context of limited promotions, as is the case for featuring items on web pages.

In our model we assume that actual demand depends on whether the item is in stock or not (in which case the demand rate further depends on the amount of time that will elapse until backorders can be filled). Some models where only a fraction of the demand is backordered when

a stockout occurs are examined in [16] [17] [20] [22].

Backorders have been the subject of extensive research in the context of stochastic models. An order point order quantity model with a mixture of backorders and lost sales is investigated in [19]. Lost sales will occur when backorders exceed a certain threshold level. General backorder costs in stochastic inventory models are discussed in [4], and in [3] backorder costs have fixed and proportional components.

Another approach to modeling the effect of stock-outs can be found in [18], where it is assumed that the demand rate is influenced by backorders. The approach of modeling backorders as dependent on the time until they can be filled was used by us in a somewhat different context in [8].

There is also extensive research on perishable inventories, when the stock at hand may decay, or become obsolete. One representative paper [14] integrates the stocking decision with backordering. While we do not have perishable inventories, we have “perishable” backorders, in the sense that backorders grow less than proportionately with the elapsed stockout time.

Finally, [13] uses an exponential pent-up demand function in the context of stochastic lead times. The focus is on algorithms to obtain the optimal stockout period without deriving any structural results. In this paper we model customer response to backorders through a general function, which allows various reaction curves to be fitted using available customer data. For details see [8].

The paper is structured as follows. In the next section we develop a general model for integrated promotion and inventory management over a finite time horizon. This model will be seen to be too complicated to solve optimally, hence we develop a simpler average cost version of the model in section 3. In section 4 we show how the single item average cost version of the model can be solved optimally, and in section 5 we will extend the analysis to the multiple item problem. Section 6 will discuss several numerical examples while in section 7 we give conclusions and ideas for further work in this area.

2. The Finite Horizon Model

We introduce the following notation.

N = the number of items in the assortment, indexed by i ,

T = length of the planning horizon,

D_i^H = demand rate for product i when it is being promoted,

D_i^L = demand rate for product i when it is not being promoted,

p_i = net margin (excluding inventory holding cost, fixed costs and promotions costs) per unit sold for item i ,

h_i = inventory holding cost (per unit per time period) for item i ,

F_i = fixed ordering cost for item i ,

$k_i(u)$ = fraction of demand that can be backordered

when item i is out of stock if the backorder will be filled in u time units, assumed to be non-increasing in u ,

c_i = cost per time unit of running the promotion for item i ,

w_i = promotional “weight” for item i , measures how much promotional capacity is consumed by fixed ordering cost for item i when it is being promoted,

W = total promotional capacity available (cannot be exceeded at any point in time),

$X_i(t) = 1$ if item i is being promoted at time t , 0 otherwise,

K_i = total number of replenishment orders placed during the planning horizon for item i ,

Q_i^k = order quantity for item i at the time that the k -th order is placed for item i ,

T_i^k = time that the k -th order is placed for item i ,

$S_i(t)$ = physical inventory for item i at time t ,

$\Theta_i(t)$ = amount of time (measured from time t) until the next delivery is received for item i ,

$\hat{D}_i(t)$ = effective demand rate at time t for item i .

We assume that the demand for each item is deterministic. While there is physical inventory for item i , the demand rate is D_i^H while the item is being promoted, and D_i^L while it is not being promoted. If there is no physical inventory for item i , and it is u time units before the next delivery, the effective demand rate is $D_i^H k_i(u)$ while the item is being promoted and $D_i^L k_i(u)$ while it is not being promoted. Hence promotion affects the base demand rate, while physical inventory and the time until the next delivery affect the fraction of the base demand rate that is converted into sales. With these assumptions, the sales rate for item i at time t is equal to

$$\hat{D}_i(t) = (D_i^L + (D_i^H - D_i^L)X_i(t)) \times (I_{\{S_i(t) > 0\}} + k_i(\Theta_i(t))I_{\{S_i(t) \leq 0\}}). \quad (1)$$

The company will thus try to maximize

$$\sum_{i=1}^N \left[\int_0^T p_i \hat{D}_i(t) - c_i X_i(t) - h_i S_i(t) dt - K_i F_i \right] \quad (2)$$

subject to the following constraints.

Don't exceed the promotional capacity:

$$\sum_{i=1}^N w_i X_i(t) \leq W, \quad 0 \leq t \leq T. \quad (3)$$

Definition of sales:

$$\hat{D}_i(t) = (D_i^L + (D_i^H - D_i^L)X_i(t)) \times (I_{\{S_i(t) > 0\}} + k_i(\Theta_i(t))I_{\{S_i(t) \leq 0\}}), \quad (4)$$

$$0 \leq t \leq T, i = 1, \dots, N.$$

Physical inventory balance constraints:

$$S_i(u) = \left[S_i(0) + \sum_{k: T_i^k \leq u} Q_i^k - \int_0^u \hat{D}_i(t) dt \right], \quad (5)$$

$$i = 1, \dots, N; 0 < u \leq T$$

Order must clear the backlog:

$$\sum_{i=1}^k Q_i^s \geq \int_{t=0}^{T_i^k} \hat{D}_i(t) dt, \quad k=1, \dots, K_i; i=1, \dots, N. \quad (6)$$

Order sequencing:

$$T_i^k < T_i^{k+1}, \quad k=1, \dots, K_i-1; i=1, \dots, N. \quad (7)$$

Definition of θ_i :

$$\theta_i(t) = T_i^k - t, \quad T_i^{k-1} < t \leq T_i^k; k=1, \dots, K_i; i=1, \dots, N. \quad (8)$$

$X_i(t)$ is binary:

$$X_i(t) \in \{0,1\}, \quad 0 \leq t \leq T_i^k, i=1, \dots, N. \quad (9)$$

Clearly this problem is NP-Complete and would be extremely difficult to solve in the general case. Instead of attempting this (or developing heuristics for it) we instead formulate a simplified version in the next section.

3. A Simplified Model

In this section we will simplify the general problem formulated in the previous section in several ways. First, we will assume that only one item can be promoted at a time. This corresponds to assuming that $w_i = 1$ for all items and that $W = 1$. The second simplification is achieved by formulating an average profit version of the model, by assuming that all items are on the same replenishment cycle, and by requiring that an item can be promoted only once per cycle. Hence in this problem we have the following decision variables (in addition to the notation introduced earlier):

T = the common cycle length for all items,

φ_i = the amount of time that item i is promoted during the cycle, and

Q_i = the order quantity for item i .

Finally, we define

$\Pi_i(\varphi_i, T)$ = maximum profit that can be achieved for item i in a cycle of length T when a single promotion of length φ_i is used and a single replenishment order is placed for item i .

We assume that a stationary policy is followed (clearly this is optimal in the simplified model), and since every item can be promoted only once per cycle, a feasible promotion schedule exists as long as total promotion time during a cycle does not exceed the length of the cycle. Hence the problem we want to solve can be formulated thus:

$$\Pi^* = \left\{ \begin{array}{l} \max \quad \frac{1}{T} \sum_{i=1}^N \Pi_i(\varphi_i, T) \\ \text{s.t.} \quad \sum_{i=1}^N \varphi_i \leq T \\ \varphi_i \geq 0, \quad i=1, \dots, N \end{array} \right\}. \quad (10)$$

In the next section we will show how $\Pi_i(\varphi_i, T)$ can be found efficiently for a given φ_i and T .

4. Solving the Single Item Sub-problem

In this section we will formulate the single item sub-problem, derive properties of the objective function, and give an efficient algorithm to solve it. Since we will

only consider one item here, we simplify the notation somewhat by dropping the subscript i in this section.

We will define a cycle to run from the moment the item runs out of stock (at time 0) until the item runs out of stock again (time T). Let x = the time at which the replenishment order arrives. During the cycle we can distinguish two distinct periods: when $0 \leq t < x$, backlog accumulates at a rate of $k(x-t)$ times the demand rate (which depends on whether a promotion is in effect). When $x \leq t < T$, sales occur directly from stock. (Note that in an extreme case it is possible that $x = 0$, i.e., the item is never stocked, the company takes orders and fills those orders when a replenishment order arrives.) The first issue to decide is when the promotion (which is assumed to have a length $\varphi < T$) should be scheduled.

Proposition 1. Let x (= the time during a cycle that the inventory runs out) be given. Let y = the start time of the promotion that maximizes the per cycle profit. Then

$$y \leq x \leq y + \varphi \leq T \quad (11)$$

Proof. It is tedious but not difficult to show that all the other cases are dominated by one that satisfies equation (11).

Next, define $z = x - y$. Then (11) is equivalent to

$$\max(0, \varphi + x - T) \leq z \leq \varphi \quad (12)$$

For given stockout time x and promotion start time y satisfying (11), the total units sold per cycle is given by

$$Q(x, z) = [T - K(x)] D - \int_0^{\varphi} K(x-t) D - z D \quad (13)$$

where

$$K(x) = x - \int_0^x k(t) dt \quad (14)$$

and total inventory (in units of product \times time units) is

$$H(x, z) = \frac{1}{2} (T - x)^2 D + \frac{1}{2} (\varphi - z)^2 D - z D \quad (15)$$

Note that K is convex, and hence $Q(x, z)$ is jointly concave in x and z . Since $H(x, z)$ is jointly convex in x and z it follows that $\Pi(x, z) = pQ(x, z) - hH(x, z) - F$ is jointly concave.

Proposition 2. The policy (\hat{x}, \hat{z}) that maximizes the profit per cycle for a given promotion length φ and cycle length T can be characterized as follows. If $hT \leq p(1 - k(0))$ then $\hat{x} = 0$, otherwise \hat{x} solves the equation

$$k(x) - \frac{h}{p} x - \left(1 - \frac{hT}{p}\right) = 0. \quad (16)$$

If $h\varphi \leq p(1 - k(0))$ then $\hat{z} = 0$, otherwise \hat{z} solves the equation

$$k(z) - \frac{h}{p} z - \left(1 - \frac{h\varphi}{p}\right) = 0. \quad (17)$$

Proof: Note that

$$\frac{\partial \Pi(x, z)}{\partial x} = [h(T - x) - p(1 - k(x))] D^L, \quad (18)$$

$$\frac{\partial \Pi(x, z)}{\partial z} = [h(\varphi - z) - p(1 - k(z))] (D^H - D^L). \quad (19)$$

Hence the first order conditions are equivalent to (16) and

(17). However, these don't give the solution if any of the constraints in (12) is violated. It is easy to show that the left hand sides of (16) and (17) are decreasing in x and z . If we substitute $z = \varphi$ in the LHS of (17) we obtain a non-positive number, and hence $\hat{z} \leq \varphi$. If we substitute $z = 0$ in the LHS of (17), we obtain a positive number as long as $h\varphi > p(1 - k(0))$, and hence in that case \hat{z} satisfies equation (17).

Substituting $x = T + \hat{z} - \varphi$ into equation (16) yields a non-positive number since the second term cannot exceed $k(\hat{z}) - 1$ by equation (17). Hence $x \leq T + \hat{z} - \varphi$. Finally, substituting in $x = 0$ into (16) concludes the proof.

To conclude this section, we prove the following proposition.

Proposition 3. Assume $\lim_{x \rightarrow \infty} \frac{1}{x} \int_0^x k(t)dt = 0$, then

- (i) $\lim_{T \rightarrow \infty} \frac{1}{T} \max \{ \Pi(x, z) \} = 0$
- (ii) $\lim_{T \downarrow 0} \frac{1}{T} \max \{ \Pi(x, z) \} = -\infty$

Proof: To prove (i), first note that $Q(\hat{x}, \hat{z})/T$ is bounded from above by D^H as $T \rightarrow \infty$, while $H(\hat{x}, \hat{z})/T$ approaches ∞ as long as $(T - \hat{x})^2/T \rightarrow \infty$. So assume $(T - \hat{x})^2/T \leq U$ for all T . Then \hat{x} grows about as fast as T , and the assumption insures that $Q(\hat{x}, \hat{z})/T \rightarrow 0$ as $T \rightarrow \infty$. To prove (ii), note that $\Pi(\hat{x}, \hat{z}) \rightarrow -F$ as $T \rightarrow 0$.

5. Solving the Multi Item Problem

In this section we give an efficient algorithm to solve the multi-item problem (10) formulated in section 3. First of all, using the derivation in the previous section it is not hard to show that note that $\Pi_i(\varphi_i, T)$ is jointly concave in φ_i and T . Hence the objective function in (10) is quasi-concave. To solve (10) we adopt the following approach. Define

$$G(T) = \left[\begin{array}{l} \max \sum_{i=1}^N \Pi_i(\varphi_i, T) \\ \text{s.t.} \sum_{i=1}^N \varphi_i \leq T \\ \varphi_i \geq 0 \ (i = 1, \dots, N) \end{array} \right], \quad (20)$$

$$f_i(u; S, D) = \left(p_i(S - K(u)) - \frac{1}{2} h_i (S - u)^2 \right) D, \quad (21)$$

$$g_i(S; \lambda, D) = \max \{ f_i(u; S, D) - \lambda S : u \geq 0 \}, \quad (22)$$

then

$$\Pi_i(\varphi, T) = g_i(T; 0, D_i^L) + g_i(\varphi; 0, D_i^H - D_i^L) - F_i, \quad (23)$$

and the Lagrangian of (20) can be written as follows.

$$G(T) = \sum_{i=1}^N g_i(T; 0, D_i^L) - \sum_{i=1}^N F_i + \min_{\lambda \geq 0} \left\{ \lambda T + \sum_{i=1}^N \max_{\varphi_i \geq 0} g_i(\varphi_i, \lambda, D_i^H - D_i^L) \right\} \quad (24)$$

Note that we can write the inner maximizations in (24) as follows:

$$\max_{\varphi_i \geq 0, z_i \geq 0} \left\{ \left[p_i(\varphi_i - K(z_i)) - \frac{1}{2} h_i (\varphi_i - z_i)^2 \right] (D_i^H - D_i^L) - \lambda \varphi_i \right\}, \quad (25)$$

and that the objective function in (25) is jointly concave. Using the first order conditions and (17), one readily shows that the optimal solution to (25) is given by

$$\begin{aligned} \hat{z}_i(\lambda) &= 0, \hat{\varphi}_i(\lambda) = 0 & \text{if } \lambda r_i \geq 1 \\ \hat{z}_i(\lambda) &= k_i^{-1}(\lambda r_i) \\ \hat{\varphi}_i(\lambda) &= \hat{z}_i(\lambda) + \frac{p_i}{h_i}(1 - \lambda r_i) & \text{otherwise} \end{aligned} \quad (26)$$

where $r_i = 1/(p_i(D_i^H - D_i^L))$. Hence these sub-problems are particularly easy to solve. The second major term in (24) is therefore a standard Lagrangian optimization problem that is quite easy to solve numerically. Similarly, note that finding $g_i(T; 0, D_i^L)$ merely requires solving (16).

Therefore $G(T)$ can be readily found for any T . So we are finally ready to give the approach to solving the problem

$$\max \{ G(T)/T : T > 0 \} \quad (27)$$

which of course is merely a different way of stating (10). Define $B(T; \alpha) = G(T) - \alpha T$. It is not hard to show the following

Proposition 4.

- (i) If $B(T; \alpha) > 0$ for some $\alpha \geq 0$ and $T > 0$ then $\Pi^* > \alpha$.
- (ii) If $\max \{ B(T; \alpha) : T \geq 0 \} \leq 0$ then $\Pi^* \leq \alpha$.
- (c) $B(T; \alpha)$ is concave in T .

Using this one can easily devise efficient algorithms to solve equation (10). The details will be left to the reader. For other examples of this approach see [6] [8].

6. Numerical results

In this section we will provide the results from a modest numerical study. In the study we assume that $k_i(u) = e^{-u_i}$ throughout. Example 1 has $N = 4$ identical products with parameters as follows:

$$D_i^H = 20, D_i^L = 14, p_i = 3, h_i = 0.2, F_i = 10, \mu_i = 1 \quad (28)$$

For this case the optimal solution is

$$\begin{aligned} x_i &= 0.1862, z_i = 0.0436, \varphi_i = 0.6837, \\ T &= 2.735, \Pi_i = 39.17, \Pi = 156.69. \end{aligned} \quad (29)$$

First of all, it is interesting to see what happens when marketing and operations don't coordinate on setting the cycle length T . Figure 1 shows the total profit that is achieved when marketing arbitrarily chooses the cycle length and the inventory policy used is optimal given the cycle length.

The figure clearly shows a substantial penalty in terms of lost profit when the promotion cycle is too short, and a much less severe penalty when the promotion cycle is longer than optimal. Part of the steep decline in profits with a short cycle may be due to the model assumption that inventory cycles and promotion cycles must coincide.

When promotion cycles become very short, one replenishment order might be placed to cover two or more promotion cycles. We don't consider this possibility here.

Figure 1: Maximum total profit given the cycle length T for Example 1.

Next, we consider the impact of the customers' willingness to wait for an out of stock item. This is captured in the model through the parameter μ of the function $k(u)$. The larger μ , the less willing customers are to wait. In the base case when $\mu = 1$, the fraction of customers that is willing to wait one time unit is equal to $\exp(-1) = 0.368$. In Figure 2 we show base case profit as a function of T for $\mu = 0.1$, $\mu = 0.5$ and $\mu = 2.0$, with other parameters as in (28).

Figure 2. Impact of promotion cycle length T for varying customer willingness to wait for Example 1.

This shows that the profit is less sensitive to long promotion period lengths when customers are less sensitive to stockouts. For short promotion periods there is virtually no difference, which is accounted for by the fact that stockout durations are very short when the order cycle is short and hence fewer lost sales occur.

Figure 3: Optimal policy and profit as functions of fixed cost F_i for Example 1.

Next, we consider the impact of the fixed cost on the optimal policy and its cost, see Figure 3. This figure uses the base case parameters but varies the fixed cost F from 1 to 50. As expected, the optimal cycle length T increases as the fixed cost increases, and the optimal profit Π^* decreases. Since there are 4 products with identical parameters in this example, the optimal policies are identical as well. The promotion length φ is always equal to 25% of the cycle length T and the parameters x , y and z show little change when expressed as a proportion of the cycle length.

Finally, we will consider an asymmetrical example. The parameters for Example 2 are:

$$\begin{aligned} D_1^H &= 22, D_2^H = D_3^H = D_4^H = 20, \\ D_1^L &= 14, p_i = 3, h_i = 2, \mu_i = 1 \end{aligned} \quad (30)$$

Figure 4. Optimal policy and profit for item 1 as functions of F_i for Example 2.

The optimal policies for item 1 are shown in Figure 4. In this example we see that when F_i is small (less than about 4), $y_i = 0$, $\varphi = T$ and $x_i = z_i$, i.e., item 1 is always being promoted, even though the item is not always in stock. The duration of the stockout is short enough however to prevent serious loss sales. As the fixed cost F_i increases, increasing inventory holding costs make it more advantageous to incur more stockouts for item 1 and therefore it becomes less attractive to do promotion on item 1, which allows promotions to be scheduled for the other items as well. Note that the optimal profit for item 1 is not a convex function of F_i at the point where

promotions for the other items become attractive. The optimal policies and profits for items 2, 3 and 4 are depicted in Figure 5.

Figure 5. Optimal policy and profit as functions of F_i for items 2, 3 and 4 in Example 2.

Items 2, 3 and 4 are not scheduled for promotion until the fixed cost F_i exceeds about 4, and these items consume more and more of the total promotion budget as the fixed cost increases (at $F_i = 50$, about 40% of a cycle is used to promote item 1, and about 20% is used for each of the other three items). Note that the optimal policies in this example are neither convex nor concave functions of F_i .

7. Discussion

It is not hard to come up with interesting generalizations of our model. In the first place, the reaction of customers to promotions is very simple in our model. An obvious modification would be to make the sales rate during promotions a function of how long the promotion has been going on, similar to the backlogging rate being dependent on how long the customer has to wait until the item will be delivered. A second modification could be to allow several promotions to go on simultaneously, possibly accompanied by a segmentation of customer market. Both these modifications would make the model more realistic, but estimating the necessary parameters would become more difficult. We have demonstrated that it is quite possible to combine logistics aspects and marketing aspects in a comprehensive model. The advantage of this is obvious: as companies acquire better and more comprehensive information systems, much more details about customer preferences and behavior become available, and companies can use this information to improve both the service to their customers and their own bottom line.

The models in this paper are just the beginning, however. An operational model takes into account the specific information available in a practical situation, and uses this to make recommendations that tally with the business model that the company is trying to implement. This requires a lot of customization in the modeling approach. On the other hand, information system implementers need to take into account what information is needed to estimate and implement the more and more

sophisticated models that researchers develop. It is our hope that this paper can make a contribution to this necessary dialogue.

A Preliminary Research Study of the Implications of Web Services Innovation for General Adopters: Findings and Recommendations (Extended Abstract)

Huinan Xu
School of Management
University of Surrey, UK
H.Xu@surrey.ac.uk

Abstract

Among emerging Service-oriented technologies, Web Services as representative of such innovation has gained increasing attention and received extensive studies from both academia and industry. In this study, we look at Web Services innovation from a more theoretical viewpoint. Based on hypothetical presumptions, we propose a dual-core model that treats such innovation at a strategic level according to its peculiar characteristics. We question the validity of using two prevailing innovation theories, Tornatzky and Fleischer's contextual framework, and Swanson's innovation typology respectively. We argue that simply apply either of above theories would miss important attributes of Web Services; if use both, it would be too complex and lose the foci. We therefore compose a synthetic viewpoint, on the basis of Web Services primary characteristics in order to obtain a thorough understanding of this innovation and give recommendation to general adopters. We also suggest that adoption of IS innovation is conjectured to be patterned in terms of the scope of e-business enablement across organizations, particularly in small and medium-sized enterprises (SMEs). The argument is exemplified through the diffusion of Web Service innovation in order to make our analysis focused on a representative case of IS innovation among organizations as well as keep generalization for articulating further research into issues which share common attributes of Web Services.

Key words: Web Services, Information Technology, Technology Innovation, e-Business, IS Adoption.

1. Introduction

Web Services are becoming the primary way in which business processes are exposed and accessed in the enterprise. As these processes are exposed, it will become easier for organizations to integrate their business operations with those of their partners. At the same time, portals have rapidly emerged to become the Web user interface of choice for accessing enterprise-wide heterogeneous data and applications. The central challenge for IT has been, and will continue to be, the

integration of inter- and intra-enterprise applications. To stay competitive today, businesses need to be able to instantly and easily interoperate with different divisions within organization - as well as reach outside to customers, partners, and suppliers. But barriers such as inconsistent platforms, languages, and protocols often stand in the way. Web services break through these barriers by providing loosely coupled, language-neutral, and platform-independent methods for connecting people, processes, and applications behind or outside the firewall. The term "Web Services" refers¹ to the technologies that allow for making connections. More specifically, Web Services is "any service that is available over the Internet, uses a standardized XML messaging system, and is not tied to any one operating system or programming language." (Cerami 2002). Hence, Web Services² are perceived as building blocks that fundamental for creating distributed applications, which are able to be published and accessed over the Internet, as well as corporate intranets. Understandably, from this conceptual viewpoint, Web Services could be thought to construct co-operative Inter or Intra-Organizational Systems (IOS) that allow trading partners to conduct transactions through connecting separate computer applications. IOSs are telecommunication-based computer systems that are used by two or more organizations to support the sharing of data, and sometimes applications, among users in different organizations (Barrett and Konsynski 1982; Cash 1985). In order to be classified as a full-fledged IOS, Web Services must be deployed at departmental level within an organization; or at organizational level among firms. However, due to the fact that each individual organization has varied perception and policy towards introducing new technologies to existing information systems, thus the adoption depth and breadth of Web Services innovation in organizations may vary considerably. However, with no exception, such decisions are all inherently consistent with each firm's adoption strategy which is

¹ When use singular form of Web Services, it denotes a special term of an IS innovation;

² We address that a service is the endpoint of a connection, which has some type of underlying computer system that supports the connection offered. Web Services herein used as a plural form to emphasize a whole subset of their functionalities.

affected by contextual factors. A number of research work studying the adoption of IS innovations is using this fashion towards contributing knowledge to general innovation theory. As an emerging technology, theories about Web Services innovation and its adoption in organizations are still lacking. It is presumable that classical technological innovation theories can provide useful guidelines for studying Web Services innovation; new findings are able to be gained by applying empirical frameworks in Web Services study. Nonetheless, any borrowed theories should be tailored to particular context in studying a specific innovation. Implications of this proposition suggest that, when featured variants are introduced to certain empirical frameworks with respect to distinct characteristics of each innovation, the research methodology should be reconsidered, and the early frameworks might subsequently need to be amended in order to design an appropriate research model which is used to conduct the later study. In accordance with these considerations, in the study of Web Service innovation, we first identify its unique characteristics which make it distinct to all other innovations; we then examine the appropriateness of two prevailing models in studying the Web Services innovation. We later recommend a dual-core research model in order to clarify the ambiguity in understanding the adoption of Web Services innovation in organizations. During this approach, this article addresses two issues: (1) what are the major determinants affecting the scope and pattern of Web Services adoption in organizations; (2) what is the role of Web Services providers and how can they assist in constructing unified e-business platform for organizations, particularly SMEs to participate in large-scale e-commerce practices.

The phrase “Web Services” in this paper denotes the architecture that consists of a set of Internet-accessible software components, which are able to extend organizations’ Information Systems (IS) to broader external business environments. While empirical researches contributed foundations towards understanding IS innovation and its role in organizational and business process innovation in general; however most studies of such relations were confined to examining separate technological silos and their impacts within a single organization or among few organizations. Nevertheless, existing literatures explain little about the strategic adoption of those innovations at inter-organizational level within a given context. In this paper, we suggest that adoption of IS innovation is conjectured to be patterned in terms of the scope of e-business enablement across organizations, particularly in small and medium-sized enterprises (SMEs). The argument is exemplified through the diffusion of Web Service innovation in order to make our analysis focused on a representative case of IS innovation among organizations as well as keep generalization for articulating further research into issues which share common attributes of Web Services. We identified that

two main patterns are associated with the dimensions of Web Services adoption: Pattern I adoption confined to integrating discrete business processes within enterprises; Pattern II adoption is implemented across enterprises boundaries to wider business environments. Web Services herein is posited to be layered throughout organization’s information systems in an amorphous manner which is fundamental for fluid e-business functionalizing. The vantage point of each adoption pattern is associated with organization’s e-business strategy and also consistent with firm’s vision towards Web Services innovation in a long term run. Implications of this paper are two fold. First, the characteristics of Web Services are identified to be openness and modularity; second, a dual-core adoption model is developed accordingly as a road map that organizations could use to help make adoption decision. Finally, we expect longitudinal studies and qualitative case analysis in order to examine our theory. In considering these issues, we reviewed empirical researches on strategic information systems and IS adoption literatures. Based on our preliminary findings on primary characteristics of Web Services, we then present a dual-core research model. Variables and factors for evolving the adoption between patterns are also identified.

2. Literature Review

Information technology usage has been recognized by many researchers as a key dependent variable in MIS research (e.g., DeLone and McLean, 1992; Karahanna and Straub, 1999). Historically, its determinants have been empirically examined in wider contexts (e.g., Adams et al 1992; Davis 1989, 1993; Mathieson 1991; Moore and Benbasat 1996; Taylor and Todd 1995; Thompson et al 1991; Iacovou et al 1995). Most of studies have used the diffusion of innovation theory (Rogers 1983) to identify attributes of innovation that influence its adoption, however many researchers have questioned the validity of its application to complex technological innovations at the organization level (e.g., Attewell 1992; Downs and Mohr 1976). Nevertheless, empirical innovation studies attempt to investigate either individual’s or firm’s beliefs and attitude towards innovation and its adoption consequences, therefore, the temporal dimension of most adoption studies has been confined to explaining the diffusion of innovation and the interaction with single adopter (e.g., often an individual or organization unit).

However, with exceptions, there are also quite a few of researches which have assessed the adoption of IS innovation at organizational level among organizations (e.g., Swanson 1994; Rai and Howard 1993). Notwithstanding this point, as stated in a study of Open Systems adoption (Chau and Tam 1997), current diffusion theories yet not explain completely the inconsistency in report results when generalizing findings of individual adoption to the organization level

if considering the differences in unit of analysis, environment, and technology characteristics. Furthermore, as Zmud (1982) notes in his studies of the diffusion of modern software practices among IS development groups that, a set of heterogeneous innovations might be influenced quite differently by the same factors in a single organizational context; and a lack of homogeneity in either innovations or organizational contexts may result in inconclusiveness of any certain type of diffusion framework in a variety of business environments with specific organizational context involved. Thus, simply use the empirical contextual framework (e.g., Tornatzky and Fleischer 1990) to analyze innovation process would not be capable to tackle a complex technological innovation, and not able to explain clearly its diffusion pattern in organization with respect to the emphasis on the other contextual factors that existing in the same framework.

In dealing with this, Fichman (1992) argues in a review of empirical IT innovation studies that classical diffusion variables by themselves are unlikely to be strong predictors of adoption and diffusion for complex organizational technology, suggesting that additional factors, either as independent or control variables, should be added to organizational level innovation adoption studies.

Alternatively, besides continuous attempts to optimize such empirical contextual framework, Swanson (1994) proposed a three-layer IS innovation typology model. Swanson claimed that the IS innovation itself could be typed according to its usage in different organization hierarchies. The IS task-nature is a key determinant to decide the type of each IS innovation. His study contributed a new ground towards understanding IS innovations through making analysis with focus on IS innovation itself; the innovation type is associated with organizational contexts, and implies the further usage of an IS innovation. Swanson's work bridges the IS innovation characteristics and its usage, and served as a roadmap to assist understanding new IS innovations within organizational context.

However, in the study of Web Services innovation, the appropriateness needs to be examined when considering applying the above two prevailing theories to the present study. A temporal hypothesis is therefore arising that:

H1:

The empirical innovation process framework looks at a single IS innovation in three contexts (respectively: the external environmental context, the technological context, and the organizational context); while Swanson's typology theory categorizes IS innovations in terms of their tasks and organizational hierarchies. For Web Services innovation, according to its peculiar technological characteristic and thereafter implications

for further adoption, either of above theories may not be able to provide complete explanation; thus a new model that blended above two with a synthetic manner is expected, in order to leverage the foci, and fit the Web Services research.

Web Services Innovation Characteristics

Cerami (2003) describes that the role of today's World Wide Web (WWW) has transformed to what now is regarded as an intermediate platform which is "for interactive access to documents and applications ... such access is by human users, typically working through Web browsers, audio players, or other interactive front-end systems. The Web can grow significantly in power and scope if it is extended to support communication between applications, from one program to another". To this end, Web Services is defined and invented to bridge the gap to such paradigm. We herein use both capital (majuscule) letters to indicate this phrase is a special term. Web Services was initiated by leading IT vendors³ and soon became standards of W3C⁴. Regardless each vernacular use of this phrase that practitioners tout with, the story of Web Services is the story of connecting systems of diverse types. Conceptually, Web Services represents a model in which discrete tasks within e-business processes are distributed widely throughout a value net; and Web Services is consist of a stack of emerging standards that describe service-oriented, component-based application architecture. Succinctly, from a technical viewpoint, Web Services is reified by loosely coupled, reusable software components that semantically encapsulate discrete functionality and are distributed and programmatically accessible over standard Internet protocols. Unlike other technological artefacts studies in previous IS research which have a specific application, the scope of Web Services is wide, affecting every component of an IS infrastructure. Again, as Sleeper and Robins (2001) and Cerami (2003) suggested, a complete Web Services is interpreted in many aspects, and summarized as:

1. Web Services are reusable software components;
2. These software components are loosely coupled and discoverable via a simple find mechanism;
3. Web Services is able to semantically encapsulate discrete functionality;
4. Web Services can be accessed programmatically through a standardized XML messaging system;
5. Web Services are distributed over the Internet by making use of existing, ubiquitous transport protocols.

³ Examples of representative Web Services are Microsoft .NET; SUN ONE (Open Network Environment); IBM Web Services; Oracle Network Services.

⁴ World Wide Web Consortium. <http://www.w3c.org>

Identifying the Primary Characteristics of Web Services Innovation

The organizational context describes the characteristics of an organization, such as firm size, degree of centralization (or diversity), formalization, complexity of its managerial structure, and the quality of its human resources, and the amount of slack resources available internally (Chau and Tam 1997, p4; Swanson 1994, p1080). Such characteristics would have substantial influence on organization's propensity to adopting certain innovations; and the evidences about the links of these two have been reported in Tornatzky and Fleischer's (1990) study. Likewise, the adoption of Web Services innovation and its impact on organizational changes should also be consistent with classical diffusion theories. Differentiating from trade press, due to the fact that Web Services is a type of recent innovation brought to academic agenda, therefore, literatures of systematic and scholarly studies on Web Services innovation are relatively scarce. Nonetheless, in a preliminary research study, Wu and El Sawy (2003) reported that a wide range of business benefits is proposed for Web Services adoption, including easier, faster and cheaper enterprise application integration (EAI), dynamic business partnership, lowering of market entry barrier, and even industry structure change. Through their study and thorough review of existing innovations characteristics; the four salient characteristics of Web Services are identified to be:

1. IS technological process innovation: Web Services practices are currently IS technological process innovation;
2. High compatibility: Web Services has its roots in three existing IT trends (match with existing values; inheritance of past experience; compatible with other Web Services characteristics);
3. High divisibility: Web Services is a loose-bundle innovation with multiple visions and multiple associated products;
4. High customizability: Reinvention of Web Services occurs inevitably.

The last point of Wu and El Sawy's findings is not a contingency; this reflects again what has been suggested by Rogers (1983) and Swanson (1994) in their earlier studies, where Rogers (1983) contends that reinvention occurs at the implementation stage for certain innovations and for certain adopter; and Swanson (1994, p1079) states "Significantly, innovations of all three types are likely to evolve over time across their domains, as they are successively adopted. Both strong-order and weak-order effects provide impetus for this evolution, which is marked by incremental changes to the innovation's feature composition. New features are likely to be introduced to complement existing features, reconfiguring the concept and often facilitating the adoption process".

From a broader viewpoint, on the basis of preliminary research findings and the ground on which Web Services was initiated, as well as classical innovation theories depict, Web Services innovation does not necessarily need to have a fixed form or construct in the organizational adoption context; rather, it exists ubiquitously within the infrastructure of enterprise information systems in an amorphous manner, and therefore, we term this attribute as polymorphism⁵. Therefore, the primary characteristics of Web Services innovation, apart from those which have already been studied, are perceived as openness and modularity. Consequently, as a result, the deployment of Web Services among organizations would present many variations through each diffusion practice, which are selective adoption and creative implementation. The former allows potential adopters to select necessary and critical components to fit in more appropriately to the task requirements respectively; while for the latter, due to large diversity of each task's specification, Web Services implementation also needs to be configured individually that tailors to adopters' needs (for example, enterprise application integration-EAI).

3. Dual-core Research Model

The power and presence of information technology (IT) have expanded at a rapid rate that reaching every level in organizations and it has been viewed as a resource ever more critical to the success for host organizations (Carr 2003). Thus, information systems (IS) featured with increasing ubiquity are perceived to be of more strategic value. Different levels in the management hierarchy are now using IT where once its sole domain was at the operational level. The aim now is not only to improve efficiency but also to facilitate e-business effectiveness. On a more strategic level, information may be passed from an organization to its suppliers or customers in order to gain or provide a better service (Cash 1985), that assure to stay ahead in a short term than competitors and gain a long-term advantage by continual improvement. Such competitive forces include (Somogyi and Galliers 1987): (1) building barriers against new entrants; (2) changing the

⁵ This term is initially dedicated to explaining the concept that different objects do "the right thing" through an example of how a Pegasus class bridges between a Horse class (horse can whinny and gallop) and a Bird class (bird can fly) in object oriented programming (i.e., in C++ programming language). We "borrow" its meaning here in order to address that Web Services is application-centric and task-oriented vehicle for facilitating e-business automation, and adopters no necessarily need to know how it works or its implementation details. References for definition and examples of polymorphism are found at Liberty (2001, p10, p111-114, p376, p435).

basis of competition; (3) changing the balance of power in supplier relationships; (4) tying in customers; (5) switching costs; (6) creating new products and services.

These perceived benefits may best explain, to a certain extent, the reasons that motivate organizations to swiftly adopt new IT innovations as a planned approach to making their information systems additional strategic value; and continually invest in IS may therefore be posited as a business strategy in order to compete in marketplace. This however might result in a dilemma in the end – most of companies realize the importance of IS and follow the investment pattern associated with new emerging information technologies, believing this is their proprietary resource to assure a leading competition position by ruling out the threat from the others who do not possess such advantage. However with comparatively less focus on continually enhancing their core business, companies would finally realize that such IT developments policy will not provide increased profitability. In fact, it is presumable that as the utilization of information technologies is becoming increasingly ubiquitous for all stakeholders in marketplace, the strategic importance of enterprise information systems would diminish to a level of what earlier technologies have reached, and the competitive advantages brought by such gradually infrastructuralized⁶ information systems would therefore become less salient than the initial expectations. Nonetheless, interestingly, we noticed the recent progress achieved in software engineering community for migrating the use of powerful high performance computing (HPC) from dedicated scientific instrument to commoditized, pervasively used mainstream business IS infrastructure, viz. Grid Web Services Provisioning, through parties external to the host organization – vendors and providers of outsourced services (Foster et al 2001; Juhasz 2002; Xu and Hackney 2003), which is all the attempts to turn the above assumption into reality. As Attewell (1992) highlighted that the role of the innovation suppliers which in our study the service providers are to facilitate significantly in the knowledge transfer process, now are seen to be of critical importance in facilitating the process of IS infrastructuralization through service-sharing on a lease or rent basis (Xu and Seltsikas 2002).

New Approach for Web Services Research

⁶ This term herein refers to the IS services and technologies that are becoming commonly used and commoditized basic facilities that functionalize enterprises e-business process. This is represented by Web Services and available most often through outsourced service provisioning. However, the source and path of such technology diffusion may vary considerably (i.e., the theories of Rogers 1983; and the study of Attewell 1992).

The peculiar characteristics of Web Services innovation shape its adoption profoundly. First, Web Services permeates both the information technology itself and the business processes it serves. Thus, Web Services innovation spans both technological and business process domains and is unlikely to be characteristic of innovation of either. Second, Web Services integrates disparate applications within an enterprise through EAI⁷, but it is also rapidly elaborating and possessing an unusual degree of plasticity for informational layering and inter-organizational linking that articulates collaborative e-business and e-commerce. In this sense, Web Services makes enterprise information systems no longer proprietary; indeed, Web Services may be conjectured as an IS infrastructural innovation that will reshape the pattern for enterprises running e-business. Analyzing Web Services from this vantage point may help organizations obtain solid understanding of this innovation that assists making adoption decision, and subsequent adoption process. Therefore, the second hypothesis is:

H2:

Web Services is basically an IT infrastructural innovation. In order to clarify ambiguity, and interpret precisely the large variation of subsequent IS innovations that derived from Web Services innovation, the research model should be associated consistently with Web Services primary characteristics; and the research direction is led by the emphasis on the scope of e-Business enablement.

(1) Proprietary Core.

Where the IS is decentralized within a company into smaller units, and there is a stronger need to integrate disparate IS applications, the pattern 1 proprietary core is most likely taken. Web Services may be thought as a means for re-engineering organizations existing applications in order to achieve integrated e-business process (i.e. EAI) and the internal information systems retain a proprietary nature. From this viewpoint, companies would concentrate on their core-business by addressing sustainable competence with increased IS infrastructure effectiveness. In addition, this adoption pattern also allows companies to develop and maintain fairly customized software applications in order to serve particular business contents, as well as keep advantageous added-value through the differentiation. Web Services innovation is therefore understood as technological process innovation (type 1b), which is seen as an IS infrastructural optimizer that glue previously disparate business processes; and constant IS availability is therefore assured.

⁷ We herein refer to 'standard' EAI, which is based on a common set of software protocols include WSDL, SOAP, UDDI through XML messaging.

(2) Infrastructural Core

Where IS is centralized and as a slack resource with economies of scale, pattern 2 infrastructural core is likely to happen that companies retain marketing advantages with extended connectivity among business partners. Web Services adoption is represented by outsourcing infrastructuralized e-business processes that facilitated by service providers. Web Services is obtained through commoditized sharing network of application service provisioning (ASP or xSP of all kinds) community. Within such virtual organization (VO), enterprise is able to gain best of breed e-business functionalities, and conduct e-commerce activities within unified e-business environment. Although the ASP/xSP business model has received considerable debates, however, with the rise in the availability of scalable network technologies and resources, ASP/xSP has become increasingly more feasible sources for obtaining IS services (Foster et al 2001; Jayatilaka et al 2002; Xu and Seltsikas 2002; Xu 2002). This is illustrated in

Thus, prevalent adopters of pattern 2, particularly SMEs, are technologically with the 'lagging-edge' philosophy during the diffusion of innovations (Huff and Munro 1985); by taking up the role-shifting to ASP/xSP, pattern 2 adopters are given the flexibilities to meet their business issues with solution, as Clark (1992) pointed out that the most consistent adoption strategy ought to be through a planned approach to systematically integrate fortuitous business issues with the occurrence of technologies. The service provisioning is thus likely to increase the probability of such opportunistic match.

(3) Intermediate Middle Layer

Where the enterprise IS is integrated by Web Services for providing consistent IS availability that keeps proprietary but would selectively connect to external business environment, the third pattern intermediate core is most likely to happen. As Tornatzky and Fleischer (1990, p. 161) argued, because organizational slack is fungible, it therefore implies IS centralization or decentralization. The installed application system portfolio of the IS unit provides another foundation for its innovation (Swanson 1994). As a result, beyond above two recommendations, a minor domain describes a blended adoption strategy, where the enterprise mission critical information systems are connected to business partners through Web Services interface, in order to expedite e-business automation in a broader dimension.

We illustrate the domain of Web Services innovation adoption in organizations with a dual-core representation in Figure 2. in order to obtain a more intuitive perception of their relationships.

In this study, the organization's IS management strategy is identified as a major determinant that affecting the adoption pattern of Web Services innovation; and this should also be taken into account for organizations in considering the adoption dimensions in terms of the scopes of e-business enablement with hypothesis that the above presumption holds.

According to these dispersed visions of enterprises strategies towards information systems development, our study of Web Services innovation spans two domains: proprietary and infrastructural respectively. How should Web Services innovation be understood in each domain? Recalling the above discussions, Web Services innovation may involve a new IS work technology confined to enterprise boundary that remains proprietary or as a private technology; it may also involve a new collaborative service across enterprises boundaries that residing on a common standardized information systems infrastructures, forming virtual e-marketplace through joining members, and expediting integrated inter-organizational e-business processes. Each of these reshapes the content, extent, and organization of the IS task. Both two domains are not exclusive to each other. A middle layer is of permeable that exists, in the case that company may view the mission-critical information systems proprietary, and the other part as infrastructural interface linking external e-business environments.

4. Implications and Future Research Directions

In this study, we look at Web Services innovation from a more theoretical viewpoint. Based on hypothetical presumptions, we propose a dual-core model that treats such innovation at a strategic level according to its peculiar characteristics. We question the validity of using two prevailing innovation theories, Tornatzky and Fleischer's contextual framework, and Swanson's innovation typology respectively. We argue that simply apply either of above theories would miss important attributes of Web Services; if use both, it would be too complex and lose the foci. We therefore compose a synthetic viewpoint, on the basis of Web Services primary characteristics in order to obtain a thorough understanding of this innovation and give recommendation to general adopters.

Qualitative research will also help obtain additional findings and discover new features. Hypotheses arising in this article need to be further examined through appropriate methodologies. The implications of the present work will also extend to other innovation domain. We attempt to generalize a research model that is useful for the study of new innovations sharing commonalities. The implication of Web Service innovation for service providers (xSPs) is not included in this study.

IS Innovation Taxonomy (Summarized by Grover, Fiedler and Teng 1997; Originally adapted from Swanson 1994)

Subtype	Innovation Core	Description	Illustration from Swanson (1994)	Illustration used for Current Study
Type 1a	IS Administrative Process Innovation	Innovation that focuses on the management and administrative support for IS work	CIO Maintenance Systems Programming CASE DBMS Chief Programmer Team Data Administration Prototyping	IS Outsourcing
Type 1b	IS Technological Process Innovation	Innovation that focuses on the technical task, i.e., changes the nature of IS work		CASE OOPS Large Scale Relational DBMS
Type 2	IS Product and Business Administrative Process Innovation	Innovation involving IS products and services that affect the administrative core of the host organization	Accounting Systems Payroll Systems Executive Information Systems Information Centres	Executive Information Systems Teleconferencing Expert Systems E-Mail
Type 3a	IS Product and Business Technological Process Innovation	Innovation involving IS products and services that affect the core work processes of the host organization	MRP Systems CIM Systems Airline Reservation Systems	CAD/CAM
Type 3b	IS Product and Business Product Innovation	Innovation involving IS products and services that are inherent to or imbedded in the host organization's products or services	Interorganizational Systems with customer Airline Reservation Systems	None
Type 3c	IS Product and Business Integration Innovation	Innovation involving IS products and services that affect the integration or coordination of the host organization with its suppliers, distributors, or customers	Interorganizational Systems EDI	EDI

Resistance to Knowledge Management: Exploring the Motivational Dimensions of Codifying Knowledge within Professional Organizations.

Paul Nesbit

Macquarie Graduate School of Management
Macquarie University
Australia
paul.nesbit@mq.edu.au

Abstract

This paper explores the relationship between employee's reluctance to contribute to knowledge management (KM) systems with their perception that KM reduces their power within, and their value to, the organization. The paper will analyse a number of KM case studies focusing on professional knowledge workers. Specifically, we examine a number of case examples of KM efforts dealing with academics, research and development scientists, and lawyers. The paper concludes with identification of a number of contingent factors that enhance or reduce the motivation of knowledge workers to contribute to KM systems. Further research and management implications are also addressed. The section below presents an extended abstract of the full paper.

1. Introduction

In recent years, knowledge has increasingly become seen as a central source of economic value within organisations and societies. Academics, social commentators, executives, and even political leaders have identified the utilisation of knowledge as the source of competitive advantage in the future. For example, the South Korean president, Kim Dae-Jung, opening an APEC conference on knowledge-based-economies, said, "As we move into the new century, it is increasingly the intangible factors that matter most as new sources of growth potential, such as knowledge, information, and cultural character." Business leaders also highlight the importance of knowledge. "Knowledge capital is our most valuable asset and it drives our organization. It's what we sell (George Shaheen, Managing Partner/CEO, Andersen Consulting, [64, p. 1]." These views are also echoed by academics [14, 18].

Given the potential value attributed to knowledge in the future, it is understandable that substantial efforts have been made to manage knowledge resources. One approach seeks to utilize innovations in information and communication technology (ICT) to capture and store knowledge in databases of the organization. This has been referred to as a codification strategy [6], where employees search and access accumulated knowledge to extract useful information as required. An example of this approach is the knowledge management system of the global consultancy firm Anderson Consulting, called

'Knowledge Xchange' [5], which comprises a variety of databases about client and project information. Codification strategies have been criticized in that such systems view knowledge as a commodity, which overlooks the deep level understanding that accompanies expertise [15]. Another KM approach, the personalization strategy, [6], seeks to gain value from this deep level knowledge, which is often referred to as "tacit knowledge". The personalization strategy of KM seeks to facilitate exchange and contact between those who have knowledge and those who need it rather than capture knowledge directly in databases. Such approaches typically comprise communities of practice [11], based around specialist topics. Users can post questions to the community, via electronic bulletin boards, to access the collective knowledge of the community of users. Answers can be circulated and discussed and the discussion can be taken off-line using more conventional communication mediums as required. This approach is used by Buckman Labs, a US based chemical supply company, which utilizes 54 online discussion groups revolving around the main products of the company. In this strategy, knowledge is spread throughout the organization rather than being isolated with selected individuals.

Whatever the specifics of the KM strategy, three aspects remain constant to all systems. First, the intention is to enhance the utilization of employee knowledge. Second, the system employs innovations in ICT in the process of managing information and knowledge. Third, the systems' ultimate effectiveness will depend on the motivations of employees to contribute information and knowledge to the KM system.

Given the substantial ICT costs that organizations may incur in operationalising knowledge strategy a substantial amount of research attention on knowledge management has focused on technological issues [12, 13, 15]. However, recently, more research attention has focused on the motivation of users [2], in KM systems. Such research, generally seeks to identify the reasons for poor employee utilization of KM systems.

2. Motivational Challenges

A variety of challenges have been identified that influence the motivation of employees to be involved in KM systems.

For example, many employees find it difficult to find time to contribute to database systems. Another issue limiting employee motivation to use KM is the lack of training and comfort with the technologies of the system. In addition to these process issues, employees are concerned that they may lose power associated with their knowledge, if they contribute to KM. As suggested by [5], "There is an incentive to evaluate the level of knowledge sharing that is "wise" given the competitive nature of the labour market. This incentive is reinforced by the rise of the advocacy of the virtues of "employability", that is, the notion that employees should think of their career in terms of the accumulation of a portfolio of skills and experiences that make them "marketable property". (p. 296). In other words, employees may feel reluctance to contribute to KM because they perceive that such contribution may decrease their value to the organization, or to the labor marketplace, or both.

In the remainder of the, paper, the validity of these concerns will be examined. It will be argued that the impact of digital technology for the employment relationship is associated with both deskilling and upgrading of workers value. Hughes and Lowe [7] refer to this as their polarization thesis. Braverman [3], discussing pre-Internet technology, outlined the case for deskilling influences of division and labour and scientific management principles. Braverman argued that the tacit and explicit knowledge of workers had been transferred to systems owned by capitalist through the use of technology in the design of work systems. For example, automotive workers who once used craft skills in the construction of cars were radically deskilled to the point that they operated as cogs in a machine. Of course the use of technology can also upgrade the value of employees by requiring enhanced skills and knowledge. Upgrading skills is associated with "knowledge workers" and to the value of knowledge in the value creation process [10, 16]. However, the increasing popularity of KM systems which are designed to capture, store, sort and disseminate corporate information residing with these high value employees, can be seen as a way of reducing the reliance by organisations on these employees. These KM systems can be construed to resemble the efforts to capture "tacit" knowledge of workers as outlined by Braverman [3].

Efforts to capture "tacit knowledge" of knowledge workers through technological systems remains elusive because of the intangible nature of this knowledge. Nevertheless, the increasing sophistication of knowledge management is resulting in many elements of knowledge work being devalued. The full paper will discuss and critically examine these impacts. For example, many of the activities of business consultants, such as accountants and lawyers, are repeated from project to project. The use of databases of past projects can help to reduce the costs associated with working on similar projects. Unfortunately, many of these organisation's clients are aware of this trend and are expecting discounted prices on services. Reduced value to customers also reduces the value of people's skills

and knowledge to the organisation.

In summary, it is argued that there is both a trend for upgrading and decrease in employee value resulting from KM systems. It is suggested that this trend is likely to grow as the codification of knowledge accelerates and sophistication of technological systems advances.

This paper explores the reluctance of professional knowledge workers to contribute to KM systems from the perspective that employees may resist giving away power inherent in their ownership of knowledge. The extant literature is reviewed and a number of case studies are presented to reflect on the issue of employee reluctance to contribute to KM efforts of organizations. Specific professional groups examined include, academics, research and development scientists, and lawyers. The paper concludes with identification of a number of contingent factors that enhance or reduce the motivation of knowledge workers to contribute to KM systems. Further research and management implications are also addressed.

3. Method

The discussion of case examples presented at the conference presentation are extracted data from a larger study examining the impact of ICT on HRM practices. The study uses semi-structured interviews with HR managers of forty mid to large Australian organizations. These interviews took on average 60 minutes to complete. Questions were directed to ascertaining the details about organizational culture, strategy changes, the make-up of HRM support services, and current and future uses of ICT within HR activities. HR activities was interpreted widely and examined not only the traditional aspects of recruitment and selection, training and development, performance management systems but also the utilization of ICT into knowledge management systems. Thus the perspectives given here reflect the HR managers perspective within these organizations. Interviews were supplemented with additional phone interviews and with collection and analysis of publicly available documents, such as web sites, annual reports and media releases and media reports.

Discussion given here relates to the interview aspects that centred on knowledge management within the organizations. Given the ethic clearance requirements for the study, organizations and respondents cannot be identified. However broad characteristics of the firms discussed are given.

4. Case Example

Organization A is a medium player in the pharmaceutical industry that has expanded operations across Australia, New Zealand, the United States, and Europe. At present the employee number is around 4,000 and is growing rapidly as the organization is engaged in a high growth

strategy via acquisitions. Indeed the central HR issue confronting the organization is the integration of new people, and cultures into the parent organization. The organization has a strong research base and is dominated by highly skilled scientists mainly from a chemistry background. The organization has recently begun knowledge management initiatives.

The KM strategy is jointly advocated by the IT and HRM departments. Interviews suggest that both groups see KM as mutually beneficial and both are cooperating on its implementation. There is a clear recognition of the differences between codification and personalization strategies among the two respondents of the organization and the both indicated that organizational leaders are aware of the concept. Indeed there has been a recent appointment of a Chief Information Officer, although it appears that this person is seen as the traditional head of the IT department. The IT department, while playing an important role in the organization, does not have a high profile in terms of senior management.

The KM initiative is focused on intranet development at the earliest stages with a clear aim to “get runs on the board” in terms of impact and getting the attention of managers. There is also a desire to create a learning organization concept, especially in terms of learning to better integrate new businesses into the parent company. The rapid growth of the company has tended to hinder integration efforts and the KM system is seen as one way to increase the integration process. The approach is to develop the KM strategy in the Australian operations then roll it out to the rest of the organization overseas. Research and development and customer relationship management are the two areas most targeted by the KM initiative. These two areas however, are not well integrated in terms of non-ICT initiatives, so it is suggested that a cultural shift in the organization is needed. However, cultural change seems low on the agenda of top management as they focus on the business realities of successfully negotiating the next acquisition.

The HR manager noted a number of obstacles to the KM initiatives. First, the question of top management support has not been clearly gained. Top management has been relatively stable despite the rapid growth and acquisitions, but does not see ICT as a significant strategic issue. Indeed, top management has a very personal focus on relationships. Specifically, those relationships require face-to-face interaction and cannot be developed via ICT. This has resulted in the preferred use of face-to-face meetings among managers, even if this means long and expensive air flights. Given the rapid growth of the company there seems to be little attention to cost efficiency that could be gained by the use of ICT to mediate communication. This attitude by top management has hindered the utilization of technology generally.

The existing KM initiative is focused on the utilization of technology to capture and sort information. This is due to the top management culture of personalization requiring

people related communication, as well the involvement of the IT group. HR group although knowing of the personalization strategy for KM tend to take the view that it is all about small steps and progress in developing KM and that the codification strategy may be the most appropriate beginning point.

The organisations’ approach seem to duplicate the description of Storey and Barnett [15] who outlined a failed knowledge initiative in a large international resources firm. They concluded that a number of issues where related to its failure. Top management support was initially forthcoming, but across the length of the knowledge project, and in face of dynamically competitive marketplace this commitment tended to decline. The authors conclude that the project was considered more as a “nice to have” than a strategically critical initiative. Failure at the senior level to monitor and protect the integrity of the project led to the escalation of micro-political maneuvers that eventually led to disintegration in the initial support for the project. For example, the project seemed to be high jacked by the IT department who commandeered expertise on the technological issues. It was viewed as trying to achieve a dominant position in strategy, methodology and budget through the project. So too in the organization under review, the lack of top management support has led to a maladaptive behavior of some users of the system. In particular, there is some reluctance to extend knowledge of the use of the system to others. Thus power users tend to gate keep access and information derived from the KM systems. This is aided by a general reluctance of individual users to acquire skills and knowledge about the system. This reflects less a direct effort of control than relying on the general inertia of adoption of a new system that seems to require more effort to use than perceived benefits. Thus an important role in the spread of KM would be to ensure that the system’s benefits are highlighted and go beyond “nice to have”.

The remainder of the paper will examine three more case studies from the rich data sourced from the HRM and ICT study.

Performance Measurement of Outsourcing Logistics: A Model Development and Implications

Simon, Sheung Man YUEN and Xinping SHI

Department of Finance and Decision Sciences

Hong Kong Baptist University, Hong Kong

01400517@hkbu.edu.hk

ABSTRACT

Outsourcing logistics or third party logistics (3PL) has become an important source of competitive advantages, increasing the efficiency and effectiveness of a company's logistics function. This paper aims to review research and current 3PL in Hong Kong and to provide ideas for future research. Comprehensive review in the literature has found that the linkage between 3PL service providers and its supply chain partners and 3PL quality performance are required to study further to fill research gap in current literature.

Keywords: Supply Chain, Third Party Logistics, Outsourcing, Performance Measurement

1. Introduction

Logistics and Supply Chain Management (SCM) are the critical factors for firm's success in today's business world as the result of the globalization of the economy and development of information technology [30]. From the Council of Logistics Management, Logistics is part of supply chain process in which it plans, implements, and controls the efficient, effective flow and storage of goods, services and related information from the point of origin to point of consumption in order to meet customers' requirements.

The use of third party logistics (3PL) services providers has gained the benefits above in SCM context. 3PL is defined as the outsourcing of logistics activities to another company [18]. Firms taking this approach employ an outside company to perform some or all of the firm's logistics activities. 3PL firms can provide improved inventory and lead time performance while concurrently capturing economies of scale resulting from higher volumes obtained by aggregating demand across a large number of customer.

Outsourcing of logistics activities to 3PL service providers is widely prevalent in Europe, North America and Australia since 1990s. Also, some studies have focus on logistics issues in Asia Pacific region like Hong Kong, South China, Japan and South Korea [22]. However, it seems to lack of comprehensive studies reported in the literature that have focused on the linkage between 3PL service providers and its supply chain partners in Hong Kong. Thus, this paper provides a review of research and current development of 3PL in Hong Kong and provides ideas and a basis for the future research.

2. Research on Third Party Logistics (3PL)

2.1. Review of Literature in 3PL

There is generally a dearth of literature that deals directly with the strategies and operational characteristics of 3PL. Most of the logistics literature focuses on the management of the logistical function from within supply chain [6,14,24]. Studies that directly address the 3PL tend to adopt narrow scopes and focus on specific areas. Review of the previous literature, three major aspects of research directions has been identified by 3PL. There are:

- Extent of the use of 3PL logistics services
- Decision making process for choosing 3PL service provider
- Impact of the usage of 3PL

In the *Extent of the use of 3PL logistics services*, Lieb et al. [20] compared the experience of the US and European manufacturers in using 3PL services, it identifies that the longer the relationship between 3PL and its supply chain partners, more extensive would be the use of 3PL, higher level of commitment to the relationship on either side and firms would willing to use 3PL services.

Dapiran et al. [9] have presented on overview of the 3PL usage by large Australia firms. The findings indicates that the Australian firms are comparable to US firms in their usage of 3PL services, with more than one-fifth of the firm characterizing their commitment to 3PL as extensive and one quarter of the firms allocating more than fifty percentage of their total logistics cost for 3PL. Moreover, McMullan [21] found that transportation, maintenance and warehousing were among the most outsourced functions among the clients of the consulting group in Asia Pacific. Bardi and Tracey [1] in a survey of the transportation practices of US manufacturers, found that freight bill auditing and payment, and transportation reports were among the most frequently

outsourced transportation functions. Thus, it appears that usage of 3PL service and commitment of resources increases over time as the two parties become more comfortable in their interaction with one another.

Another research on 3PL would focus on *decision-making process for choosing 3PL services*. Firms outsource logistics functions for variety of reasons. Sheffi [25] suggested several reasons for the growth of 3PL in USA. There are need to focus on core business; better transportation solutions; cost savings and improved services; development of necessary technological expertise and computerized systems the following which is beyond the scope of many companies and need for more professional and better equipped logistics services.

Richardson [24] found that 3PL brought about several benefits for the companies surveyed. The benefits included distribution saving, greater control of business, better customer service and satisfaction and the addition of expertise to supplement the capabilities of the internal organization. Other benefits included reduction in capital investment in facilities, equipment and information technology, improved customer service and delivery and reduction in the complexity of logistics operations [7,8,17, 23,24]

As the previous discussions, 3PL is a complex decision, arising out of a variety of reasons. 3PL service providers need to understand the objectives that buyers are seeking to accomplish by 3PL services.

For the *impact of usage of 3PL services on the organization*, 3PL is a strategic partnership between 3PL and its supply chain partners. Before making the decision to outsource, the impact on the organization should be considered. Bowersox [5] indicates that a

necessary imperative for the relationship to succeed is a match between the cultures of the two organizations.

Dapiran et al. [9] found that the impact of 3PL on the internal logistics performance and the logistics costs had been positive among Australia companies. However, introduction of 3PL services into a company represented an important shift in the way business was conducted, related training of the internal staff was found to be necessary.

Also, Dapiran et al. [9] found that the company must plan for the implementation of the partnership by educating the 3PL about the firm's requirements, developing programs to place redundant employees, correcting attitude of internal staff and integrating the information systems of both 3PL service providers and its supply chain partners.

In summary, there is three major aspects of research directions have been identified by 3PL: extent of the use of 3PL logistics services; decision-making process for choosing 3PL service provider and impact of the usage of 3PL. However, it is lack of a sound and comprehensive foundation for the research framework for analyzing the 3PL industry. Also, the quality performance, trends of 3PL service in future and industrial practices in 3PL is required in future research.

2.2. Research on Outsourcing Logistics in Asia and Hong Kong

As growing importance of outsourcing logistics, the extent of its usage has been widely examined in the US and Europe. Sheffi [25] describes how the 3PL industry in the US has developed and mentions several economic, regulatory and technological trends driving the development. Kakabadse studies the trends of 3PL in US

and Europe. It identifies both US and European companies provide the most preferred relationship between 3PL service providers and its supply chain partners who has an industry focused, proven track record.

In Asia, some studies have outlined the linkage between manufacturing firms and 3PL service providers in Hong Kong, South China, Japan and South Korea [22]. In the south East region, it was reported that Singapore based firms are generally satisfied with the services of 3PL service provider [29]. Also, it has a survey of 3PL services in Malaysia [27].

In Hong Kong, academic studies on logistics management in Hong Kong are confined to several commercial reports, consultation papers on specific topics. Wong et al. [33] has investigated the relationships for quality improvement in the Hong Kong supply chain by using theory of co-operation and competition. Voon and Ho [31] studies the economic impacts of logistics infrastructure development in Hong Kong. It concludes that substantial social benefits could be derived from investment in logistics development in Hong Kong. Both public and private sectors will be interested to assess the returns to their investments and to know the impact of their investments on the economy.

However, it is rather limited research focus on either logistics in supply chain context and 3PL in Hong Kong. A comprehensive study reported in the literature that has focused on the linkage between 3PL service providers and its supply chain partners and 3PL quality performance are required to fill the research gap.

3. Performance Measurement of Outsourcing Logistics

Performance measurement is defined as the process of quantifying effectiveness and efficiency of action [28]. In modern business management, performance measurement contributes on business management and performance improvement in the industries. Sink and Tuttle [26] claims that you cannot manage what you cannot measure. Harrington [13] states that “If you cannot measure it, you cannot control it. If you cannot control it, you cannot manage it. If you cannot manage it, you cannot improve it.” Thus, the importance of performance measurement is obvious for management of logistics and SCM.

In management perspective, performance measurement provides necessary information of management feedback for decision making. It plays the critical roles of monitoring performance, enhancing motivation and communication, and diagnosing problems. Moreover, performance measurement provides an approach to identifying success and potentials of management strategies, and facilitating understanding of progress and position. It cannot only assist in directing management attention, revising company goals, but also re-engineering business processes [14,16,32]. Therefore, making proper performance measurement of supply chain is necessary as it cultivates understanding between member forms in the supply chain for performance improvement and implementation [10,11,19]. An appropriate performance measurement is conducive to successful SCM implementation.

According to Beamon [2], there is inadequate literature available in performance measures selection for supply chain management. Beamon [3] categorizes the existing performance measures involving customer satisfaction and customer responsiveness, flexibility and supplier performance. Beamon [2] identifies three types of measures: resources, output and flexibility. Gunasekaran

and Tirtiroglu [12] develops a framework for measuring the strategic, tactical and operational level performance in supply chain, which mainly deals with supplier, delivery, customer service, and inventory and logistics costs.

In fact, logistics and supply chain management concepts have received significant attention in both academic and practitioners for years. Despite this attention, inter-organizational supply chain performance measurement appears to be limited instead of buyer-seller relationship. Keebler et al. [15] surveyed about 3100 logistics executives regarding their logistics and supply chain activities, and concluded that “few if any firms are measuring full supply chain network performance is significant” It implies that the existence of comprehensive supply chain performance measurement system is fewer and insignificant.

Three observations can be made from the literature regarding to supply chain performance measurement. Much attention has historically been placed on individual measures rather than on systems of measure [2]. In addition, many studies in the literature are prescriptive in nature and emphasize the attributes that good metrics and measurement system should have [4]. Furthermore, little empirical research has been conducted to holistic supply chain management system such as outsourcing logistics.

Keebler et al. [15] indicates that relatively few firms are measuring logistics supply chain performance especially outsourcing logistics. In relation to supply chain performance measurement, it has been based on a relatively limited systems perspective. Besides, very little empirical research exists in relation to supply chain performance measurement from a broader system perspective such as organizational performance

measurement.

Although academicians attempt to build new measures and metrics for supply chain management, most of current performance measurement of supply chain has some defects to meet with supply chain management requirements [15]. Current supply chain performance measurement is inadequate because it relies heavily on the use of cost as primary (if not sole) measure, it is often inconsistent with the strategic goals of the organization, and does not consider the effects of uncertainty [2].

Thus, the objective of research which determines the organizational performance measurement of outsourcing logistics in Hong Kong transport logistics industry by using organization theory approach can provide significant information for organizational performance measurement of outsourcing logistics in Hong Kong. It leads to be a better performance of outsourcing logistics service providers in Hong Kong to gain competitive advantages over others and promote Hong Kong as a transport, trading and logistics hub in this and next several decades.

4. Model and Implications

In a serviced partner perspective, outsourcing logistics is expected as a value-added process for those organizations that third party logistics (3PL) is intentionally used to enhance organizational co-operative advantages, in addition to low cost, produce / service differentiation, and focus strategies. However, this expectation may be undermined by lacking measurement of outsourcing logistics service performance to manage service vendors. In a provider perspective, on the other hand, the outstanding performance is expected outcomes of outsourcing

logistics services that should be tangibly and intangibly defined to reflect its operations.

However, there is a dearth of studies in logistics and supply chain management literature to reflect the demand of performance measurement of outsourcing logistics services. Based on literature review, we provide a research framework in organizational theory perspective, to elaborate the causal effect relationships among outsourcing logistics' capacity and services; relationship management with serviced partners, and the outsourcing logistics performance; intending to fill the gap of current literature, and to provide insightful understanding of outsourcing logistics performance measurement and management.

The 3PL capacity and services are examined with respect constructs of tangible logistics services, reliability and responsiveness of services to serviced partners; cost and value-added to service process; the core competency of 3PL service providers; and empathy and adaptiveness to environmental changes.

The relationship management is studied in terms of the commitment of 3PL to serviced partners, the extent of trust and trust development in the process of business collaboration and / or partnership; and 'Guanxi', a social culture or context related issue, in daily business and service interactions.

The outsourcing logistics service performance is investigated in two construct categories: (1) tangible outputs include financial performance, productivity and cycle time of services with industrial benchmark; (2) intangible outcomes involved reputation and goodwill of the 3PL, and the partner's appreciation of 3PL services will be included in the framework.

Hence, a study of organizational performance measurement of outsourcing logistics in Hong Kong transport logistics industry can identify the collaborative relationship among outsourcing logistics service providers and supply chain partners that affect channel relationship in the supply chain and therefore enhance the effectiveness of services delivered. It is imperative that firms have to excel in quality assurance, on which the efficient and effective flows of goods, information and financial within supply chains, it would not only improve outsourcing logistics service quality but also achieve business success.

5. Conclusion and Future Research

Outsourcing logistics has become an important source of competitive advantages, the outsourcing of logistics activities to specialized 3PL service providers can increase the efficiency and effectiveness of a company's logistics function. In order to maintain a competitive advantage, 3PL must enhance its ability to plan, take action and manage and control products, services and information from supplier through customer as an integrated process rather than as a series of discrete functions.

To achieve this, a comprehensive study reported in this paper that has focused on the linkage between 3PL service providers and its supply chain partners. And, future research will be found on change their performance measurement systems of 3PL in order to provide improve its service quality within supply chain.

Abstract: A framework of stochastic multilevel programming is proposed for modelling decentralized decision-making problem in stochastic environment. According to different decision criteria, the stochastic decentralized decision-making problem is formulated as expected value multilevel programming, and chance-constrained multilevel programming. In order to solve the proposed stochastic multilevel programming models for the Stackelberg-Nash equilibriums, genetic algorithms, neural networks and stochastic simulation are integrated to produce a hybrid intelligent algorithm. Finally, two numerical examples are provided to illustrate the effectiveness of the hybrid intelligent algorithm.

Keywords: Multilevel programming; stochastic programming; neural network; genetic algorithm

1 Introduction

In many decision processes, there are multiple decision makers arranged within a hierarchical administrative structure. These decision makers have divergent even conflict objectives, which intervenes in the decisions to be made. This is the so called decentralized decision-making problems, which has long been recognized as an important and challenging topic in many research areas including economics [1][8][16][23], transportation [9][56][59], engineering [19][52], and so on.

Multilevel programming was first proposed by Bracken and McGill [14][15] for dealing with decentralized decision-making problems. After that, a special case called bilevel programming, which is equivalent to a two person Stackelberg game, has attracted much attention. In [10], Ben-Ayed and Blair proved that the bilevel programming problem is NP-hard. However, many numerical algorithms have been designed for solving this problem. For example, implicit enumeration scheme [17], the k th best algorithm [12][13], complementary pivot algorithm [13][28], grid search algorithm [4][5], branch-and-bound algorithm [7][25], descent algorithm [53]. General cases with multiple followers [6][32] or multilevel levels [2][4][5][57] were also discussed.

Real-world situations are often not deterministic. For instance, in economic systems, costs and demands are often subject to fluctuations and difficult to measure.

In engineering, external conditions and measurement or manufacturing errors introduce uncertainty into the problems. These situations emphasize the need for models which are able to tackle uncertainty inherent in decision systems. However, there is little research in literature about decentralized decision making problem in uncertain decision systems. In [50], Patriksson and Wynter discussed stochastic mathematical programs with equilibrium, which includes stochastic bilevel programming as a special case. In [51], Sakawa, *et al.* dealt with multilevel programming problems with fuzzy parameters by a fuzzy interactive approach [30][31][54]. The fuzzy interactive approach is formulated by combined use of the fuzzy tolerance membership functions and multi-objective decision-making, which makes the original problem much more simplified, and much easier to solve. However, it differs the traditional solution concept, Stackelberg-Nash equilibrium, because it is assumed that decision makers at all levels are essentially cooperative.

For the purpose of tackling uncertainty in decision systems, various stochastic programming models have been formulated in literature, among them we want to mention expected value model, and chance-constrained programming model [18]. Motivated by the above mentioned works, in this paper, we propose two classes of stochastic multilevel programming models including expected value multi-level programming model (EVMLP) and chance-constrained multilevel programming (CCMLP), and design an intelligent algorithm for Stackelberg-Nash equilibrium of the proposed stochastic models. Besides a new model CCMLP, the proposed EVMLP may have multiple followers, which distinguishes from stochastic mathematical programs with equilibrium [50]. Furthermore, we employ the Stackelberg-Nash equilibrium solution concept, which distinguishes our work from that of [51].

The purposes of this paper are twofolds, one is to establish an EVMLP and a CCMLP for a stochastic decentralized decision making problem with multiple followers. The other is to design efficient numerical algorithms for the Stackelberg solution. Toward that end, the following sections are organized as follows. Section 2 discusses the formulation of EVMLP and CCMLP, then the concepts of Nash equilibrium and Stackelberg-Nash

equilibrium are defined in this section. In Section 3.1, we first discuss how to approximate the uncertain functions involved in the proposed models. The motivation of the method is as follows, when searching for Nash equilibrium and Stackelberg-Nash equilibrium, we need many times of stochastic simulation to evaluate the uncertain functions. It is known that stochastic simulations are time-consuming processes. In order to speed up the solution process, we desire to use relatively simple functions, neural networks (NNs), to replace these uncertain functions after they are well-trained by input-output data produced by stochastic simulations. After that, Section 3.2 discusses approaches on computing Nash equilibrium with respect to a given control vector. Based on the above discussion, Section 3.3 discusses how to solve the EVMLP and CCMLP for the Stackelberg-Nash equilibrium. To do this, we embed the above trained NNs, and algorithms for the Nash equilibrium into a GA to produce a hybrid intelligent algorithm (HIA). At the end of the paper, two numerical examples are provided to show the effectiveness of the proposed algorithm.

2 Stochastic Multilevel Programming

In order to formulating a stochastic version of multilevel programming, we start from a deterministic one.

Consider a decentralized two-level decision system in which there are one leader and m followers. Assume that the leader and followers may have their own decision variables and objective functions, and the leader can only influence the reactions of followers through his own decision variables, while the followers have full authority to decide how to optimize their own objective functions in view of the decisions of the leader and other followers. Let \mathbf{x} and \mathbf{y}_i be the control vectors of the leader and the i th followers, $i = 1, 2, \dots, m$, respectively. We also assume that the objective functions of the leader and i th followers are $F(\mathbf{x}, \mathbf{y}_1, \dots, \mathbf{y}_m, \mathbf{b})$ and $f_i(\mathbf{x}, \mathbf{y}_1, \dots, \mathbf{y}_m, \mathbf{b})$, $i = 1, 2, \dots, m$, respectively, where \mathbf{b} is a vector represents the problem parameters.

In addition, let S be the feasible set of control vector \mathbf{x} of the leader, defined by

$$G(\mathbf{x}, \mathbf{b}) \leq 0 \quad (1)$$

where G is a vector-valued function of decision vector \mathbf{x} and 0 is a vector with zero components. Then for each decision \mathbf{x} chosen by the leader, the feasible set of control vector \mathbf{y}_i of the i th follower should be dependent on not only \mathbf{x} but also $\mathbf{y}_1, \dots, \mathbf{y}_{i-1}, \mathbf{y}_{i+1}, \dots, \mathbf{y}_m$, and generally represented by the expected constraint

$$g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \mathbf{b}) \leq 0 \quad (2)$$

where g_i are vector valued functions, $i = 1, 2, \dots, m$.

Multilevel programming offers a means of studying decentralized decision systems. Assume that the leader

first chooses his control vector $\mathbf{x} \in S$, and the followers determine their control array $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$ after that. Then a general bilevel programming has the following form,

$$\begin{cases} \max_{\mathbf{x}} F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \mathbf{b}) \\ \text{subject to:} \\ G(\mathbf{x}, \mathbf{b}) \leq 0 \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \begin{cases} \max_{\mathbf{y}_i} f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \mathbf{b}) \\ \text{subject to:} \\ g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \mathbf{b}) \leq 0. \end{cases} \end{cases} \quad (3)$$

Now, assuming that the problem parameters are random, and represented by a random vector ξ . Then the objective function $F(\mathbf{x}, \mathbf{y}, \xi)$ and $f_i(\mathbf{x}, \mathbf{y}, \xi)$, $i = 1, 2, \dots, m$ become stochastic. Moreover, the stochastic constraints $G(\mathbf{x}, \xi) \leq 0$ and $g_i(\mathbf{x}, \mathbf{y}, \xi) \leq 0$ do not define the feasible set of the optimization problem of the leader and the followers mathematically. According to different decision criteria, we propose two types of stochastic programming models in the following subsections.

2.1 Expected Value Multilevel Programming

With the idea of optimizing the expected value of objective functions subject to some expected constraints, we propose the first type of stochastic multilevel programming: expected value multilevel programming (EVMLP).

Let the feasible set of control vector \mathbf{x} of the leader be defined by the expected constraint

$$E[G(\mathbf{x}, \xi)] \leq 0 \quad (4)$$

where G is a vector valued function and 0 is a zero vector. Then for each decision \mathbf{x} chosen by the leader, the feasible set of control vector \mathbf{y}_i of the i th follower should be dependent on not only \mathbf{x} but also $\mathbf{y}_1, \dots, \mathbf{y}_{i-1}, \mathbf{y}_{i+1}, \dots, \mathbf{y}_m$, and generally represented by the expected constraint

$$E[g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \leq 0 \quad (5)$$

where g_i are vector valued functions, $i = 1, 2, \dots, m$.

Assume that the leader first chooses his control vector \mathbf{x} , and the followers determine their control array $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$ thereafter. In order to maximize the expected return of the leader, we have the following EVMLP,

$$\begin{cases} \max_{\mathbf{x}} E[F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \\ \text{subject to:} \\ E[G(\mathbf{x}, \xi)] \leq 0 \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \begin{cases} \max_{\mathbf{y}_i} E[f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \\ \text{subject to:} \\ E[g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \leq 0. \end{cases} \end{cases} \quad (6)$$

A Nash equilibrium of followers is the feasible array $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ with respect to \mathbf{x} if

$$\begin{aligned} & \mathbf{E} [f_i(\mathbf{x}, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \\ & \leq \mathbf{E} [f_i(\mathbf{x}, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \end{aligned} \quad (7)$$

for any feasible $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*)$ and $i = 1, 2, \dots, m$.

A Stackelberg-Nash equilibrium to the EVMLP is the array $(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ satisfying

$$\begin{aligned} & \mathbf{E} [F(\bar{\mathbf{x}}, \bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m, \boldsymbol{\xi})] \\ & \leq \mathbf{E} [F(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \end{aligned} \quad (8)$$

for any feasible $\bar{\mathbf{x}}$ and the Nash equilibrium $(\bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m)$ with respect to $\bar{\mathbf{x}}$.

2.2 Chance-Constrained Multilevel Programming

Chance-constrained programming, which was initialized by Charnes and Cooper [18], offers a powerful means for modelling stochastic decision systems. The essential idea of chance-constrained programming is to optimize the optimistic return with a given confidence level subject to some chance constraints. Inspired by this idea, we propose the second type of stochastic multilevel programming: chance-constrained multilevel programming (CCMLP).

By chance constraint we mean that the stochastic constraints will hold at a confidence level provided as an appropriate safety margin by the decision-maker. Let the feasible set of control vector \mathbf{x} of the leader be defined by the chance constraint

$$\Pr \{G(\mathbf{x}, \boldsymbol{\xi}) \leq \mathbf{0}\} \geq \beta_0 \quad (9)$$

where G is a vector valued function, $\mathbf{0}$ is a zero vector, and β_0 is a confidence level at which it is desired that the stochastic constraints hold. Then for each decision \mathbf{x} chosen by the leader, the feasible set of control vector \mathbf{y}_i of the i^{th} follower should be dependent on not only \mathbf{x} but also $\mathbf{y}_1, \dots, \mathbf{y}_{i-1}, \mathbf{y}_{i+1}, \dots, \mathbf{y}_m$, and generally represented by the chance constraints

$$\Pr \{g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq \mathbf{0}\} \geq \beta_i \quad (10)$$

where g_i are vector valued functions, β_i is a confidence level at which it is desired that the stochastic constraints hold, and $i = 1, 2, \dots, m$.

Because of the stochastic parameters characterized by $\boldsymbol{\xi}$, the objective function is stochastic, which results that $\max_{\mathbf{x}} F(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi})$ is meaningless. A natural idea is to provide a confidence level α_0 at which it is desired that $F(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi}) \geq \bar{F}$, where the confidence level α_0 is provided as an appropriate safety margin by the leader. Then the objective of the leader is to maximize \bar{F} with a chance constraint as follows,

$$\Pr \{F(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi}) \geq \bar{F}\} \geq \alpha_0, \quad (11)$$

where \bar{F} is referred to as the α_0 -optimistic return of $F(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi})$. Then for each decision \mathbf{x} chosen by the leader, the objective of the i^{th} follower is to maximize the α_i -optimistic return of $f_i(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi})$, \bar{f}_i , with a chance constraint as follows,

$$\Pr \{f_i(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \alpha_i, \quad (12)$$

where α_i is a confidence level provided as an appropriate safety margin by the i^{th} follower.

Assume that the leader first chooses his control vector \mathbf{x} , and the followers determine their control array $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$ thereafter. In order to maximize the α_0 -optimistic return of the leader, we have the following CCMLP,

$$\left\{ \begin{array}{l} \max_{\mathbf{x}} \bar{F} \\ \text{subject to:} \\ \Pr \{F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{F}\} \geq \alpha_0 \\ \Pr \{G(\mathbf{x}, \boldsymbol{\xi}) \leq \mathbf{0}\} \geq \beta_0 \\ \text{where each } \mathbf{y}_i \ (i = 1, 2, \dots, m) \text{ solves} \\ \left\{ \begin{array}{l} \max_{\mathbf{y}_i} \\ \text{subject to:} \\ \Pr \{f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \alpha_i \\ \Pr \{g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq \mathbf{0}\} \geq \beta_i. \end{array} \right. \end{array} \right. \quad (13)$$

A Nash equilibrium of followers is the feasible array $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ with respect to \mathbf{x} if

$$\begin{aligned} & \max \{\bar{f}_i \mid \Pr \{f_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \alpha_i\} \\ & \leq \max \{\bar{f}_i \mid \Pr \{f_i(\mathbf{x}, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \alpha_i\} \end{aligned} \quad (14)$$

for any feasible $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*)$ and $i = 1, 2, \dots, m$.

A Stackelberg-Nash equilibrium to the CCMLP is the array $(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ satisfying

$$\begin{aligned} & \max \{\bar{F} \mid \Pr \{F(\bar{\mathbf{x}}, \bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m, \boldsymbol{\xi}) \geq \bar{F}\} \geq \alpha_0\} \\ & \leq \max \{\bar{F} \mid \Pr \{F(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \geq \bar{F}\} \geq \alpha_0\} \end{aligned} \quad (15)$$

for any feasible $\bar{\mathbf{x}}$ and the Nash equilibrium $(\bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m)$ with respect to $\bar{\mathbf{x}}$.

3 Hybrid Intelligent Algorithm for Stackelberg-Nash Equilibrium

It is known that multilevel programming, even in the simplest case, is NP-hard [10]. Thus, successful implementations of multilevel models rely largely on the development of efficient algorithms. In the past two decades, many intriguing numerical algorithms have been developed. These algorithms may fall into four categories:

- vertex enumeration approach, which aims to seek a comprising vertex by simplex algorithm based on adjusting the control variables [13][17];

- transformation approach, which transforms the lower level problems into constraints for the higher level by use of Karush-Kuhn-Tucker conditions or penalty functions [3][12][21][23].
- heuristic approaches like gradient techniques [20][22][29][55], and branch and bound method [6][7][21][23][25].
- intelligent algorithms like genetic algorithm [32][52], and simulated annealing [60], which are especially suited for solving NP-hard problems like the multilevel programming problems.

As an extension of multilevel/stochastic programming, stochastic multilevel programming will further complicate ordinary multilevel programming. Correspondingly, resolution strategies will in many cases require some approximate methods for solving stochastic multilevel programming models. In the following subsections, we take the EVMLP as an example to discuss the numerical solution methods.

3.1 Uncertain function approximation

By uncertain functions we mean the functions with uncertain parameters. The uncertain functions in stochastic multilevel programming (6) and (13) may fall into three types. Due to the complexity, we design stochastic simulations for computing the uncertain functions.

The first type of uncertain function is

$$U_1 : (\mathbf{x}, \mathbf{y}) \rightarrow \mathbf{E}[F(\mathbf{x}, \mathbf{y}, \boldsymbol{\xi})]. \quad (16)$$

In order to compute it, we design a stochastic simulation as follows,

- Step 1.** Set $U_1 = 0$
- Step 2.** Generate $\boldsymbol{\omega}$ from Ω according to the probability measure Pr .
- Step 3.** Compute the function value $F(\mathbf{x}, \mathbf{y}, \boldsymbol{\omega})$ and denote it by c .
- Step 4.** $U_1 \leftarrow U_1 + c$.
- Step 5.** Repeat the second to fourth step for M times, where M is a sufficiently large number.
- Step 6.** return $U_1 \leftarrow U_1/M$

The second type of uncertain function is

$$U_2 : (\mathbf{x}, \mathbf{y}) \rightarrow \max \{ \bar{F} \mid \text{Pr} \{ F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{F} \} \geq \alpha \}. \quad (17)$$

A procedure of stochastic simulation is given as follows.

- Step 1.** Generate $\boldsymbol{\omega}_1, \boldsymbol{\omega}_2, \dots, \boldsymbol{\omega}_M$ from Ω according to the probability measure Pr , where M is a sufficiently large number.
- Step 2.** For each $\boldsymbol{\omega}_k$, compute the function value $F(\mathbf{x}, \mathbf{y}, \boldsymbol{\omega}_k)$ and denote it by c_k .

Step 3. Set M' as the integer part of αM

Step 4. Return the M' -th least element in $\{c_1, c_2, \dots, c_M\}$.

The third type of uncertain function is

$$U_3 : (\mathbf{x}, \mathbf{y}) \rightarrow \text{Pr} \{ F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{F} \}. \quad (18)$$

We also design a stochastic simulation as follows.

- Step 1.** Set $M' = 0$
- Step 2.** Generate $\boldsymbol{\omega}$ from Ω according to the probability measure Pr .
- Step 3.** Compute the function value $F(\mathbf{x}, \mathbf{y}, \boldsymbol{\omega})$ and denote it by c .
- Step 4.** If $c < \bar{F}$, set $M' \rightarrow M' + 1$.
- Step 5.** Repeat the second to fourth step for M times, where M is a sufficiently large number.
- Step 6.** return M'/M

Although stochastic simulations are able to compute the uncertain functions, they are a time-consuming process. In order to speed up the solution process, we need relatively simple functions to approximate the uncertain functions. Multilayer feedforward NN, which was initially designed by Minsky and Papert [49], is essentially a nonlinear mapping from the input space to the output space. It has the high speed of operation after they are trained. It has been shown that the multilayer feedforward NNs with an arbitrary number of hidden neurons are universal approximators for continuous functions (Cybenko [11], Hornik et al [27]). For our purpose, multilayer feedforward NNs are used to approximate uncertain functions, and then are substituted for the work of simulation in the solution process. For detailed discussion on uncertain function approximation, the reader may consult Chapter 3 in the book [33] by Liu.

In order to train NNs to approximate uncertain functions, we should first determine a region Θ on which to approximate the uncertain function $U(\mathbf{x}, \mathbf{y})$. The region Θ may be a bit too large so that it has simple forms like multi-dimensional hypercube. Then the computer can easily sample points (\mathbf{x}, \mathbf{y}) from the hypercube, where the vector \mathbf{y} is not necessarily the Nash equilibrium of the followers with respect to \mathbf{x} . In order to get a set of input-output data, we designed a computing procedure as follows.

Step 1. Set $k = 1$.

Step 1. Generate a random point $(\mathbf{x}_k, \mathbf{y}_k)$ from the hypercube Θ .

Step 2. Compute the function value by stochastic simulation and denote it by z_k .

Step 7. Repeat Step the first to sixth step for N times.

Step 7. Return the set of input-output data $\{(\mathbf{x}^{(k)}, \mathbf{y}^{(k)}, z^{(k)}) \mid k = 1, 2, \dots, N\}$.

Now we hope to train a feedforward NN to approximate the function $U(\mathbf{x}, \mathbf{y})$. Given the number of neurons and architecture, then the network weights may be arranged into a vector \mathbf{w} . Thus the output of mapping implemented by the NN may be characterized by $U(\mathbf{x}, \mathbf{y}, \mathbf{w})$. A training process is to minimize the error function

$$Err(\mathbf{w}) = \frac{1}{2} \sum_{k=1}^N |U(\mathbf{x}^{(k)}, \mathbf{y}^{(k)}, \mathbf{w}) - z^{(k)}|^2 \quad (19)$$

so as to find a weight vector \mathbf{w} that provides the best possible approximation of $U(\mathbf{x}, \mathbf{y})$. Sometimes, we are interested in the average error defined as

$$Err(\mathbf{w}) = \frac{1}{N} \sum_{k=1}^N |U(\mathbf{x}^{(k)}, \mathbf{y}^{(k)}, \mathbf{w}) - z^{(k)}|. \quad (20)$$

Backpropagation algorithm is the original learning algorithm for multilayer feedforward NN. It is essentially a gradient descent minimization method. Here we use the backpropagation algorithm for the NN with one hidden layer. In order to speed up the learning process, we use an improved error function

$$E_k = \frac{1}{2} [\lambda(z^{(k)} - U(\mathbf{x}^{(k)}, \mathbf{y}^{(k)}, \mathbf{w}))^2 + (1 - \lambda)\Phi(z^{(k)} - U(\mathbf{x}^{(k)}, \mathbf{y}^{(k)}, \mathbf{w}))^2] \quad (21)$$

where $\Phi(x) = \ln(\cos(\beta x))/\beta$, $\lambda = \exp(-\mu/E^2)$ is an adaptive parameter, μ and β are constant numbers between 0 and 1, for example, $\mu = 1$, $\beta = 4/3$.

Step 1. Initialize \mathbf{w} , and set $\mu = 1$, $\beta = 4/3$, $\alpha = 0.05$, $\eta = 0.01$, $E_0 = 0.05$, $\lambda = 1$, and $k = 0$.

Step 2. $k \leftarrow k + 1$.

Step 3. Adjust the weights \mathbf{w} .

Step 4. Calculate the error E_k .

Step 5. If $k < N$, go to the second step.

Step 6. Set $E = \sum_{k=1}^N E_k$.

Step 7. If $E > E_0$, then set $k = 0$, $\lambda = \exp(-\mu/E^2)$ and go to the third step.

Step 8. End.

For detailed exposition to backpropagation algorithm, the reader may consult the books [58].

3.2 Computing Nash equilibrium

Define symbols

$\mathbf{y}_{-i} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_{i-1}, \mathbf{y}_{i+1}, \dots, \mathbf{y}_m)$, $i = 1, 2, \dots, m$.

For any decision \mathbf{x} revealed by the leader, if the i^{th} follower knows the strategies \mathbf{y}_{-i} of other followers, then the optimal reaction of the i^{th} follower is represented by a mapping $\mathbf{y}_i = r_i(\mathbf{y}_{-i})$, which should solve the subproblem

$$\begin{cases} \max_{\mathbf{y}_i} E[f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \\ \text{subject to:} \\ E[g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \xi)] \leq 0. \end{cases} \quad (22)$$

In order to search for the Stackelberg-Nash equilibrium of an EVMLP, we should first compute the Nash equilibrium with respect to any decision revealed by the leader. It is clear that the Nash equilibrium of the m followers will be the solution $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$ of the system of equations

$$\mathbf{y}_i = r_i(\mathbf{y}_{-i}), \quad i = 1, 2, \dots, m. \quad (23)$$

In other words, we should find a fixed point of the vector-valued function (r_1, r_2, \dots, r_m) . In order to solve the system of equations (23), we should design some efficient algorithms. The argument breaks down into three cases.

Case I. If we have explicit expressions of all functions r_i , $i = 1, 2, \dots, m$, then we might get an analytic solution to the system (23). Unfortunately, it is almost impossible to do this in practice.

Case II. In many cases, no analytic solution of (23) can be obtained. Thus the system of equations (23) might be solved by some iterative method that generates a sequence of points $\mathbf{y}^{(k)} = (\mathbf{y}_1^{(k)}, \mathbf{y}_2^{(k)}, \dots, \mathbf{y}_m^{(k)})$, $k = 0, 1, 2, \dots$ via the iteration formula

$$\mathbf{y}_i^{(k+1)} = r_i(\mathbf{y}_{-i}^{(k)}), \quad i = 1, 2, \dots, m \quad (24)$$

where $\mathbf{y}_{-i}^{(k)} = (\mathbf{y}_1^{(k)}, \dots, \mathbf{y}_{i-1}^{(k)}, \mathbf{y}_{i+1}^{(k)}, \dots, \mathbf{y}_m^{(k)})$. When we solve some given problem on a computer, we might employ the iterative method. The procedure of the iterative method is given as follows.

Step 1. For a given control vector \mathbf{x} , initialize a feasible vector $\mathbf{y} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$.

Step 2. Calculate $\mathbf{y}'_i = r_i(\mathbf{y}_{-i})$.

Step 3. Calculate $\sum_{i=1}^m \|\mathbf{y}'_i - \mathbf{y}_i\|$.

Step 4. $\mathbf{y} \leftarrow \mathbf{y}'$.

Step 5. Repeat the second to fourth step until $\sum_{i=1}^m \|\mathbf{y}'_i - \mathbf{y}_i\| \leq \varepsilon$ where ε is predetermined small number.

Step 6. Return the vector $\mathbf{y} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$ as the Nash equilibrium.

However, generally speaking, it is not easy to verify the conditions on the convergence of the iterative method for practical problems. If we indeed find a solution, then the problem is solved. Otherwise, we have to try other methods.

Case III. If the iterative method fails to find a fixed point, we may do it by solving the following minimization problem,

$$\begin{cases} \min R(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m) = \sum_{i=1}^m \|\mathbf{y}_i - r_i(\mathbf{y}_{-i})\| \\ \text{subject to:} \\ \mathbf{E}[g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \leq 0 \\ i = 1, 2, \dots, m. \end{cases} \quad (25)$$

If an array $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ satisfies that

$$R(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*) = 0, \quad (26)$$

then $\mathbf{y}_i^* = r_i(\mathbf{y}_{-i}^*)$ for $i = 1, 2, \dots, m$, and $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ must be a solution of (23). In a numerical solution process, if an array $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ satisfies that

$$R(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*) \leq \varepsilon, \quad (27)$$

where ε is a small positive number, we can also regard it as a solution of (23). That is, if the minimizing solution $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ of the minimization problem (25) is such that equation (26) or inequality (27) hold, then $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$ is a solution of (23). Otherwise, the system of equations (23) might be considered inconsistent. In other words, there is no Nash equilibrium of followers in the given bilevel programming.

Now let us take attention to the optimization problem (25). On the one hand, the objective function $\sum_{i=1}^m \|\mathbf{y}_i - r_i(\mathbf{y}_{-i})\|$ involves m mappings $r_i(\mathbf{y}_{-i})$, $i = 1, 2, \dots, m$, which we cannot expect to have perfect properties such that the objective function have good mathematical properties. On the other hand, the feasible set defined by the system of constraints $\mathbf{E}[g_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \leq 0$, $i = 1, 2, \dots, m$ may not be convex. For solve model (25), we have to employ some algorithms, which does not require specific mathematical analysis, but can provide good solutions of complex optimization problems.

GA is a stochastic search and optimization procedure motivated by natural principles and selection. GA starts from a population of candidate solutions rather than a single one, which increases the probability of finding a global optimal solution. Then GA improves the population step by step by biological evolutionary processes such as crossover and mutation, in which the search uses probabilistic transition rules, and can be guided towards regions of the search space with likely improvement, thus increasing the probability of finding a global optimal solution. In brief, the advantage of GAs is just able to obtain the global optimal solution fairly. In addition, GAs do not require the specific mathematical analysis of optimization problems, thus can be easily used to solve complex decision systems. Herein, we use genetic algorithms to search for the Nash equilibrium. For detailed exposition of GAs, interested readers may consult books [24][26][48].

For the optimization problem (23), each subproblem of the followers is a parametric optimization which may be solved by existing means of mathematical programming when the parameters are given. Since they are problem dependent, we do not discuss them here. Given a control vector \mathbf{x} , in order to solve the optimization problem (23) for the Nash equilibrium of the followers, we give the following GA procedure.

Step 0. Input a feasible control vector \mathbf{x} .

Step 1. generate *pop_size* chromosomes $\mathbf{y}^{(j)}$, $j = 1, 2, \dots, \text{pop_size}$ at random from the feasible set.

Step 2. Compute the system of equations $r_i(\mathbf{y}_{-i})$, $i = 1, 2, \dots, m$ for each chromosome $\mathbf{y}^{(j)}$, and then the objective values $\sum_{i=1}^m \|\mathbf{y}_i - r_i(\mathbf{y}_{-i})\|$, $j = 1, 2, \dots, \text{pop_size}$.

Step 3. Compute the fitness of each chromosome according to the objective values.

Step 4. Select the chromosomes by spinning the roulette wheel.

Step 5. Update the chromosomes by crossover and mutation operations.

Step 6. Repeat Steps 2–5 until the best chromosome satisfies inequality (27).

Step 7. Return the Nash equilibrium $\mathbf{y}(\mathbf{x}) = (\mathbf{y}_1(\mathbf{x}), \mathbf{y}_2(\mathbf{x}), \dots, \mathbf{y}_m(\mathbf{x}))$.

3.3 HIA for Stackelberg-Nash Equilibrium

For any feasible control vector \mathbf{x} revealed by the leader, it is reasonable for us to suppose that there always exists a Nash equilibrium with respect to it. Denote the Nash equilibrium with respect to \mathbf{x} by $(\mathbf{y}_1(\mathbf{x}), \mathbf{y}_2(\mathbf{x}), \dots, \mathbf{y}_m(\mathbf{x}))$, then the EVMLP (6) can be simplified as follows,

$$\begin{cases} \max_{\mathbf{x}} \mathbf{E}[F(\mathbf{x}, \mathbf{y}_1(\mathbf{x}), \mathbf{y}_2(\mathbf{x}), \dots, \mathbf{y}_m(\mathbf{x}), \boldsymbol{\xi})] \\ \text{subject to:} \\ \mathbf{E}[G(\mathbf{x}, \boldsymbol{\xi})] \leq 0. \end{cases} \quad (28)$$

The uncertain objective function $\mathbf{E}[F(\mathbf{x}, \mathbf{y}_1(\mathbf{x}), \mathbf{y}_2(\mathbf{x}), \dots, \mathbf{y}_m(\mathbf{x}), \boldsymbol{\xi})]$ involves not only uncertain parameters, but also a complex mapping $\mathbf{x} \rightarrow (\mathbf{y}_1(\mathbf{x}), \mathbf{y}_2(\mathbf{x}), \dots, \mathbf{y}_m(\mathbf{x}))$, which makes the optimization problem difficult to solve. Therefore, GA is a good choice for solving such model for the Stackelberg-Nash equilibrium, although it is a relatively slow way.

Now we integrate stochastic simulations, NNs, and GAs to produce an HIA for solving general EVMLPs. In the HIA, input-output data of uncertain functions are first generated by stochastic simulation. Then NNs

are trained on these sample sets to approximate uncertain functions. After that, the trained NNs, and the iterative method (or GA) for Nash equilibrium are embedded into a GA so as to search for Stakelberg-Nash equilibrium efficiently. The procedure of the HIA is given as follows.

Step 1. Generate input-output data of uncertain functions.

Step 2. Train NNs by backpropagation algorithm.

Step 3. Initialize *pop_size* chromosomes $\mathbf{x}^{(i)}$, $i = 1, 2, \dots, \text{pop_size}$ randomly.

Step 4. Compute the Nash equilibrium with respect to each chromosome $\mathbf{x}^{(i)}$ by Algorithm 3 (or 4), and then the objective values $\mathbf{E}[F(\mathbf{x}^{(i)}, \mathbf{y}_1(\mathbf{x}^{(i)}), \mathbf{y}_2(\mathbf{x}^{(i)}), \dots, \mathbf{y}_m(\mathbf{x}^{(i)}))]$ via the trained NNs, $i = 1, 2, \dots, \text{pop_size}$.

Step 5. Compute the fitness of each chromosome according to the objective values.

Step 6. Select the chromosomes by spinning the roulette wheel.

Step 7. Update the chromosomes by crossover and mutation operations.

Step 8. Repeat Steps 4–7 for a given number of cycles.

Step 9. Return the best chromosome as the optimal solution.

4 Numerical Examples

The computer code for the HIA to general EVMLPs with multiple followers has been written in C language. In order to illustrate its effectiveness, we provide two numerical examples performed on a personal computer.

Example. We consider a stochastic decentralized decision making problem in which there is one leader and three followers. Assume the control vector is $\mathbf{x} = (x_1, x_2)$, and the control vectors of the three followers are $\mathbf{y}_i = (y_{i1}, y_{i2})$, $i = 1, 2, 3$. Its EVMLP is given

as follows.

$$\left\{ \begin{array}{l} \max_{x_1, x_2} \mathbf{E} [(x_1 + y_{11} + y_{21} + y_{31} + \xi_1)^2 \\ \quad + (x_2 + y_{12} + y_{22} + y_{32} + \xi_2)^2] \\ \text{subject to:} \\ x_1 + x_2 \leq 10, x_1 \geq 0, x_2 \geq 0 \\ \text{where } y_i = (y_{i1}, y_{i2}) \ (i = 1, 2, 3) \text{ solve} \\ \left\{ \begin{array}{l} \max_{y_{11}, y_{12}} \mathbf{E} [\sqrt{x_1^2 + y_{11}^2 + 2y_{12}^2 + \eta_1^2}] \\ \text{subject to:} \\ y_{11} + 2y_{12} \leq x_2, y_{11} \geq 0, y_{12} \geq 0 \\ \max_{y_{21}, y_{22}} \mathbf{E} [\sqrt{x_1^2 + y_{21}^2 + 2y_{22}^2 + \eta_2^2}] \\ \text{subject to:} \\ 2y_{21} + 3y_{22} \leq x_2, y_{21} \geq 0, y_{22} \geq 0 \\ \max_{y_{31}, y_{32}} \mathbf{E} [\sqrt{x_1^2 + y_{31}^2 + 2y_{32}^2 + \eta_3^2}] \\ \text{subject to:} \\ 3y_{31} + 4y_{32} \leq x_2, y_{31} \geq 0, y_{32} \geq 0, \end{array} \right. \end{array} \right.$$

The stochastic parameters in the above model are given as follows:

$$\left\{ \begin{array}{l} \xi_1 \sim \mathcal{N}(3, 1) \\ \xi_2 \sim \mathcal{N}(4, 1) \end{array} \right\} \text{ and } \left\{ \begin{array}{l} \eta_1 \sim \mathcal{U}(0, 1) \\ \eta_2 \sim \mathcal{U}(1, 2) \\ \eta_3 \sim \mathcal{U}(2, 3). \end{array} \right.$$

In order to solve this problem, we generate input-output data for the uncertain functions

$$\begin{aligned} U_0 : (\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \mathbf{y}_3) &\rightarrow \mathbf{E} [(x_1 + y_{11} + y_{21} + y_{31} + \xi_1)^2 \\ &\quad + (x_2 + y_{12} + y_{22} + y_{32} + \xi_2)^2] \\ U_1 : (\mathbf{x}, \mathbf{y}_1) &\rightarrow \mathbf{E} [\sqrt{x_1^2 + y_{11}^2 + 2y_{12}^2 + \eta_1^2}] \\ U_2 : (\mathbf{x}, \mathbf{y}_2) &\rightarrow \mathbf{E} [\sqrt{x_1^2 + y_{21}^2 + 2y_{22}^2 + \eta_2^2}] \\ U_3 : (\mathbf{x}, \mathbf{y}_3) &\rightarrow \mathbf{E} [\sqrt{x_1^2 + y_{31}^2 + 2y_{32}^2 + \eta_3^2}]. \end{aligned}$$

by stochastic simulation. Then we train four NNs to approximate the uncertain functions U_i , $i = 0, 1, 2, 3$, respectively. Table 1 gives the number of input-output data, input, hidden, and output neurons of the four NNs, and the error defined by (19). In order to further illustrate the accuracy of the trained NNs, three types of samples are used for testing. The first is to select 1000 input-output data from the train set randomly. The second is to sample 1000 new input-output data from the predetermined domain. Another 1000 input-output data is generated by sampling 1000 feasible control vector, computing out their corresponding Nash equilibrium, and then the function values by stochastic simulation. From the comparison results of the average errors of the three type of samples in Table 2, we can see that the maximum average error defined by (20) is less than 2.8%. So the NNs are good approximations of the four uncertain functions.

uncertain functions	input-output data	input neurons	hidden neurons	output neurons	sum_squred error
U_0	3000	8	10	1	2100
U_1	3000	4	7	1	7.54
U_2	3000	4	7	1	2.16
U_3	3000	4	7	1	1.96

Table 1: Parameters in the four NNs of example 1

uncertain functions	number of samples	average error_1 (%)	average error_2 (%)	average error_3 (%)
U_0	1000	0.1855	0.3735	2.4455
U_1	1000	0.9681	1.8205	1.3860
U_2	1000	0.5692	1.1595	1.7615
U_3	1000	0.3858	0.7639	2.7921

Table 2: Comparison errors of three type of samples of example 1

In the GA procedure for the Stackelberg-Nash equilibrium, there are some parameters such as the population size (*pop_size*), the probability of crossover (P_c), the probability of mutation (P_m). In Table 3, we compare solutions when different parameters are taken with the same generations as a stopping rule. It appears that all the optimal solution and the optimum differ little from each other. In order to account for it, we present a parameter, called percent error, i.e. (actual value - optimal value)/ optimal value $\times 100\%$, where the optimal value is the minimal one of all the six maximum obtained above. The last column named by "error" in Table 3 is just this parameter. It follows from Table 2 that the percent error does not exceed 0.2% when different parameters are selected, which implies that the HIA is robust to the parameter settings and effective to solve model (6).

According to the computing result in Table 3, we can see that x_1 is very close to 0, and that x_2 is very close to 10. A direct computation of the control vector $(x_1, x_2) = (0, 10)$ shows that the optimal return of the leader is 652.77, the Nash equilibrium of the followers is

$$(\mathbf{y}_1^*, \mathbf{y}_2^*, \mathbf{y}_3^*) = (9.9999, 0, 4.9999, 0, 3.3333, 0),$$

and the optimal return of the three followers are 9.9876, 5.5016, and 4.1140, respectively.

5 Concluding Remarks

In this paper, two classes of stochastic multilevel programming models were first proposed for dealing with decentralized decision making problem in stochastic environment. In order to solve general the proposed models for the Stackelberg-Nash equilibrium, an HIA was designed by integrating stochastic simulation, NNs, GA, and iterative method. One numerical example showed that the HIA is robust and effective.

Abstract

The study aims to explore the factors that may trigger one to click through internet advertisements when one is searching for production information on the web. We begin our exploration with Nelson's ([5]) renowned theory where it asserts that goods with "search" qualities produce more search efforts than goods with "experience" qualities would do. The study shows that this assertion may not be true in the internet due to some specific features of the net.

1. Introduction

Internet advertising in recent years has become an important alternative to traditional advertising media, such as newspapers, magazines, television and so on. As the number of visitors in the internet increases, internet advertising also becomes the major metaphor to reach certain consumers who used to acquire information from magazines and newspaper but switch to internet nowadays. Nevertheless, the lack of effective measure for the performance of internet advertising dims advertisers' confidence for the new advertising medium. To this end, academics ([3]; [7]) have tried to align this new advertising medium along with its traditional rivals. It is enticing of doing the alignment with the traditional media, because if one could position this new media on the landscape composed of those traditional advertising media properly, one could conveniently apply traditional measurements directly or with minor adjustments onto this new medium.

Instead of attacking the measurement problem straightforwardly with the alignment approach above, rather, the present study seeks to explore the determinants affecting consumer's product information search behavior on the webs. Particularly, we would like to examine a specific feature – the click-through – which is a function that is only available in the internet advertising to conduct our observation of consumer's information search behavior. While traditional advertising media are difficult to trace viewers' encountering with the advertisements, the internet's click-through function provides an excellent tracing mechanism that can record web visitors' moves among web pages. This particular mechanism is achieved by monitoring and recording the so called IP (Internet

Protocol) address inherited by each web page. With this mechanism advertisers are able to investigate the advertising banners or icons on certain web pages whether or not they are perceived by web visitors. In other words, the click-through could be more precise tool in discovering whether or not a web visitor does aware of the presence of the advertisements on web pages. For the smart mechanism we are enticed to revisited Nelson's renowned theories about product information search behavior ([5]) as follows.

Nelson([5]) uses dress and canned tuna fish as examples to demonstrate that product quality information may be distinguishable as "search" quality and "experience" quality. A typical consumer who is looking for a dress may seek to try the dress with some fitting efforts whereas one is for a canned tuna fish may just buy the canned tuna fish and experience it at home. The key is whether or not the procurement is led with a prior search effort. The search effort typically comes with searching costs. Hence, Nelson's theory suggests that customers may reduce the sampling size for different brands when searching cost increases. Applying the theory to the internet advertising case, one may expect more click-through for the search goods than for the experience goods. In other words, when consumers are shopping on the web, they may choose to click on advertising banners or icons more often for search goods, e.g., dress, than for experience goods, e.g., canned tuna fish.

2. Research design

To test our hypothesis, we design a laboratory experiment to collect the necessary data for the testing. According to the Theory, experience goods are those products that their utilities to consumers cannot be justified before uses whereas searching goods can be compared solely according to product specifications. In the experiment, we firstly ask 60 experiment participants (call them subjects hereafter) to present they attitudes toward search and experience with respect to twenty-four products that are on the list of the most popular products on the web. The list is published by a government sponsored information provider.

^a Correspondent author.

We pick six products for our next stage experiment. Of the six products, two (computer magazine, Taipei-Kaohsiung fly ticket) are in the search goods domain where they show high scores on the search attitude, two (color in-jet printer, mobile phone) are in the middle where they toward neither the search nor the experience ends, and the other two (notebook computer, computer games) in the experience goods domain with high average experience attitude.

In the second stage, we ask another 33 subjects to participate the shopping experiment. The new subjects are asked pretending that they are perspective consumers for the chosen six products and need to collect product information on the web. Subjects browse through the internet to search for the product information. All of the web pages that subjects have been through are recorded as the log files in dedicated computers. In particular, the IP addresses with respect to each web page that subject visited are recorded. The log files are our raw data for

further analyses. Subjects are asked to finish the search within 90 minutes and are paid with NT\$ 300 dollars. (The regular pay for students in campus is around NT\$ 80 dollars for reader's reference.) After the search for six products' information is finished, subjects are ask to fill a questionnaire (translated from Zaichkowsky's ([4]) scale for Personal Involvement Inventory) about product involvement, subjective conceptions of the adequacy of information on the web, satisfaction regarding the information they gain through their searching, and some demographic questions.

3. Data analysis

Table 1 shows the web sites that are most popular to our subjects. The data is organized and analyzed with software – Webtrends.

Table 1 Most popular websites list (source: webtrends reports)

Most Popular Sites				
	Organization	Hits	% of Total	User Sessions
1	http://tw.yimg.com	3323	3.79%	40
2	http://www.china-airlines.com	3280	3.74%	8
3	http://w3.epson.com.tw	2615	2.98%	8
4	http://www.sogil.com.tw	1951	2.22%	23
5	http://www.enova.com.tw	1558	1.77%	12
6	http://ticket.ezfly.com	1514	1.72%	20
7	http://www.kimo.com.tw	1251	1.42%	39
8	http://shopping.yam.com	1214	1.38%	5
9	http://shopping.pchome.com.tw	1163	1.32%	13
10	http://www.evair.com.tw	1156	1.31%	6
Subtotal for Sites Above		19025	21.7%	174
Total for Log File		87649	100%	42

The experiment is conducted with real web pages, that is, we do not limit subjects within certain web pages. Consequently, the collected raw data, the log files, contains web pages that do not carry any advertisement. Thus, the web pages collected are firstly divided into two categories: with and without advertisements. To our testing we only analyze those web pages with advertisements. We would like to investigate whether or not the subjects choose to click-through or ignore those advertisements.

In addition to the cleanup of web pages without advertisements, we divide the advertisements into two types of either banner or non-banner type advertisements. This a control variable that may help our understanding that is the formats of internet advertisements a factor affect viewer's click-through choice.

Since the click-through data carries a count format, that is, either zero or positive integers, we conduct the analyses with Poisson regressions or Negative Binomial regressions ([1];[2]). To make a proper choice between the two analyses, we could utilize the Likelihood Ratio test (T_{LR}) and the Wald (T_W) test to test whether or not the count data is over-dispersed. Test results show that $T_{LR} = 109.77 > \chi^2_{0.98(1)} = 5.41$ and $T_W = 56.66 > Z_{.99} = 2.33$. This concludes the over-dispersion property for the count data. . As a result, we choose the Negative Binomial regressions for data analysis.

4. Results

Negative Binomial regressions on the dependent variable -- the count of click-through numbers of advertisements -- are shown in Table 2. There are two models in Table 2. The difference is in the independent variables that measure search goods attitudes or experience goods attitudes toward each product.

According to Nelson's([5]) theory, we expect to

observe more advertisement click-through for the search goods than for the experience goods. However, to our surprise, the counts of advertisement click-through are not positively correlated with search goods attitudes. The coefficient is -0.06 but not statistically significant. Rather, the counts are positively correlated with the experience goods attitudes. The coefficient is 0.10 and statistically significant at 95% level.

Table 2 Negative binomial regression on click-through count data

	Search goods model			Experience goods model		
	coefficient	Std.	Z	coefficient	Std.	Z
Search goods attitudes	-0.06	0.04	-1.25	—	—	—
Experience goods attitudes	—	—	—	0.10	0.05	2.19 *
Price	0.24	0.09	2.74 *	0.23	0.09	2.69 *

log likelihood	-529.619			-527.980		

Note. * presents p-value < 0.05

In addition to the contradiction results to our hypothesis, we have the following findings. First, price is a significant factor that would induce more advertisement click-through. The finding might be attributed to consumer's risk-averse attitude toward high value procurement. Second, banner type advertisement is less attractive to other types. This may be due to that viewers are insensate to the often seen advertisement format. Third, one who is used to collect product information on web for procurement references is more likely to click

through internet advertising banners or icons. Fourth, one who prefers internet advertising to TV advertising would incline to click through internet advertisements; nevertheless, this is not true for other media, including radio stations, magazines, outdoor advertising board and direct mailing. Finally, those who pay more attention to internet advertisements, their advertisement click-through counts drop significantly.

5. Conclusions and discussion

The contradiction result regarding the experience

goods attitude surprises us very much. Subjects made more click-through for the experience goods than the searching goods. According to Nelson's theory, consumers shall make more efforts to search for information regarding the searching goods. This is because consumers can fully identified products' utility of searching goods based on their specifications. And make fewer efforts to search for product information of experience goods, because the utility in consuming the kind of goods is difficult to communicate. Further investigation for the contradictive result was then conducted.

We went through those web pages that subjects had click through and found that for most of the searching goods, it is much easier for web-page information providers to construct complete information regarding the goods that the web sites aim to offer. For instance, a site called "EZtravel" is a local travel agent that provides fly tickets information. Web visitors can obtain a complete side-by-side comparison list regarding the flights during a certain period that visitors indicate; the visitors do not need further information search for the good.

However, on the other hand, for experience goods, it is much difficult for web-page information providers to construct a web site contains thorough information regarding the goods that the site is dedicated to. This is due to the difficulty in giving a full description of an experience good. Interestingly, internet is also a wonderful place for the sort of goods. A perspective consumer may seek other users' experience through some discussion forums. For instance, photo.net is a popular web site for people with photography hobby. The forums of the site provides thousands users' experience and comments regarding all sorts photography equipments. Our investigation showed that subjects spent most of their time in surfing around to gather the information they need for experience goods. As a result the number of click-through is less for searching goods compared to experience goods, which looks contradictive to Nelson's Theory.

In addition to the finding contradictive to Nelson's ([5]) theory, our results show a list of factors that may trigger or retard web viewers' interests in clicking through advertisements. We found that the price of goods increase the likelihood of click-through, and person with habit in collecting product information for one's procurement references, and person with preference of internet advertising over TV advertising are prong to click through

advertisements. Banner type advertisements retard viewers' inclination to click through and one who pays more attention to internet advertisements, their advertisement click-through counts drop significantly

Our study may contribute to the understanding of Nelson's Theory by amending a moderation factor to the Theory's projection, that is, the need for experience sharing and the cost to achieve the sharing.

Besides, the result may help to advice practitioners in advertising to aware his/her strategy in conducting advertisement on the web. According to our result, searching goods are much simpler to implement advertisement campaigns. It is less costly for searching goods to be promoted on the web. On the other hand, experience goods would take up more efforts to provide product information. It would be helpful to construct user forums to share their experience to convince perspective customers.

Even today, after the internet has been commercialized for almost a decade, the potentiality of the internet advertising, such as the banners and icons, may not be fully recovered. Internet advertising, for instance, provides an interactive environment where advertisement viewers can be promptly presented with the information they are interested in. Meanwhile, advertisers are obliged to the well built internet barebones system, so that they can deliver their internet advertisements inexpensively. Furthermore, internet advertising is not constrained with space and time horizon. On traditional media, magazines for example, the advertisements fade away with the deterioration of magazines. Also, the space that a magazine can provide is very limited; Advertisers may like to impress their perspective customers with more information. For all these merits that the internet advertising can provide, there is a dearth for our attention in discovering the full potentiality in it.

Abstract

Information systems (IS) outsourcing is an important issue of IS practices in organizations. To achieve better IS outsourcing performance, it is critical for organizations to develop appropriate outsourcing strategies. A prediction model is useful to forecast the possibility of a failure or to point out unforeseen problems. Based on a prediction model of IS outsourcing success, this study applied a constraint-based evolutionary approach for backward tracking the optimal values of organizational IS attributes that best approximate the target success level of IS outsourcing. One hundred forty-six real IS outsourcing cases, each with 22 features and 8 outcome features, are collected. The proposed system demonstrated that valuable suggestions can be made regarding the increase or decrease levels of adjustable IS attributes for organizations outsourcing their IS functions.

1. Introduction

Information systems (IS) outsourcing is an important option in managing the increasingly complex IS functions of organizations. Decisions for organizations to outsource part or all of IS functions are typically motivated by advantages in the competitive business environment. The main reasons for a corporation outsourcing IS functions include cost savings, accessing to new technologies and IS/IT expertise, focusing on its core business, improving IS service, and et al. [20]. However, without convincing possibilities of gaining such advantages, few organizations are willing to commit enormous resources and risk the loss of control over an important management function [23]. To make better IS outsourcing decisions and to achieve higher IS outsourcing performance, it is critical for organizations to develop appropriate IS outsourcing strategies.

Basically, appropriate IS outsourcing strategies can be formulated if effective models in predicting IS outsourcing success are employed. A prediction model can be used as a “What-If” mechanism to forecast the possibility of a failure outcome or to point out unforeseen problems. Our previous research developed a case-based system with a two-level weights design to predict IS outsourcing success [10, 11]. With the IS attributes of organizations as the case features, the proposed prediction model is able to forecast the potentially resulted benefits of IS outsourcing.

Based on the prediction model, this study further applies an evolutionary-based optimization technique to find out the decent values of adjustable IS attributes that best approximate the target success level of IS outsourcing. This is a parameter design problem that requires a backward tracking mechanism in search for the corresponding optimal values of adjustable input variables to match the target values of the outcome variables. That is, the optimal value of each adjustable input variable in the prediction model can be found to meet the expected outcome of IS outsourcing success within its valid value range if exists. The constrained-based genetic algorithms (CBGA) approach is employed for reducing the huge search space occurred in a parameter design problem.

The next session discusses the nature of IS outsourcing, strategy and success. This is followed by the methodology section that describes the CBR, a review of our previous study, that is, the case-based prediction model of IS outsourcing success, then the CBGA approach intended to resolve the parameter design problem in the domain of IS outsourcing. The final two sections discuss the experiment, the potential use of the results, and the possibilities for future research.

2. IS Outsourcing, Strategy, and Success

Today IS outsourcing has changed in many ways. For example, outsourced IS services are more likely to be telecommunication planning and applications [18], systems integration [8], and covering multiple systems and larger assets [7]. These changes make IS service providers increasingly involve in the business operations of the outsourcing corporations. The corporations therefore be more dependent on the capabilities of their IS service providers. Traditional “make or buy” thinking of IS outsourcing ignores the long-run and possible strategic implications [13]. IS outsourcing has become more strategic important than the view in the past.

As the scope and complexity of IS outsourcing expand, the reasons for corporations outsourcing their IS functions focus on business and technical considerations in addition to mere financial purposes. Financial benefits include cost saving and control, the economy of scale for IS resource and et al [9, 5]. Technical benefits include improving IS service, accessing to new technologies and technical talent [15]. Business benefits refer to the ability of a firm to focus on its kernel business and the enhancement of IT

capabilities [9, 21].

Grover et al. [9] assessed IS outsourcing success in terms of attainment of these benefits and defined success of outsourcing as the satisfaction with benefits from outsourcing gained by an organization as a result of deploying an outsourcing strategy. Their result showed that the relationship between the extent and success of outsourcing is likely to vary with different IS functions especially with system operations/ network management and maintenance. Lee [16] also examined the relationship between knowledge sharing and IS outsourcing success. His findings indicate that the service receiver's ability of absorbing the needed knowledge has a significant effect on IS outsourcing success.

In addition to the IS outsourcing extent and the knowledge sharing ability, a successful IS outsourcing practice also needs to address some important issues such as outsourcing evaluation [3], risk assessment [6], IS service provider selection [12], contract negotiation [14], and partnership cultivation [24]. However, most IS outsourcing researches focused on the decision model, the contract design and the relationship development required for effective outsourcing rather than IS resources management within an organization. This study employs a constraint-based evolutionary approach to determine the optimal values of organizational IS attributes. The result can be applied in guiding the IS resource allocation and investment so that the performance of the delivered IS resources can best approximate the target success level of IS outsourcing.

3. Methodology

3.1 Case-based Reasoning

CBR is a problem-solving method that is similar to the analogical decision making process. CBR can be considered as a reasoning process shown in Figure 1 [4].

Figure 1. The CBR process

Figure 2. Two-level weight design

A description of the current problem as the input case is put into the CBR systems. The system retrieves the similar cases stored in a case base and then adapts similar cases to construct a solution for the current problem. The solution is later evaluated through feedback from the user or the environment. The new case can be incorporated into the case base for the use in future problem-solving.

A case is represented with features tied to a context. A case base consists of previous cases and their corresponding solutions. For each input case, features are used as indexes for retrieving similar cases. A weight is usually assigned to each case feature representing the importance of that feature to the match of the input case and retrieved cases. To design an appropriate case-retrieval mechanism in the retrieval stage, there are many evaluation functions for measuring the degree of similarity. An example of a similarity function containing the weights in the formula is shown in the following equation (1).

$$\sqrt{\sum_{i=1}^n W_i \times (f_i^I - f_i^R)^2} \quad (1)$$

where W_i is the weight of the i th feature, f_i^I and f_i^R are the value of feature i in the input and retrieved case, respectively.

3.2 A Review of Previous Study

3.2.1 Two-level Weight Design

Hsu et al. [10, 11] have developed a case-based system with a two-level weight design to predict IS outsourcing success. To apply CBR to the IS outsourcing domain, IS outsourcing cases are collected from the questionnaire consists several IS attributes constructs within which question items are incorporated. These items are used to measure the constructs that are adapted from IS outsourcing literatures [2, 19, 17, 1, 9].

In the two-level weight design, as shown in Figure 2, there are several features sets ($Group_i$) according to the specific domain knowledge tied to the constructs. Each feature (f_{ij}) has a weight (w_{ij}) representing the importance of that feature to its corresponding group in the first level. In the second level, each feature set also has a weight (W_i) representing the aggregate importance of the group to the match of the input and retrieved cases.

where $i = 1$ to m , m is the total number of feature groups in a case. $Group$ is the i^{th} feature group. $j = 1$ to n_i , and n_i is the number of features in the i^{th} group. f_{ij} is the value of the j^{th} feature in the i^{th} Group. w_{ij} is the weight of the j^{th} feature in Group i , and capital W_i is the weight of the i^{th} Group.

In Figure 3, a similar notation is applied to the outcome features. Assume that there are q outcome features, where $i = 1$ to q , q is the total number of outcome features, and O_i is the i^{th} outcome feature value.

Figure 3 . Outcome feature

3.2.2 The Case-based Prediction Model

The overall system framework of the case-based prediction model is presented in Figure 4. The system consists of four major processes: *similarity process*, *weighting process*, *adapting process*, and *evaluation process*. The first two are corresponding to the retrieval phase in Figure 1.

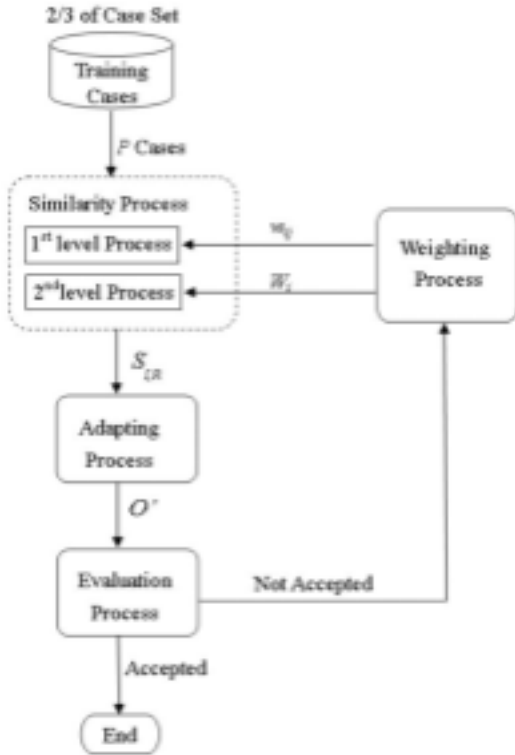

Fig 4. System architecture of prediction model

To effectively retrieve similar cases, the Similarity Process computes the similarity ($S_{i,R}$) between the input case and retrieved cases. The Weighting Process generates the weights to support the Similarity Process in which the GA is employed to determine w_{ij} and W_i . The $S_{i,R}$ is computed through two levels. In the first level, the similarity process computes similarities for each feature group ($S_{Group i}$) based on equation (2). In the second level, the similarity process computes the aggregate similarity

($S_{i,R}$) between the input and retrieved cases based on equation (3).

$$S_{Group i} = \sqrt{\sum_{j=1}^{n_i} w_{ij} \times \frac{1}{1 + |f_{ij}^I - f_{ij}^R|}} \quad (2)$$

$$S_{i,R} = \frac{\sum_{i=1}^m W_i \times S_{Group i}}{\sum_{i=1}^m W_i} \quad (3)$$

where $i = 1$ to m , m is the total number of feature groups in a case. $j = 1$ to n_i , n_i is the number of features in the i^{th} group, w_{ij} is the weight of the j^{th} feature in Group i , f_{ij}^I and f_{ij}^R are the values of the j^{th} feature in Group i for the input and retrieved cases, respectively. $S_{Group i}$ is the degree of similarity for the i^{th} Group, W_i is the weight of the i^{th} Group, and $S_{i,R}$ is the aggregate similarity degree between the input and retrieved cases.

The Adapting Process aims to apply the outcome features of the most similar cases to generate a solution for the current problem, that is, the expected outcome features for a certain input case. This process adopts the cases with top 10% $S_{i,R}$ to generate a solution for the input case. If there are k cases with top 10% $S_{i,R}$, the expected outcome feature O_i' is computed based on equation (4). The composite outcome feature O' is computed by averaging the sum of all the expected outcome features O_i' , as shown in equation (5).

$$O_i' = \frac{\sum_{t=1}^k [S_{i,R}^t \times O_i^t]}{\sum_{t=1}^k S_{i,R}^t} \quad (4)$$

where $t=1$ to k , k is the number of cases with the top 10% $S_{i,R}$, $S_{i,R}^t$ is the t^{th} case with 10% $S_{i,R}$. O_i^t is the i^{th} outcome feature of the t^{th} case with the top 10% $S_{i,R}$. O_i' is the i^{th} expected outcome feature.

$$O' = \frac{\sum_{i=1}^q O_i'}{q} \quad (5)$$

where $i=1$ to q , q is the number of outcome features and O' is the composite outcome feature.

The Evaluation Process compares the expected outcome feature with the real one. As shown in equation (6), the Mean Absolute Error (MAE) is applied to evaluate the result.

Minimize

$$Y = \frac{\sum_{t=1}^p |O_t' - O_t|}{p} \quad (6)$$

where $t=1$ to p , p is the number of training cases. O_t' and O_t are the expected and real outcome feature of the t^{th} training case, respectively. Y is the Mean Absolute Error (MAE).

Chromosomes of the GA are designed for encoding the two-level weights. The fitness function is defined as the equation (6). The entire learning process stopped after 500 generations and generated the best approximate two-level

weights. Once these derived values were applied, this case-based prediction model demonstrated more accurate results than the equal weights approach and the regression method [10, 11].

3.3 A CBGA Approach

The overall CBGA system framework is presented in Figure 5. The CBGA approach integrates the constraint-based reasoning technique into the GA process. In general, the GA deals with constraints either by integrating a penalty into the fitness function (denoted as soft constraints) or by abandoning those invalid chromosomes after the whole population has been generated (denoted as hard constraints). The CBGA uses the constraint-based reasoning technique to perform the chromosomes filtering before each chromosome is constructed. For every gene in a chromosome, the CBGA checks the defined valid range to assure that chromosomes are made valid. That is, chromosomes are made to satisfy the requirements of constraints. Instead of checking chromosomes after they are constructed, the CBGA

excludes invalid chromosomes being made and therefore considerably reduces the search space compared with the general GA approach. The CBGA approach is especially suitable for solving a parameter design problem in which the search space could become very huge as the number of adjustable input variables increases.

Figure 6 illustrates the CBGA chromosome filtering process. A constraint-based reasoning technique called the local propagation is adopted. The local propagation uses the information local to the constraints to define the valid gene range (G_j domain). According to the restricted valid range denoted by the satisfactory universe S_{G_j} , the value of gene g_j is replaced by a value randomly selected from S_{G_j} if the gene value is inconsistent with the constraints. By continuously executing the validation process on chromosome $C_i(g_{i1}, g_{i2}, \dots, g_{ij}, \dots, g_{im})$ in sequence ($j=j+1$), the new chromosome C'_i is thus able to satisfy the constraints. As a result the local propagation offers an efficient way to guide the GA toward searching for the optimal solution by reducing the search space already filtered because of the constraints.

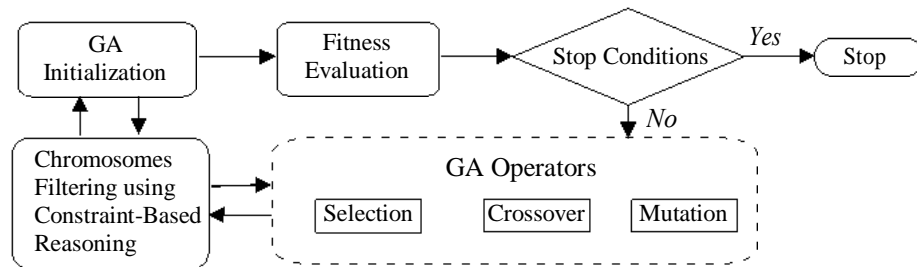

Figure 5. The CBGA system framework

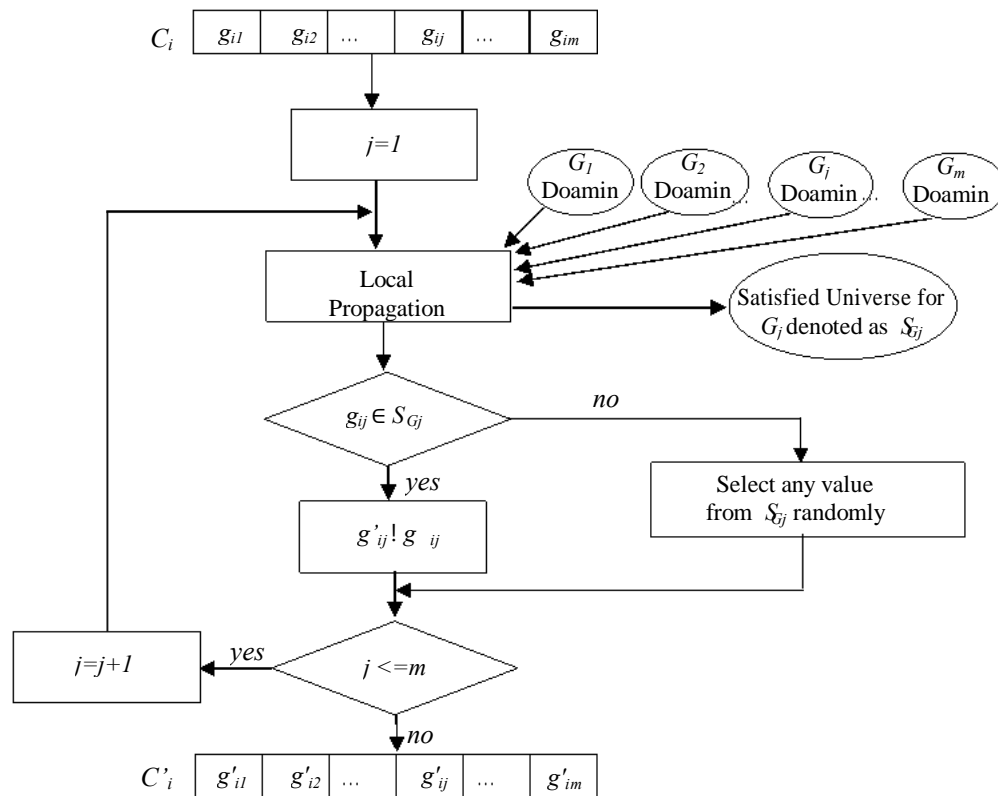

Figure 6. The chromosome filtering process

To apply CBGA to the IS outsourcing success domain, chromosomes are designed for encoding the values of the adjustable IS attributes. Their valid value ranges are considered as possible constraints. The fitness function is defined as the equation (7) in which the case-based prediction model ($CBR()$) is used to determine the predicted success level (O') for each chromosome (C') in the population. And O represents the target success level of IS outsourcing which has been set in advance. The function is to minimize the overall difference between the predicted outcome and the target one.

$$\text{Minimize} \\ \text{fitness} = |O - O'|; \text{ where } O' = CBR(C') \quad (7)$$

4. The Experiments and Results

4.1 Case Description

Companies may outsource various services and products. To differentiate IS outsourcing from the diversity of outsourcing, the characteristics of the outsourcing target, IS attributes, are the basic components in describing the IS outsourcing situation. As shown in Table 1, four IS attributes are proposed as features for the IS outsourcing case, including IS asset specificity, IS measurement problem, IS strategic importance, and IS capability. The alphanumeric marks in the brackets used in Table 1 are the same as that used in Figures 2.

Table 1. Features for the IS Outsourcing Case

IS Asset Specificity($Group_1$)	
Hardware & Other Equipments($f_{1,1}$)	
Required IS Knowledge & Skills($f_{1,2}$)	
Required Domain Knowledge & Skills($f_{1,3}$)	
Operational Procedure($f_{1,4}$)	
Trainings of IS Personnel($f_{1,5}$)	
IS Requirements of Business($f_{1,6}$)	
IS Measurement Problem($Group_2$)	
Procedures of Most IS Activities($f_{2,1}$)	
Change Frequency for Above Procedures($f_{2,2}$)	
Output Quality Prediction($f_{2,3}$)	
Proportion of Routine Tasks($f_{2,4}$)	
Efficiency of IS Problem Solving($f_{2,5}$)	
IS Strategic Importance($Group_3$)	
The Way of Doing Business($f_{3,1}$)	
Product or Service Differentiation($f_{3,2}$)	
Timing of Market Entry($f_{3,3}$)	
Imitation by Competitors($f_{3,4}$)	
Contribution to Product or Service($f_{3,5}$)	
Connection to Business Strategy($f_{3,6}$)	
IS Capability($Group_4$)	
Hiring of Best IS Personnel($f_{4,1}$)	
Learning of Advanced IT($f_{4,2}$)	
Periodical Education Training($f_{4,3}$)	
Morale of IS Personnel($f_{4,4}$)	
Problem Solving Capability of IS Personnel($f_{4,5}$)	

IS asset specificity. This attribute refers to the degree to which an IS asset can be applied to alternative uses or users with loss of value. The specificity arises when firms have their IS assets for customized usage. The asset items are selectively adapted from Loh [17], Aubert et al. [2], and Ang and Cummings [1].

IS measurement problem. This attribute indicates the difficulty (or problems) of measuring the IS services and their output qualities. The minor is the IS measurement problem, the clearer the procedures of most IS activities. The measurement problem items are derived from Aubert et al. [2].

IS strategic importance. This attribute means the importance of using IS for a corporation to achieve its strategic goals. The strategic importance items are integrated from Loh [17] and Nam et al. [19].

IS capability. This attribute refers to the IS knowledge and skills capacity possessed by the IS personnel in a corporation. The IS capacity items are primarily adapted from Nam et al. [19].

The outcome features, IS outsourcing success, describes the eight IS outsourcing benefits including the degree of (a) focusing on kernel business, (b) the enhancement of IS capability, (c) accessing to the channels of IS professionals, (d) the economy of scale for human resource, (e) the economy of scale for IS resource, (f) the control of IS expenditure, (g) reducing the risk of outdated IS/IT, and (h) accessing to the channels of key IS/IT. These benefit items are primarily adapted from Grover et al. [9].

4.2. Case Collection

Based on the above case description, a cross-sectional questionnaire was developed for collecting IS outsourcing cases from a group of large-sized organizations in Taiwan. Formal interviews with five IS managers were conducted to provide valuable ideas and insights into developing the questionnaire. Ten other IS managers were pre-tested with the entire questionnaire to ensure the face validity. The sample population consisted of 1729 large organizations in Taiwan, including the top 1000 firms in the manufacturing industry, top 500 in the service industry, top 100 in the financial industry, and 129 government institutions. The final questionnaires were distributed to IS managers at 576 organizations by systematically sampling one third of this population. Each IS manager was asked to rate on a scale of 1-5 about his or her perception with the questionnaire items. One hundred forty-six IS outsourcing cases were collected, yielding an effective response rate of 25.57% (146/571).

4.3 CBGA Control Parameters

Chromosomes are designed for encoding the values of the adjustable IS attributes. The fitness function is defined as the equation (7). The key defined CBGA parameters consist of the population size, crossover rate, and mutation rate. A theory that can concisely guide the assignment of these values is rarely seen [22]. Initially, the

following values were adopted in this research. The population size was 100, crossover rate was 0.6, and mutation rate was 0.01. The entire process stops either that the solution converges or after 500 generations.

4.4 An Example and Potential Use of the Result

This research suggests that appropriate organizational IS attributes can be found to best approximate the target success level of IS outsourcing. The success level of IS outsourcing is rated on a scale of 1-5 regarding attainment of the eight IS outsourcing benefits. Assume an organization is not satisfied with benefits from outsourcing gained as a result of deploying an outsourcing strategy. In order to explore the appropriate organizational IS capability at the success level of four for instance, the CBGA system can generate suggestions about the optimal levels of the capability items of in Table 1, including the effort to recruit the best IS personnel ($f_{4,1}$) and to learn the advanced IT ($f_{4,2}$), the frequency to provide periodical education training ($f_{4,3}$), the endeavor to raise IS personnel moral ($f_{4,4}$) and to improve the problem solving capability of IS personnel ($f_{4,5}$). Chromosomes are designed for encoding the values of the five adjustable IS capability

items, which may use a number of -1 ~ 1 (that is the range of -100% ~ +100%) to represent the recommended change direction and percentage. The constraints can be set as their feasible ranges of adjustment (that is any ranges between -100% ~ +100%). The results make suggestions regarding the increase or decrease levels of these IS capability items for organizations to modify their IS resource allocation decisions and investment plans. This research provides the information with highly strategic values as IS outsourcing becomes a more strategic important practice to organizations.

5. Future Research

As shown in Figure 7, the entire system consists of the CBR prediction module and the proposed optimization module. Users can issue queries to inquire the possible outsourcing outcomes as well as to wait for the optimization module to prompt the suggestion leading to target outcomes. In the future, the proposed system is planned to be installed on the Web portal for public access after thorough system verification and testing.

Abstract

The Monte Carlo approach is a valuable and flexible computational tool in modern finance, and is one of numerical procedures used for solving option valuation problems. In recent years the complexity of numerical computation in financial theory and practice has increased and require more computational power and efficiency. Monte Carlo simulation is one of the numerical computation methods used for financial engineering problems.

The drawback of Monte Carlo simulation is computationally intensive and time-consuming. In attempt to tackle such an issue, many recent applications of the Monte Carlo approach to security pricing problems have been discussed with emphasis on improvements in efficiency. This paper presents a novel approach combining system simulation with GA-based optimization to pricing options. This paper shows how the proposed approach can significantly resolve the option pricing problem.

Keywords: Option Valuation, Financial Engineering, Monte Carlo Simulation, Genetic Algorithms

1. Introduction

As pointed out by Hull and White [19, p.237], many option pricings appear to present intractable pricing problems. Therefore, most of them lack straightforward closed form solutions. The various approaches including analytic approximations [3] [22] and numerical procedures [5] [9] [10] [27] have been suggested for calculating option prices when there is no closed form solutions. In recent years the complexity of numerical computation in financial theory and practice has increased enormously, putting more demands on computational speed and efficiency. One of the numerical computation procedures, the Monte Carlo approach, was suggested by Boyle [5], and has proved to be a valuable and flexible computational tool in modern finance. The method simulated the process generating the returns on the underlying asset and invokes the risk neutrality assumption to derive the value of the option.

Numerical methods are used for a variety of purposes of finance. The Monte Carlo approach is a useful tool for many of numerical calculations, evidenced in part by the voluminous literature of successful applications, such as the stochastic volatility applications [11] [18] [20] [29], the valuation of mortgage-backed securities [28], the valuation of path-dependent options [21], the portfolio optimization [25], and the valuation of interest-rate derivative claims [8].

The Monte Carlo approach is flexible and easy to implement and modify. In addition, the increased availability of powerful computers has enhanced the attractiveness of the approach. Anyhow, there are some disadvantages of the approach but in recent years progress has been made in overcoming them. One drawback is that for very complex problems a large number of replications may be required to obtain precise results. Different variance reduction techniques have been developed to increase precision. Two classical variance reduction techniques are the control variate approach and the antithetic variate approach. The introduction of an appropriate control variate provides a very efficient variance reduction technique. However, in some problems it may be difficult to find a suitable control variate. Another alternative approach, the antithetic variate is often easier to apply since it concentrates on the procedure used for generating the random deviates. Essentially this technique relies on the introduction of negative correlation between two estimates. The performance of antithetic variate is better than Monte Carlo approach, but not good as control variate approach.

All these numerical approach have a dual objective of accuracy and computation speed. Therefore, improvements in numerical efficiency are of interest in solving option pricing problems for existing numerical procedures. The main purpose of this paper is to show how system simulation with optimization mechanism can be used to improve the efficiency of the numerical approach. And the result of our experiments has proved that our proposed approach has the better performance either in accuracy or speed of computation than Monte Carlo approach and antithetic variate approach.

2. Methods for Option Evaluation

2.1 System Simulation

Real-world problems always contain too many uncertain factors to be simply described by decision models. Simulation is one of the possible ways to be used to model real-world problems. Many aspects are concerned when adopting simulation approach to a complex problem [26].

- (1) It can be used to experiment with a new design or scheme before implementing it.
- (2) It can be used to enable the study of the internal interactions of a complex system or subsystem within a complex system.
- (3) It provides the analyst with a tool to conduct various experiments that can be done in real time.
- (4) Organizational and environmental changes can be simulated and the effect of these changes on the model's behavior can be observed.
- (5) It can be used as a tool to validate analytic results.
- (6) Simulation provides a flexible mean to experiment with the system or its design. Such experiments can reveal and predict valuable information to the designer, user, manager and purchaser.
- (7) Simulation is a cost-effective tool for capacity

planning and tuning of system or subsystems.

In addition, system simulation has several major advantages as listed as follows [26] :

- (1) Flexibility: It permits controlled experiments.
- (2) Speed: It permits time compression operation of a system over extended period of time.
- (3) It permits sensitivity analysis.

However, system simulation has some disadvantages. These are listed below [26] :

- (1) It may become expensive in terms of computer time and manpower.
- (2) There are some hidden critical assumptions that may affect the credibility of the simulation outputs.
- (3) It may encounter extensive development time.
- (4) It may encounter difficulties in model's parameters initialization.
- (5) Not all of parameters are considered when developing system simulation.

Although system simulation has those shortcomings as mentioned above, there are still some ways to improve these drawbacks. GAs can be adopted to enhance its lack of search efficiency to bring better outcomes. For input of parameters, the previous fixed parameters can be replaced with different statistic distribution to more closely reflect real world situations. The process of system simulation is shown in Fig. 1.

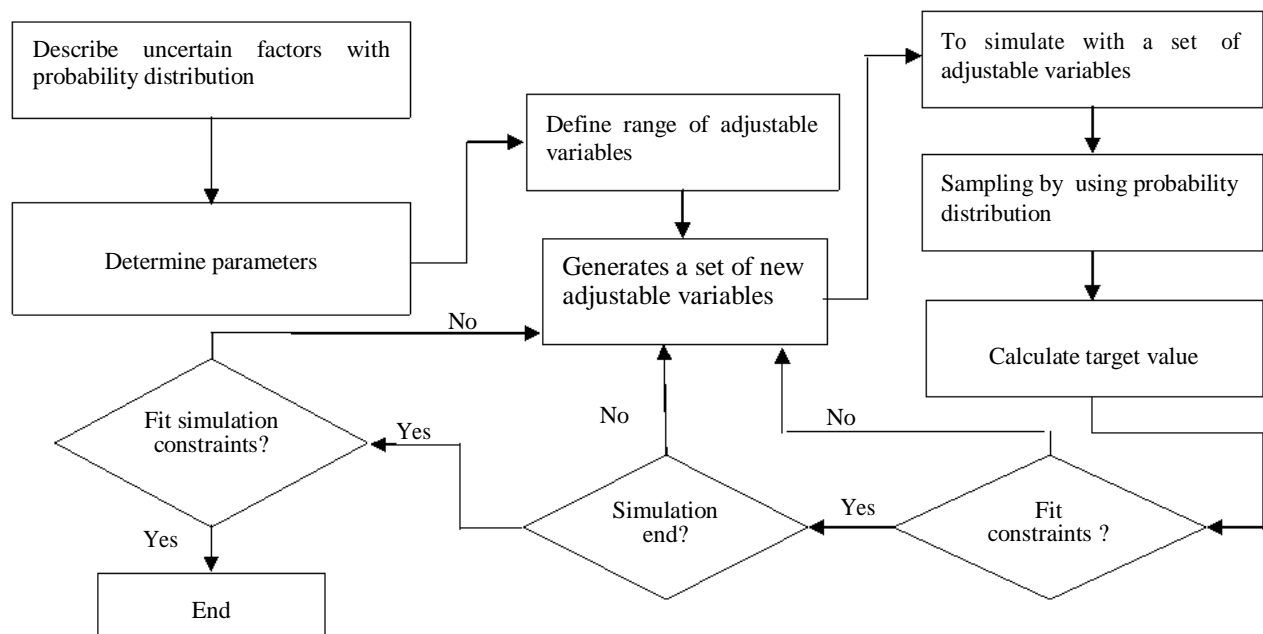

Fig. 1 The Concept of System Simulation

2.2 Monte Carlo Simulation

System simulation takes different environmental factors into consideration to produce different outcomes. We can observe the pattern of environmental changes by system simulation technique. System simulation provides an elastic environment and system to show the results

that is valuable information for managers [2] [6].

There are three main methods for system simulation technique. They are Monte Carlo simulation [1] [2] [29] [31], trace-driven simulation [24] and discrete event simulation [24]. Monte Carlo simulation is a static system simulation technique and does not include time factor. It's widely used in statistic models

whose property will not shift as time goes. It can also be used in non-probability expression (by statistic technique). It allows users to set up statistic distribution or object function along with randomly generated values and iterative computation to figure out all possible solutions. In this way, computers will test every set of inputs to achieve optimization.

System simulation technique can reflect various kinds of solutions or projects under uncertainty [24]. Its solutions, however, are not necessarily the optimized ones. Combining with optimization techniques is then becoming worth developing. Some lectures in addition reveal that using GAs when optimizing can speed up the time to search for solution [31].

In the iterative simulative process, the statistic distributions in variables will be sampled with one new value during every system simulation. This action is a method to simulate risks. After all variables are given values, they will be the inputs of the optimization process. Monte Carlo simulation can be applied to optimization problems with uncertainty and huge search space. When combining system simulation and GAs, we can solve problems with uncertainty quickly by guiding the direction of expected solutions. This has been proposed in [30][32].

2.3 Genetic algorithms

Optimization is a process of finding out an optimum solution from a problem where the searching space is likely enormous. Most of these problems contain many variables, which are restricted by some given constraints [13] [14] [22].

Genetic algorithm (GAs) is one of optimization algorithm [12] [25]. It uses fitness function to determine the direction of searching and does organism-like computation. It converts “The fittest survives” from Darwin to simulate reproduction, crossover and mutation of chromosomes. Through the above computation process, it selects out successful evolving chromosome, that is, the desired chromosome [16]. There are three basic operators in GAs computation process:

- 1.Reproduction: it duplicates one chromosome directly.

- 2.Crossover: it takes two chromosomes to exchange their genes to produce the other two chromosomes.

- 3.Mutation: some genes in a single chromosome may change to produce the other different chromosome.

After generations of reproduction, crossover and mutation, genes in chromosomes change and the chromosome is selected with the highest fitness value. It can promise a chromosome with better genes than before. In this way, GAs is a method to search for optimized solution and can be applied to problems with enormous solution space. The concept of GAs process is shown in Fig. 2. It uses a loop from fitness evaluation to

stop condition along with mechanisms of reproduction, crossover and mutation to make a new solution (new generation) evolve.

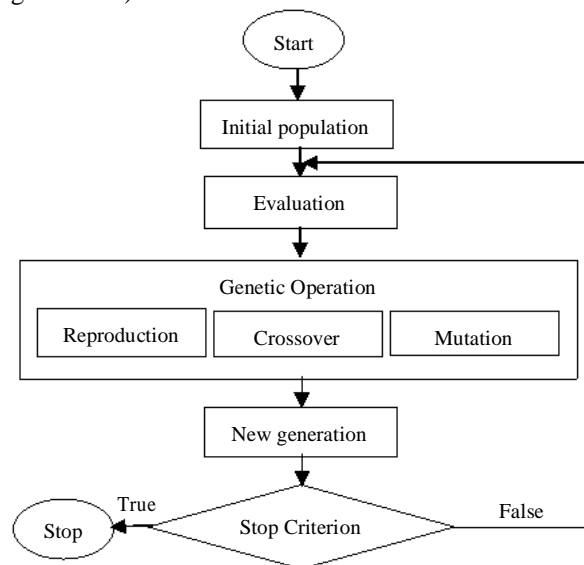

Fig. 2 The Genetic Algorithm Process

2.4 Simulation Optimization

Simulation optimization is an optimization in itself; however, it requires additional mechanism to make the entire optimization process much closer to real world [1]. The concept of simulation optimization can be conceptualized in Fig. 3.

Fig. 3 The Concept of Simulation-Optimization
abstracted from [34]

The optimization strategy is improved through generations. The improving process is, however, slightly different from other original GAs methods. It is influenced by the simulation model that iteratively sample values from statistic distributions of the optimization model. The iterative samplings are called iterations in this paper, and one single simulation consists of iterations. The amount of iterations in one single simulation can be arbitrary, however, the more the better. That's because from statistic viewpoint, more sampling values can represent more statistic population and can reflect much closer to the real-world situation. The concept of simulation combined with GAs is illustrated in Fig. 4.

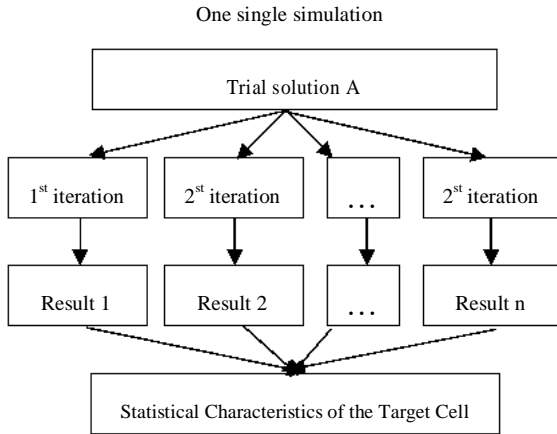

Fig. 4 The Iteration Concept

It can be briefly described that one single simulation equals to one chromosome in GAs, but simulation consists of additional computations, that is, iterations. As a result, the fitness value for each generation is no longer one value but statistical characteristics, such as mean, standard deviation, variation, skewness, kurtosis and so on. Usually the mean is a good choice for its stable property to stand for population. Therefore, the proposed methodology attempts to employ simulation-optimization concept in the option pricing problem.

3. Methodology

3.1 European Call Option Evaluation Model

Consider European Call Option [17] dependent on a single market variable S (stock price) that provides a payoff at time T . Assume that interest rates are constant, and we can value the derivative as follows:

- (1) Sample a random path for S in a risk-neutral world. Using the properties of the lognormal distribution that we can generate the distribution of stock prices one period hence by forming the random variables,

$$S_{t+1} = S_t \exp\left((r - 0.5\sigma^2)\Delta t + \sigma\epsilon\sqrt{\Delta t}\right) \quad (1)$$

where ϵ is a normally distributed random variable with zero mean and unit variance. S_t represents the current stock price and Δt is the stock price changes in a small time.

- (2) Calculate the payoff from the European Call Option (i.e. $\max[S_T - E, 0]$). E represents exercise price.
- (3) Repeat steps 1 and 2 to get many sample values of the payoff from the derivative in a risk-neutral world.
- (4) Calculate the mean of the sample payoffs to get an estimate of the expected payoff in risk-neutral world.
- (5) Discount the expected payoff at the risk-free rate to get an estimate of the value of the derivative.

3.2 Simulation Optimization

In this study we adopt simulation optimization method in order to research European call option pricing problems. Although system simulation has some advantages such as flexibility, speed, and sensitivity analysis etc., it may encounter difficulties in model's parameters initialization and not all of parameters are considered when developing system simulation. Genetic algorithms could provide strong multi-dimensions search ability to find fitness parameters and an optimal combination from different parameters. Therefore, system simulation could integrate with genetic algorithms, not only to make up genetic algorithms without simulation framework, but also to express problems with high uncertainty to raise system fault tolerance ability. System simulation integrated with genetic algorithms will bring both sides advantages, not only to construct models more fit in real world, but also to find better decision information.

The integration of system simulation and genetic algorithms procedure framework is shown in Fig. 5, and the execution steps are illustrated as blow:

- (1) To describe uncertain factors characters, then search fitness probability distribution, and determine simulation statistics parameters (ex. a mean value, standard deviation).
- (2) Determine input variables, and settle adjustable variable's range of value.
- (3) Generate a set of new adjustable variables with genetic algorithms.
- (4) To estimate new population's fitness function.
- (5) To test if new population meet conditions? if not matched, then repeats step 4.
- (6) To simulate with a set of new adjustable variables.
- (7) Sampling with probability distribution and compute target value.
- (8) If target value out of range of adjustable variables, then repeat steps 3~8, otherwise go to the next step.
- (9) To check if simulation procedure is completed or not? If yes, then go to next step, otherwise repeat step 6~9.
- (10) To check if target value is within the scope of simulation? If yes, then go to the next step, otherwise repeat step 3~10.
- (11) If the value is optimal, then end, otherwise repeat step 3~10 until the value is optimal.

The simulation optimization methodology as mentioned above uses system simulation to do sampling and the genetic algorithms to find adjustable variables, which procedure is shown in Fig. 6. It could help to understand how system simulation integrated genetic algorithms method finds the best value. Here, the system simulation technique is Monte Carlo simulation. Its main concept is to sample very large size of data from the given statistic distribution (that is, stock price here) and they apply these values to the optimization solution mentioned before. Doing so will make the optimization process of simulation much closer to the real world situation.

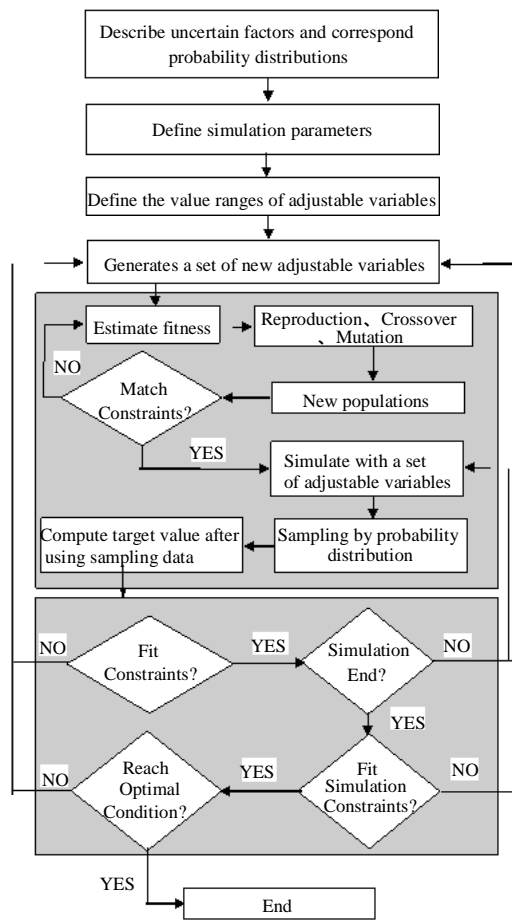

Fig. 5 The System Simulation Optimization Process

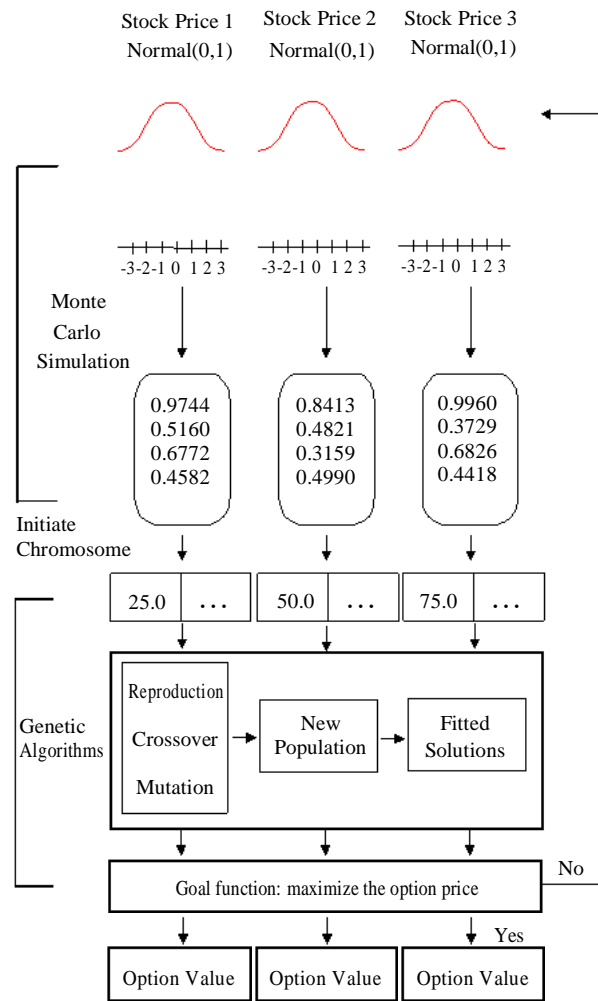

Fig. 6 The Process by Monte Carlo Integrated Genetic Algorithm

4. The Experiments

4.1 Data Sets

Eq.1 is used to obtain the estimates of European call options values on dividend paying stocks.

Let

S_t = the current stock price at time t ($S = 25, 50, 75$ respectively)

r = the risk-free rate per quarter compounded continuously ($r = 0.015$),

σ^2 = the (assumed constant) variance rate per quarter on the underlying stock ($\sigma^2 = 0.025$)

D_t = the dividend payable at time t ($D = 0.25$),

E = the exercise price of the option ($E = 50$),

T = the expiration date of the option.

In this case, the assumption used is same as that mentioned in the Boyle's article [5, p328-329]. It is

assumed that time is measured in the unit of one quarter. Assume that S_t represents the stock price just after the quarterly dividend D_t has been paid. To set up the simulation method in this case a value of S_{t+1} is generated. If this value is greater than D_{t+1} then $(S_{t+1} - D_{t+1})$ is used as the initial value in the beginning of the second period and the procedure continues until a value of S_t is obtained. If at some stage S_{t+m} ($m = 1, 2, \dots, (T-t-1)$) is less than or equal to the corresponding dividend payment D_{t+m} , then the process stops. In this case another simulation trial is started again from time t . A series of simulation trials is carried out in this way and the expected value of $\text{Max}[S_T - E, 0]$ is found. This quantity is then discounted at the risk-free rate to yield an estimate of the option value [5].

4.2. Optimization Model Parameters Settings

The proposed optimization model applies GAs evolutionary mechanisms; as a result, some parameters in a formal GAs model must be determined first. They are population size, crossover rate and mutation rate respectively. Because the model is a hybrid of GA and simulation techniques, the iteration number is a required parameter to be defined. All settings are specified as follows:

Table 1 Model Parameter Settings

Population size	50
Crossover rate	0.5
Mutation rate	0.06
Iteration number	500

The iteration number here is set to 500; however, the number can be variable. That is the optimization model which will stop the iterations when the expected statistic characteristics converge. Assigning a fixed value here is to make further comparison easier later on.

4.3 The Comparison

A comparison was made among the performance of the Monte Carlo approach, control variate, antithetic variates, and GA-Based optimization to pricing options. For this comparison, the estimates of option values on dividend paying stocks in the case of European call options were obtained. The data we used is same as that given in the Boyle's article [5]. The results we obtained are compared with those results as listed in the article.

Table 2 indicates the results of the simulation method for selected values of the underlying parameters. It is assumed that $r = 0.015$, $\sigma^2 = 0.025$ per period, $D = 0.25$ per period and $E = 50$. The estimates of options with even maturities ranging from 2 to 20 are provided.

From the results as shown in Fig. 7, 8, 9, we can see the best performance is control variate, which provides a very efficient variance reduction technique in this problem. In some problems it may be difficult to find a suitable control variate. The alternative method, the antithetic variate method, is often easier to be applied since it concentrates on the procedure used for generating the random deviates, but its performance is not good as the proposed GA-Based methodology.

5. Conclusion

Although Monte Carlo simulation model provides a flexible tool to obtain numerical estimates of a European call option on a stock which pays discrete dividends, it is very time-consuming. Based on the example given in the Boyle's article [5], when the current stock price is 50 and option has 20 periods to maturity, the option value of the crude Monte Carlo estimate (5000 trials) is 17.190 with standard deviation 0.479. Therefore, the 95 percent confidence limits are 17.190 ± 0.958 . Reducing the range of these confidence limits to ± 0.05 would require increasing the number of trials from 5000 to 1,835,500. A number of effective techniques for reducing the variance of the estimates have been developed. One of the most effective methods is control variate. However, it is very difficult to find a suitable control variate in real case.

In this paper, we propose the powerful approach based upon the coupling of a Monte Carlo simulation with a genetic algorithms-optimization procedure for solving complex option pricing problems. The genetic algorithm considers a population of chromosomes, each one encoding a different alternative design solution. For a given design solution, the Monte Carlo simulation allows us to evaluate the system performance over a specified mission time, in terms of a pre-defined net profit function. This latter constitutes the objective function to be maximized by the genetic algorithm through the evolution of the successive generations of the population.

In order to avoid an explosion of Monte Carlo simulation runs and an overwhelming use of computer time, each potential solution proposed by the genetic algorithm is explored only by few hundreds Monte Carlo simulation. Due to the fact that during the genetic evolution the superior chromosomes appear repeatedly many times, statistically significant results for the solutions of interest (i.e. the best ones) are obtained. This approach coupled with the 'evolutionary guidance' in the search procedure by the genetic algorithms allows one to efficiently perform the analysis of a realistic system in reasonable computing times.

In the future, we try to apply simulation optimization methodology to handle American call options problems. The problems of this kind of option, which can be exercised at any time during its life, would become more complicated and challenging.

Table 2 Option values using Crude Monte Carlo , control variate, antithetic variate method, and GA-Based simulation; 5000 trial per estimate.

Abstract

Flexible, secure and cost effective in comparison to traditional solutions, IP-VPNs exhibit many of the traits enterprises are seeking today. Mobile VPN users have special requirements relating to resource adoption and customization. In this paper we have discussed how mobile agent technology can be applied to IP-VPN in finding a route for a tunnel with QoS features and also how can it provide service capabilities to mobile users. In our approach, we have considered the requirement from a group of VPN users. We have developed a framework to use active packets that can help us in discovering an optimal QoS route based on the available bandwidth and link cost. Also we have described an alternative approach for resource management between two agents. Taking into account, the structuring mechanisms enabled by standard mobile agent platforms, like regions, agencies grouped within regions, and places belonging to agencies, we have applied these structural principles to our target mobile communications environment. We have assumed that service providers have access to node's control environment, algorithms and states. A possible framework for supporting mobile user groups after the deployment of the VPN is suggested in this paper. We have considered the concept of Place Oriented VPNs that are based on agent technology and can be built on top of existing VPN infrastructure.

1. Introduction

The Internet revolution has dramatically altered the networking requirements & opportunities of the enterprise. The deployment of new IP applications and the availability of tremendous capacity i.e. high connectivity has promised to facilitate the exchange of critical information both within the enterprise and throughout its sphere of influence. However, this way of expanding the value of a network as a business asset does present challenges. There are many ways of handling this. IP-VPN is one of the better solutions. In this sluggish corporate spending environment, Internet Virtual Private Networks continue to attract attention as a way to reduce remote access costs for enterprise networks. But while the number of implementations is clearly on the rise and VPN technology has become well understood, it also continues to be in many respects, a work in progress. A VPN is a communications network, built for the private use of the enterprise, over a shared public infrastructure [8]. There are two primary applications covered by this

definition: remote access connectivity and site-to-site connectivity (see Figure 1). VPNs can be categorized into three types as Remote Access, Intranet, and Extranet. Remote access connects remote users to corporate LAN, Intranet connects branch offices to corporate LAN, and the Extranet VPN gives access to business partners.

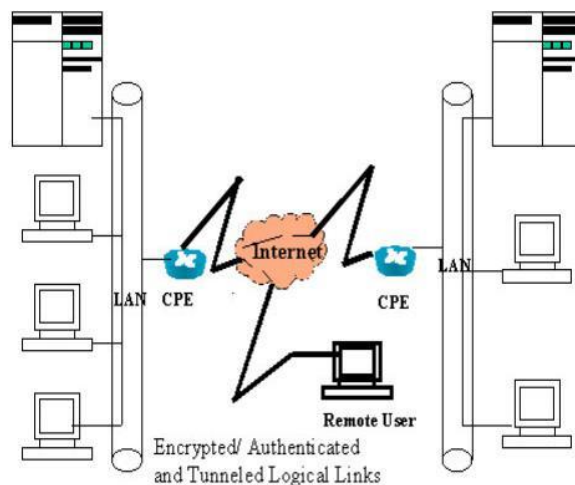

Fig.1. An Example of IPVPN

The motivation for building VPNs is numerous. However, a common thread in each is the requirement to make some portion of the public network 'invisible' to outside people, while taking advantage of the efficiency of a common communication infrastructure. The two basic motivations are (a) cheap cost and (b) need for communication privacy. The general conclusion [1] is that a collection of virtual networks implemented on a single common physical communications plant is cheaper to operate than the equivalent collection of smaller physically discrete communications plants, each serving a single network client.

The majority of theoretical work being done recently on the performance enhancement of the VPNs concerns security [2]. Researchers have focused on devising different architectures for different deployment scenarios. Little has been done to provide QoS support in a VPN

environment and also to support roaming users (users who often move from one network to another). The main problem we face in supporting mobile users is the technology integration. These traveling VPN users must be supported in small groups or separately. We discuss here, how can we use agent technology and active networking concept to support our roaming users to get the VPN services from the corporate network. Also the tunnel that is to be formed between source and destination should guarantee maximum quality of service requirements. VPNs are designed mostly with static users in mind and little has been done to integrate mobile users or to provide mobile user support after their deployment. The problem here is that the availability of information and communication services varies from place to place and from time to time. The major requirement here is that for dynamic reconfiguration of the new environment and customization.

The advent of high-speed networking technology has enabled many multimedia applications like video conferencing, medical imaging and VOIP. These applications have different performance requirements of bandwidth, delay, jitter and loss rate, which leads to an important issue of how to support QoS on the modern high-speed virtual private networks.

It is known that the original Internet is a “best-effort” network, which has no QoS support for different classes of services. However, there may not exist one solution to all the problems of QoS support, because the application-specific state of QoS should be frequently changeable or easily deployable when needed, while the conventional network is simple and stateless. Now, recent research has shown that the programmable “Active Networks” may be a better solution to guarantee QoS in the VPNs.

2. Related Work

2.1 Place Oriented VPNs

A PO-VPN is an alternative virtual private network [4]. It differs from a legacy VPN where the legacy VPN has its own resources which are managed by its own users in a policy related way. But current VPNs are not sufficiently flexible, have long set up and deployment times, are not dynamic enough to accommodate rapid changes, and can’t be controlled by the users. It is again more difficult to manage if the VPN spawns different networks with different policies. PO-VPNs are a right solution for this problem. These are built on top of existing physical networks and are controlled by agents.

2.2 Active Networks

Active networks are a novel approach to network architecture in which the switches of the network perform customized computations on the message flowing through

them. The first piece of this architecture is a protocol that would replace original “passive” IP packet with the “active” object code. The motivation of active networks is to permit applications to inject programs into the nodes of networks and then to support faster service innovation by making it easier to deploy new network services. Active networks are highly programmable networks that perform computations on the user data that is passing through them. In contrast, nodes of the traditional networks, such as ATM switches or IP routers, are closed, integrated systems, whose functions and interfaces are determined through standardized processes. These nodes transport packets (or cells) between end-systems and the processing of these packets is limited to operation on the header, primarily for the routing purposes. Specially, the network nodes neither interpret nor modify the packet payloads. Active networks, in the other hand, break this tradition by letting the network perform customized computation on the packets, including their payloads. There can be mainly two approaches to active networks: discrete and integrated, depending on whether programs and data are carried discretely.

Programmable switches – a discrete Approach: In this approach, the existing packet formats are remained and it provides a discrete mechanism that supports the downloading of programs, which separates the injection of programs from the processing of messages.

Capsules – An Integrated Approach: In this approach, the existing “passive” packet will be replaced with the “active” miniature programs, called “capsules”, which are encapsulated in the transmission frames and executed at each node along their path. User data, the payload, will be computed and embedded in the capsules.

2.3 Agent System

Mobile agents [3] are software components that act alone or in communities on behalf of an entity and are delegated to perform tasks under some constraints or action plans. The essential characteristics of these agents are mobility that allows them to move from one node to another and continue their execution. An agent is a process that enables users to control their system, and at the same time, to allow sharing of resources, that is it controls the access to resources of a remote computer, and also provides protection. An agent system consists mainly of places. A place is a context in which an agent is executed [4]. This context can provide services like access to local resources. A place consists of place name and address of agent system within which the place resides. A place can contain other places. All places follow parent child relationship. The assignment of places to agent system is done by ways like dynamically as they enter into different nodes based on some criteria like originating from same user or statically assigned per entity i.e. per user or per enterprise.

2.4 Active Node

The active node consists of a programmable router at the lowest layer, above which a node OS lies, which again supports Execution Environments. At the top, we have the application programs running [4].

3. Our Approach

VPNs are designed with static users in mind and almost all the recent VPN technologies do not support mobile users, i.e. once the VPN is deployed if the user is moving into another network (a third party) then again the same VPN has to be reestablished with the new network as the source. To do this, we must also have the required client software available at the new node and also it should support VPN connections. If everything is right, we then have to reestablish the whole VPN connection starting from the scratch. This scenario of VPN deployment can also be called as Flexible VPN. This requires resource adaptation and customization. To make this feasible, we have applied the concept of Agent technology & Active networks. The Mobile agents used are active, mobile, and can travel. They may reside in a host or client computer, and roam other computers, networks, or the Internet to execute their tasks. They are frequently used to collect data, information, or changes. The use of these agents have several advantages like reducing the network load, overcoming network latency, encapsulating protocols, executing asynchronously and autonomously, dynamic and heterogeneous. These mobile agents can migrate along with mobile users, adopt local and remote resources dynamically and generally manage and mediate all requirements of mobile users.

3.1 Mobile User Support

To support mobile users, we have allowed each user to act within his own place. This place hosts one or more cooperating agents that keep track of user's requirements and current status. Agents here take the role of customer, the service provider and the network provider. These agents reconfigure the services that user wants in the new environment. They also see that the adoption is optimal in the new environment. The reconfiguration is fully transparent to the users.

A VPN with mobile users comprises of a graph with changing nodes. As the user moves, we face the challenge of re-assigning the connections between the nodes in order to provide the same services. This whole process does take place without the notice of the user. To support mobility, we have to dynamically and flexibly provision VPNs. The deployment should take minimal time. There are multiple network and service providers in the underground infrastructure on top of which we want to build our VPN. Here, we consider three agents UA (user agent), VPN SPA (service provider agent), and NPA (network provider agent). The process for supporting mobile users is two fold:

3.1.1 Initial VPN provisioning

1. UAs negotiate and decide upon a common set of requirements and services desired by the users.
2. All UAs elect a leader using the Bully leader election algorithm (using the priority number, election and coordinator messages), and the leader is called as GA, the group agent.
3. Then GA tries to find out an optimal tunnel path for the VPN topology on the basis of bandwidth and link cost covering all the UAs. Here, GA issues self-routable packets, which travel in the network and get happiness levels from NPAs. The self-routable packet contains a time stamp according to which it has to follow back to GA. GA also negotiates with VPN NPAs to find out different resource supports.
4. Now GA interacts with the SPA in order to find out which topology supports the desired services. At the end of this phase, GA has a network topology that supports the services desired fulfilling the SLAs demanded by the user or customer or the UA.
5. GA then, integrates all the information received and uses a rule-based system to process the information. The happiness levels are averaged and the deviation is measured. The rule based system acts as a control element using this deviation as input.
6. It then issues active packets based on the rule-based system, which tries to restore the happiness levels. The happiness is here nothing but the bandwidth consumption and link cost. Thus routes are added and deleted from the routers dynamically to redirect the load so that the VPN is happy or well behaved. The GA does this thing. It can also consider other parameters like error statistics, reputation of nodes, cost security etc in deciding an optimal path for the VPN.
7. Finally GA requests service and network providers to set up the services and the connections. As, a last step, GA informs all UA that the VPN is ready to use, after which it may die or remain alive as a central authority to monitor future requests and topologies.

3.1.2 Dynamic VPN adoption

When a user moves from one network to another, his services must be maintained in the new environment. The steps below are needed to achieve this:

1. When a user moves from the home network, all the User Agents stop after getting a "operation stop" signal from the system. All the UAs then inform the GA, the central agent that the user is no more active in his home network.
2. When the user logs into another network after migrating, this new location address is sent back to the User Agents

those were available in the previous domain but were stopped.

3. With this information, all the user agents migrate themselves to the new environment after authenticating themselves in the new domain.

4. The UA after establishing itself over the new domain examines the services needed by the user and whether these are supported & provided by the new domain. If yes, it configures those in the new environment. If not, UA may ask the old node to get the active code that implements the missing services in the new domain. This is where, active networks concept comes into play. The other possibility is having an agent based resource management system as depicted below:

Fig. 2. Relationship Between Different Processes

Local agent must perform the following actions:

- a. Locate a remote computer with the required resources
- b. Negotiate with that Computer to borrow the resources
- c. Invoke the service requested by the client
- d. Handle the Exception Conditions (resource revocation, and location of a new host and deportation of the guest process) in a way that is transparent to the client and guest

The remote agent process has to lend the resources and protect the interests of the computer owner. In particular it should perform the following actions:

- a. Receive the borrowing request from an agent
- b. Analyze the request to determine whether the resource can be granted
- c. Create an appropriate execution environment for the guest process (Creating a new process and supplying the guest with capabilities to access other components of the system, according to the request specification, e.g. network connections to the client so that the guest and client can communicate directly).
- d. Exception handling, for example attempts to access

resources, which the guest was not allowed to utilize, revocation of rights.

Providing remote resources or services in the above type of agent based resource management system can be categorized into three phases as Negotiation, Resource Utilization, and Resource Release with different messages being labeled as shown in Figure 3.

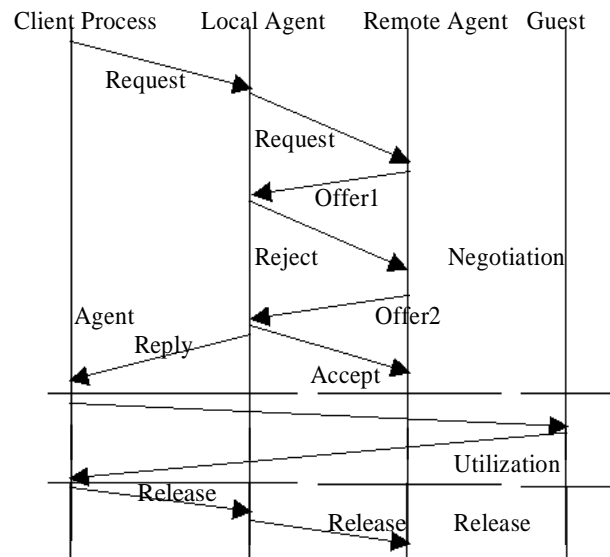

Fig.3. Negotiation and Utilization Messages

5. Finally, after establishing the new environment either with the help of active codes getting transferred or with the help of a distributed message communication model as described in the above step, UA informs GA, which in turn multicasts this new VPN node to rest all affected UAs. This is done to enable all UA to configure their local services to comply with the new topology of the VPN.

3.2 Active Quality Of Service Routing

Steps 3 to 6 of section 3.1.1 (Initial VPN provisioning) has been considered as Active QoS routing, which is based on the concepts of active networks, where the behaviors of network elements, such as routers and switches, can be modified and manipulated dynamically by injecting customized codes into the network elements. The basic functionality of active QoS routing is to find a network path to satisfy the given constraints that are required by the QoS requirements of a specific connection. In traditional routing, packets are delivered by using routing tables that are located on routers along the chosen route and the routing tables are formed only by the route information that is based on hops, source and destination address. But here selecting a path that provides QoS requires additional information, which are the traffic quality requirements such as bandwidth, delay, jitter and cost etc. In addition to the routing table, in AQR, the network elements also keep the state representation of the whole network or their sub-network and also with the

routing algorithms the best feasible route from a given source to a destination that satisfies the QoS constraints is chosen. In addition, most active QoS routing algorithms consider the optimization of resource utilization. Here we would like to introduce two of the AQR technologies.

One of the technologies is using Active Packet that is packet with a piece of executable code in its header. Basically, the idea of this technology is to find the best path according to QoS specifications by sending Active Packets from the source to destination, each time the first packet reaches the destination it sends a reply packet carrying the updated QoS and path information back to the source address. Thereafter, the subsequent packets will follow this path. With a certain interval, the Active Packets are sent again to detect the network state, then, the source may change the path according to the reply packet information.

The other one is using agent code at chosen routers through the network. Basically the agent is an independent executing code that can autonomously perform in response to events. With AQR, for the router to select the best path, the QoS parameters and traffic specifications are the most important factors, so these parameters are going to be kept in the agent routers' routing table. For example, the QoS parameters are residual bandwidth, loss probability, delay, Jitter, security status and cost etc. The traffic specifications can be categorized as video conferencing, FTP, email, audio stream and video stream or voice etc. As a result, the routing tables become multiplex and complex, which are called as search matrix as shown in the figures below.

Table 1. Search Matrix

	R0	R1	R2	R3
R0		R01	R02	R03
R1	R10		R12	R13
R2	R20	R21		R23
R3	R30	R31	R32	

In the above table, the entry R01 to R32 refer to the costs incurred by traffic delivering between two routers in the sub- networks, for example R01 is the cost of traffic from R0 to R1. The following table illustrates every kind of the cost. As shown below, the cost depends on the QoS requirements and the types of traffic. With all these information the router will decide which path is the optimal and effective route, but probably not the shortest path, for the specific traffic. Off-course, every connection will not include every cost, it depends on the grade of QoS service that this connection requests. Like the routing table in OSPF (Open Shortest Path First) algorithm, the matrices are going to be updated with a certain interval. Otherwise the rapid changing link parameters will cause incorrect routing decisions.

Table 2. Different Kinds of Cost for Different Traffic

	Bandwidth	Cost	Delay	Hops
Video-Conf	M00	M01	M02	M03
FTP	M10	M11	M12	M13
Email	M20	M21	M22	M23

3.2.1 Active Packet Format

An active packet is the basic entity on which the whole Active Network Infrastructure is built. The structure of this packet is as follows:

Seq No.	Type	Uniqueid
Groupid		pn
Data		

Fig. 4. Active Packet Format

SEQ NO is an integer field that denotes the sequence number of the packet. The protocol used for their transmission is UDP hence proper assembling requires some ordering as datagrams arrive out of order. TYPE field can carry binary values of 0 and 1, where Zero denotes that payload is some code while one denotes that it is either normal user data or data used by some code previously sent. UNIQUEID field is used to authenticate the packet as having a valid ID. The field is also helpful in constructing the filenames for various protocols sent by multiple users. GROUPID field assists the above field of uniqueid in verification and differentiating among protocols sent by multiple users over the network. PN is the priority number over of the packet. DATA is the normal user data. Only here it is wrapped around with another layer of headers for active identification of this packet.

These packets are wrapped in a UDP packet and sent for transmission. UDP is chosen to wrap it because the packet can itself control the reliability by the code in it. Also if the code is written in perspicacious manner the packets can also self-route itself based on the conditions imposed by the code & data placed in it. Here, the idea is to place intelligence in the packet, and not on the devices controlling the packet.

3.2.2 Server & Client Implementation

Server and client programs are used to send and receive active packets at various machines. Both the server and the client implementation are required at both the ends if they want to communicate. This is so because the nature of packet object is recursive, in the sense it can go to destination and try to contact back the master.

These two programs can be together called as the execution environment. The server process listens to connections from various hosts and receives packets from them. If they contain code then the packets are not only saved on the machine but also compiled and executed to change the behavior of the machine.

These daemons receive the active packets wrapped under the UDP cover. They open the UDP layer and read the active layer headers. Validate the packet. Set an environment with access restrictions as laid by the system administrator for these packets at that end host.

As shown in figure below, the execution environment consists of three processes namely daemon process, server process and client process, which are running together and using IPC (inter process communication) between them. First the daemon listens at UDP layer and picks up all active packets and delivers them to EE of the machine. The EE SERVER process of the machine understands the code in the packet. If valid the code is sent for further processing else the active packet is dropped. The EE manipulator segregates the packet into code and data and forks a copy of it. The child process exec's to load on the executor and executes the code inside the packet. If this packet has code, which demands for new packet formation and delivery, then the EE CLIENT side is used to frame such packets and deliver them to UDP via DEAMON process for delivery. The acknowledgements of the active packets are in turn active packets again and use the same EE CLIENT side process.

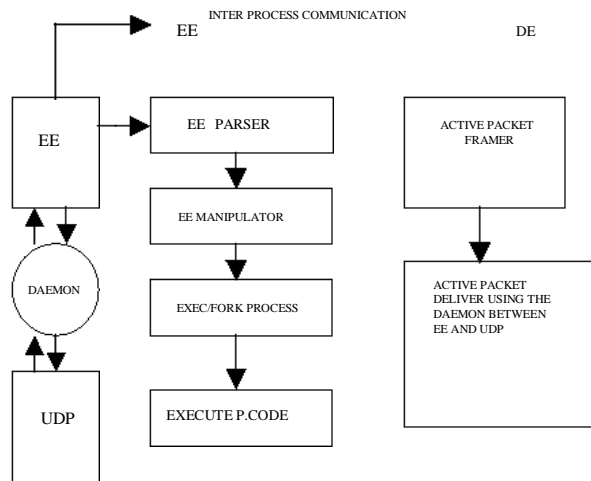

Fig. 5. Structure of Execution Environment

3.2.3 Route Optimization & Routing Agent

Route optimization is implemented using two QoS parameters i.e. bandwidth & cost of the link. Their tables are maintained as explained in one of the sections above on Active QoS routing. Routing Agent is a simple C code that is transferred using the client to server where it is assembled and installed. The routing agent queries the route optimization algorithm, giving it the destination and

asking it for next best possible router to move at. The Route Optimization code can be transferred prior to Routing agent on the routers on the path and installed over there using the active network scheme. The Routing agent just queries this to find the next possible position. The routing algorithm returns a structure called "routeLink" which has the information regarding the next IP to go to and bandwidth available along with the cost of the link. The routing agent also connects back to the home address to tell the current router specification where it is. As this initial packet follows the whole route it keeps sending the "communicator Packets" regarding the information of links it is traversing. The failure or loss of this initial packet shall not lead to catastrophic failure of the whole system as the information about the whole route is being queued at the end point.

As the information is built up at the end node the rest of the data packets can follow the route that is built up. After some time another routing agent can be sent to get the route, as changes are possible over the path because of ascertain behavior of the parameters on which the system is working.

4. Results and Conclusion

The Internet as of today does not support secure communication between a group of mobile users with minimal effort. We have considered the notion of PO-VPNs suggested in [4], an alternative form of VPNs whose aim is to provide an infrastructure for groups with special characteristics like short time to live, low population etc.. These PO-VPNs can be deployed on top of existing VPNs and offer customized services in a flexible, interoperable and cost effective way. We have implemented the active QoS routing (section 3.2) using Unix socket API. As a result of this implementation, we found a path for a VPN tunnel (between a mobile user and corporate office) satisfying the QoS requirements as demanded by the user's SLA. To fulfill the requirement of mobile user group, a virtual environment with the help of active networks and intelligent agents can be a better option as described in our approach. Also in our approach, an alternative to active networks is suggested, where for resource management in the new environment the agents can communicate with each other as described in step 4 of section 3.1.2. But this option is a slower one because of message communication overhead. This can only be preferred when we have access restrictions or security problems in supporting active networks concept. It can be seen that active networks have many advantages over the traditional networks to support QoS. Firstly, it is an adaptive scheme that can support many classes of services. Secondly, it is more scalable than RSVP and possible to develop a simpler architecture to enable QoS than using IntServ and Diffserv together. Thirdly, active networks support user-driven computation and provide more powerful way for user to shape the traffic for particular QoS requirements. As a future work, we plan to implement

a simulated environment for supporting mobile VPN users group under a legacy VPN set up which will include tunneling, and encryption algorithms as well. This will also embed our QoS routing part presented in section 3.2 (VPN path selection). Also we would like to analyze the performance of the VPN supporting mobile users when the number of mobile users is large.

Abstract

This paper attempts to integrate concepts of service quality and in-depth interviews with experts master on hospital management or medical care to build a framework for influencing factors of service quality for outpatient clinical care and empirically explore it. Data are collected through a survey of a large-scale medical center located in a megalopolis area that is actively involved in research and development of medical care. Five dimensions of service quality are constructed as process of healthcare, waiting for inspection and administration, environment of clinical visiting process, hospital environment, and supporting personnel by Factor Analysis in this study. The dimension of waiting for inspection and administration included service quality of inspection units, waiting time for inspection and inspection documentation. To improve and to computerize inspection process might upgrade customer satisfaction. Waiting for a doctor diagnosis is included into environment of clinical visiting process, so a comfortable waiting corner and plenty of seats near to a diagnosis waiting room might reduce complaints of a long waiting time for a doctor diagnosis. The convenient transportation and enough parking spaces are important for clinical visiting a large-scale hospital located in a megalopolis area.

1. Introduction

In Taiwan, the amount of spending on healthcare has tremendously increased in the past few years. Although healthcare and medical treatment business generates more and more profits, a medical center still concern her market share within her geography area. How to enhance the service quality for increasing her market share and to retain the loyalty from original patients are become a big challenge for managers in most of medical centers. Researches have demonstrated the strategic benefits of quality in contributing to market share, return on investment, lowering operating costs, and improving productivity, so enhancing on service quality in healthcare can be a path to achieve the goal.

Market share and loyalty are related to satisfaction of a consumer expected service and perceived service, therefore, this research tries to cover the findings of studies on service quality. The research methodology is comprised of three approaches:

- (1). Literature review for building a Research Model.
- (2). In-depth Interviews with experts master on health management or medical care to validate and justify

the Research Model.

- (3). Questionnaire Survey based on the Research Model and Factor Analysis was used to explore the influencing factors of service quality for hospital visiting.

Goal of this research is hence to present the Research Model for influencing factors of enhancing service quality in a medical center. These factors may create valuable information for hospital administrators to build appropriate strategies for their businesses.

2. Literature Review

Research has demonstrated the strategic benefits of quality in contributing to market share and return on investment as well as in lowering operating costs and improving productivity [1, 10, 14]. Most of literatures on services suggest three underlying themes: (1) Service quality is more difficult for the consumer to evaluate than goods quality, (2) Service quality perceptions result from a comparison of consumer expectations with actual service performance, and (3) Quality evaluation are not made solely on the outcomes of a service; they also involve evaluations of the process of service delivery. Consumers compare the service they expect with perceptions of the service they receive in evaluating service quality. Researchers and managers of service firms concur that service quality involves a comparison of expectations with performance [2, 5].

Satisfaction is related to the size and direction of the disconfirmation experience where confirmation is related to the person's initial expectation [3, 7, 8, 11, 13]. Parasuraman, Zeithaml and Berry [12] attempted to obtain an extensive exploratory investigation of quality in four service businesses and by developing a model of service quality. A set of key discrepancies or gaps exists regarding executive perceptions of service quality and the tasks associated with service delivery to customers. Five gaps are (1) consumer expectation-management perception gap will have an impact on the consumer's evaluation of service quality, (2) management perception-service quality specification gap will affect service quality from the consumer's viewpoint, (3) service quality specifications-service delivery gap will affect service quality from the consumer's standpoint, (4) service delivery-external communications gap will affect service quality from a consumer's standpoint, (5) expected service-perceived service gap that a consumer perceives in a service is a function of the magnitude and direction of the gap between expected service and

perceived service. Expected service-perceived service gap depends on the nature of the gaps associated with the design, marketing and delivery of service.

Three quality dimensions are also proposed by researchers [5,9] as physical quality, which includes the physical aspects of the service (e.g. equipment or building); corporate quality which involves the company's image or profile; and interactive quality which derives from the interaction between contact personnel and customers as well as between some customers and other customers. Gronroos [5] also postulated that two types of service quality exist; technical quality, which involves what the customer is actually receiving from the service, and functional quality, which involves the manner in which the service is delivered. Research of Parasuraman et al. [12] also revealed that, regardless of the type of service, customers used basically similar criteria in evaluating service quality. The criteria seem to fall into 10 key categories which are labeled "service quality determinants". They are reliability, responsiveness, competence, access, courtesy, communication, credibility, security, understanding and tangibles. 10 important items of quality in healthy services are proposed by Hyde [6] as knowing the patient's needs, designing to meet them, faultless service, reliability, certified performance, clear instructions, suitable packing, punctuality, Efficient back-up service, and feedback.

3. Research Model

According to 10 key categories of "service quality determinants" revealed by Parasuraman et al. [12], several health managers and medical experts related to healthcare were selected for in-depth experts' interview to find resources for provide a satisfied healthcare service is summarized in Table 1. Based on the mapping between 10 key categories of "service quality determinants" revealed by Parasuraman et al and resources of healthcare service, an initial healthcare satisfaction model for a patient's hospital visiting is proposed as Figure 1. Expected service quality of healthcare is defined as the importance of a patient's cognitive feeling about hospital environment, waiting time and services from hospital resource during his visiting. Experienced Quality of healthcare is defined as the experience of services from hospital resource during his visiting. Degree of satisfaction is defined as the difference between the expected service quality and the experienced service quality of a patient during his visiting. Hospital environment includes public facilities and complaint solving by resources of healthcare service in Table 1. Patient attribute includes identify, gender, age, marital status, education, residency, occupation, clinic section visiting today, and reasons for this hospital visiting. Identity of a patient attribute is classified as patient himself, patients' family members or patient's accompanist. Resources of hospital and clinical operations related to each dimension in expected or experienced service quality were constructed by 10 important items of quality in healthy services which proposed by Hyde [6] and validated by in-depth

Table 1 Determinants and sources of service quality

Service quality determinants	Source of healthcare service
Access (approachability and ease of contact) -waiting time for services is acceptable -convenient office visiting hour	waiting time
Communication (keeping customers informed in language they can understand) -explaining the service thoroughly -complaint handling nicely	complaint solving
Competence (possession of the required skills and knowledge to perform the service) -knowledge and skill of service personnel -knowledge and skill of supportive personnel	medical staffing, supportive staffing
Courtesy (politeness, respect, consideration, and friendliness of contact personnel) -clean and neat appearance of personnel	medical staffing, supportive staffing
Credibility (trustworthiness, believability, honesty) -characteristics of service personnel -Attitude involved in interaction with customers	medical staffing, supportive staffing
Reliability (firm honors its promises, firm performs the service right the first time) -accuracy in billing -keeping records correctly	medical staffing, supportive staffing
Responsiveness (willingness or readiness of employees to provide service) -transferring patient's slips immediately -calling the customer back quickly	medical staffing, supportive staffing
Security (freedom from danger, risk, or doubt) -physical safety -confidentiality	public facilities, medical staffing, supportive staffing
Tangibles (the physical evidence of the service) -appearance of personnel -tools and equipment used to provide the service	public facilities, medical staffing, supportive staffing
Understanding/knowing the customer (the effort to understand the customer's needs) -learning the customer's specific requirements -providing individualized attention -recognizing the regular customer	medical staffing, supportive staffing

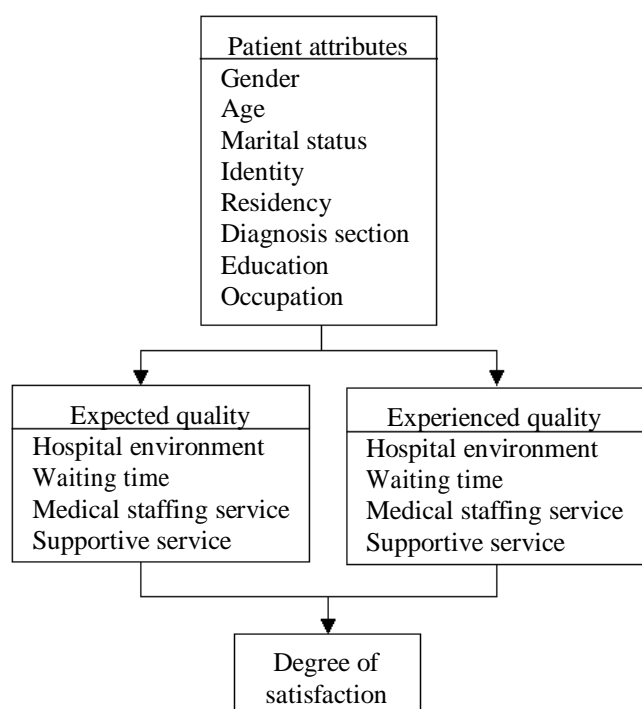

Figure 1 Initial hospital visiting satisfaction model

interviews with personnel of hospitals.

Excellent public facilities (public telephone, water fountain, toilet, etc), service quality of clinical appointment via phone are classified in hospital environment dimension. Waiting time of a patient's hospital visiting can be classified as service quality of clinical appointment via Internet, via personal register, or via clinic nurse, waiting time for a doctor's diagnosis, waiting time for payment billing, waiting time for blood drawing and urine checking, waiting time for X-ray, waiting time for medicine feeding. Medical staffing service includes doctor's medical skill, doctor's show up on time, doctor attitude, doctor kindly treatment, doctor's detailed diagnosis and explanation, nurse's friendly attitude, privately respected by nurses, convenient process for applying documentation of diagnosis or patient history, detailed descriptions for medicine taking. Supportive service quality includes registering windows, inspection operations, x-ray operation, Pharmacy, Q & A Desk, or complaint solving.

4. Primary Questionnaire Survey and Research Findings

A questionnaire with 33 questions was designed to conduct the initial framework of this study. Identity of a patient attribute is classified as patient himself, patients' family members or patient's accompanist. Residency is classified as city, countryside, or suburban, etc. Diagnosis section is defined as the diagnosis section that a patient is visiting today. Questions of the expected service quality operation are measured by five-point Likert scales to classify the degree of importance (4: absolutely important, 0: no influence), and five-point Likert scale of the experienced service quality during this visiting is used,

Table2 Reliability of the initial model

Item	Dimensions of clinic operation	Expected quality	Experienced quality
1—10	Hospital Environment	0.9006	0.8505
11—18	Waiting Time	0.8939	0.8166
19—27	Medical nursing service	0.9375	0.9002
28—33	Supportive Service	0.9025	0.8348

Table 3 Process of healthcare dimension

Item	Factor loading	Expected quality (Mean)	Experienced quality (Mean)	Satisfaction gap
Doctor's medical skill	0.72	3.71	3.21	-0.50
On time doctor's show up	0.75	3.47	3.03	-0.44
Doctor attitude	0.88	3.67	3.31	-0.37
Doctor kindly treatment	0.91	3.64	3.27	-0.37
Doctor's detailed diagnosis and explanation	0.89	3.70	3.17	-0.53
Friendly nurse attitude	0.80	3.56	3.23	-0.33
Privately respected by nurses	0.78	3.62	3.15	-0.47
Detailed descriptions for medicine taking	0.67	3.52	2.88	-0.64

too. (4: Very satisfactory, 0: Very dissatisfactory).

The content of this questionnaire was constructed from literature reviews and in-depth interviews with several professors or experts who master on Hospital Management or Medical Care, thus validity of experts is acceptable. Data were collected through a survey of patients visiting different diagnosis sections with inspection operations and medicine feeding during their visiting in a large-scaled medical center in Taiwan. 700 questionnaires were delivered and 537 were collected (94.2%). 506 are considered effective (34.14%). For

Table 4 Waiting for inspection and administration dimension

Item	Factor loading	Expected quality (Mean)	Experienced quality (Mean)	Satisfaction gap
Waiting time for blood drawing and urine checking	0.69	3.07	2.64	-0.44
Waiting time for x-ray	0.75	3.05	2.70	-0.35
Waiting time for medicine feeding	0.64	2.99	2.58	-0.41
Convenient process for applying documentati on of diagnosis and patient history	0.70	3.24	2.71	-0.53
Registering windows service quality	0.81	3.19	2.65	-0.55

% variance	8.840%			
Cronbach α	0.8844			

examining the degree of satisfaction on hospital visiting, the number of effective questionnaire is reduced to 227 with effective answers in both sides. There are 91 from male patients and 129 from female patients. Pearson correlation analysis, Factor Analysis and Analysis Of Variance (ANOVA) are utilized to analyze the data. Pearson correlation analysis was also applied to validate correlation between the pairs of each two questions among 33 questions. Principal Components Analysis is used for extracting dimensions with eigenvalue > 1 and Promax. Level of significance is all up from 0.05 to 0.01, so Promax method in Factor Analysis was selected. ANOVA analysis and T test is used to test hypotheses. The reliability Cronbach's α for each dimension in the initial research model are shown on Table 2.

Five dimensions are extracted; they are named as process of healthcare, waiting for inspection and

Table 5 Environment of clinical visiting process dimension

Item	Factor loading	Expected quality (Mean)	Experienced quality (Mean)	Satisfaction gap
Comfortable and plenty seats in the waiting room	0.67	2.93	2.69	-0.25
Clearly sign for position of clinic	0.70	3.30	2.77	-0.53
Completely health facilities	0.76	3.63	2.98	-0.65

ANOVA and T Test; the summaries of analysis are shown on Table 9 and Table 10.

In a significant level of 0.05, the results of T test indicate that patients with different gender have significantly different expected service quality for process of healthcare, for waiting for inspection and administration, for environment of clinical visiting process, and from supporting personnel. Female patients have higher expectation of service quality for these four dimensions than these for male patients. Results of T test also reveal that patients with a different resident location have significantly different expected service quality for hospital environment; experienced service quality for process of healthcare, and experienced service quality from supporting personnel.

Table 7 Supporting personnel dimension

Item	Factor loading	Expected quality (Mean)	Experienced quality (Mean)	Satisfaction gap
Service quality of clinical appointment via Internet	0.62	2.90	2.80	-0.10
Pharmacy service quality	0.78	3.30	2.75	-0.54
Q&A service quality	0.79	3.25	2.92	-0.33
Complaint solving	0.76	3.26	2.65	-0.60
Dimension total		3.17	2.78	-0.39
Eigenvalue	1.304			
% variance	3.951%			
Cronbach α	0.7963			

**Figure 2 Proposed hospital visiting satisfaction model**

Patients who lived in city have a higher expected quality of hospital environment than one who doesn't live in city. In the other words, patients who don't live in city have a higher experienced quality for process of healthcare, from supporting personnel than one who lived in city. In other words, patients who don't live in city that the hospital located have a higher degree of satisfaction. The reason is the shortage of parking lots and traffic jam around the area that the hospital located.

Results of ANOVA analysis denote that patients with a different occupation have significantly different expected service quality for process environment of clinical visiting, and experienced service quality of waiting for inspection and administration. Patient whose occupation belongs to business or industry has a lower expected service quality for environment of clinical visiting process than one with other occupations. And a public official has a lower experienced service quality of waiting for inspection and administration than one with other occupations. In the other words, public officials feel waiting for inspection and administration during his hospital visiting longer than what he expects, but students are willing to wait for longer during their visiting. Results also indicate that patients attending a different diagnosis section have significantly different expected service

Table 8 Hypothesis testing

Hypothesis		Accept
Hypothesis 1: No significant difference between gender on the expected service quality		
1-1	No significant difference between gender for process of healthcare	No
1-2	No significant difference between gender for waiting time	No
1-3	No significant difference between gender for environment of hospital visiting process	No
1-4	No significant difference between gender for hospital environment	Yes
1-5	No significant difference between gender from supporting personnel	No
Hypothesis 2: No significant difference between resident location on the expected service quality		
2-1	No significant difference between resident location for process of healthcare	Yes
2-2	No significant difference between resident location for waiting time	Yes
2-3	No significant difference between resident location for environment of hospital visiting process	Yes
2-4	No significant difference between resident location for hospital environment	No
2-5	No significant difference between resident location from supporting personnel	Yes
Hypothesis 3: No significant difference between resident location on the experienced service quality		
3-1	No significant difference between resident location for process of healthcare	No
3-2	No significant difference between resident location for waiting time	Yes
3-3	No significant difference between resident location for environment of hospital visiting process	Yes
3-4	No significant difference between resident location for hospital environment	Yes
3-5	No significant difference between resident location from supporting personnel	No
Hypothesis 4: No significant difference between occupation on the expected service quality		
4-1	No significant difference between occupation for process of healthcare	Yes
4-2	No significant difference between occupation for waiting time	Yes
4-3	No significant difference between occupation for environment of hospital visiting process	No
4-4	No significant difference between occupation for hospital environment	Yes
4-5	No significant difference between occupation from supporting personnel	Yes

Table 8 Hypothesis testing (cont.)

Hypothesis		Accept
Hypothesis 5: No significant difference between occupation on the experienced service quality		
5-1	No significant difference between occupation for process of healthcare	Yes
5-2	No significant difference between occupation for waiting time	No
5-3	No significant difference between occupation for environment of hospital visiting process	Yes
5-4	No significant difference between occupation for hospital environment	Yes
5-5	No significant difference between occupation from supporting personnel	Yes
Hypothesis 6: No significant difference between diagnosis section on the expected service quality		
6-1	No significant difference between diagnosis section for process of healthcare	Yes
6-2	No significant difference between diagnosis section for waiting time	Yes
6-3	No significant difference between diagnosis section for environment of hospital visiting process	Yes
6-4	No significant difference between diagnosis section for hospital environment	Yes
6-5	No significant difference between diagnosis section from supporting personnel	No

Table 9 T test summary

Item	T	Sig. (2-tailed)
Gender vs. expected service quality for process of healthcare	-2.10	0.037*
Gender vs. expected service quality for waiting time	-2.19	0.030*
Gender vs. expected service quality for process environment of hospital visiting	-2.29	0.023*

quality from supporting personnel. Patients visiting Pediatrics, Obstetrics and Gynecology sections have a higher expected service quality from supporting personnel than one visiting other sections. So, service quality training is needed to enhance in these two departments.

Table 10 ANOVA summary

Item	F	Sig. (2 tailed)
Occupation vs. expected service quality for environment of hospital visiting process	3.646	0.003**
Occupation vs. experienced service quality for waiting time	2.615	0.026*
Diagnosis section vs. expected service quality from supportive personnel	2.760	0.043*

Note: *. Alpha is significant at the 0.05 level (2 tailed).

**. Alpha is significant at the 0.01 level (2 tailed).

5. Conclusion

A hospital visiting satisfaction model is proposed by literature reviews, medical experts' in-depth interviews, and an experimental study in this research. Five dimensions of service quality are constructed as process of healthcare, waiting for inspection and administration, environment of clinical visiting process, hospital environment, and supporting personnel. The dimension of waiting for inspection and administration included service quality of inspection units, waiting time for inspection and inspection documentation. To improve and to computerize inspection process might upgrade customer satisfaction. Waiting for a doctor diagnosis is included into environment of clinical visiting process, so a comfortable waiting corner and plenty of seats near to a diagnosis waiting room might reduce complaints of a long waiting time for a doctor diagnosis. The convenient transportation and enough parking spaces are important for clinical visiting a large-scale hospital located in a megalopolis area.

The findings of this study reveal female patients have higher expectation of service quality for process of healthcare, for waiting for inspection and administration, for environment of clinical visiting process, and from supporting personnel than these for male patients. Patients who don't live in city that the hospital located have a higher degree of satisfaction. Public officials feel waiting for inspection and administration during his hospital visiting longer than what he expects, but students are willing to wait for longer during their visiting. Service quality training is needed to enhance in Department of Pediatrics and of Obstetrics and Gynecology.

Hong Kong, P. R. China

whwong@baf.msmail.cuhk.edu.hk

Abstract

The rapid development of e-Business urges the need for online integrative partnership and collaborative business process management. These trends call for a new dimension of decision support: online multiplicative decision interoperability. We define it as a decision support platform for e-Business, which facilitates inter-organizational decision making process allowing dynamic partnership. As it is not the common decision support system we familiar with, we propose a new architectural framework of this decision support platform. This framework carries a set of unique characteristics that should be incorporated in the design and development of such platform.

Keywords: decision support system, inter-organizational system, e-Business, platform

1. Introduction

World Wide Web revolutionizes business trading, from a reactive information based e-commerce portal in the early 1990's, to the interactive buy-sell e-commerce website of mid 1990's. At the beginning of the 21st century, business-to-business e-commerce further foretells the impact of Internet technology deep into the core business of every industry. A new dimension – integrative website – is beginning to emerge [15] [17]. Coupled with interactivity, websites seek to develop capability to integrate business processes online. This new integrative era witnesses the emergence of e-Business processes such as e-supply-chain-management, e-collaboration and e-reengineering. The online management of e-Business is needed. For example, a management e-Platform for the logistics industry is being proposed [15] [16]. One issue that is critical to the integrative era is how to enable decision making in the dynamic electronic environment where partnership is formed and collaborative management of cooperating business processes is conducted.

Online decision support system is still at its infancy for corporations. The design of an online decision support (DS) for e-Business requires a different approach to that of a stand-alone DSS [4] [23]. We believe that online DS is likely to play a significant role in the next phase of e-evolution. Particularly, DS is a key to the provision of online knowledge management and sharing, a critical

e-Business process of the future. As companies leverage the knowledge-rich Web to conduct effective e-Business processes, websites with knowledge management capability will proliferate. Companies and industries will need to re-engineer their internal and external processes to tap into this powerful resource.

In this paper, we investigate the nature of decision making process in this new emerging era where online e-Business prevails. Online decision support takes on a different identity in the new electronic environment (e-environment) where needs and situations are dynamic. We call this new decision support apparatus the e-DSP. E-Decision Support Platform is a platform where decision support is enabled within this e-Business operating environment. In the following sections, we first describe the current business environment on the web and the needs that arise. We then develop the underpinning of the role of e-DSP. Characterization of e-DSP will follow with a proposed architectural framework for technical design consideration.

2. New e-Business requirements

As the development of e-commerce has become well established, the business world is now focusing on how to enable e-Business. With effective e-Business, a company can strengthen and improve customer relationships, streamline supply chain, automate processes, improve efficiencies, flexibility, scalability and availability [28]. Therefore, everyone is fascinated to join the e-environment. This accelerated participation quickens the emergence of new requirements in e-Business, especially in the decision support realm. A new dimension of decision support emerges – no longer as singular in nature as traditional DSS, but as a multiplicative partnership in an e-Platform environment. An e-Platform is a virtual space where participants conduct any-to-any interactive activities. Two key contributing e-Business trends to this e-decision support platform, or e-DSP, will be discussed next.

2.1 Collaborative business model

In the 21st century, companies believe specialization and outsourcing is one way to make their business success and long lasting. Thus, companies tend to emphasize on their core competencies and reduce operating costs by

outsourcing them to strategic partners who have top talent and state-of-the-art technology [2]. Closer collaboration among companies greatly increased with Web technology, creating a need for online management of business processes. This collaboration, working together with intellectual efforts, highlights the needs and difficulties of system integrations between different companies. This kind of system integrations becomes more complicated if they need to make decision together dynamically. There is no existing organizational management systems can support this new model of business practice.

2.2 Dynamic alliance

World Wide Web also gives companies opportunities to reach and contact companies and customers all over the world. In other sense, each company now also face with plenty competitors worldwide. Many companies realize that forming fixed partnership with few companies can no longer tackle the fast pace and on demand business environment. Instead, ad hoc companies tend to temporarily chain up to fulfill the requirement of an e-Business process so as to collaboratively satisfy the customer's needs and maintain their individual competitiveness in this market. Undoubtedly, during this partnership formation, decision making processes are plenty and diversified. Also, the membership of the partnership stabilized most likely after rounds of online strategic positioning and BCR evaluation (optimization steps individually and globally with respect to the partnership). The traditional DSS still can maximize the benefits for a single corporation, but no long can meet the demand of this new multiplicative decision making in an electronic environment. Conclusively, the necessity of a new approach to facilitate consensual decision making among collaborating partners is needed. The approach must solve three key issues that we will describe next.

3. Multiplicative decision making issues

The singular nature of traditional DSS can no longer be able to handle the multiplicative needs of online e-Business management. There are three key issues that one needs to deal with:

3.1 Multiplicity of Business Processes Needs to be Managed

Due to the competitive nature of business world, people began to realize that it is definitely not enough to focus on their own solely. They recognized that collaboration - sharing resources with intellectual effort - between different parties is a very important practice for them to survive in this new economy. This collaborative measure allows companies to develop shared vision and build

interdependent system to address issues and opportunities [6] [12] [26]. As a result, many single business models are linked up and integrated to form a value chain in order to satisfy customer's needs - a chain of multiplicative business processes. Moreover, the time lag between the downstream request and the upstream response has to be minimized. However, the reality is that different companies are running their own systems with totally different design and languages. This incompatibility makes integration online complicated, let alone integrative decision making. It takes designers and solution providers great deal of effort trying to link up different systems with success only in a few EAI and information systems [14] [22]. There is not yet any real-time and efficient inter-organizational system integration emerges. As most of the designers and solution providers are still struggling with the application integration; they are far from dealing with the online decision integration.

3.2 A Common Goal Needs to be Derived for Partners' Consensus

Today, things are no more as simple as one company face one type of customer with the support of one supplier. Many value chains are formed in e-Business practice. In this kind of chains, each party plays the role of a customer, a company and a supplier at the same time. Decisions involved in each role can be totally different and sometimes conflicting. This gives rise to a conflict of interests. First, all decision-making processes are inter-related in the value chain processes. Each process is affected by both its customers and suppliers. Next, it is also affected by its multiple roles playing in this chain. It becomes much more difficult to handle if the conflicts comes from each company is actually having different goals on the process. Therefore, a reliable conflict management tool across companies is needed to facilitate individual parties arrive at a mutually acceptable common goal. This idea also has similar view with Dr. Hua Lee's belief that an intelligent e-market, one kind of the e-Business processes, should have decision support systems to evaluate alternative contract terms, and facilitate both parties to come to agreements quickly [13].

3.3 An Integrative Partnership Needs to be Reached

With e-Business, the composition of partners is evolving online with the purpose of matching and optimizing of partnership. We address this as integrative partnership. This partnership needs collaboration with people and systems from various part of the world with different knowledge background. Such collaboration is required to occur towards real time, ad hoc, dynamic, multi-directional flows of data and information. Dynamic

collaboration also implies the partnership changes as the formulation of a business deal is in progress. Many processes involve a number of different partners participation, and most of the time they are making their own decision without knowing others decision. Therefore, a decision-making tool that facilitates various parties make decision collaboratively is critically necessary.

4. Defining of e-DSP

In here, we propose a platform for decision support in an electronic environment, or e-DSP, to provide the solution to a multiplicative decision making need. An e-DSP is a virtual platform that allows participants in e-Business to individually and collectively to make the best decision. e-DSP provides the necessary tools and mechanism to facilitate this decision making process online, on-demand and real-time. e-DSP has these key features – 4th party, net-enabled web environment, collaborative business process management, integrated decision making process and integrative partnership.

First of all, it must facilitate various companies group together dynamically to make decision. Next, unlike the traditionally DSS [4] which only focus on individual benefits, it must help all the parties involved in the decision making process to arrive an agreement by providing choices which benefit everyone. At the same time, it also needs to help resolving inter-organizational conflicts brought on by the business in an e-environment. Such decisions sport a different identity and demands different attentions, creating a genre of its own. Considering the nature of such decisions making processes, it can be very complicated which definitely cannot be solved by a single DSS. Instead, as it requires different parties' involvement along the whole process, a platform design will be more appropriate.

As the purpose of this platform is to facilitate various parties make decision, it does not have real participation or interest on particular decision. Thus, we propose a 4th party e-Decision Support Platform (e-DSP), a decision infrastructure that allows online business process and decision integration so as to facilitate inter-organizational decision making with dynamic partnership.

To the best of our knowledge, there is no existing conceptualization of such a platform for decision support. There are ongoing research related to this approach by Leung [15] [16] [17]. In the next section, we will provide a guiding architectural framework for the technical design and implementation of such e-Platform.

5. Design of e-DSP – An Architectural Framework

Our e-DSP design is based on two aspects: DSS and inter-organizational environment with partnership

formation. First of all, it should inherit all the basic DSS functions. After studying the trend of DSS development [1] [7] [20] [21] [23] [27], the most similar model to e-DSP is the distributed DSS stated by Pinson in 1997. They included diversified expertises, multi-agent approach, global goal and sub goal concepts, conflict resolution mechanism which all are relevant to our study [20]. However, its target users are still within one organization or enterprise, their global goal and sub goals have similar aims and it is the top management to make the final decision. In addition, Markus[9] also suggested a organizational decision process pattern : Emergent Knowledge Process (EKP). It is an emergent process of deliberations with no best structure or sequence with highly unpredictable potential users and diversified information requirements [9]. Although there are some similarities between EKP and e-DSP, they are quite different from the design purpose. EKP is designed for organizational users with no prior knowledge, so the system must implicitly guide users to desirable direction based on general principles. While e-DSP is designed for inter-organizational decision makers with different level of prior knowledge and there is no restrictions or guides to the desirable solution. On the other hand, the use of AI tools was also mentioned by Nikos [11], who gave a more detailed description on how to combine AI tools and OR techniques in an open GDSS. Their findings provide us some understanding on how to combine various DSS tools into one enterprise context. Next, Saxton [25] and Paul B [18] suggested the third party roles play in the decision making and cyberspace respectively. Saxton suggested 3 roles: expert, provocateur and legitimizer [25]. Paul suggested 4 roles: cybermediaries, cybercommunication, reputation tracking and online mediation arbitration of disputes [18]. As the e-DSP is a 4th party platform, it should facilitate and support 1st to 3rd parties work on it. Thus, we include some of the roles suggested above into the e-DSP design, while for the other roles, we will make use of the existing 3rd party applications which provide those service.

e-DSP should also adopt the current technology and system design for inter-organizational e-Business [5] [8] [10] [19] [24]. Both Marielle[8] and Gyeung-Min[5] mentioned about architecture for inter-organizational coordination, but not inter-organizational collaboration. Later, Finnegan[3], suggested an inter-organizational System (IOS) planning proposal which clearly suggested how to form such kind of system and define individual organization's role, yet the incorporation of an essential element: DSS needed to be introduced. Thus, a new framework is proposed. The architectural framework is intended as a reference for technical design consideration, providing a guiding approach of key system components to implement.

5.1 The e-DSP Architectural Framework

e-DSP is formed by three components: a supportive data store, a analysis model and a collaborative and integrative decision model as shown in Figure 1. First, inherit the structure of traditional DSS and the characteristics of a decision supported by IT, e-DSP also consists of the basic data store and analysis models to support decision making process. It also can make use of the information and analysis model supplied by other companies. Whereas the most important and new component is the collaborative and integrative decision model. It comprises of three features: collaborative business process management, integrated decision making process and integrative partnership which is a optional part. In the next section, we will further characterize this new component.

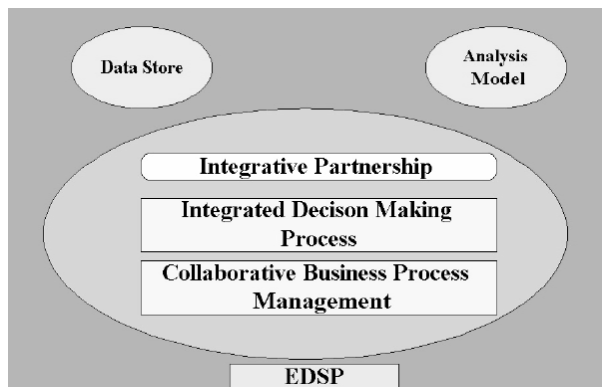

Figure 1. e-DSP architectural framework

5.2 Characterization of collaborative and integrative decision model

Here we characterize the new component according to the following three features: collaborative business process management which facilitate inter-organizational business and decision making process integration in a timely manner with reliable result; integrated decision making process which facilitate collaborative decision making with ability to perform integration and conflict resolution; integrative partnership which allow various companies group together dynamically to make decision by chaining up different companies and DSS with e-DSP dynamically.

1. Collaborative Business Process Management

This feature has the following characteristics:

- Process Integration: For some business processes which involve decision making, e-DSP should able to integrate with different decision and analytical tools from various DSS by understanding their decision and range of acceptance so as to know where can improve or adjust.
- Process Synchronization: With process synchronization, various systems or human can understand and coordinate with each other dynamically through the web in making the

decision. It also need to set stage parameters and attributes for decision making and keeps track of progress. Sometimes, e-DSP has to facilitate and mediate so as to help them arrive at a common decision.

- Process automation: Time has become very critical as customers are having high expectation and requirements on providers with very low tolerance on waiting. Therefore, process automation by standardization and agreement can accelerate the whole process.
- Fulfillment Trust: With such dynamic partnership building, all participants must build trust other partners in the group that each one has the capability to fulfill the task distribution based on the decision made. This trust establishment is very important because if only one of participants fail to complete the task, it brings to the failure of the whole chain. With this trust, we can ensure the reliability of the business decision making.

2. Integrated Decision Making Process

It includes a set of mechanisms which consists of two main parts:

- Complex Goal-oriented: the nature of problems that e-DSP helping to solve always comprises of global goal and sub goals which involved different parties' benefits. Therefore, it must have the ability to separate them by applying its knowledge and intelligence to identify their inter-relationship and dependence. In order to meet this need, it must equip with various decision tools and optimization methods to find out the best decision. With this, participants with different knowledge background can also make use of it to make decision together.
- Guided Conflict Resolution: It should adopt the various conflict management techniques, like those mentioned in [20], in order to solve problems produced by single goal and global goal towards a business process. It should be able to identify and detect the conflict areas with respect to different parties. It should also have a defined mechanism which set steps and stages for solving the conflict.

3. Integrative Partnership

This feature has the following characteristics:

- Any-to-any Interaction: Allow interaction among more than one and non-determinant number of parties by having an open public communication channel with the ability to uniquely identify each one dynamically on the web.
- Dynamic Group Morphing: With reference to IOS planning processes stated by Finnegan in [3], different parties can dynamically group up together on the web in order to serve specific customer's need. Each chain is unique and only valid for duration of particular business or job. Thus, a company can have different role in different business processes. e-DSP must support any number of participants, human or agents forming groups in various ways: sequential chains, webs or networks.

Besides the above characteristics, there are still other

points needed to take into considerations while designing and implementing such platform, they are mentioned in the next section.

6. Remarks

The neutrality nature of e-DSP is apparent from its 4th party structure. The role of each participant and their relationship with each other must be transparent to the e-DSP, and in some cases, for all partners. e-DSP is built for a web-based environment, it is assumed to equip with all the current computer and web technologies. These technologies facilitate e-Business activities and encourage collaboration and integrations between partners. Yet we need to further investigate so as to make improvements on the stability, interoperability and reliability of channel establishment, data communication between partners.

With a general understanding of e-DSP's characteristics we believe that it is indispensable to the development of e-Business by facilitating collaborative decision making with dynamic partnership. The framework provides technical design to develop such decision platform with respect to different industry needs. We will explore the current and emerging technology required to implement this platform.

Proposing a Paradigm for e-Collaboration

Gang Chen[§], Waiman Cheung, Sung-Chi Chu and Wai Hung Wong

Hong Kong, P. R. China

[§] chengang@baf.msmail.cuhk.edu.hk

Abstract

E-Collaboration has been attracting more and more attention and interest of academic researchers and industry practitioners. However, the paradigm of e-Collaboration has yet to be established. Various researches often incline to label subjective research studies relate to inter-organization interaction or integration with the hot title. To clarify terminology used and to remove ambiguity on e-Collaboration, the paper aims to provide a cohesive framework of e-Collaboration from the perspective of inter-organizational integration. The framework highlights the core feature of e-Collaboration—joint intellectual efforts, which has been neglected by existing studies. Moreover, a mathematical modeling approach is further used to illustrate the differences among each levels of integration in a two-party context. The descriptive and modeling approaches both attempt to establish a paradigm for e-Collaboration. And the future research directions will be indicated based on the paradigm.

Keywords:

e-Collaboration, Integration, Paradigm

1. Introduction

Several related concepts appeared under the umbrella of collaboration, such as e-Collaboration and collaborative commerce, attracting more and more attention from academic researchers and practitioners [9] [11] [15] [25] [26]. However, there is no consensus of what e-Collaboration is. Different interpretations lead to difficulty in the differentiation of related concepts such as cooperation, contribution, coordination, cooperation and collaboration. A paradigm of e-Collaboration must be established.

As we all know, the incommensurability of paradigms is crucial to the development of scientific theories. “Scientists who pursue different paradigms are, in a sense, living in different worlds.” They cannot communicate nor share insights on “the problems to be solved, the theories to be employed, or the terminology to be used” [1] [20]. Hence, to benefit the pullulation of e-Collaboration in electronic environment, an agreeable and acceptable paradigm of e-Collaboration is needed to facilitate idea communication, theory development and knowledge accumulation within the research community.

The paper firstly surveys the current views on

e-Collaboration. Consequently we attempt to bring the diverse views into a unified framework of e-Collaboration, based on levels of inter-organizational integration. And a mathematical modeling approach is further used to illustrate the details of framework in a two-party context. Both descriptive and mathematical illustrations of e-Collaboration framework provide concrete theoretical foundation for paradigm of e-Collaboration. Furthermore, the framework can be used to organize current research findings and share insights on future directions.

2. Literature Review

2.1 Importance of e-Collaboration

Collaboration plays a major role in many differing business processes. Various research on collaboration spanned across topics that include manufacture production [3] [7] [21], supply chain management, logistics management [6], process reengineering [8] [24]. Highly competitive markets impose new requirements on inter-organizational relationship among ventures [4] [17]. Especially those processes that now operated in an electronic environment, online inter-organization activities often involve various degrees of e-collaboration. Such collaboration involved sharing of information, resource, risk and responsibility should be achieved in a more effective and efficient manner using electronic means. The success of inter-organizational systems [13], a kind of implementation of e-Collaboration, for example, is essential for co-operative ventures in electronic environment.

2.2 Diverse views of e-Collaboration

Although quite a number of researchers have offered their insights on e-Collaboration, few have directly indicated a specific definition. A common understanding has not been reached. Pinsonneault and Kraemer [25] and Dasgupta et al. [10] referred to “collaboration among individuals” as they are being “engaged in a common task using electronic technologies.” Blevins [23] highlighted the newness of e-Collaboration as “electronic automation of collaboration interactions”. And Lee and Whang [22] specifically took e-collaboration as an application of e-business existing in such functions as information sharing, collaborative decision-making and product change management. However, the diverse views mainly

consider e-Collaboration as simply a sum of collaboration and electronic technologies and do not indicate or expose the core feature of collaboration. More importantly, “common task” is not the sufficient condition of e-Collaboration. And we cannot classify some process or applications in the scope of e-Collaboration simply based on its using in information sharing, collaborative decision-making or electronic automation of collaboration interactions. The above interpretations contribute to understand some features of e-Collaboration, but they do not touch on the essential feature of e-Collaboration, joint intellectual efforts. And the problem of using the same term to indicate different levels of interaction, limits the ability to compare, and build or improve, on existing concepts.

Existing studies pay little attention on the different levels of integration, and the outcomes based on various kinds of technologies with respective to integration could not be collectively claimed as impacts of e-Collaboration. Lefebvre et al. [23] assessed the impacts of the eight so-called web-based collaboration tools on innovativeness and performance of firms in a telecommunications equipment supply chain. However, these tools facilitate the enforcement of the different levels of integration, not sole for collaboration.

In addition, research on taxonomies and classifications of e-Collaboration systems embodied most information systems, and classified the systems in such dimensions as technical consideration, group issues, application, time/space, etc., but do not in the perspective of integration [2] [19] [12]. Such classifications further deepen the diversity of views on e-Collaboration.

3. A Framework of e-Collaboration

To begin our attempt to conceptualize the idea of e-Collaboration, we base our development on the insights of Taylor-Powell [26]. They contributed an important edification on interpreting the concept of collaboration in an intact framework—integration. They ranked communication, contribution, coordination, cooperation and collaboration by the different extents of integration and preliminarily described their differences. To allow a clear differentiation of different efforts in collaboration, the specialties of each level must be established. A framework of e-Collaboration will be proposed to clarify terminology used and to remove ambiguity on e-Collaboration. An essential uniqueness in our approach is the specification in the framework for e-Collaboration — joint intellectual efforts, a feature that is not considered by existing research in imprudence.

3.1 Levels of Integration

In our framework, communication is the lowest level, supporting dialog and common understanding in general. Contribution benefits participant parties by mutual support based on communication. And coordination integrates parties in deeper extent by matching needs and adjusting activities. To achieve common goals, higher

integration — cooperation is required by parties. When the demanding requirements deduce the joint intellectual, comes collaboration and e-Collaboration in electronic environments.

Thus, e-Collaboration can be referred to the process of working together with joint intellectual efforts in electronic environments. Information technologies are used to facilitate the parties to work together and to contribute joint intellectual efforts. And the benefits of e-Collaboration are, for example, to facilitate the offering existing or newly created common products or services with reallocation of controlled resources, even with new production skills or marketing methods.

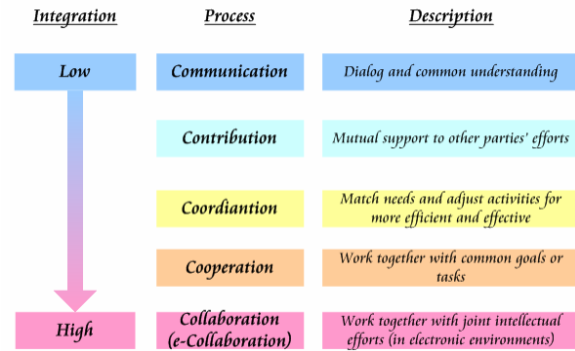

Figure 1: Description of Levels of Integration

However, researchers may hold different interpretations on common understanding, mutual support, working together or joint intellectual efforts. Thus, we develop a cohesive interpretation by using mathematical modeling approach, to delineate the different levels of integration and to quantify the activities within each.

3.2 Mathematical Modeling

Assumption

Let us assume two parties integrate to maximize the respective sum of individual outputs originally. Each of them produces the products or services by some specific production skills with the controlled resources as inputs. Let: B_i denotes the vector of resources of party i ; X_i denotes the vector of outputs of party i ; and A_i denotes the matrix of coefficient of production of party i ($i=1$ or 2 , in this case).

Then the decision making of production of each party can be modeled in L-P equations.

$$\begin{aligned}
 \text{Max } Z_1 &= f_1(X_1) & \text{Max } Z_2 &= f_2(X_2) \\
 \text{s.t. } A_1 X_1 &\leq B_1 & \text{s.t. } A_2 X_2 &\leq B_2 \\
 \text{or } A_1 X_1 + C_1 &= B_1 & \text{or } A_2 X_2 + C_2 &= B_2 \\
 C_1 &\geq 0 & C_2 &\geq 0 \\
 B_1 &\geq 0 & \text{and } B_2 &\geq 0
 \end{aligned}$$

Where C is the slack variables of the L-P equations.

Modeling Communication

Communication in electronic environments can establish common understanding on some terms or facts. Thus, it can be abstracted as exchanging and

understanding declaration of variables in our model.

Modeling Contribution

With the contribution mechanism, parties involved in integration can share their information by exchanging some values of common variables. These exchanged values can support parties to make decision more efficient and effective. A better optimal solution of L-P equations can be reached, compared to the stand-alone situation. Such level of integration—contribution, has been shown to have positive impacts and benefits for parties, e.g. on information sharing in supply chain.

Modeling Coordination

Coordination mainly focuses on finding out feasible solutions on adjustment of activities, removal of duplication, or allocation of resources to improve the performance of resource usage. In L-P modeling, the possible degree of adjustment of resources is represented by the scale of slack variables.

Modeling Cooperation

Cooperation refers to working together with joint goals. Thus it is logical to deduce that the objective functions of two parties must have at least one common component to denote the existence of joint goals. And both should reallocate their controlled resources beyond the limitation of slack variables to meet the requirements of joint goals.

Modeling Collaboration

Collaboration differs to other levels of integration in incorporating joint intellectual efforts. In producing products or offering services with controlled resources and skills on hand, the joint intellectual efforts can be shown specifically in creating new joint products or new services (X_4), generating or enrolling new production skills (A_4), coming up new marketing methods to joint products or services (F), and optimizing the production process of joint outputs.

Consequently the variables need to be redefined to show the possible change of collaboration. X_1 will be divided into X_{11} for local products, X_{13} for existing common products and X_{14} for new created common products. So will X_2 as X_{21} , X_{23} and X_{24} . Then the common output X_3 is the sum of X_{13} and X_{23} , and X_4 the sum of X_{14} and X_{24} . Concurrently f_1 may break into f_{11} and f_{13} , f_2 into f_{21} and f_{23} , B_1 into B_{11} for local products and D_{12} for common products, and B_2 into B_{21} for local products and D_{22} for common products. Therefore, the optimization of common products is

$$\begin{aligned} \text{Max } & f_3'(X_3) + f_4'(X_4) \\ \text{s.t. } & A_3'(X_3) + A_4'(X_4) \leq D_{12} + D_{22} \\ & 0 \leq D_{12} \leq B_1 \\ & 0 \leq D_{22} \leq B_2 \end{aligned}$$

For party 1, it will make its optimal solution for the amount of each output.

$$\begin{aligned} \text{Max } & Z_{11} + Z_{13} + Z_{14} = f_{11}(X_{11}) + f_{13}(X_{13}) + f_{14}(X_{14}) \\ \text{s.t. } & f_{11}(X_{11}) + f_{13}(X_{13}) + f_{14}(X_{14}) \leq Z_1 \\ & A_{11}(X_{11}) \leq B_{11} \\ & B_{11} + D_{12} \leq B_1 \\ & \frac{\partial Z_{11}}{\partial B_{11}} \leq \frac{\partial (Z_{13} + Z_{14})}{\partial D_{12}} \\ & X \geq 0, \quad B \geq 0, \quad D \geq 0 \end{aligned}$$

For party 2,

$$\begin{aligned} \text{Max } & Z_{21} + Z_{23} + Z_{24} = f_{21}(X_{21}) + f_{23}(X_{23}) + f_{24}(X_{24}) \\ \text{s.t. } & f_{21}(X_{21}) + f_{23}(X_{23}) + f_{24}(X_{24}) \leq Z_2 \\ & A_{21}(X_{21}) \leq B_{21} \\ & B_{21} + D_{22} \leq B_2 \\ & \frac{\partial Z_{21}}{\partial B_{21}} \leq \frac{\partial (Z_{23} + Z_{24})}{\partial D_{22}} \\ & X \geq 0, \quad B \geq 0, \quad D \geq 0 \end{aligned}$$

4. Remarks

The proposed paradigm clearly describes the differences of concepts at various levels of integration. And the modeling framework further details the different requirements of information sharing, resource sharing, process management, and marketing of products or services in different levels. Moreover, the paradigm can illustrate some promising potential research issues in e-Collaboration: (1) benefits or impacts of each level of integration, including e-Collaboration; (2) interdependency and interaction between e-Collaboration and intra-organizational structure or inter-organizational relationships; (3) establishment, manipulation and assessment of information infrastructures or systems of e-Collaboration. In addition, from the viewpoint of development, issues such as the negotiation of forming partners, adjustment or change of intra-organizational structure and inter-organizational relationships, implementation guideline of information systems, and acceptance and adoption of e-Collaboration are alike in importance in e-Collaboration research.

Abstract

Customer loyalty has been recognised as an important driver of company profitability. In the electronic environment the importance of attracting loyal, profitable customers is essential, because the acquisition costs are even higher than in traditional business. The wireless environment offers all kinds of companies possibilities to serve their committed customers independent of time and place and strengthen the customer relationships with supporting mobile services or wireless marketing communication. A key challenge is how to identify loyal customers and keep them loyal in the mobile environment. Therefore, it is important to develop accurate measures for loyalty that identify the characteristics of customer loyalty in a new wireless environment that takes into account the context based nature of mobile service usage situations as well as attitudinal loyalty towards a brand and commitment to the service provider. So far, traditional loyalty measurement scales have not been tested in the mobile service context and modifications are needed. This study explores the nature of loyalty to mobile services and suggests a scale for measuring it.

1. Introduction

"Where, in the past, customer loyalty was just one weapon to use against competitors, today it has become essential to survival" [29] p.179].

It has been suggested that customers are less loyal in electronic environments, because it is easier to find information about competing products and companies. Research has shown that in the electronic environment it is more expensive to acquire new customers than in the traditional environment. In addition to customer acquisition costs, customers tend to choose well known brands that they trust [30] [29]. It also seems that after people become more experienced in using the Internet they concentrate the visits to just a few websites. In the mobile environment switching from one service provider to another is considered easy and building customer relationships is challenging. Nevertheless, electronic environment is supposed to have a tremendous potential for creating customer loyalty, because of the possibility of provision of quality information and standardisation of firm-customer interaction. [15] Currently, mobile services are offered mostly by tele operators. However, the

wireless environment offers all companies new opportunities to strengthen their customer relationships with the means of supporting mobile services or wireless marketing communication.

The importance of customer loyalty for company profitability is widely accepted. Customer loyalty is believed to accumulate revenues and to lower the costs of serving customers [16] [28] [11] [10]. Companies should target customers that are likely to do business with the firm in the long run and they should earn customers' trust by offering consistently superior service experiences [28] [30]. Building a loyal customer base requires investments and is profitable only when customer relationships last long enough to cover the costs of relationship building (identifying customers' needs, customising offerings, monitoring performance). Companies can benefit from identifying the customers that are most willing to maintain a relationship. [5] A key challenge is thereby to identify the potentially loyal customers and understand how loyalty can be enhanced.

Mobile services are relatively new to most customers in many markets and many are trying these services for the first time. It is important to examine the determinants of customer loyalty in order to enhance it and build sustaining customer relationships by offering positive experiences to the right customers from the beginning. There is a lack of empirical research on the concept of loyalty in a mobile service context. Most empirical research on electronic services has focused on the Internet, whereas mobile services have received less attention. So far, surveys have mainly tested the willingness of respondents to adopt certain mobile services [27] [1]. There is a lack of empirical research that considers loyalty to mobile service providers or brands that takes into account the context based nature of mobile service usage. The measures need to be developed further in order to capture the attitudinal loyalty towards a service and commitment to the service provider. In-depth studies of the nature of loyalty in mobile services from a customer's point of view are necessary to advance research in electronic services in general, and more specifically to enable customer-oriented development of mobile services as well as loyalty enhancing relationship marketing.

2. Aim of the study

The aim of the study is to explore the nature of customer loyalty to mobile services and to suggest a scale for measuring it.

3. Mobile Services

The mobile phone is nowadays used for many more purposes than just a communication device as mobile content and entertainment services are developed further. U.S. currently lags behind Japan and Western Europe in terms of mobile data usage, but all in all prospects for mobile services seem positive in the future. Ovum projects that by 2007 world-wide revenues generated from mobile services (information & entertainment) will rise from USD 16.7 billion in 2003 to total USD 77.8 billion in 2007. [31] Most potential is seen in mobile commerce, location based services and entertainment. [19]

Current mobile services are offered for example by tele operators, mobile portal owners, mobile service providers as well as companies offering their customers supporting services via the mobile phone. Usually, services can be accessed regardless of which tele operator the customer uses. Even tele operators face the challenge of building brand loyalty in the market, where switching tele operators has become popular. Tele operators are currently spending more to differentiate their services and sell premium services that build revenue.[18] The focus of this paper is on loyalty to mobile services in general, regardless of who offers them.

3.1. Definition of Mobile Services

There does not yet exist a conceptual agreement on the term mobile commerce. Generally, the nature of mobile commerce is that services can be accessed anywhere, at any time. Mobile services are often referred to as wireless services. Nevertheless, wireless is not necessarily mobile. The definition of mobile includes the notion of mobility and emphasises the importance of communication-in-motion. [2] Wireless service can be for example an Internet service accessed via a wireless local network (LAN) area by a laptop computer at an airport. Mobile service on the other hand is, in principle, entirely independent of physical location, e.g. obtaining a stock quote over a mobile phone sitting in a bus on the way to work. Mobile service usage is not restricted to mobile phone users. Services can be accessed with all kinds of handheld devices with wireless applications e.g. personal digital assistants (PDA). Nevertheless, because penetration of other handheld devices are still small compared to mobile phones, this paper will mainly concentrate on services that are accessible via a mobile phone. I define mobile services as any kind of service that can be accessed via a mobile device, and that is delivered in interaction between an organisation and a customer.

Thereby including customer relationship communication and excluding text messaging to private persons.

Some existing mobile services are presented in Figure 1 in order to illustrate the special conditional nature of mobile services. Mobile commerce unleashes the limitation of physical barriers present in electronic commerce, because the customer can carry the service around as he or she moves from one place to another. Services can be accessed anytime, anywhere in a location-independent manner.

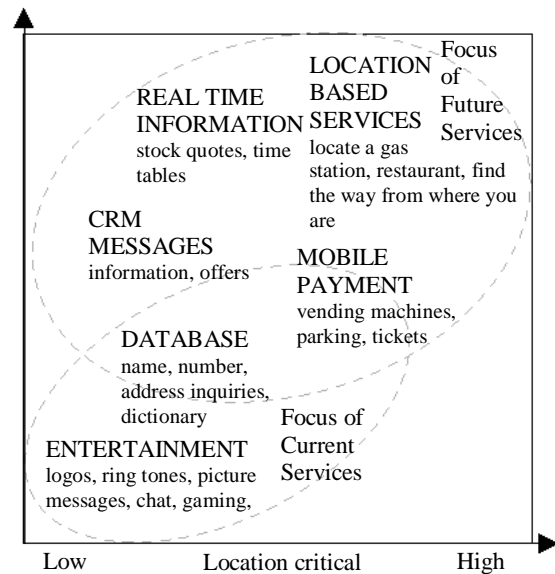

Figure 1: The Domain of Mobile Services

In the mobile environment the following things, which are depicted as the three axes in Figure 1, are considered to be important compared to other options (Internet and traditional channels):

- 1) Location: the relative location of the user, when the service is used.
- 2) Time: the relative immediacy of the needed service and the task that is being completed. [21]

Next, some of the mobile services depicted in Figure 1 are described more in detail. Entertainment services are very dominant in the current mobile service market. Normally customers order logos, ring tones and similar services where and when they want to, but ordering these services is not location or time critical. They can be ordered anywhere. Location based services on the other hand, are a good example of highly location and time critical mobile services. In a situation when a task has to be done, or information obtained, immediately in a certain location, the benefits of mobile services are distinguished best. For example, you can with the help of a location based service locate yourself or others (e.g. spouse, children, elderly people) in case of an emergency and get information how to take the shortest way to the place you want to go to. Mobile payment is often used in situations when cash is not available, or just because it is

convenient to pay parking fees, metro or bus tickets with the mobile phone, or because you are in a hurry and do not have the time to purchase the ticket beforehand. Real time information refers to information ordered to the mobile phone that is highly time critical, e.g. Ordering stock quote information or information about flight delays. Customer relationship communication to customers who have given permission to contact them through the mobile channel can be for example SMS message that your car is ready to be picked up from the garage or alerts on a limited time promotional airline fare or a SMS reminder that the seminar you have signed to begins at 9 o'clock and gives instructions how to get there and maybe even asks you to reply to the SMS message, if you prefer red or white wine at conference dinner. Information that is acquired from databases, e.g. name, number or address information inquiry services are not that dependent on location, but normally ordered in a situation when you expect to get the information easily within a reasonable time.

The most fruitful domain of mobile services is a highly time critical and highly location critical service that is perceived highly valuable by the customer. The competitive advantage of the mobile channel compared to other channels is highlighted in services that offer these kinds of solutions. The services that until now have reached the great mass of customers (e.g. entertainment services) will naturally exist in the future as well and will be perceived valuable be the right target group. But from the loyalty viewpoint, the most important mobile services in the future will be services, that serve the customer better, more personally and enhance the relationship between the service provider and the customer as well as support other service channels in time and location critical contexts.

4. Literature Review

Next, the concept of loyalty is defined based on previous literature. The nature of loyalty is discussed more in detail in order to highlight the special context based nature of mobile service usage situations. A list of suggested scale of items for measuring loyalty to mobile services is presented at the end of this paper.

4.1. Customer Loyalty

Traditionally customer loyalty has been defined as repeat purchases [24]. Nowadays, the loyalty concept in marketing research typically includes the two-dimensional nature of customer loyalty consisting of a physical and mental dimension. Even though researchers have included the attitudinal factor, companies still often tend to assess loyalty based on behavioural measures.

Day [8] was one of the first to emphasise the importance of attitude in addition to loyal behaviour and to distinguish between intentional and spurious loyalty.

The following quote depicts the attitudinal aspect of loyalty i.e. commitment.

"Loyalty is a deeply held commitment to rebuy or repatronize a preferred product / service consistently in the future, thereby causing repetitive same-brand or same brand-set purchasing, despite situational influences and marketing efforts having the potential to cause switching behaviour." [24, p. 34]

Commitment can result from either dedication (affective commitment) or constraints (calculative commitment). Attitudinal loyalty is equivalent to affective commitment. [5] Attitudes influence behaviour and several researchers have found positive relationships between attitudes i.e. commitment and behavioural loyalty [17, 23].

Mobile services are often based on a contract with the service provider or the services are used on a pre paid account. Such constraints, make it hard to change service providers, and are indicators of calculative commitment. Bendapudi and Berry [5] suggest that constraint based relationship maintenance can lead to staying in the relationship, but dedication based relationship maintenance leads to enhancement of it through affective commitment. Therefore, attention should mostly be given to affective commitment.

In this study commitment refers to "a buyer's enduring desire to continue a relationship with a seller accompanied by his willingness to make efforts at maintaining it" [23, p. 64]. This conceptualisation includes the attitudinal aspect of loyalty and it has been successfully used in a recent study by Odekerken-Schröder [23]. Similar definition has been used e.g. by Morgan and Hunt.[22].

In this study customer loyalty is defined as a combination of loyal behaviour and commitment. Hence, a loyal customer is someone, who believes that an object firm's products continue to offer the best choice alternative and thereby ignore communications from competitive firms. [24]

4.2. Consequences of Loyalty

Loyalty can be expressed in multiple ways, including saying positive things about the company to others [6], recommending the company or service to others [25], paying a price premium, and remaining loyal to the company. [37]

Zeithaml et al. [37] developed a conceptual model of the impact of service quality on behaviour that signals whether customers intend to remain with or defect from a company. The scale items for the model depicted word-of-mouth communication, purchase intentions, price sensitivity, and complaining behaviour. To clarify the

relationship between loyalty and its consequences, the measures should in my opinion be separated into different constructs. This view is supported by e.g. Hennig-Thurau et al [17] who defined word-of-mouth as a consequence of commitment [17]. Harrison-Walker [36] also posit that affective commitment as an antecedent of word-of-mouth communication. Dick and Basu [9] also claim that consequences of loyalty include word –of-mouth, resistance to counter persuasions and search motivation. Moreover, attitudinal loyalty has been proven to lead to willingness to pay a higher relative price [7] [12]. Therefore, in this study word-of-mouth communication and willingness to pay more are considered to be consequences of loyalty. Switching behaviour is considered to be a possible consequence of low commitment.

Switching to another service provider is considered easy in the mobile service context. However, the learning process in general, including downloading the necessary software and settings to be able to use new mobile services requires time and effort. The help and advice of friends is very important when people are trying mobile services for the first time. Hence, it can be assumed that positive word-of-mouth communication is more important in the mobile service context than it is in traditional or e-business context.

Moreover, in a mobile service context the awareness of brands and service providers and knowledge how to use the services is essential for initial use. Previous research [26] shows, that the most common problems in using mobile services are that people do not remember how to access the services, or perceive using the mobile services very difficult. Price sensitivity might be of less importance in mobile services than in traditional services, because they are often used in a context when other media is unavailable.

4.3. Special Characteristics of Loyalty to and Consequences of Loyalty to Mobile Services

In the future, when people get used to using the mobile technology, users of mobile services will be more illoyal, informed, impatient and goal oriented. They will expect independence, control, experiences, personalisation, freedom of place and a digital co-operation partner. The greatest value for customer is created when communication, information and transaction are integrated in the physical and social context where the customer is. [35] Especially the access to real-time information services can be criteria to choose a service provider. The perceived value of mobile services will rise if the customer can access relevant information that is specified to a certain place and time.[33]

People are currently trying the services for the first time and when the novelty effects wear down, probably only the best services offered by the best known service providers will be used frequently in the future. In the

Japanese market some loyalty effects of mobile services have already emerged. Hence, iMode users personalise their phones with entertaining icons, ring-tones, cartoons, buddy programs and individual browsing preferences, which has lead to the lowest global churn rate. In general, personalised services are expected to create strong customer relationships that encourage transactions and prevent customers from switching to different services. [3].

However, loyalty is complex to estimate in a market, where there are many different actors contributing to the delivery and invoicing process. The complex invoicing principles in Europe do not really support the development of mobile services. In Japan, the business structure is clearer than in Europe. NTT DoCoMo provides a central portal through which the service providers offer their services [3]. Invoicing may also base on prepaid account. However, the pre-paid account does not allow specific tracking of use of the services, which probably makes it more difficult to assess the behavioural loyalty to the services offered.

In mobile services, loyalty consists of a loyal attitude towards the service provider or brand as well as loyal behaviour – ordering the same service frequently or always as the situational need arises for the service. Loyal behaviour in mobile services may be expressed by ordering a variety of services from the same service provider, ordering the same service again or ordering more sophisticated services from the service provider. Attitudinal loyalty has been proven to be an especially important factor influencing customer relationship in services where customer relationships are often based on service contracts with the service provider [12].

In general, it is easy to track behavioural loyalty of some mobile services, for example how many times and how frequently the owner of the tele operator's account has ordered a mobile service (e.g. paying your parking fair, bus ticket or vending machine purchase with a mobile phone), because the transactions are often invoiced on a monthly phone bill. Tele operators, mobile service providers and mobile portals have the best opportunities to combine customer information with their consumption data. Other companies have difficulties in accessing the consumption data, because they have no invoicing relationship with the customers.[33] Nevertheless, it is difficult to define who in fact has ordered the service and even more difficult to assess how the customer perceived the service and if he or she is going to use it again. These kinds of core mobile services are today mainly targeted to new customers. Supporting mobile services, which are offered to current customers (e.g. real time information about account balance, or information sent to the mobile phone when your car is ready to be picked up from repair) are easier to track, because it is possible to link the customer data and the service usage data. However, these behavioural measures of mobile service use do not reveal how committed the

customers are to the service provider and what their purchase intentions are in the future. Neither do they reveal the share of wallet or if the customer is also using competing mobile services. Therefore, other measures for customer loyalty are needed to complement the behavioural loyalty measures.

Commitment can be expressed e.g. telling friends and colleagues positive things about the usage experiences of mobile services, giving advice how to use the services, expressing willingness to pay more for customised services, replying to CRM-messages, forwarding valuable information to your friends, updating the mobile phone configurations to be able to access e.g. picture messages etc.

The consequences of loyalty: word-of-mouth communication, price sensitivity and switching are depicted by traditional behavioural intentions battery suggested by Zeithaml, Berry and Parasuraman [37]. However, Harrison-Walkers [36] set of items generated to measure separately activity (enthusiasm and detail) and praise (favourableness) word-of-mouth were included in the scale items. Activity items are specified to measure how often the word-of-mouth communication takes place and to how many people the word-of-mouth sender communicates to. Praise items are designed to measure the favourableness of the word-of-mouth. These constructs were included, because in a context based environment, word-of-mouth is a more complex construct than in the traditional environment. In Internet and mobile channels it is easier to forward messages to many friends and therefore the number of recipients, the frequency of the communication as well as the quantity of information provided are all important components of word-of-mouth measures. [36]

Switching intentions in mobile services are often expressed as intentions to switch service provider even if the service provided is satisfactory. Even if the mobile service meets the customer needs and is delivered excellently, problems often arise in customer service and transactions in the billing phase. Therefore, it can be assumed that customers are committed to mobile services in general, but not necessarily committed to the service provider. Nevertheless, it is difficult to make a distinction between commitment to a service brand and to a service provider. Usually, the service provider markets mobile services and thereby the service and service provider are perceived as the same. However, the mobile services offered today, do not differ much from one service provider to another and thereby differentiation is mainly based on the brand perceptions as well as the image of the service provider. Opportunities exist to more personalised services and customer relationship management communication via the mobile channel.

5. Suggested Measurement Scale

The scale items for measuring loyalty are suggestions based on current loyalty literature. However, some modifications to the traditional measures have been done based on researchers' experiences from a preliminary pilot study about customer loyalty to mobile services [26]. The results indicated that many respondents agreed strongly that they would use the services again, but they would not necessarily choose the same service provider again. Furthermore, the choice of service channels is important, because mobile services are often used in situations where other service channels are not accessible. Therefore, the loyalty measures are divided into three separate sections: service provider specific questions, mobile service specific questions and channel specific questions. The commitment measures have been given special attention because attitudinal loyalty is especially important in service environment. If customers do not feel committed to the service provider, the relationship will not last.

The scale items were developed so that the questions fit different kinds of mobile services, but are so general that users of different services can answer the same questions. The scale items in the Appendix 1 are preliminary suggestions for measuring loyalty to mobile services. The scale items will be developed further and the reliability of the measures will be tested later on with the help of a separate survey that will be conducted on end users of different mobile services.

6. Conclusions and Suggestions for Further Research

Models that are built based on empirical research of traditional services are rarely applicable as such for assessment of new electronic services. This paper contributes to earlier research on loyalty by suggesting a measurement scale for loyalty to mobile services. However, the reliability of the suggested measures should be tested empirically preferably with samples including end users of different type of mobile services provided with several service providers. The relationships between loyalty and consequences of loyalty as well as the relationship between commitment and behavioural loyalty in mobile services need to be viewed critically and researched further in the future.

Appendix 1: Scale items

Mobile service is any kind of service that can be accessed via a mobile device, and that is delivered in interaction between an organisation and a customer. Thereby including customer relationship communication and excluding text messaging to private persons.

Each item will be accompanied by a 7-point likelihood scale (1= totally disagree and 7= totally agree).

(-) = will be reverse coded.

Dimension	Scale item	Source
	SERVICE PROVIDER SPECIFIC QUESTIONS service provider = the organisation that offers the service to the customer (tele operator, mobile portal, other company offering a mobile service)	
Commitment	I consider this service provider my first choice to order mobile services	Modified from [20, 37]
	I am proud to use the services of this provider	[36] [13]
	I care about the fate of this service provider	[36]
	I like the way this service provider organisation operates	[36]
	I feel loyal to this service provider	[13, 23]
	It would be difficult for me to change to another service provider	modified from [32] [4] [36]
	Changing to another service provider would be impractical	[36]
Behavioural	Next time, when I need such services, I will choose this service provider	[34]
Intentions	I intend to continue ordering from this service provider over the next few years	[14]
	As long as the present service is offered, I doubt that I would switch service provider	[14]
	I will order more services from this service provider in the future	modified from [37]
Switching	I will order less services from this service provider in the future (-)	modified from [37]
	I will order mobile services from another service provider in the future that offers better benefits (-)	modified from [37]
WOM	I will recommend the service provider to someone who asks my advice	modified from [37]
	I say positive things about this service provider to other people	modified from [37]
(activity)	I mention this service provider to others quite frequently	[36]
(activity)	I've told more people about this service provider than I've told about most other service providers	[36]
(praise)	I have only good things to say about this service provider	[36]
(praise)	I am proud to tell others that I use this service provider's services	[36]
Price sensitivity	I will continue to order services from this service provider even if the prices increase somewhat	modified from [37] [12]
	I will accept higher prices if this service provider raises its' prices	[12]
	SERVICE SPECIFIC QUESTIONS Service = the mobile service the respondent has used (e.g. Paying for parking fee, buying a metro ticket, ordering a ring tone, ordering stock quotes)	
Commitment	I use the same service via different channels (internet, store, phone) depending on where I am, when the need for the service arises.	
WOM	I will recommend this particular mobile service to someone who asks my advice	[37]
	I say positive things about this particular mobile service to other people	[37]
	I would gladly help friends and relatives to use this mobile service for the first time	
Price sensitivity	I will continue to order this mobile service even if its prices increase somewhat	[37] [12]
	I would pay a higher price for the mobile service than competitors charge for the benefit I currently receive from this service provider.	[37] [12]
	CHANNEL SPECIFIC QUESTIONS	
Commitment	I consider the mobile channel my first choice to order this service	Modified from [20, 37]
	It would be difficult for me to order this service via other channels (internet, store)	
Behavioural	Next time, when I need this service, I will order it via mobile channel.	[20]
Intentions	I will order more mobile services in the future	[37]
Switching	I will order less mobile services in the future (-)	[37]
WOM	I will recommend mobile services in general to someone who asks my advice	[37]
Price sensitivity	I will continue to order services via the mobile channel even if the prices increase somewhat	[37] [12]
	I would pay a higher price for the mobile service than for the benefit I currently receive via other channels.	[37] [12]

Game Industry in Asian Tigers: Analysis and Suggestions

Abstract

According to a recent report, the game industry, including PC games and video games, have already grown larger than the movie industry in the last a few years. The phenomenon represents that the game industry will be one of major entertainment industries in the very near future. Asian Four Tigers, including Korea, Taiwan, Hong Kong, and Singapore, have all developed the game industry as one of their future industries. As we have seen in other traditional industries, each country has experienced different levels of success, and faced different situations in this highly competitive battlefield. This study is an attempt to examine the potential of Korea, Taiwan, Hong Kong and Singapore in the game industry and to investigate the problems they might encounter on the way to attain globalization. Also, some suggestions are also made in the paper for those four Asian Tigers to improve their future competitiveness in the global markets of the game industry.

1. Introduction

The game industry is booming in a thunder-fast pace no matter in what kind of formation or on what kind of platform. According to Interactive Digital Software Association's research, 225.1 million of computer and video games were sold in 2001 in U.S. alone, which means the industry made 6.35 billion dollars from the sale [11]. According to the Market Intelligence Center (MIC) of the Institute of Information Industry, the global market for game consoles and software reached over \$26 billion in 2001. PC and video games accounted for about 80 percent [6].

Americans bought a record \$10.3 billion worth of video games, consoles and accessories in 2002 - more than they spent on going to the movies [3] - a figure which has become an important indicator that shows the era of a brand new type of entertainment is coming. Moreover, the global sales revenue of the game industry was estimated to reach to \$34.3 billion in 2003, 12 percent more than 2002 [21]. Compared with most industries that suffered in these years because of the world recession, the steady growth of the game industry could attract much more attention than ever before very easily. According to a latest research from Pew Internet, male college students in U.S. spend on an average of 15 hours per week on playing games [12]. Based on this substantial amount of number, more and more companies all around the world,

such as Sony and Microsoft, because conscious that the video and PC game industry could be one of their most important arenas in the near future and are trying to focus on this market in order to keep their leading positions in related industries.

Any company in any specific industry which could possibly connect to the game industry would not give this market up easily and many of them are eager to invade this territory in order to capture the market share in the early period. One of those examples is Nokia's latest cell phone N-Gage, which is the game controller-like cell phone designed specially for game playing. Compared with the platform of PC or video games, this is still the virgin land of the game industry with a great deal of potential.

2. The Importance of the Game Industry in Asian Tigers

Asian Tigers had played critical roles in Asian economy for many years mainly by manufacturing, especially Taiwan and Korea. Although two countries had made substantial profit by exporting electronic components that was ordered by the U.S. and companies from other countries, not much innovation or creativity were involved in it. According to the old experiences, incomes from this style of industry usually could not stand for a long period of time. The movement of those companies and investment into China could be a clear warning signal for two countries to become aware of this nature of the trend.

The rise of the game industry in these few years could give two countries a great chance to transform their IT industry to another new era. Since these two countries had already cultivated IT related infrastructures from the '90s, the environments are comparably more mature than other countries in East Asia. The online population in Taiwan was 8.59 million by the end of 2002, accounting for 37.35% of the total population. The broadband population was 2.10 million, accounting for 24% of the total online population [22]. These figures mean that about one-fourth of the people who had access online were using broadband service. Since the online gaming market is growing steadily since 1997 when Electronic Arts published the world's first successful multiplayer online role-playing game, the available rate of the broadband Internet service also became a critical indicator for the game industry. According to research done by Point-Topic in September 2002, Korea, Taiwan,

and Hong Kong are the top three in the list of DSL available rates worldwide. The U.S. was not in the list of top ten [17].

Compared with most major industrialized countries in the world, the size of Asian Tigers is tiny. The largest one in four, South Korea, which is only about the size of Hungary or half of New York [13]. Therefore, physical resources in the Four Tigers are scarce and high-value-added industries are eagerly needed. As Switzerland did with the watch and chocolate industries, the value added by games with the combination of programming, art, and entertainment could lead to a substantial profit for these countries, since both the game, watch, and chocolate are all the industries that add the maximum value to a single product.

2.1. Korea

Except for Japan, Korea and Taiwan play the major roles in the game industry in East Asia, especially Korea. Although Taiwan was in the leading position in the game industry among the Tigers in the early 1990s, Korea had already taken its place and expanded enormously. The Korean gaming industry posted revenue of \$833 million in 1999 and \$2.5 billion in 2001. The game developers there exported \$130 million in 2001 alone. According to the data from an assistant manager of Korea Game Development and Promotion Institute, a non profit association in the game industry that is entirely subsidized by Korean government, there are 2,600 game related companies in Korea, 1,900 companies are developing games and 700 companies are publishing at the point of January 2003. There are also eight companies developing video games for Sony's PS2.

Although both Taiwan and Korea are comparatively strong in the game industry among Tigers, Korea has more resources than the other three. The Korean government plays a very important role after 1998 in developing its game industry by supporting game companies and PC rooms (Internet Café). Young men in Korea even could avoid the obligation to serve in the military after passing the national test and working in the game industry for more than five years [10]. Moreover, the game developing courses were also offered in the high schools since ten years ago [20]. By combining these resources, Korea has a very special sustainable competitive advantage on developing its game industry, and it could be very helpful for it to transform its IT manufacturing industry into a content generating industry.

The prospering of the electronics industry could also have a great impact on the game industry. Contributed by the advanced technology, gaming platforms are not limited on PCs or TVs in recent years. Mobile phones could be a good example. Since Samsung had already made a great success by making a \$35 billion revenue worldwide in 2001[23] and had occupied the second largest market share, next to Motorola, in the U.S. market

[25], there could be a chance for Korean game companies to integrate their games into cell phones without cooperating with cell phone companies in other countries.

2.2. Taiwan

The competitive advantages of Taiwan are very similar to those in Korea. Both of these two countries had dedicated semiconductor experience to the IT industry for many years. However, the resources in these two countries could be definitely different in several aspects. Compared with the Korean government, the Taiwanese government spent little on game related investments. Game companies in Taiwan suffered by lacking budgets and quality personnel. The education aspect could be one of the major weaknesses on developing game industry in Taiwan. Although there were some schools and institutes began to educate students on game developing by setting up game related majors, the contribution was quite limited since the priority was still focused on short-term profit making. Since Taiwan is not the leading country in the game industry, instructors from other countries might be needed in order to make a breakthrough in this highly technological and entertainment oriented industry.

Taiwan was also one of those countries that set the IT industry as its primary target developing industry in the 21 century. The transformation from the high-tech manufacture industry is needed in the era that more and more people would agree that digital contents are more valuable than physical equipment. The success of the game industry also could be a critical indicator of Taiwan's innovation and transformation.

2.3. Hong Kong and Singapore

Hong Kong and Singapore are far behind Korea and Taiwan in the game industry. Although about 70% of households in Singapore have at least one PC inside [1] and 62% in Hong Kong [24], most of the games played by people who live here are still from the U.S., Europe, Japan, Taiwan, or Korea. Although there are still some game companies in Hong Kong and Singapore, the inability to reach their customers results from the lack of strong publishing companies is one of the major problems for them to make profits. Since most people here speak Chinese, they rely heavily on publishing companies from Taiwan in order to enter the Chinese markets, which include China, Hong Kong, Singapore, Indonesia, Malaysia, and Taiwan. Some companies in Hong Kong and Singapore target their market globally. Therefore, they would try to make their games locally, but publish them globally. The recent example would be the game Capitalism that was made by Enlight Software in Hong Kong, but published by UBI Soft, a France based global game publishing company that makes the game so that it could be bought worldwide.

Both the Singapore and Hong Kong governments were conscious about the trend of this prospering industry and

had invested some capital in it. The Government of Singapore Investment Corporation had invested in NCsoft Corporation, the Korean leading game company, by accumulating a 5% stake of it in the year of 2002 [19]. The Hong Kong government also set up the Secretary for Commerce, Industry and Technology to develop multimedia entertainment, including the game industry. Hong Kong also led game related companies to join the Electronic Entertainment Expo and Tokyo Game Show, which were two of the most important game expositions held annually in Los Angeles and Tokyo, Japan. Hong Kong, which has the second large entertainment film industry in the world [8], has an advantage as more and more films combine computer technologies in them. Movies like Final Fantasy in 2001, Matrix, and others integrated a great amount of advanced computer technologies making audiences used to accepting those fancy pictures. As the relationship between the film and game industries in these years grew closer, people there who were used to making films to entertain people could be familiar with the ways to do so in the game industry. The experiences in the film industry could be one of the most important assets for Hong Kong to get into the game industry in these few years.

3. What fields are cultivatable for game companies in four Tigers?

3.1. Hardware

Asian Tigers have no local-brand game console manufacturer. Manufacturers in Taiwan are concentrating on supplying OEM game consoles and accessories for Sony's PlayStation 1 and 2, Microsoft's Xbox and Nintendo's GameCube [7]. Since the worldwide console market was already dominated mainly by Sony, Microsoft, and Nintendo, it could be less possible for companies from Four Tigers to innovate any new console platform and to maintain competitiveness at the same time. Although the market of the game accessories is not what most game companies focus on, companies making game accessories like Logitech and Thrusmaster are still making good profits by producing joysticks for PC gaming. Four Tigers could concentrate on this part and do as innovative as possible within limitations.

However, it is not totally impossible for the Tigers to keep far from the console platform market. The Korean company Samsung Electronics could be one of Sony's toughest competitors in the very near future. Samsung had already got rid of the image of inferior goods by spending a great deal of money on advertising and developing new marketing strategies. It also has the technology to produce the large size plasma TVs and slim laptops that made Michael Dell shock and place the order from it immediately. Moreover, Samsung also had invested part of its resources on the game industry. The World Cyber Game competition held in Korea annually as the game Olympic could be one of those examples.

Once Samsung integrated all of its experience and expertise, a strong power can be generated, but its management decision making processes and financial structures still need to match NASDAQ's high standard in order to be a public company in the US [5].

3.2 Software

3.2.1. Platform – PC or Console?

There are only a few companies within Tigers to make console games. The amount of companies in Korea that are making console games are about eight, less than five in Taiwan, and no clue shows that there are any companies in Hong Kong and Singapore doing so.

Unlike PC with its open environment that any company can make games to fit its standard, the developing environment on console games is much closer and thus has more limitations. The obstacles of making console games therefore could be much more than making a PC version and thus could explain the phenomenon that there are only eight companies in Korea making console games.

3.2.2. Genre

According to NPD Tech World's research, the most popular game genre was sports on consoles and strategy on PC in 2001 [16]. Popular genres of the games differ from platform to platform mainly because of the nature of the functions created from the platform or game itself. People would not expect a video game player would use a mouse and plug a USB keyboard into the machine to play real-time strategy games. It would be also difficult for PC game players to control Jason Kidd, a star basketball player in NBA, to have some fancy movements before scoring by pressing a series of keys on the keyboard.

Not only the closed and inconvenient developing environment of the console games made the Tigers avoid developing them, but the sports genre also limited them. There are no such international famous sports in those four countries and area like the NBA, MLB (Major League Baseball), or European League soccer so that many people who do not live in America or Europe still could recognize those players easily. Therefore, the characteristics of comparable non-boundary strategy games (STG) or role-playing games (RPG) became the most popular genre of those game developing companies in the Tigers. The situation would likely still be the same in the future unless Asian professional sports could be well accepted by the whole world, or companies could not make it possible to make other genre of games with a hope to be competitive in the global market.

3.2.3. Online, Match, or Single Player Games

Since the success of Ultima Online made by Origin System and published by Electronic Arts in 1988, online

games became one of the most promising and competitive markets in the game industry. DFC Intelligence is saying that the online game market will grow from \$875 million (in 2002) to over \$5 billion worldwide in 2008. DFC, for reference, has reported before on the growth of the gaming industry and Nintendo's continued financial strength despite weak performances by GameCube. The majority may still have to do with PC-based subscription services, but there is a rapid increase in support of online capabilities by console systems. DFC also forecasts that the installed base of online-capable videogame systems will be over 100 million worldwide by 2008 [18].

Although the single player games and match games still have their markets, everybody's attention is on the online game market in recent years. For a game company, counterfeiting and piracy is one of the most serious problems it needs to solve, especially if its market is in Asia. Since the structure of an online game is totally different from a match game or a single player game, the company's revenue could be secured very well. An online game consists of two parts of programs. One part of the programs is installed in users' PCs or consoles make them as the client machines, while the other part is in the companies' headquarters or in ISPs (Internet Service Providers) machines and make them as the server machines. There is no access for any player to play any online game without connecting the client machines with the server ones through the Internet. Once a player's PC connects with the server, a unique ID and password will be requested. Therefore, it is useless for a player to just simply copy those client programs in a desire to get into the game.

Korea and Taiwan are doing very well on online game market. NCsoft Net, a Korean leading game company had 36 million subscribers on its online game-Lineage, 3 million of these subscribers were from Taiwan [14]. Because of the income secured and easy addictive characteristics of online gaming, it had already become a gold mine to many game companies. Moreover, the life cycle of a successful online game is usually about five years or longer (Ultima Online since 1998, Everquest since 1999), which also means the risk of inventing a brand new game could be eliminated once one online game could be accepted by enough players. According to the reasons listed above, the online game market could be one of the most important markets for game companies in Asian Tigers.

4. Where are the Markets?

For most companies in the game industry, game titles usually were designed for at least two similar markets in different countries. Game companies like Soft-World International Corp. from Taiwan could export their games easily to Hong Kong, China, Singapore, Malaysia, or even Indonesia and sell them to those Chinese origins. Theoretically speaking, game markets between these

countries could be circulated easier than marketing a game from Korea or other countries. However, because of the internationalization it became much easier to get information from other countries in the 21st century as boundaries between countries with minimum cultural differences could be eliminated. The best example to explain this phenomenon could be the Korean game market in Taiwan and China. By translating their contents into Chinese characters, the Korean game companies had already had 48.65% of the online game market share in China [2]. They also had 65% of the market share in Taiwan [9]. Since many Korean games were developed based on non-existing fantasy medieval stories, they minimized the resistance from different cultures and therefore could be accepted by consumers in other countries. The local markets for Asian Tigers are too small for companies to make substantial profits from them. Companies not only in the game industry, but also in other industries in Asian Tigers are all trying to sell their products regionally or even globally. Samsung Electronics could be an example of doing so.

For game companies in Asian Tigers, the easiest way to sell their games and to get acceptable profits could be to sell them regionally. Many game companies from Korea and Taiwan already did so and are making substantial profits. Although there is no successful example that can show companies from the Tigers get succeeding in the global market so far, Lineage II, a fantasy based online role playing game that made by NCsoft from Korea could be a new hope later in this year. NCsoft tried to use Lineage, its well-known and most popular game title in Asia to enter the U.S. market in 2000. However, mainly because of its relatively poor graphics and non-dynamic game play it failed in America. After that, the company obtained a lot of support from Richard Garriott, the creator of the world's first successful online game to develop Lineage II and is almost ready to start a new battle in the U.S. market. It could be an important milestone for Asian game companies to examine if their techniques of making games could match the needs of the global markets after several years' efforts this time.

5. How to Market Games in the Global Markets

Like other industries, the marketing aspect of the game industry is very dynamic and could be very challenging. The strategy that Asian game companies used to give their online game software away to players with a minimum or even with no charge is not suitable for the U.S. market. As a game company, a subscriber for an online game needs to pay the maintenance fee monthly and therefore it could generate a stable income for a game company. Based on this way of thinking, the income from the retail software is comparatively unimportant and it also could be an obstacle if the company wants to gain the largest market share with a standard software charge.

The situation in the game industry in U.S. is somewhat like that in Japan in other industries. Most people would believe a quality game always has a higher price. That is why Star War Galaxies, the latest online game published by Lucas Arts charges its subscribers for the software only at the price of \$49.99. Comparably, NCsoft charged its subscribers no software fee in 2000 when it came to the U.S. market for the first time. Subscribers just need to download the software of Lineage and pay the maintenance fee monthly. The media gave it a negative comment almost immediately and said it is a poor game that looks like there is always gauze in front of the screen because of the bad resolution. Other companies that wish to public their games globally should notice the impact of adopting different marketing strategy in different markets.

Unlike Korean and Taiwan, many other countries do not have as many Internet cafés as they have. Moreover, customers' activities in the Internet cafés are also different from country to country. Because of the high density of the Internet café and the major activities in it is playing games, it plays as one of the most important channels for game companies in Korea and Taiwan. However, the situation is not the same outside those two countries. Take the U.S. for instance, where consumers rely heavily on traditional retail stores or online virtual stores to purchase their game software. The cooperation within game developers, publishers, and distributors is comparably more important than it is in the East. Companies also need to adjust their resources in order to be suitable under this kind of environment.

6. The Problems Game Companies May Encountered

Although the game industry is in the field of entertainment as the movie industry, problems these companies face are always as serious as those in other industries. The government policy and legal problems could be one of the major problems that game companies need to face.

The U.S. District Judge Robert Lasnik issued an injunction blocking enforcement of the Washington State law banning the sale of certain violent video games to minors. The law was due to take effect on July 27, 2003, and would have imposed a \$500 fine on retailers selling games depicting violence against law enforcement officers to anyone under the age of 17 [15]. Although there are still some disputes on this topic, it could somewhat had an impact on the whole game industry while it is still not illegal to sell mature rated DVD or VHS to minors so far.

As we mentioned in the former part in this paper, the sociocultural problem is also a very critical aspect for a game company to take more attention. Tony Hawk's Pro Skate, published by Crave Entertainment, was one of the best-selling games in North America and had a supreme reputation, but it would not be the same if this game went

to the East. The same situation happened on The Sims, which was developed by Maxis and published by Electronic Arts. More than seven million copies of The Sims have sold in the U.S., making it the top-selling PC game of all time. Combined with all the expansions (Living Large, House Party, Hot Date, Vacation, and Unleashed), Electronic Arts has sold an outstanding 17 million units. However, this title sold less than 0.1 million copies in Taiwan when it was published there. Consumers in Taiwan who live in small apartments obviously do not consider the virtual reflects the facts of their daily lives while all avatars in it live in American style villas.

7. Conclusions and Suggestions

The game industry used to be the last choice for quality college students to work for. Parents might think that there is no future if their children like to work in a game related company. However, according to Fortune's latest research, the leading company in the game industry-Electronic Arts (NASDAQ: ERTS) - was announced in the list of 100 Best Companies to Work For in 2003 [4]. Game related jobs even had already become one of the first choices for top college graduate students to work with. In those four Asian Tigers, most competent college graduates go into the game industry. Actually, it is not strange to find that lots of CEOs of game companies in those countries are graduates from prestigious colleges and university in the world, including Ivy League schools in the States. It is certainly not an industry for making toys for children only any more.

For Asian Tigers, the education and investment could be the most important part for them to catch up at beginning stage of booming. Like other industries, the game industry would be more and more professionalized and therefore professional knowledge would be needed. Only by setting formal, serious and scientific methods on developing games could be successful in the future.

Setting professional schools or departments in the university also could be very helpful for developing quality workers in the future. Korea is already doing so, but Taiwan, Singapore, and Hong Kong still have a long way to go.

The attitudes of the governments are also very critical. Taiwanese government is seriously lagging on this aspect while governments in Korea, Singapore and Hong Kong invested a great amount of money in the game industry in these years. Without support from governments, companies would find it very difficult to overcome problems like capital collecting and related regulations.

The potential for Korean game companies is very huge, especially in these years. After NCsoft launches its Lineage II in late 2003, it is clear that Korean-made games have already become internationalized or still has its regional markets. Taiwan's development in game industry would be much better if the government could support its game companies instead of seeing them as toy

making companies. Referring to Hong Kong and Singapore, because of the scarcity of resources no matter on capital or human resources, they could develop very specialized expertise in certain areas such as visual design, music composing or animation in the whole game making chain. Outsourcing would be needed once the game industry getting more advanced.

Generally speaking, Korea, Taiwan, Hong Kong or Singapore all have great potential and some of them even already have solid foundations in the game industry, especially the online gaming market. Governments and companies should seize the chance and adopting suitable methods in order to gain the benefits of this newly risen industry in time.

Abstract

Designed to track how growth of the Internet and the burst of the dot.com bubble might affect strategies of the firms, this study found that most respondents want to become more entrepreneurial and risk-taking when exploiting the opportunities afforded by the Internet. Based on the findings of the study, we note that firms that are more entrepreneurial will assimilate the Internet as a technology. The Internet is an enabling technology that provides a set of tools that could be used in any industry as part of a firm's strategy, and the brick and mortar firms must integrate the Internet so as to enhance the distinctiveness of the strategy of the firm.

1. Introduction

It is safe to suggest that despite the recent bust of dot com firms, the Internet has become a popular tool for not only individuals who want to stay in touch with friends and families, but for corporations to execute business transactions with other corporations and customers. Some believe the Internet's growing popularity in the corporate arena is due to its ability to reduce cost of internal coordination as well as executing transactions. A study by the Center for Research in Electronic Commerce at the University of Texas estimated that web-commerce or e-commerce in 1999 totaled US \$301 billion. This number includes the sales from industrial and consumer goods and services as well as the equipment and software that provide support to e-commerce and e-business.

The growth of the Internet has not only spurred new entrepreneurial firms, such as Amazon.com and ebay.com, but the fact is that the existing brick and mortar firms are also significant players in the game. For example, successful use of the Internet technologies by firms, such as Cisco Systems, Inc., and FleetBoston Financial Corp., indicates that the "entrepreneurial" use of the Internet need not be limited to only a handful of startup firms. Cisco Systems adopted Internet technologies to gain efficiency in their customer and vendor management system. According to a special report in the Business Week, Cisco generates and fulfills 68% of its orders through the web and resolves 70% of its service calls online [1]. Business Week also reports that FleetBoston

Financial Corp. combined its online banking services with its online brokerage business, Quick & Reilly, to create a customer base of more than a million.

Introduction of a new technology can bring ambiguity about products, services and customers [2]. While new entrants (mostly entrepreneurial firms) can easily support a new technology because they don't have to abandon or modify any existing technology, the more successful and established firms tend to maintain the established technologies and to an extent avoid dealing with new and disruptive technologies [3]. The Internet – a new technology - has however, been successfully adopted by some established brick and mortar firms, such as Cisco and FleetBoston. The authors of this report examined the motivation of the existing brick and mortar firms in embracing the Internet and how these firms plan to exploit the opportunities afforded by the Internet.

2. Sample

The findings of this study are based on a survey conducted in collaboration with the Eastern Technology Council in Fall 2001, after the bust of the dot.com era.

As shown in the figure above, a majority (38 percent) of the 180 survey respondents were CEOs. The average respondent for this survey was 42 years old with over 20 years of work experience. Twenty-seven percent of the respondents were females, and thirty-seven percent had a graduate degree. The average sale of participating firms in 2001 was \$1.35 billion.

3. Findings

3.1. Perceived Impact of the Internet

The respondents seem to perceive the Internet to have the greatest impact on their own firms and the least on their suppliers (see Figure below).

When prompted further, the respondents seemed to admit that they face a greater threat from their existing competitor that has adopted the Internet rather than an Internet start-up (see Figure below).

3.2. What have they Changed (or Will Change) in Response to the Internet?

In response to the changes in environment due to the Internet, the respondents seem to have altered their systems and procedures more so than the products or markets served (see Figure below). When asked about their plans and strategies to exploit the opportunities afforded by the Internet, the respondents are likely to become more innovative and proactive rather than offer more autonomy to its divisions.

3.3. Alliance with an Internet Firm or Takeover?

When asked about their plans to exploit the opportunities afforded by the Internet, respondents favored to create an alliance with an Internet firm rather than create a completely new start-up.

When new innovations (such as growth of the Internet) are very different from a firm's usual brick and mortar business, it is likely that the firm will not have sufficient internal resources to create a completely new corporate venture, external to the bounds and constraints of the existing company.

3.4. Does Technological Orientation Make a Difference?

Among many interesting revelations, high-tech survey respondents stated that their firms would most likely exploit the opportunities afforded by the Internet by creating (top three in order of preference):

1. an alliance with an Internet firm
2. a complete in-house start-up
3. an acquisition of a competitor actively using the Internet (close third).

Low-tech firms had the same first choice for the same question — an alliance with an Internet firm, while the acquisition of a competitor actively using the Internet was the second top choice. Creating an equity-based joint venture with an Internet firm was a close third for low-tech firms.

4. Conclusion

Many inferences can be obtained from the findings of this study. First, the growth in the Internet seems to concern the existing brick and mortar firms that perceive a threat from their competitors that have adopted the Internet. At the time of the survey, participating firms had changed their systems and operating processes in response to changes in the business environment due to the Internet rather than the geographic markets served. They also seem to consider being more innovative and proactive, i.e., being more entrepreneurial, to exploit the opportunities created by the development and growth of the Internet. Further, firms are more inclined to seek out external partners rather than focus on Internal Start-ups to exploit the opportunities afforded by the Internet. Finally, there are differences in perceptions of the firms depending upon their technological orientation.

In conclusion, we contend that firms that are more entrepreneurial will assimilate the Internet as a technology. The Internet is an enabling technology that provides a set of tools that could be used in any industry as part of a firm's strategy, and the brick and mortar firms must integrate the Internet so as to enhance the distinctiveness of the strategy of the firm [4]. The same sentiment is reflected in the following quote [5]:

Today it is easy to believe e-business is not all that impactful. The reality is that e-business is a tremendous tool for cost reduction. It's a tremendous tool to help you get closer to your customer. It's a tremendous tool for what used to be called Old Economy companies to apply to our current processes. The winners will be those that view the Internet as a complement to, and not a cannibal of, their traditional way of competing.

Strategies to Enhance E-commerce in Rural Areas

Prashanth Nagendra Bharadwaj & Ramesh G. Soni
Eberly College of Business and Information Technology
Indiana University of Pennsylvania
Indiana, PA 15705, USA
pnb@iup.edu

Abstract

Recent economic statistics and future projections by experts indicate that opportunities for economic growth in the future is going to come mainly from businesses of the “new economy” that utilize the powerful strategy of e-commerce. The recommendations in this article emanate from extensive primary research in the rural parts of North East USA with special focus on the rural parts of Pennsylvania. The primary research is combined with secondary research of the status of e-commerce in rural parts of several other countries thereby rendering the recommendations generically applicable.

1. Introduction

It is important to determine if the rural parts of a state, country or region have the necessary ingredients to participate in the “new economy” and reap the economic benefits that certain other regions of the world are experiencing. For example, the rural parts of Pennsylvania State had been a leader in the steel and coal industries of the 20th century but have been slow in adapting to e-commerce and attracting high-technology businesses. Small businesses that dominate the economy in most rural parts need to be capable of engaging in e-commerce and be convinced about the business advantages of engaging in e-commerce. There are very few studies that assess the awareness of e-commerce issues in rural areas and develop strategies to enhance e-commerce activity. This comprehensive study fills that void. This article describes the results, conclusions and recommendations from this study.

2. Problem Description

The following are some broad issues that were dealt in this study:

- a. The need to and the process used to understand the perception and assess the readiness of rural business owners pertaining to e-commerce especially in the areas of: a) safety and security of the Internet, b) access and availability of technological and human resource infrastructure, c) tax and government incentives and d) business advantages of engaging in e-commerce.
- b. Assessing the needs of small businesses pertaining to communication and Internet-related infrastructure in the region, and availability of human resources (staffing, hiring & training needs), government support, and incentives.
- c. Benchmarking e-commerce activity and infrastructure in their region with other “successful” regions in their country and similar regions in other parts of the world.
- d. Making policy recommendations to region, state and federal governments that can help enhance e-commerce activity in rural regions.

3. Related Literature

Literature is replete with articles pertaining to advantages, success stories and drawbacks of e-commerce. However, almost all of these articles are descriptive in nature or they present basic statistical results. Also, most articles address either the technological aspect of e-commerce or issues pertaining to dot.com businesses. A brief literature review related to issues pertaining to e-commerce and small business is presented in the following paragraphs. However, a detailed bibliography is attached in the appendix.

In spite of the recent economic downturn, the US Census Bureau reports that “retail e-commerce (B2C e-commerce) sales in the US during the final three months of 2001 (Q4) came to over \$10 billion, slightly more than one percent of the country's total retail sales of \$860 billion. The latest e-commerce figures from the US government are the highest ever, by a margin of over \$1.1 billion, since the bureau began keeping such records in late 1999. Moreover, while total retail sales in the US were up only 5.3 percent from the same time in 2000, e-commerce sales saw a 13 percent increase” [12]. In addition, the Forrester Research estimates the Business-to-Business (B2B) e-commerce revenue to increase from \$109 billion in 1999 to \$2.7 trillion in 2004 (forrester.com). For these to occur, the small businesses constituting about 50% of the nation's economy, need to participate in e-commerce in a significant way. Long reports the findings from a 1999 Computer Reseller News survey [29] that although 55% of the small businesses polled (mostly with 25 or fewer employees) were using the Internet for business, e-commerce still may be in “the feeling-out stage” for most of them. Wallace [56] discusses the lack of diverse routes in rural areas of the country through separate switching links to AT&T, MCI, Cable & Wireless, etc. This lack of alternate switching links is a drawback for these rural businesses since their Web sites will not have the highest level of availability. Several businesses have started providing web-based services and

solutions for small businesses [6], [19], [[23], [57]. However, many of these businesses focus their activities on “high-tech” areas such as Seattle, San Francisco, etc. [44].

Many countries in the world and the states in the U.S. are encouraging e-commerce activity by providing tax breaks. In addition, please observe the following examples of government assistance in developing e-commerce. Singapore is developing infrastructure, providing education, and creating an e-savvy culture [39]. Canada is developing an unique relationship between the government’s space agency and Telesat Canada which will enable Telesat to support initiatives such as e-commerce through its satellite services to citizens in urban, rural and remote communities in the country [7]. The Australian federal and state governments, in partnership with industry, are encouraging the use of e-commerce among small and medium enterprises through a combination of training and awareness programs, access to web-based information resources, etc.

In 1999, Ernst & Young’s e-Commerce Coalition addressed two issues of greatest concern to business and government: (1) the impact of e-commerce on state and local government tax revenues, and (2) the challenge of reporting and collecting sales tax (especially by small businesses) in the online world [32]. Proponents of e-commerce vehemently oppose taxing e-commerce as they claim it to be a major hurdle for small businesses in utilizing the Internet for their competitiveness. Since sales tax represents more than 25% of total state tax revenues across the US [38], critics of the Internet Tax Freedom Act have delineated negative effects of loss of sales tax revenues for the state governments such as cutting funding for state schools, hospitals, fire/police departments, etc. (e.g., [2]).

The benefits and challenges of e-commerce are discussed and debated at length in the literature. However, the reported empirical research in the area of E-commerce is minimal while that pertaining to small businesses and e-commerce is infinitesimal. The Winter 2000 Newsletter of AACSB-I, the premier accrediting body of business schools, underscores the need for the type of research outlined in this current proposal—“...the best research that can be done with e-commerce now is fundamental research that has an applied emphasis.” This e-commerce project had a strong applied research emphasis.

4. Research Methodology and Focus

- A comprehensive mail survey was sent to a stratified sample of 5,000 rural businesses in nine industry categories (the response rate was close to 10%).
- In-depth telephone and personal interviews of rural businesses that have been successful in deploying e-commerce were conducted to better understand the perceptions and needs of small businesses. The interviews also addressed the region-specific

opportunities provided and the challenges posed for rural businesses to engage in e-commerce.

- In depth telephone interviews of technology businesses were conducted to understand their telecommunication infrastructure and their pertinent service offerings to rural businesses in the region.
- Secondary research of relevant catalogs, brochures, journals, magazines and web sites was conducted to determine the educational offerings, and the telecommunication and human resource infrastructure in the region pertaining to e-commerce.
- A policy-making focus group session was conducted to: a) discuss the research findings pertaining to e-commerce deployment in the region, b) have an interactive dialogue on relevant e-commerce issues among a diverse, knowledgeable and influential group of individuals and c) devise strategies to develop policy recommendations to enhance e-commerce activity in rural parts of the state. The focus group participants included state legislators, representatives from Department of Community and Economic Development, county planning offices, e-commerce experts, business college dean, small business owners, venture capital experts and technology experts.

Five prominent regional parameters that the rural businesses indicated as important ingredients for e-commerce growth were explored in more depth:

- ! Conducive business climate
 - ! Readily available venture capital
 - ! Knowledgeable/skillful workforce
 - ! Strong collaboration/networking among a region’s public and private sectors
 - ! Image of the region possessing a technology culture
- Internet security issues that the businesses were concerned with while conducting e-commerce:
- ! Secured trading and access of information
 - ! Assurance of confidentiality
 - ! Precision of authentication
 - ! Guarantee of integrity
 - ! Reliability of service
 - ! Minimal threat of virus attack and other e-crime
 - ! Trouble-free back-up and data recovery services

5. Findings & Conclusions

- It is evident that e-commerce is more prevalent in manufacturing, service and Finance, Insurance and Real-estate (FIRE) than in other sectors. The agriculture sector is far behind all other sectors in engaging in e-commerce.
- Businesses are engaging in mainly the marketing aspects (B2C—business to consumer) of e-commerce (e.g. advertising / selling / customer service) and very little in the supply chain management (B2B—business to business) aspects of e-commerce.
- The top reasons for businesses to engage in e-commerce are improving flow of information, enhancing organization’s image and increasing productivity. These three were also the top benefits experienced. Surprisingly, increased sales and access to new market

were not reported as top reasons to engage in e-commerce.

- Statistical analysis confirmed that businesses that had identified a specific initial reason for deploying e-commerce reaped greater corresponding benefits in that category.
- Top reasons for businesses to not engage in e-commerce include: a) strategically not important for business (overwhelming reason), b) uncertainty of Internet's performance, reliability and security, c) lack of affordable technical infrastructure and d) lack of knowledgeable and skillful workforce.
- There is no real barrier in the rural areas to get started in e-commerce—technology is available in all rural areas. Practically every point in the rural region can be served by telecommunication providers, but the cost of service can be extremely prohibitive in some remote areas.
- Inadequate bandwidth and lack of redundancy to assure uninterrupted service were the two major technological deficiencies.
- Businesses, in general, are in favor of not taxing e-commerce and do not believe that it will result in lost revenues for the state and local governments.
- There is a general lack of awareness on e-commerce legal issues—e.g., legality of e-signatures in some regions.
- Businesses successful in deploying e-commerce attributed their success to management basics—performing careful strategic analysis and cost/benefit analysis.
- If the region as a whole does not have an image of being high-tech, it results in disadvantages such as lack of critical mass of technology businesses and lack of availability of skilled workforce and consultants.
- Many rural businesses outsource their web-hosting activities to third-party providers, many of whom were located outside the rural regions.

6. Recommendations

To promote e-commerce among rural businesses, the following are suggested:

- Educate entrepreneurs and small business owners & managers about the strategic importance of e-commerce and its potential benefit to businesses.
- Develop resources for providing short-term, practically oriented, hands-on training and free consultancy to small, rural businesses to adopt e-commerce.
- Develop and promote initiatives to encourage public-private funding for developing technological infrastructure in the region.
- Encourage public-private partnership to develop more sources of venture capital to promote high tech businesses.
- Attract and keep the younger generation in the region.

- Aggressively foster the right image—changing the image of “blue collar workers” to “smart people living a smart life” is very useful.
- Do no tax e-commerce.
- Publicize a few e-commerce success stories to serve as a role model to attract other e-businesses.

This study was made possible, in part, by a grant from the Center for Rural Pennsylvania, a legislative agency of the Pennsylvania General Assembly

A Group Decision Making Approach for Dealing with Fuzziness in Decision Process

Guangquan Zhang and Jie Lu

Faculty of Information Technology
University of Technology, Sydney
PO Box 123, Broadway, NSW 2007, Australia

Abstract

In order to deal with various imprecise opinions and preferences of decision makers in group decision-making process, this paper proposes a fuzzy group decision-making approach. The approach has three advantages from existing approaches. First, it can handle simultaneously group members' fuzzy preferences for alternative solutions, fuzzy judgments for solution selection criteria and fuzzy weights for their roles in group decision-making to arrive a group consensus decision. Second, it allows group members to generate selection criteria for the best solution rather than assume them to be given before a group meeting. The third is that it uses general fuzzy number to express linguistic terms which is used to describe the fuzziness of individual preferences, judgments and weights in group decision-making. It therefore accepts any forms of fuzzy number, including triangular fuzzy number, rectangle fuzzy number and continuous fuzzy number, when applying the group decision-making approach.

1. Introduction

As the complexity of organizational decision making increases the need for decision meetings and for working in groups increases [12]. A 'decision group' is the term for a "small, self-regulating, self-contained task-oriented work group" that "typically focuses on organizationally assigned decision-making tasks" [1]. Generally, the goal of a decision group is to determine an optimal solution to a decision problem called a group decision.

A group decision is often based on a set of optimal alternative solutions for a decision problem. The set of solutions can be generated by a suitable model and made by multiple decision makers [3]. A set of selection criteria is used for assessing, or ranking, the alternatives. These criteria can be generated by the group during the meeting, or determined before the meeting. alternatives. Group members can be each awarded a weighting. The final group decision will be made through aggregating group members' preferences on alternative solutions under their weights

and judgments on selection criteria. The final decision is expected to be the most acceptable by the group.

In real environments, group decision-making has to confront various conditions [7]. As the process of decision-making is centered on human beings, with their inherent subjectivity and imprecision in the articulation of opinions, one of the conditions is fuzziness. There is much more in the fuzziness of group decision making process than just the fuzziness of models. The decision makers may be each awarded a fuzzy weighting, say, 'an important person' or 'a very important person'. The decision makers would like to express their preferences to alternatives by linguistic terms, such as 'good' or 'very good' [10]. The evaluation for alternatives is under a set of criteria and decision maker may have uncertain comparison results for these criteria individually. Particularly the decision-making procedure has to be performed through many uncertain negotiations among a group of decision makers [6]. Conflicts of interest are inevitable, and support for achieving consensus and compromise is required. Further information can trigger an alternative solution which appears preferable to the current best, or a new selection criterion is proposed.

Literature has shown that fuzzy mathematical models, in particular, fuzzy numbers are identified as the most proper way to deal with linguistic terms. A relatively practical introduction of fuzzy set theory [14] into conventional decision-making models was presented by Bellman et al. [2], Yager et al. [13] and Zimmermann [16]. Following this, further research was carried out in the area of fuzzy decision-making in the last twenty years. Existing fuzzy group decision-making approaches have handled respectively each of the three main aspects of the fuzziness in arriving a group decision-making: individual fuzzy preferences on alternative solutions (such as [5], [11]), individual judgments on solution selection criteria (such as [8], [4]), and individual roles in attempting to reach optimal solutions (such as [9]). Linguistic terms have been used in each of the three aspects of fuzziness in group decision-making [10][15].

However, there are two limitations in existed research. The first limitation is that the fuzziness regarding personal weights, alternatives and criteria in group decision-making

is studied respectively, but they can exist simultaneously. Another is that the fuzziness in generating criteria during a meeting has less attention. The third limitation is that only triangular number form of fuzzy number is used to describe linguistic terms in related algorithms. Using triangular numbers to express fuzzy values is a simple way and easy to be calculated, but it cannot describe wholly all characteristics of fuzzy values. Particularly, many fuzzy values cannot be expressed by triangular numbers.

This study proposes a fuzzy group decision-making approach to handle wholly the three fuzzy properties discussed above, support selection criteria generation during a group meeting, and allow various forms of fuzzy numbers to be used. The approach is designed to achieve the following goals: (1) to make the final solution to reflect the various roles of group members in a decision-making process; (2) to reach a ‘better’ solution by aggregating the various opinions of group members; (3) to improve the decision quality by allowing the knowledge expression by linguistic terms; (4) to suit more real situations of group decision-making by support criteria generation, and (5) to generalize the applications of fuzzy group decision-making approaches by allowing any forms of fuzzy numbers to describe the fuzziness.

2. An integrated multi-criteria fuzzy group decision-making approach

Let $S = \{S_1, S_2, \dots, S_m\}$, $m \geq 2$, be a given finite set of solutions for a decision problem and $P = \{P_1, P_2, \dots, P_n\}$, $n \geq 2$, be a given finite set of decision makers. The proposed approach consists of seven steps within two levels:

Level 1: selection criteria generation

Step 1: Each decision maker P_k ($k = 1, 2, \dots, n$) proposes one or more selection criteria ($C_{k_1}^k, C_{k_2}^k, \dots, C_{k_p}^k$). These criteria are then put into a criterion pool. These criteria are sorted based on the number of group members proposing the criterion for each criterion. Finally top-T criteria, $C = \{C_1, C_2, \dots, C_t\}$, are chosen to be selection criteria for the group.

Level 2: Individual Preference Generation

Step 2: Decision maker P_k ($k = 1, 2, \dots, n$) determines the weight of selection criterion C by using the Analytic Hierarchy Process (AHP) method.

By pairwise comparison of the relative importance of selection criteria, the pairwise comparison matrix $E = [\tilde{e}_{ij}^k]_{t \times t}$ is established, where \tilde{e}_{ij}^k represents quantified judgments on pairs of selection criteria C_i and C_j or “*”. The comparison scale belongs to a set of linguistic terms that contain various degrees of preferences required by the decision maker P_k ($k = 1, 2, \dots, n$). The linguistic terms for variable “preference” are shown in Table 1 or “*” represents decision maker P_k ($k = 1, 2, \dots, n$) don’t know the relative

importance of selection criteria C_i and C_j .

Table 1 Linguistic terms for the comparison scale of selection criteria

Linguistic terms	Fuzzy numbers
Absolutely not important (ANI)	a_1
Not important (SNI)	a_2
Less important (WNI)	a_3
Important (EI)	a_4
More important (WI)	a_5
Much more important (SI)	a_6
Absolutely important (AI)	a_7

Consistent weights w_i^k ($i = 1, 2, \dots, t$) for every selection rule can be determined by calculating the geometric mean of that e_{ij}^k ($j = 1, 2, \dots, t$) is no “*” of each row of the matrix $[\tilde{e}_{ij}^k]_{t \times t}$, and then the resulting fuzzy numbers are normalized and denoted as $\tilde{w}_1^k, \tilde{w}_2^k, \dots, \tilde{w}_t^k$, where $\tilde{w}_i^k \in F_T^*(R)$ and

$$\tilde{w}_i^k = \frac{w_i^k}{\sum_{i=1}^t w_i^k}, \text{ for } i = 1, 2, \dots, t; k = 1, 2, \dots, n.$$

Step 3: Against every selection rule C_j ($j = 1, 2, \dots, t$), a belief level can be introduced to express the possibility of selecting a solution (i) under rule (j) for a decision maker (k). The belief level b_{ij}^k ($i = 1, 2, \dots, m$, $j = 1, 2, \dots, t$, $k = 1, 2, \dots, n$) belongs to a set of linguistic terms that contain various degrees of preferences required by a decision maker P_k ($k = 1, 2, \dots, n$) or “*”. The linguistic terms for variable “judgment” are shown in Table 2 or “*” represents the decision maker P_k ($k = 1, 2, \dots, n$) don’t know a belief level for expressing the possibility of selecting a solution (i) under rule (j).

Table 2 Linguistic terms for the belief levels of selection criteria

Linguistic terms	Fuzzy numbers
Very low (VL)	b_1
Low (L)	b_2
Medium low (ML)	b_3
Medium (M)	b_4
Medium high (MH)	b_5
High (H)	b_6
Very high (VH)	b_7

Step 4: Belief level matrix (b_{ij}^k) ($k = 1, 2, \dots, n$) is aggregated in to belief vector (\bar{b}_j^k) ($j = 1, 2, \dots, t$, $k = 1, 2, \dots, n$).

$$\bar{b}_j^k = \tilde{w}_{i_1}^k * b_{i_1}^k + \tilde{w}_{i_2}^k * b_{i_2}^k + \dots + \tilde{w}_{i_s}^k * b_{i_s}^k,$$

where b_{ij}^k ($i = 1, 2, \dots, s$) is no “*”.

Based on belief vectors, the decision maker P_k ($k = 1, 2, \dots, n$) can make an overall judgment on the solutions,

called an individual selection vector. All individual selection vectors can compose a group of selection matrixes $(\tilde{b}_j^k)_{n \times m}$.

Level 3: Group Aggregation

Step 5: As group members play different roles in an organization the relative importance of each decision maker may not equal in a decision group. Some are more important than the others. Therefore, the relative importance weighting of each decision maker should be considered. The linguistic terms $\tilde{v}_k, k = 1, 2, \dots, n$ are shown in Table 3.

Table 3 Linguistic terms for the weights of decision makers

Linguistic terms	Fuzzy numbers
General decision person (GP)	c_1
Weakly important person (WP)	c_2
Strongly important person (SP)	c_3
The most important person (TP)	c_4

The normalized weight of a decision maker $P_k (k = 1, 2, \dots, n)$ is denoted as

$$\tilde{v}_k^* = \frac{\tilde{v}_k}{\sum_{i=1}^n v_{i0}^R}, \quad \text{for } k = 1, 2, \dots, n.$$

Step 6: Considering the weights of all decision makers in a group, we can construct the weighted normalized fuzzy decision vector

$$(\tilde{r}_1, \tilde{r}_2, \dots, \tilde{r}_m) = (\tilde{v}_1^*, \tilde{v}_2^*, \dots, \tilde{v}_n^*) (\tilde{b}_i^j)_{m \times n},$$

where $\tilde{r}_j = \sum_{k=1}^n \tilde{v}_k^* \tilde{b}_i^k$.

Step 7: In the weighted normalized fuzzy decision vector the elements $\tilde{v}_j, j = 1, 2, \dots, m$ are normalized positive fuzzy numbers, and their ranges belong to closed interval [0, 1]. We can then define fuzzy positive-ideal solution (FPIS, r^*) and fuzzy negative-ideal solution (FNIS, r^-) as:

$$r^* = 1 \quad \text{and} \quad r^- = 0.$$

The positive and negative solution distances between each \tilde{r}_j and r^* , \tilde{r}_j and r^- can be calculated as:

$$d_j^* = d(\tilde{r}_j, r^*) \quad \text{and} \quad d_j^- = d(\tilde{r}_j, r^-), \quad j = 1, 2, \dots, m$$

where $d(\tilde{a}, \tilde{b}) = \left(\int_0^1 \frac{1}{2} [(a_l^L - b_l^L)^2 + (a_l^R - b_l^R)^2] dl \right)^{\frac{1}{2}}$ is

the distance measurement between two fuzzy numbers.

Step 8: A closeness coefficient is defined to determine the ranking order of all solutions once the d_j^* and d_j^- of each decision solution $S_j (j = 1, 2, \dots, m)$ are obtained. The closeness coefficient of each solution is calculated as:

$$CC_j = \frac{1}{2} (d_j^* + (1 - d_j^-)), \quad j = 1, 2, \dots, m.$$

The solution S_j that corresponds to the largest CC_j is the best satisfactory solution of the decision group. If the solution cannot be accepted by the group, two actions can be taken. One is to alter the selection criteria. For example, add or remove a selection criterion. Another is to remove one or more of the worst alternative solutions and redo the process. The 'worst' solution is that which corresponds to the $\text{Min}\{CC_j; j = 1, 2, \dots, m\}$.

3. An Application of the Approach

Two solutions S_1, S_2 have been obtained as alternatives by a group which is organized by three members, P_1, P_2 and P_3 . The group will select one from S_1, S_2 under three selection criteria C_1, C_2, C_3 . The three members have different weights and are allowed to express their individual fuzzy preferences for the two solutions and imprecise judgments for the goals of the three criteria using linguistic terms. The approach allows any forms of fuzzy numbers to describe these linguistic variables. Table 4, 5 and 6 show what we used.

Table 4 Linguistic variables and related fuzzy numbers for the comparison scale of selection criteria

Linguistic variables	Fuzzy numbers
Absolutely not important (ANI)	$\bigcup_{l \in [0,1]} l \left[0, \frac{\sqrt{1-l}}{10} \right]$
Not important (SNI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{l}}{10}, \frac{\sqrt{9-8l}}{10} \right]$
Less important (WNI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{8l+1}}{10}, \frac{\sqrt{25-16l}}{10} \right]$
Important (EI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right]$
More important (WI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{24l+25}}{10}, \frac{\sqrt{81-32l}}{10} \right]$
Much more important (SI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{32l+49}}{10}, \frac{\sqrt{100-19l}}{10} \right]$
Absolutely important (AI)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{19l+81}}{10}, 1 \right]$

Table 5 Linguistic variables and related fuzzy numbers for the belief levels of selection criteria

Linguistic variables	Fuzzy numbers
Very low (VL)	$\bigcup_{l \in [0,1]} l \left[0, \frac{\sqrt{1-l}}{10} \right]$
Low (L)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{l}}{10}, \frac{\sqrt{9-8l}}{10} \right]$
Medium low (ML)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{8l+1}}{10}, \frac{\sqrt{25-16l}}{10} \right]$

Medium (M)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right]$
Medium high (MH)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{24l+25}}{10}, \frac{\sqrt{81-32l}}{10} \right]$
High (H)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{32l+49}}{10}, \frac{\sqrt{100-19l}}{10} \right]$
Very high (VH)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{19l+81}}{10}, 1 \right]$

Table 6 Linguistic variables and related fuzzy numbers for the weights of decision persons

Linguistic variables	Fuzzy numbers
General decision person (GP)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right]$
Weakly important person (WP)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{24l+25}}{10}, \frac{\sqrt{81-32l}}{10} \right]$
Strongly important person (SP)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{32l+49}}{10}, \frac{\sqrt{100-19l}}{10} \right]$
The most important person (TP)	$\bigcup_{l \in [0,1]} l \left[\frac{\sqrt{19l+81}}{10}, 1 \right]$

Step 1: by using the AHP method, three pairwise comparison matrices are established:

$$E^1 = E^2 = E^3 = \begin{pmatrix} EI & EI & * \\ EI & EI & * \\ * & * & EI \end{pmatrix} = \begin{pmatrix} a_4 & a_4 & * \\ a_4 & a_4 & * \\ * & * & a_4 \end{pmatrix}.$$

Through computing the geometric mean of each row of the matrices, the normalized resulting numbers are obtained. As

$$\begin{pmatrix} w_1^1 \\ w_2^1 \\ w_3^1 \end{pmatrix} = \begin{pmatrix} w_1^2 \\ w_2^2 \\ w_3^2 \end{pmatrix} = \begin{pmatrix} w_1^3 \\ w_2^3 \\ w_3^3 \end{pmatrix} = \begin{pmatrix} \sqrt[3]{a_4 a_4} \\ \sqrt[3]{a_4 a_4} \\ a_4 \end{pmatrix}$$

$$= \begin{pmatrix} a_4 \\ a_4 \\ a_4 \end{pmatrix} = \begin{pmatrix} \bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right] \\ \bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right] \\ \bigcup_{l \in [0,1]} l \left[\frac{\sqrt{16l+9}}{10}, \frac{\sqrt{49-24l}}{10} \right] \end{pmatrix}$$

and $\sum_{i=1}^3 w_{i0}^{1R} = \sum_{i=1}^3 w_{i0}^{2R} = \sum_{i=1}^3 w_{i0}^{3R} = 2.1$. So we have

$$\begin{pmatrix} \tilde{w}_1^1 \\ \tilde{w}_2^1 \\ \tilde{w}_3^1 \end{pmatrix} = \begin{pmatrix} \tilde{w}_1^2 \\ \tilde{w}_2^2 \\ \tilde{w}_3^2 \end{pmatrix} = \begin{pmatrix} \tilde{w}_1^3 \\ \tilde{w}_2^3 \\ \tilde{w}_3^3 \end{pmatrix} = \frac{1}{2.1} \begin{pmatrix} a_4 \\ a_4 \\ a_4 \end{pmatrix}$$

Step 2: Assesses

$$\begin{pmatrix} b_{11}^1 & b_{12}^1 & b_{13}^1 \\ b_{21}^1 & b_{22}^1 & b_{23}^1 \end{pmatrix} = \begin{pmatrix} M & VL & ** \\ VH & ** & M \end{pmatrix} = \begin{pmatrix} b_4 & b_1 & ** \\ b_7 & ** & b_4 \end{pmatrix},$$

$$\begin{pmatrix} b_{11}^2 & b_{12}^2 & b_{13}^2 \\ b_{21}^2 & b_{22}^2 & b_{23}^2 \end{pmatrix} = \begin{pmatrix} ** & M & VL \\ M & VH & ** \end{pmatrix} = \begin{pmatrix} ** & b_4 & b_1 \\ b_4 & b_7 & ** \end{pmatrix},$$

$$\begin{pmatrix} b_{11}^3 & b_{12}^3 & b_{13}^3 \\ b_{21}^3 & b_{22}^3 & b_{23}^3 \end{pmatrix} = \begin{pmatrix} VL & ** & M \\ ** & M & VH \end{pmatrix} = \begin{pmatrix} b_4 & ** & b_1 \\ ** & b_4 & b_7 \end{pmatrix}.$$

Step 3: We have

$$\bar{b}_1^1 = \tilde{w}_1^1 b_{11}^1 + \tilde{w}_2^1 b_{12}^1 = \frac{1}{2.1} (a_4^2 + a_4 a_1),$$

$$\bar{b}_2^1 = \tilde{w}_1^1 b_{21}^1 + \tilde{w}_3^1 b_{13}^1 = \frac{1}{2.1} (a_4^2 + a_4 a_7),$$

$$\bar{b}_1^2 = \tilde{w}_2^2 b_{12}^2 + \tilde{w}_3^2 b_{13}^2 = \frac{1}{2.1} (a_4^2 + a_4 a_1),$$

$$\bar{b}_2^2 = \tilde{w}_1^2 b_{21}^2 + \tilde{w}_2^2 b_{22}^2 = \frac{1}{2.1} (a_4^2 + a_4 a_7),$$

$$\bar{b}_1^3 = \tilde{w}_1^3 b_{11}^3 + \tilde{w}_3^3 b_{13}^3 = \frac{1}{2.1} (a_4^2 + a_4 a_1),$$

$$\bar{b}_2^3 = \tilde{w}_2^3 b_{21}^3 + \tilde{w}_3^3 b_{23}^3 = \frac{1}{2.1} (a_4^2 + a_4 a_7).$$

Step 4: Assesses: The important weight v_1 of P_1 is TP ; the important weight v_2 of P_2 is GP and the important weight v_3 of P_3 is GP . Then

$$v_1 = c_4, v_2 = v_3 = c_1, \text{ and } \sum_{i=1}^3 v_{i0}^R = 2.4,$$

therefore

$$v_1^* = \frac{c_4}{2.4} = \frac{a_7}{2.4}, v_2^* = v_3^* = \frac{c_1}{2.4} = \frac{a_4}{2.4}.$$

Step 5: We have

$$\tilde{r}_1 = v_1^* \bar{b}_1^1 + v_2^* \bar{b}_1^2 + v_3^* \bar{b}_1^3 = \frac{1}{2.1 \times 2.4} (a_7 + 2a_4)(a_4^2 + a_4 a_1)$$

$$= \bigcup_{l \in [0,1]} l \left[\frac{(16l+9)\sqrt{19l+81} + 2(16l+9)^{\frac{3}{2}}}{5040}, \right.$$

$$\left. \frac{10(49-24l) + 10\sqrt{(1-l)(49-24l)} + 2(49-24l)^{\frac{3}{2}}}{5040} \right.$$

$$\left. + \frac{2(49-24l)\sqrt{1-l}}{5040} \right],$$

$$\tilde{r}_2 = v_1^* \bar{b}_2^1 + v_2^* \bar{b}_2^2 + v_3^* \bar{b}_2^3 = \bigcup_{l \in [0,1]} l \left[\frac{3(16l+9)\sqrt{19l+81}}{5040} \right.$$

$$\left. + \frac{2(16l+9)^{\frac{3}{2}} + (19l+81)\sqrt{16l+9}}{5040}, \right.$$

$$\left. \frac{30(49-24l) + 100\sqrt{49-24l} + 2(49-24l)^{\frac{3}{2}}}{5040} \right].$$

Step 6: We get

$$\begin{aligned}
d_1^* &= d(\tilde{r}_1, r^*) = \int_0^1 \frac{1}{2} \left[\left(\frac{(16l+9)\sqrt{19l+81} + 2(16l+9)^{\frac{3}{2}}}{5040} \right. \right. \\
&\quad \left. \left. - 1 \right)^2 + \left(\frac{10(49-24l) + 10\sqrt{(1-l)(49-24l)}}{5040} \right. \right. \\
&\quad \left. \left. + \frac{2(49-24l)^{\frac{3}{2}} + 2(49-24l)\sqrt{1-l}}{5040} - 1 \right)^2 \right] dl = 0.8727 \\
d_2^* &= d(\tilde{r}_2, r^*) = 0.6295 \\
d_1^- &= d(\tilde{r}_1, r^-) = \int_0^1 \frac{1}{2} \left[\left(\frac{(16l+9)\sqrt{19l+81}}{5040} \right. \right. \\
&\quad \left. \left. + \frac{2(16l+9)^{\frac{3}{2}}}{5040} \right)^2 + \left(\frac{10(49-24l) + 10\sqrt{(1-l)(49-24l)}}{5040} \right. \right. \\
&\quad \left. \left. + \frac{2(49-24l)^{\frac{3}{2}} + 2(49-24l)\sqrt{1-l}}{5040} - 1 \right)^2 \right] dl = 0.1546 \\
d_2^- &= d(\tilde{r}_2, r^-) = 0.4423
\end{aligned}$$

Step 7: Finally, we have

$$CC_1 = \frac{1}{2}(d_1^- + (1-d_1^*)) = 0.1409 \quad \text{and} \quad CC_2 = 0.4064.$$

Since CC_2 is higher than CC_1 , the group selects the solution S_2 as the most satisfactory solution for the research planning problem.

4. Conclusions

The paper proposes a general group-making approach to deal with fuzziness of decision maker's preference for alternatives, decision makers' judgment for selection criteria, and decision maker's weighting. The approach aggregates these fuzzy elements into a group decision which is the most acceptable for the group. As the approach supports criteria generation during a group meeting it is very practical. In particular, it is suitable for any types of fuzzy number, in the practice, decision maker can choose a most suitable one for specific decision problems and in specific environment

Abstract

Manufacturers of integrated circuits (IC) frequently utilize c-charts to monitor wafer defects. The clustering of wafer defects increases with the surface area of the wafers. The clustering of defects causes the Poisson-based c-chart to show many false alarms. Although Neyman-based c-chart has been developed to reduce the number of false alarms, it has some shortcomings in practical use. This study presents a process control chart that applies Fuzzy theory and the engineering experience to monitor the clustered defects on a wafer. The proposed method is simpler and more efficient than that of the Neyman-based c-chart. A case study of an IC company in Taiwan demonstrates the effectiveness of the proposed method.

Keywords: Integrated circuits; wafer; defect; statistical process control; defect clustering; Fuzzy theory

1. Introduction

As the information industry grows rapidly, manufacturers of IC are focusing on upgrading their production capabilities in response to strong competition. Therefore, increasing wafer yield is becoming an important issue.

Wafer yield is defined as the percentage of dies that pass the final specification test. The wafer manufacturing process includes hundreds of steps, such as alignment, lithography, etch, deposition, doping and others. In such a complex process, some defects are inevitably produced on the wafer surface, sometimes causing the wafers to be faulty and reducing their yield. Consequently, the number of defects is a significant factor in determining the wafer yield. As IC technology has developed, the surface area of wafers has increased and the clustering of defects has becomes apparent. Hence, like the number of defects on the wafer surface, the clustering of defects affects the wafer yield.

IC manufacturers usually employ c-charts to monitor wafer defects. The use of c-charts assumes wafer defects to be randomly and independently distributed; that is, the number of defects is assumed to follow a Poisson distribution. However, real defect clustering violates this assumption, sometimes causing too many false alarms. Albin and Friedman [1] presented a modified c-chart that is based on a Neyman Type-A distribution to solve this problem. The Neyman-based c-chart widens the control limits and reduces the number false alarms obtained using the Poisson-based c-chart. However, the Neyman-based c-chart can monitor only the variation in the number of defects among wafers, and cannot detect variation in the location of defects within a wafer.

This study applies Fuzzy theory and engineering experience to construct a process control chart that can effectively monitor the clustered wafer defects and defect clustering simultaneously and thus overcome the shortcomings of the Neyman-based c-chart. The proposed method is simpler and more efficient than that of Neyman-based c-charts.

2. Related Work

This section describes a cluster index for measuring the extent of defect clustering, Poisson-based c-chart, Neyman-based c-charts and Fuzzy theory.

2.1 Cluster Index

Stapper [3] indicated that the clustering of defects on a wafer becomes more pronounced as the surface area of the wafer increases. Defect clustering violates the assumption on which the c-chart is based: the defects are not independently or randomly scattered on a wafer. Some cluster indices are developed to measure the extent of the clustering of defects. Of these cluster indices, the cluster index proposed by Jun et al. [2], denoted by CI, is proven to be more effective than any others. Moreover, CI does not require any assumptions to be made about the

distribution of defects.

CI is computed as follows. Given that n defects are present on a wafer, and the coordinates of each defect in a two-dimensional plane are given by (X_i, Y_i) for $i=1, 2, \dots, n$, rearrange X_i and Y_i in ascending order to obtain $X_{(i)}$, $Y_{(i)}$, where $X_{(i)}$ represents the x coordinate of the i th defect, and $Y_{(i)}$ is the y coordinate of the i th defect. Hence, the intervals V_i and W_i

$$V_i = X_{(i)} - X_{(i-1)}, i = 1, 2, \dots, n$$

$$W_i = Y_{(i)} - Y_{(i-1)}, i = 1, 2, \dots, n$$

where $X_{(0)}$ and $Y_{(0)}$ are set to zero.

CI can now be expressed as follows.

$$CI = \min \{ \text{coefficient of variation of } V_i \}^2, (\text{coefficient of variation of } W_i \}^2 \}$$

The mean and variance of V_i can be written as \bar{V} and S_v^2 , respectively. The mean and variance of W_i can be written as \bar{W} and S_w^2 , respectively. Then, the CI can be expressed as follows.

$$CI = \min \frac{S_v^2}{\bar{V}^2}, \frac{S_w^2}{\bar{W}^2}.$$

When the defects are uniformly distributed, the CI index equals one. If CI exceeds one, the defects are clustered. A larger CI corresponds to more severe clustering.

2.2 Poisson-based c-chart

In IC manufacturing, the number of defects is the quality characteristic on which the conventional c-chart is typically based. The number of defects used to construct the c-chart must be Poisson-distributed, and so have a probability distribution function given by,

$$p(N = n) = \frac{e^{-m} m^n}{n!},$$

where n represents the number of defects on the surface

and m represents the average number of defects on a wafer.

According to the properties of Poisson distribution, the upper control limit (UCL) of the c-chart can be obtained as follows.

$$UCL = m + 3(m)^{\frac{1}{2}}.$$

Recently, as the surface area of wafers has increased from 4 inches to 12 inches, the clustering of wafer defects has becomes more apparent, such that using the c-chart to monitor the number of defects produces many false alarms.

2.3 Neyman-based c-chart

A modified c-chart based on Neyman Type-A distribution was developed to reduce the number of false alarms. The Neyman Type-A distribution is a member of family of compound Poisson distributions. Albin and Friedman [1] proposed a Neyman-based c-chart that improved on the Poisson-based c-chart. The Neyman Type-A distribution assumed that the number of defect clusters follows a Poisson distribution with mean 1 , and that the number of defects in each cluster is also Poisson-distributed with mean f . The probability distribution function of a Neyman Type-A distribution is as follows.

$$P_n(lf) = P_r(N = n) = \sum_{j=1}^{\infty} e^{-1} \frac{1^j}{j!} e^{-f} \frac{(jf)^k}{n!},$$

where n represents the number of defects on a wafer's surface; 1 represents the average number of defects on a wafer, and f represents the average number of defects per cluster.

The expected value and variance of Neyman Type-A distribution are given as follows.

$$E(x) = lf, \quad V(x) = lf(1+f).$$

The ratio of $V(x)$ to $E(x)$ is $(1+f)$, so the Neyman-based c-chart widens the control limits on the Poisson-based c-chart and can therefore effectively reduce the number of false alarms that would otherwise be determined by the Poisson-based c-chart. However, the method proposed by Albin and Friedman still has some shortcomings. They considered the number of defects on a wafer as the quality characteristic, on which to determine the control limits of the Neyman-based c-chart. Their method monitors only the variability of defects among wafers. The variability of the number of defects within a wafer cannot be detected.

2.4 Fuzzy Theory

Zadeh [5] first developed Fuzzy theory, which is utilized to deal with Fuzzy events. This section briefly reviews Fuzzy theory.

2.4.1 Fuzzy Set

Fuzzy theory is based on Fuzzy sets. The characteristic function of a crisp set is defined to be either zero or one, and the relationship of the characteristic function to a Fuzzy set is determined with reference to a dichotomy. However, the concept of dichotomy here differs from that typically used. The human language includes many vague words. Therefore, Zadeh used a membership function to represent the intensity: with which one element belongs to one set; a stronger intensity corresponds to a membership function closer to one; a weaker intensity corresponds to a function closer to zero.

2.4.2 Fuzzy logics and Fuzzy inference

A Fuzzy proposition has two forms; one is the atomic Fuzzy proposition and the other is compound Fuzzy proposition. Fuzzy logic is defined as follows.

1. If a compound Fuzzy proposition uses “and” to combine two atomic Fuzzy propositions, such as ‘X is A’ and ‘y is B’, then the membership function can be defined as $m_r(x, y) = \min(m_A(x), m_B(y))$, $(x, y) \in X \times Y$.
2. If a compound Fuzzy proposition uses “or” to combine two atomic Fuzzy propositions, such as ‘X is A’ or ‘y is B’, then the membership function is $m_r(x, y) = \max(m_A(x), m_B(y))$, $(x, y) \in X \times Y$.
3. If a compound Fuzzy proposition uses “implies” to combine two atomic Fuzzy propositions, such as ‘X is A’ implies ‘y is B’, then the membership function is $m_r(x) = \min(1, 1 - m_A(x) + m_B(y))$, $(x, y) \in X \times Y$.

Fuzzy inference is similar to inference in binary logic. The difference between these two inferences is that a Fuzzy inference involves contiguous sets, unlike in binary logics, wherein sets are defined absolutely and as opposing each other. A Fuzzy inference includes Fuzzy steps; many Fuzzy steps are combined in a computable system. Some value is imagined to be input into this system. Figure 1 depicts the process of Fuzzy inference.

Fuzzy inference provides a different method of control from the traditional method. A Fuzzy inference system includes experts’ knowledge, operators’ experience, the membership function and the development of rules; therefore, the Fuzzy inference system is essentially intelligent.

Figure 1. The process of Fuzzy inference

3. Proposed Procedure

This study develops an efficient method for monitoring the clustered defects. Fuzzy theory is utilized to construct a control chart to monitor simultaneously the number of defects across various wafers and defect clustering. The proposed procedure is described as follows.

Step 1: Obtain the wafer map using the KLA 2110 wafer inspection system.

The KLA 2110 wafer inspection system can provide in-line wafer inspection information, including the number of defects, their sizes, their locations and their types.

Step 2: Determine the number of defects and compute CI.

Step 3: Construct the membership functions that correspond to the number of defects, CI and output of the process.

Both the number of defects and clustering are important characteristics that might affect wafer yield. This study therefore considers these two quality characteristics as the input variables of the Fuzzy inference system and the output of the process as the output of Fuzzy inference system. The number of defects can be classified using seven levels – very-low, low, medium-low, medium, medium-high, high, very-high (see Fig.2), and the membership function of each Fuzzy set is constructed accordingly.

Figure 2. Seven levels of numbers of defects

Figure 3. Ten statements about clustering phenomena

Figure 4. Ten output levels

Clustering phenomena can be classified using ten statements, term 1 to term 10 (Fig. 3), and the membership function of each Fuzzy set is constructed accordingly.

The output can be classified into ten levels, represented by terms 1 to 10 (Fig. 4), respectively, the membership function of each Fuzzy set is constructed accordingly.

Step 4: Establish a warehouse of rules.

When many defects are present, without clustering, the process is considered to be out of control; when a few defects are present but clustering is significant, the process is said to be under control; the corresponding rules generated to monitor the process can be expressed as follows.

R_1 : IF Defect is very high AND CI is term 1, THEN Value is term 10

R_2 : IF Defect is very high AND CI is term 2, THEN Value is term 10

.

R_1 : IF Defect is medium AND CI is term 10, THEN Value is term 2

.

R_{70} : IF Defect is very low AND CI is term 10, THEN Value is term 1

Step 5: Make Fuzzy inference

In the system for controlling the manufacturing of wafers, (established using Fuzzy theory, the number of defects and the CI value are determined. For example, if a wafer is detected; the number of defects is 93, and the CI value is 0.866, then an input, (93, 0.866), is generated; this input activates four rules, as follows.

RKIF Defect is medium-high AND CI is term 2 , THEN Value is term 10

RKIF Defect is medium-high AND CI is term 3 , THEN Value is term 9

RKIF Defect is high AND CI is term 2 , THEN Value is term 9

RKIF Defect is high AND CI is term 3 , THEN Value is term 9

Figure 5. Fuzzy inference rules

Fig. 5 presents these four rules.

A new Fuzzy set can be obtained by utilizing Fuzzy set from the four rules, as shown in Fig. 6

Step 6: Draw the Fuzzy control chart and construct the control limits.

After the defect data are collected, the defect data are transformed into output of the Fuzzy inference rules using the six steps described above. Hence, a moving range ($\bar{X}-R_m$) control chart can be constructed to monitor simultaneously the number of defects and clustering. If all of the data plotted on the chart fall within the control limits, then these control limits can be regarded as the limits of the process control chart; if one or two points lie outside of the control limits, then the causes must be found and corrected.

Step 7: Establish rules for determining that the process is out of control.

Consider Fig. 7, for example. If a point falls inside the control limits, then the process is said to be under control.

If points fall outside the control limits, then the process is said to be out of control. With reference to Fig. 7, suppose points 1 and 2 are out of control and fall beyond the upper control limit; then, the process's being out of control is caused by an excess of defects; assume that points 3, 4 and 5 are out of control and fall below the lower control limit; then, defect clustering is determined to have made the wafer manufacturing process unstable.

4. Conclusion

The clustering of wafer defects increases with the surface area of wafers. The clustering of wafer defects not only impacts the yield of the IC production line, but also causes the Poisson-based c-chart to fail to monitor the wafer process effectively. Albin and Friedman [1] developed the Neyman-based c-chart as an improvement on the Poisson-based c-chart. The Neyman c-chart widens the control limits of the Poisson-based c-chart and reduces the number of false alarms. However, that Neyman c-chart cannot detect the clustering defects between wafers.

Figure 6. Union chart

Figure 7. A $\bar{X}-R_m$ control chart for monitoring simultaneously the number of defects and clustering

The contributions of the proposed method can be summarized as follows.

1. The Fuzzy system incorporates the knowledge of experts and the experience of engineers, and can therefore effectively monitor simultaneously the number of defects and the extent of clustering. The proposed Fuzzy control chart can also reduce the workload associated with constructing two separate process control charts to monitor the number of defects and clustering.
2. Engineers with little knowledge of Statistics can apply the proposed Fuzzy control chart easily. This chart is very helpful in judging real process conditions.
3. The proposed control chart is simpler and more efficient than both the Poisson-based c-chart and the Neyman-based c-chart.

Abstract

Electronic business (e-business) brings many new opportunities as well as several challenges to business organizations. Many organizations have turned to customer relationship management (CRM) to leverage their market orientation, customize their products and services, and build loyalty programs. However, capitalizing on the opportunities will require organizational investments in information technology (IT) and absorptive capacity. This study examines the effects of investments in IT (IT intensity) and absorptive capacity on CRM practices, particularly market orientation, customization and loyalty programs. The results suggest that a positive relationship exists among them. Thus, organizations should devote resources toward developing their IT investments and absorptive capacity to benefit from their CRM practices.

Keywords: Customer relationship management, information technology, organizational absorptive capacity, market orientation, customization, loyalty programs.

1. Introduction

Electronic business (e-business) brings many new opportunities as well as challenges to business organizations. Its Internet-enabled global reach opens many new marketplaces and as a result draws upon a broader customer base. For 2003, Forrester estimates total worldwide business-to-customer (B2C) spending at US\$133.6 billion worldwide, of which \$78.1 billion will be generated in North America, \$23.9 billion in the Asia-Pacific region and \$29.6 billion in Western Europe. Forecasts expect total B2C spending to reach \$561.8 billion (\$219.8 billion North America, \$185.2 billion Asia-Pacific, \$138.3 billion Western Europe) by 2006. Gartner [8] predicts the current 216.7 million adult worldwide Internet users to double in 2005. Thus, ample opportunities will exist for businesses that pursue global electronic markets.

Yet, with B2C e-business, organizations are finding themselves immersed in highly competitive, consumer-driven markets, often competing against virtual organizations comprised of horizontally or vertically integrated partnerships. Successful e-business organizations must now pay particularly close attention to defining clearly their products and services in such a way that allows them to establish market niches, long term

customer relationships and leadership positions. To move closer toward these advantages, many organizations have turned to customer relationship management (CRM), a marketing concept enabled by information technology (IT) and often described as a competitive tool that permits an organization to stay in tune with its customers and customize its products and services to meet their needs and expectations.

Much of the success behind e-business and CRM can be attributed to continual advances in IT and organizational knowledge. Generally, greater investments in IT afford greater technical capabilities. However, the investments must be made according to a presiding plan or architecture for the organization to reap its rewards. Hence, IT intensity or the degree to which an organization invests in IT may be a critical determinant to its success with CRM as IT represents the technological means for achieving success.

Yet, possessing IT may not be sufficient. Another critical factor may lie in its *know-how*, knowledge to recognize, understand and apply usable information. Organizational absorptive capacity, an organization's aggregated ability to recognize and assimilate new information, and apply its ensuing knowledge to commercial ends [4], represents the development of organizational knowledge. Often, investments in research and development (R&D) and other learning experiences help build organizational knowledge. Products of absorptive capacity include innovations within internal processes, and innovative products and services [3], [4], [10], and reflect the organization's ability to leverage and exploit its knowledge. As a result, absorptive capacity can strongly influence an organization's business practices.

The purpose of this paper is to examine the relationships among IT intensity, absorptive capacity and CRM practices. CRM practices represent an important aspect of CRM as they define how an organization directs its use of CRM to gain a competitive advantage, and impact its performance with CRM. This study presents and empirically tests a research model of the described relationship.

2. IT Intensity

IT intensity refers to the degree to which an organization invests in its IT infrastructure and applications. Because CRM is an IT-enabled concept that embodies relationship marketing (RM) principles, the IT infrastructure on which it is built plays a critical role as it

defines the extent of its capabilities, particularly its ability to support and promote organization-wide information and knowledge sharing. Henderson and Venkatraman [9] suggest that an IT infrastructure consists of two parts: a technical infrastructure, and a human infrastructure. The technical infrastructure represents the tangible, shared, physical resources, which includes hardware, operating system software, network and telecommunication technologies, data and core software applications [7]. Its objective focuses on effectively integrating and interconnecting the organization to support information sharing via its telecommunication network [30]. Furthermore, the technical infrastructure reflects an organization's IT architecture on which specific business activities and applications are built [5].

In contrast, the human infrastructure addresses the necessary skills and knowledge required to develop and maintain applications, manipulate data, and support end-users. The development and acquisition of these skills allows the organization to benefit from its technical infrastructure [17]. Osterman's [17] survey of organization's adopting new IT reveals differences in productivity gains and quality improvements when human resource policies are supported. The difference between organizations with low commitments to human resource policies, and either low or high investments in new IT was negligible. Thus, the human infrastructure should shadow the technical infrastructure and adjust with the adoption of newer IT.

The influence of IT on marketing activities has steadily grown over the years. IT often allows organizations to introduce continuous improvements to their marketing practices in their quest to secure a competitive advantage, principally in marketing process automation and marketing intelligence [1]. While marketing process automation helps link marketing activities to facilitate information sharing (i.e., efficiencies), marketing intelligence targets enhanced decision making through tools that provide greater insights. Process automation facilitates the coordination and cooperation among business units through the exchange of information. Other applications reduce the human element to improve information flow, including preserving its accuracy and reliability. In contrast, intelligence involves scanning the environment for information on forces that influence the organization's products and services [6], [12], and includes search activities linked to the discovery of new information, forecasts of consumer and market trends, studies in consumer behavior, the competition's offerings or a business partner's new capabilities. In many cases, continual advances in IT have led to more sophisticated marketing applications of IT [14], [15], [33].

IT has helped advance the role of marketing in the organization and opened new opportunities through the exchange and discovery of information. However, these advances come as a result of directed investments in IT, and the development and maintenance of an IT infrastructure.

3. Organizational Absorptive Capacity

Organizational absorptive capacity allows organizations to leverage their knowledge (i.e., recognize and assimilate new information, and apply knowledge) in the form of innovative responses, particularly to benefit from the insights they gather through their experiences and awareness of environmental trends. Cohen and Levinthal [4] state that the absorptive capacity of an organization results from the cumulative learning activities of individuals and the transfer of the ensuing knowledge within the organization through a common language. An organization benefits from these activities as they reinforce existing knowledge and allow further *absorption* of new knowledge. The effect of learning on knowledge development is that knowledge can be applied toward recognizing, acquiring and assimilating new and pertinent information to increase the organization's knowledge capacity, both its breadth and depth. Information can be related to the external, such as market trends and technology breakthroughs, or internal environment. In essence, the more frequently learning occurs, the greater the accumulation process, which in turn increases the organization's opportunity to yield applications of knowledge to new scenarios [2]. Furthermore, the greater the knowledge possessed and shared throughout the organization, the more it will be inclined to *absorb* new knowledge.

Although absorptive capacity is a common element to all organizations, its effect will vary relative to the resources an organization invests in developing it. Without acknowledging or foreseeing the future benefits derived through these investments (i.e., sustained innovativeness), an organization may find itself in a less capable position of achieving a competitive advantage. Thus, absorptive capacity may have an impact on how well an organization benefits from CRM.

4. CRM Practices

CRM practices underlie the extent to which an organization applies CRM to support its marketing activities. In the past, studies have identified market orientation, the customization of products and services, and customer loyalty programs as three important aspects of CRM practices.

4.1 Market Orientation

Market orientation entails the organization-wide generation, dissemination and responsiveness to market intelligence (i.e., opportunities, facts, trends, etc.), and involves information-sharing across business units engaged in orchestrated activities directed toward meeting customer needs and resulting in profits [12]. It plays a vital role in an organization as its impact on business performance has been affirmed in several studies [11], [13], [16], [19], [20], [27], [31], [32], [35], [36]. Because it directs the organization toward using information (i.e., market intelligence) to produce

innovative responses to information gathered through market intelligence and shared throughout the organization, market orientation embodies many of the concepts of organizational absorptive capacity. As Kohli and Jaworski [12] suggest, organizational factors, including senior management, interdepartmental dynamics and organizational systems, foster or discourage market orientation.

4.2 Customization

The objective of customization is to provide tailor-made products and services that appeal and more precisely fit the individual customer's needs and expectations [25]. It seeks to create a learning relationship between the organization and its customer to reach a more intimate level and gain a competitive advantage [23]. The information it gains from the relationship can then be used to customize its products and services, and add value that cannot be obtained elsewhere. Mass customization involves customizing over a broader target market. Pitta [26] suggests that IT enables mass customization as it requires the organization to collect, retain, catalog and mine large volumes of data to extract useful information that will provide it with important insights into its customers. Furthermore, mass customization relies on technology to integrate customers' preferences with the organization's production processes [26] and do it cost-effectively [23].

4.3 Loyalty Programs

In contrast, customer loyalty programs attempt to keep customers through incentives that retain them, increase their switching costs and create barriers that prevent the entry of competitors. The objective is to keep customers. Generally, retaining existing customers tends to be more fruitful and less costly than seeking new ones. Satisfied (existing) customers often purchase more over their lifetime [29], [37]. Additionally, the cost of acquiring new customers may be five times greater than that of satisfying and retaining current customers [28]. Loyalty programs often enhance customer perceptions and lead to more positive customer behaviors and better brand equity [34].

Loyalty programs, such as the frequent flier programs used in the airline industry, tend to make switching more difficult for customers by enticing their repeated business with the premiums based on cumulative *earnings* (i.e., the more points earned, the greater the premium or reward). Unless a competitor can match or exceed the program's incentives, it faces a formidable barrier of entry into the market or task to sway customers away. Thus, the driving force behind loyalty programs is the lifetime value of the relationship; the longer a customer is retained, the more profitable the relationship becomes as a result of increased purchases, reduced operating costs, referrals, price premiums and reduced customer acquisition costs [29].

5. Research Model

This study proposes that an organization's investments in IT and absorptive capacity will have positive effects on CRM practices. As both increase, CRM practices will become more effectively in tuned with meeting the needs of the organization's customers and supportive of gaining competitive advantages, and ultimately lead to achieving greater levels of CRM performance. The importance of the relationships illustrated in Figure 1 lies in the need to gain or retain a competitive advantage, particularly in highly-competitive, global electronic markets. They require organizations to understand their markets and customers (i.e., market intelligence), differentiate their products and services based on their understandings of added-value and making them difficult to duplicate, imitate or substitute, and respond to their customers' needs with innovative offerings. Yet, to achieve this level of competitiveness (i.e., CRM practices), they must be geared to compete effectively.

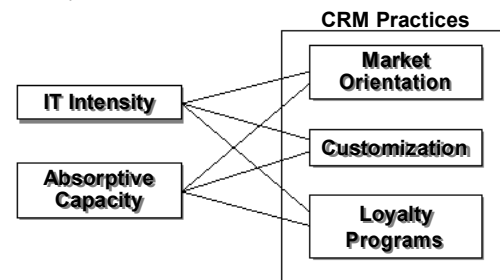

Figure 1. Research model

IT enables organizations to expand their marketing activities through automation and intelligence. In the case of market orientation, the organization must function as an orchestrated unit to maintain a competitive posture. The IT infrastructure facilitates and supports the communication and dissemination of information and knowledge among business units. It helps empower employees to quickly render decisions that are consistent with the goals and objectives of the organization through a common understanding based on shared information and knowledge, and decision support tools. Continual advances in IT have allowed organizations to develop learning relationships with their customers through the collection, retention, categorization and analysis of their information, and subsequently respond more precisely to meeting their needs and expectations. With mass customization, IT ensures customer preferences are cost effectively integrated into the organization's production processes. Knowledge of customers leads to opportunities to build their loyalty through incentives that capitalize on long term relationships. Thus, IT can be seen as an essential element to enable CRM practices that allow the organization to leverage its resources and become more competitive, particularly in global markets. Therefore, an organization's investments in IT (i.e., IT intensity) should directly influence its CRM practices, such that the greater its investments, the greater its ability

to remain competitive.

- H1: *IT intensity has a positive effect on CRM practices.*
- H1a: *IT intensity has a positive effect on market orientation*
- H1b: *IT intensity has a positive effect on customization*
- H1c: *IT intensity has a positive effect on loyalty programs*

While IT intensity represents the technical means for an organization to enable its CRM practices, absorptive capacity embodies the *know-how* or knowledge to compete. It underlies the organization's ability to recognize and apply relevant information toward developing customized products and services that focus on establishing long term relationships, and allows it to build a repository of knowledge that further expands its knowledge. In addition to *learned* knowledge of customers and environmental forces, absorptive capacity draws upon implicit knowledge that emerges from its experiences. Both types of knowledge subsequently become vital organizational resources that benefit and advance the organization when shared and disseminated among its employees. Thus, absorptive capacity tends to enhance market orientation through the directed use of information acquired from market intelligence, and lies beneath the organization's future ability to *absorb* new information. It binds information that leads to successful customization (i.e., knowing how to develop products and services based on information and knowledge) and loyalty programs (i.e., knowing how to develop incentives that improve customer lock-in). Hence, absorptive capacity plays a critical role in allowing the organization to leverage and exploit its knowledge. An organization's investment in developing knowledge will have a direct effect on its CRM practices.

- H2: *Absorptive capacity has a positive effect on CRM practices*
- H2a: *Absorptive capacity has a positive effect on market orientation*
- H2b: *Absorptive capacity has a positive effect on customization*
- H2c: *Absorptive capacity has a positive effect on customer loyalty programs*

The investments an organization places in both developing its IT infrastructure and absorptive capacity should significantly influence its CRM practices. Increases to both will improve its practices of CRM as suggested by the research model. Furthermore, both represent the underlying organizational elements that determine the extent to which an organization will eventually benefit from its CRM, and underscore their importance.

6. Research Methodology

A survey funded by the National Science Council of Taiwan was conducted of 542 financial service institutions in Taiwan. An introduction letter explaining the purpose of the survey and instructing the recipients on the survey's completion accompanied the questionnaire. The highly competitive nature of their markets and the customer-centric orientation make financial service institutions prime adopters of CRM [24].

A standard psychometric scale development procedure of Gerbing and Anderson [8] was followed to generate a series of multiple-item scales that were based on the review of the literature and interviews with several IT and marketing professionals. The items were operationalized on five-point Likert-type scales ranging from strongly disagree (1) to strongly agree (5). Pre-tests were conducted on the survey instrument among five marketing and IT managers, and subsequent refinements were made. Of the questionnaires sent, 164 usable responses were received. Missing response values contained within nine of the surveys further reduced the analysis to 155 observations.

A factor analysis with a varimax rotation (using SAS 8.2) confirmed the existence of the five hypothesized constructs: IT intensity, absorptive capacity, market orientation, customization, and loyalty programs. The factors and loadings appear in Table 1. Although three of the market orientation variables cross-loaded on the customization construct, their larger loadings give stronger support to the market orientation construct. A Kaiser's measure of sampling adequacy (MSA) of .914 strongly supports the appropriateness of the factor analysis, given the sample size of 155.

Non-response biases of the data set were examined with t-tests that compared the sample and population demographics (i.e., number of employees, capital, age of organization). No significant differences were detected.

7. Analysis and Discussion

Regression models were developed to test the six hypotheses. The models included IT intensity and absorptive capacity as the independent (predictor) variables, and organization capital and number of employees as the control variables to control their effects on the dependent variables. This ensures neither biases the results and helps increase the generalizability of the findings [18]. Because a linear relationship exists among the items of a construct, composite scores were derived from their summated responses and used in the regression models.

The data support the six hypotheses (H1a, H1b, H1c, H2a, H2b and H2c). Table 2 summarizes the results. Model I suggests that IT intensity and absorptive capacity are positively related to market orientation (H1a and H2a). The significance of their standardized coefficients indicates their support of the research model. The non-significance of the control variables (organization capital and number of employees) confirms that neither influences nor biases the results (i.e., neither has a bearing on the relationship). Also, an examination of the

variance inflation factors (VIF) reveals no collinearity problems among the independent variables. Similar results found with Models II (H1b and H2b) and III (H1c and H2c) support the research model and suggest that IT intensity and absorptive capacity are positively related to customization and loyalty programs. Interestingly, the higher standard coefficient for IT intensity in all three models indicates its greater impact on CRM practices over absorptive capacity. Thus, the data generally support the proposed research model. However, the low R-square values strongly suggest that other factors not captured in the models may account for a large portion of the variations in the model. This might be addressed in future studies.

IT intensity forms the foundation on which CRM systems are built. Yet, CRM success cannot be attributed to technology alone. How an organization applies IT as demonstrated in its practices will have a greater impact on its CRM results. The results of this study support the contention that IT investments play a vital role and have a positive effect on CRM practices; greater investments in IT lead to improved CRM practices and ultimately better CRM performance. The IT infrastructure reflects the investments and commitment an organization makes to IT, and ensures IT remains a true organizational resource. However, it is not an end unto itself, but a means to an end, such that it embodies capabilities that lead to desirable results. In particular, investments in IT support CRM in two important aspects: the internal operations and strategic planning tasks. Operationally, IT allows the organization to share data and knowledge across internal boundaries, coordinate its activities in response to market intelligence and respond as a single entity to changes in environmental forces. Strategically, continual advances in IT have opened new opportunities with tools that provide greater insight into market forces and respond competitively with customization and loyalty programs. Thus, CRM practices benefit from the degree to which the organization invests in IT (i.e., intensity).

Having the knowledge to pursue avenues that lead to products and services that better satisfy the needs and expectations of customers also plays a critical role in selecting and adopting successful CRM practices. The results of this study also lend support to the contention that an organization's investments in absorptive capacity are crucial and positively affect its CRM practices. This suggests that as organizations invest more into learning and develop their knowledge, they will be more effective in their CRM practices as they become knowledgeable in asking the right questions and selecting the right methods and information to find the right answers. Thus, absorptive capacity leads to the successful leveraging and exploitation of information. This extends from recognizing new information to expand the existing body of knowledge or capitalize on new opportunities to applying knowledge to develop innovations that ensure the long term relationships an organization cultivates with its customers. As in the case of IT intensity, investments to absorptive capacity lead to future long term benefits.

The Internet's expansive markets have lured many

organizations into e-business. With the transition to e-business, the business paradigm shifts from its emphasis on the management of physical resources to information as the primary resource. In contrast to their *brick and mortar* counterparts, e-businesses must be capable of using its information and knowledge to effectively compete in the high-stakes IT-enabled marketplace. The study of Phau and Poon [22] explored the applicability of the Peterson et. al [21] classification of products and services to Internet sales, and found that products and services having an intangible (service) value proposition and relying on relatively high differentiation were better suited for the Internet. This suggests that competing in e-business markets will be information and knowledge oriented (or intense), and implies that organizations lacking in these areas may have difficulties achieving success. Although CRM has been used to successfully gain competitive advantages in such markets, the development of its practices looms as a more dominating issue. Thus, it may behoove organizations to invest not only to carefully develop their CRM practices, but to purposefully invest in their IT infrastructure and absorptive capacity as both will affect their CRM practices.

In conclusion, IT intensity and absorptive capacity represent at least two important factors that influence an organization's CRM practices, including market orientation, customization and loyalty programs. The results of this study also suggest that other factors may influence CRM practices. Further examination of the relationships can be made to establish a causal relationship.

8. Summary

This study examined the relationships between IT intensity and absorptive capacity, and three facets of CRM practices: market orientation, customization, and loyalty programs. The analysis of survey results suggests that both (IT intensity and absorptive capacity) have positive effects on market orientation, customization and loyalty programs. Thus, it may be concluded that organizations may derive greater benefits from their CRM practices with greater investments in IT and absorptive capacity. The importance of this conclusion particularly applies to the IT-enabled e-business models which emphasize information as the organization's primary resource and the need to effectively compete in global markets.

Effect of Hedonic and Utilitarian Goals in Similarity Judgment of a Hotel-Restaurant Brand Alliance

Huey Chern Boo and Anna S. Mattila

School of Hotel, Restaurant, and Recreation Management

The Pennsylvania State University

hxb146@psu.edu

Abstract

The perception of fit between two entities in a brand alliance is an important factor in affecting consumers' evaluations of the partnership. Drawing from goal theories, the authors examine the role of consumption goals in driving consumers' fit perceptions in the context of hotel-restaurant brand alliances. In particular, they study two types of consumption goals—hedonic and utilitarian. The authors argue that consumption goals moderate the effect of image congruency on consumers' perceived fit between a hotel and a restaurant in an alliance. The results of this study indicate that a partnership involving incongruent brand images between a hotel and a restaurant can enhance the perceived fit ratings. However, the types of consumption goals seemed to moderate these effects. Specifically, our results show that incongruent brand images enhance consumers' perception of fit for hedonic consumption goals. Conversely, incongruent brand images failed to influence perceived fit ratings in the utilitarian goal condition. The findings of this study have several important implications for service organizations in search for ideal brand alliance partners.

1. Introduction

Partnering with well-known restaurant chains is becoming increasingly common, particularly for mid-priced hotels. For example, Hampton Inn has installed Pizza Hut Express outlets in lobbies, Holiday Inn has formed an alliance with TGI Friday's, and Ramada Inn has partnered with Bennigan's. As hotel companies have incorporated virtual tour in their world-wide web and consumers are capable of evaluating the hotels prior to their purchase, an alliance with an appropriate restaurant is therefore a challenge to hotel marketers. In particular, the perceived fit between the two entities is an important factor in affecting consumers' evaluations of the partnership. The goal of this paper is to examine the role of consumption goals in guiding consumers' fit perceptions in the context of hotel-restaurant brand alliances.

2. Review of Literature

The effect of perceived fit in influencing consumer evaluations is robust across different contexts, such as brand extensions [1], celebrity endorsements [2], event sponsorships [3], and brand alliances [4]. Indeed,

previous research has investigated several ways brands can be linked together—feature-based, usage-based, and schema- or concept-based. However, these bases of fit have their limitations. For example, a common consumption situation fails to explain the perceived compatibility of products that do not share a common usage occasion. On the other hand, feature-based fit and concept consistency lack a theoretical basis for identifying which product features or brand concepts are critical to the determination of congruency [5]. Overall, the bases of fit are often assumed as alternatives to, or exclusive of, one another. Furthermore, past research has generally neglected the possibility that incongruous brands may in fact fit.

Following the means-end model, Peterman [6] suggested that goal categories form a continuum from concrete to abstract. Some other researchers have further differentiated the abstract level of goals into hedonic and utilitarian types [7] [8] [9] [10] [11]. According to this group of researchers, a hedonic goal is the purchasing motivation for symbolism, value-expression, affective consideration, and the satisfaction of sensory or emotional wants. The focus of concern is on the enhancement of self, subjective meanings, and intangible features. Hence, the symbolic processing is holistic, synthetic, and image-based. Conversely, a utilitarian goal refers to functional and cognitive purchasing motivations. An individual whose consumption is motivated by utilitarian goals focuses on product functional performance, costs to benefits ratio, and tangible product features. For this type of goal, then, an individual generally processes information in a logical and rational manner.

Consumption goal theory is important in addressing the above issues. As has been widely documented, goals provide the context in which a consumer organizes information processing, makes categorizations, and reaches similarity judgments [12] [13]. Martin and Stewart [5] further demonstrate that perceived compatibility is a multidimensional construct and that product features, common usage situations, and brand concept are all linked by a shared goal. The number and structure of the bases of fit are different when products vary in the degree of goal congruency.

Previous studies demonstrated that situational goals (goal-derived categories) can enhance the perceived similarity of products that are visually quite different [14] [15] [16] [17]. Yet, prior research has failed to investigate the impact of hedonic and utilitarian goals on consumers' category representations. For example, can hedonic goals

diminish the perceived similarity of products that highly resemble each other? Or are these similarity representations so rigid as to preclude any top-down intervention? We address these questions by systematically varying the surface resemblance of brand alliance partners and the salience of hedonic and utilitarian goals in a given consumption context.

Drawing from goal theories, we argue that brand alliances involving partners with incongruent brand images (e.g., a classy hotel with a funky restaurant) can result in high perceived fit ratings as long as the two brands are consistent with consumers' consumption goals. Particularly, we hypothesize that

H1: When the restaurant image is consistent with customers' hedonic goals, the perceived fit ratings for a partnership with an image-incongruent restaurant are expected to be at least as high as with an image-congruent restaurant.

H2: When customers' utilitarian goals are unrelated to the restaurant image, the perceived fit ratings are expected to be greater for a partnership with an image-congruent restaurant than with an image-incongruent restaurant.

H3: When the image between hotel and restaurant is congruent, the perceived fit ratings are expected to be greater for hedonic than for utilitarian goals.

H4: When the image between hotel and restaurant is incongruent, the perceived fit ratings for hedonic goals are expected to be lower than that for utilitarian goals.

3. Methodology

A series of pretests were conducted for two purposes. First, the pretests were to determine two different types of restaurants that have either a calm (congruent image with the hotel) or lively image (incongruent image with the hotel). Second, they were to find realistic consumption goals or situations. All subjects were hospitality students enrolled in a large northeastern university.

The current study employed a 4 x 2 between-subjects factorial design. The components were consumption goals (hedonic: calm dining, dining in a lively environment; utilitarian: convenience, saving) and restaurant image (congruent and incongruent image with the hotel). A total of eight treatments were conducted.

3.1 Subjects

Participants were 350 travelers (25.3% of the total number of travelers approached) waiting for their planes at a national airport in the United States. These subjects were deemed appropriate because they are actual or potential hotel guests. Because the videos were of a hotel and restaurants in a northeastern university town, the subject pool is unlikely to be familiar with the actual hotel and restaurant operations shown in the video clips.

Consequently, potential confounding variables, such as familiarity and attached attitude, were minimized.

3.2 Instrument and Procedures

Subjects were randomly given one of the eight versions of questionnaire. The questionnaire contained two parts. In the first part, subjects were asked to evaluate a national hotel and restaurant chain. Subjects first viewed a video clip of a mid-priced hotel chain before answering a series of questions regarding the hotel image, their attitudes toward the hotel, and their behavioral intentions. Next, they viewed another video clip, one of a mid-priced chained restaurant. Neither the hotel nor the restaurant brand was disclosed to respondents. Each subject watched a clip of one of the two types of restaurant (calm or lively). A series of questions pertaining to the restaurant's image, subjects' attitudes toward the restaurant, and congruency ratings between the hotel and the restaurant followed the video clip.

In the second part of the questionnaire, subjects read a cover story explaining the brand alliance situation. Subsequently, subjects were asked to imagine themselves in one of the four consumption situations described in a scenario. They were told to imagine that the hotel they viewed in the video clip shown earlier was the one they stayed in, and that it had partnered with a national restaurant chain, which corresponded with the restaurant video they had been shown. Then, subjects were asked to indicate their perceptions of fit between the hotel and the restaurant. At the end of the survey were questions about socio-demographics.

3.3 Independent Variables

The first factor (consumption goals) involved the manipulation of four different consumption situations. The four levels of manipulation included (1) a calm goal, in which consumers were looking for a calm dining experience; (2) a fun goal, in which consumers were seeking to dine in a lively environment; (3) a convenience goal, in which consumers were only concerned about the location of the restaurant; and (4) a savings goal, in which consumers were on a tight budget. The first two goals are hedonic goals that involve a symbolic image-based mode of processing. Convenience and savings goals, however, reflect utilitarian goals in which functional performance, costs/benefits, and tangible features are the focus of concern.

The second factor refers to the restaurant's image. The two levels of manipulations were (1) a restaurant with a calm and relaxing image (similar to the hotel), and (2) a restaurant with a lively image (different from the hotel). In order to determine the image congruency between the hotel and the restaurant brand, a video clip about the hotel brand was included.

3.4 Dependent Variable

Three seven-point semantic differential scales developed from literature in event sponsorship, celebrity

endorsement, and brand extension [3] [18] [19] were used to assess brand compatibility. The question was: "In reference to your dining needs, what do you think about Hotel X and Restaurant Y?" The three semantic differential scales included: do not belong together/belong together, are not compatible/are compatible, and do not fit well/fit well.

3.5 Manipulation Checks

To ensure that the independent variables were perceived as intended, this study included four scales for manipulation checks: (a) image congruency, (b) restaurant attitude, (c) hotel attitude and behavioral intention, and (d) consumption needs. The first two were directed toward the hotel and the restaurant while the last tapped into the scenario manipulation.

3.5.1 Image congruency

To check if the hotel and restaurant images were congruent, the approach developed by Martin and Stewart [5] was employed: "What do you think about the image between Restaurant Y and Hotel X?" The seven-point semantic differential scales included: highly dissimilar/highly similar, and not at all alike/very much alike.

3.5.2 Attitudes

Consumers' attitudes toward the restaurant were measured via a series of seven-point semantic differential scales: bad/good, unfavorable/favorable, and negative/positive [20]. Similarly, these attitude scales were also used in measuring consumers' attitudes toward the hotel prior to the alliance.

3.5.3 Behavioral intentions

The behavioral and word of mouth (WOM) scales were composed of a series of seven-point semantic scales [21]. Consumers were asked about their likelihood to: "say positive things about Hotel X to other people", "recommend Hotel X to someone who seeks your advice", "encourage friends and relatives to do business with Hotel X", "stay in Hotel X again", and "consider staying at Hotel X in your travels."

3.5.4 Consumption needs

To determine if subjects prioritized their consumption needs according to the scenario descriptions, four questions on the manipulation of scenario were included. Based on the situation described in the scenario, subjects were asked to answer "to what extent do you want to dine in a peaceful environment", "to what extent do you want to dine in a lively environment", "to what extent is the restaurant being located in the hotel critical to you", and "to what extent is menu pricing a concern to you." They gave responses on a scale of 1 = not at all to 7 = very much so.

4. Results

The profile of the participants shows that nearly two-thirds ($n = 231$) of the participants were male. The average age of the respondents was 38.88, and the overall range was from 18 to 65. The majority of the participants were married (59%) and have at least a Bachelor's degree (79%). Only less than five percent of the respondents, 0.3% and 2%, were a widow/widower or had only some high school education, respectively. Approximately 57% of the participants earned more than 75K in annual household income. Overall, participants represented both genders, were married, and tended to be relatively young, well-educated, and affluent.

4.1 Manipulation Checks

A factor analysis of the participants' overall attitudes toward the hotel brand suggested a single underlying factor averaging the three attitude items (Cronbach's $\alpha = .967$). Similarly, the five behavioral intention items were combined to generate a single behavioral intention index (Cronbach's $\alpha = .959$). The manipulation checks for pre-alliance attitudes and behavioral intentions toward the hotel brand yield insignificant analysis of variance (ANOVA) results across all eight treatments ($p > .05$).

A factor analysis of the participants' overall attitudes toward the restaurant brand also suggested a single underlying factor averaging the three attitude items (Cronbach's $\alpha = .978$). The two similarity items were also combined to generate a single similarity index with a high Pearson correlation, $r = .929$ (Cronbach's $\alpha = .963$).

The t-test results for restaurant brand image show that the image-incongruent restaurant ($M = 2.704$) was rated significantly more dissimilar from the hotel ($t(348) = 12.457, p < .05$) than was the image-congruent restaurant ($M = 4.725$). Specifically, the image-incongruent restaurant ($M = 5.825$) was rated more lively ($t(347) = 18.369, p < .05$) than was the image-congruent restaurant ($M = 3.601$). On the other hand, the pre-alliance restaurant attitudes shows an insignificant t-test result between the two types of restaurant image ($t(348) = 1.662, p > .05$). Participants' attitudes toward the image-congruent ($M = 4.545$) and incongruent restaurants ($M = 4.799$) were not different. Hence, the manipulations of restaurant attributes (image, similarity to the hotel image, and attitudes) were successful.

In terms of consumption goal manipulation, all scenarios were perceived as realistic (mean > 4 for all scenarios, $p < .05$). Four manipulation checks focusing on the importance of each consumption goal (calm, lively, convenience, savings) were included. The repeated measures results yield only significant effect of consumption goals on scenario manipulation ($F(8.722, 991.354) = 44.193, p < .05$).

4.2 Perceived Fit

A factor analysis of the three perceived fit items confirmed a single underlying factor. Thus, the items

Table 1. Means and standard errors of perceived fit as a function of consumption goal and restaurant image

Consumption goal	Restaurant image					
	Calm (Congruent)			Lively (Incongruent)		
	<u>n</u>	<u>Mean</u>	<u>SE</u>	<u>n</u>	<u>Mean</u>	<u>SE</u>
Calm	49	4.96 _a	0.23	45	2.86 _b	0.24
Lively	31	4.75 _a	0.29	35	4.12 _a	0.27
Convenience	47	5.54 _a	0.24	46	3.52 _b	0.24
Savings	51	5.03 _a	0.22	46	4.00 _b	0.24

Note. Means in the same row that do not share subscripts differ at $p < .05$.

were averaged to form a general perceived fit index (Cronbach's $\alpha = .979$).

H1 asserted that when a restaurant image is consistent with consumers' hedonic goal (lively dining environment), the perceived fit ratings for a partnership with an image-incongruent (lively) restaurant would be at least as high as that for image-congruent (calm) restaurant. On the other hand, H2 predicted that the perceived fit ratings would be greater for a partnership with an image-congruent restaurant than with an image-incongruent restaurant when utilitarian goals are satisfied.

Table 1 summarizes the perceived fit ratings for all the experimental treatments. The ANOVA results reveal a significant interaction effect between consumption goals and image congruency on perceived fit ($F(3, 338) = 4.193, p < .05, \eta^2 = .036$). Specifically, planned contrasts show that a partnership with an image-congruent (calm) restaurant ($M = 4.96, SE = 0.23$) was rated significantly more fit ($F(1, 338) = 40.203, p < .05, \eta^2 = .106$) than with an image-incongruent (lively) restaurant ($M = 2.86, SE = 0.24$) when a peaceful environment was the participant's dining goal. However, when the consumption goal was to dine in a lively environment, the perceived fit ratings for a partnership with an image-incongruent restaurant ($M = 4.12, SE = 0.27$) and an image-congruent restaurant ($M = 4.75, SE = 0.29$) were not significantly different ($F(1, 338) = 2.525, p > .05, \eta^2 = .007$), in support of H1.

For utilitarian goals, the planned contrasts indicate that a partnership with an image-congruent (calm) restaurant ($M = 5.54, SE = 0.24$) was rated significantly more fit ($F(1, 338) = 37.042, p < .05, \eta^2 = .099$) than with an image-incongruent (lively) restaurant ($M = 3.52, SE = 0.24$) when the participant's consumption goal involved convenience. Likewise, when participants were concerned about price, the perceived fit ratings for a partnership with an image-congruent restaurant ($M = 5.03, SE = 0.22$) were significantly greater ($F(1, 338) = 10.001, p < .05, \eta^2 = .029$) than the fit ratings for an image-incongruent restaurant ($M = 4.00, SE = 0.24$). Hence, H2 was also supported.

H3 postulated that the perceived fit ratings would be greater for hedonic goals than for utilitarian goals when the partnership involved an image-congruent restaurant. On the other hand, H4 hypothesized that the perceived fit ratings would be lower for hedonic goals than for utilitarian goals when the partnership involved an image-incongruent restaurant.

To test these hypotheses, the cell means for the appropriate conditions were compared using a planned contrast procedure. Contradictory to H3, the perceived fit ratings for a partnership with an image-congruent restaurant were not significantly different between hedonic and utilitarian goals ($d = -0.329, F(1, 338) = 1.386, p > .05, \eta^2 = .004$). However, the perceived fit ratings for a partnership with an image-incongruent restaurant were significantly lower for hedonic goals than for utilitarian goals ($d = 0.903, F(1, 338) = 9.450, p < .05, \eta^2 = .027$). Hence, the result supports H4.

5. Discussion

The results of this study show that the perceived fit ratings for a partnership with an image-congruent restaurant were higher than the fit ratings for an image-incongruent restaurant. However, a partnership with an image-incongruent restaurant could be perceived as compatible if the incongruent restaurant image matched up to the hedonic consumption goals. For example, participants whose consumption goal was to dine in a lively environment judged the image-incongruent partnership as compatible as the image-congruent partnership. These findings are consistent with previous study [17].

When comparing the effect of hedonic and utilitarian goals, the perceived fit ratings were higher for utilitarian goals than for hedonic goals when a partnership involved an image-incongruent restaurant. On the other hand, the perceived fit ratings for hedonic goals were not different from that for utilitarian goals when a partnership involved an image-congruent restaurant.

Considered as a whole, these results suggest that, first, congruent image is not affected by any top-down intervention. Second, the effect of consumption goals is significant when hotels partner with image-incongruent restaurants. Specifically, hedonic goal-consistent image-incongruent partnership can alter the mental representations of two distinct brands. Image incongruent restaurant has lower negative impact when consumers' consumption goals are utilitarian than when they are hedonic.

6. Summary and General Discussion

The results for H1 support the general proposition that hotels partnering with image-incongruent restaurants may

not automatically be perceived as incompatible. These results are consistent with goal theories discussed previously, suggesting that consumption goals provide a context in which consumer process information and make similarity judgments [5] [12] [13]. Following these theories, hedonic goals direct consumers' attentions to symbolic aspects of brand image. Therefore, when the consumers' goals were to dine in a lively environment, a hotel with a calm image partnering with a lively restaurant appeared compatible, and subsequently would be favorably evaluated. However, results for H2 indicate that the effect of goals on consumers' perceptions of fit is dependent upon the types of consumption goals.

The current research provides empirical evidence for the development of hotel-restaurant brand alliance involving image congruency, consumption goal, perceived fit, attitude and behavioral intention toward the hotel brand, and image transference. This study broadens the latitude of goal-driven theory, as well as its application in several respects.

First, prior research has strongly suggested the intrinsically conspicuous role of surface level resemblance between two allied brands in the similarity judgments [4] [18]. Such a perspective implies considerable rigidity for shifts in similarity or compatibility perceptions based on factors such as individuals' goals. Previous researchers [17] demonstrated that personal goals and situational goals enhance the perceived similarity of goal-appropriate products even if the surface resemblance between the products is low. The present study extends the support for the notion that goals can enhance the perceived compatibility of two seemingly distinct brands for hedonic goals.

Second, goals are known to provide a context for information processing and similarity judgments. This study further sheds light onto the importance of distinguishing the types of consumption goals in future research. Specifically, it suggests that the effect of utilitarian goal is dependent upon the image discrepancy between two partnering brands in consumers' service brand evaluations.

Third, the effect of consumption goals on consumers' perceptions of fit of a brand alliance also differs between hedonic and utilitarian goals. In particular, utilitarian goals may attenuate the negative effect of an incongruent restaurant image on perceived fit ratings when the incongruent restaurant image is inconsistent with the hedonic goal. However, when the incongruent restaurant image is consistent with the hedonic goal, utilitarian goals are not capable of altering the perceived fit ratings. On the other hand, hedonic goal can enhance the perceived compatibility of two seemingly distinct brands.

7. Limitations and Future Study

There are several caveats and qualifications to the conclusions and interpretations of the current research findings. First, although this study sought to make a contribution by demonstrating an empirical support for

hypotheses derived in part from the goal-driven, only a limited set of consumption goals and only two specific types of restaurant image were investigated. Thus, generalizations must be made with caution.

Second, experimental approaches to examining marketplace phenomena are often criticized for lacking realism. In a real-life context, a brand name signifies additional information, such as familiarity, trust, predictability, and consistency. This brand equity may be a competitive factor to image congruency in influencing consumers' evaluations of a hotel brand. Therefore, future research employing real brands is greatly needed to shed light on the relative importance of brand name and image.

Third, it should be noted that the present research did not examine the effect when participants' utilitarian goals were not satisfied or the effect of utilitarian goal, per se. Although it is reasonable to infer from the current study that the symbolic image is more influential than the functional aspect of brand image for utilitarian goals, a definite conclusion can be drawn only when utilitarian goals are not met. Research attempting to validate the importance of image congruency, particularly in the service industry, would represent a substantial contribution to knowledge about service brand alliance.

Finally, hotel market segments are generally categorized into leisure, business, and convention types. The present study focused on leisure travelers and disclosed that restaurant brand recognition was not as important as expected. However, it seems plausible that business travelers do not usually spend a proportionate amount of time looking for a place to dine at. Familiarity and consistency of quality of a brand may be more critical to them. Thus, generalizability of the current results to business travelers must be made with further study.

Based on the results of the current research and its limitations, several avenues of further research are recommended. For example, future research can investigate the effect of hotel-restaurant brand alliance on consumers' evaluations of the hotel, as well as the possible image transference.

Besides the differences between leisure and business travelers, another interesting future area of research involves cross-cultural study. For example, hotel restaurants in Asia are generally considered as prestigious. Dining in a hotel restaurant is perceived as a luxury, even though the quality of food may be mediocre. On the other hand, mid-priced international restaurant chains receive equally high favorable attitudes among the consumers, but are limited in their number of outlets. If the idea of partnership between the two brands is well-accepted, it will be a means for international restaurant chains to venture into the foreign markets.

Finally, another challenging area of future research is the deep understanding of consumers' definitions of fit. Particularly, the type of relationship consumers contemplate between the hotel and the restaurant, whether a marriage, an affair, friendship, or master-slave, as well as the essential elements for the success of the

alliance are important. Qualitative research methods, such as the Zaltman Metaphor Elicitation Technique [22] [23] [24] could be useful in discerning more fully consumers' below surface thoughts and feelings relating to the alliance.

Abstract

A priori estimation of quality of service (QoS) levels is a significant issue in web services since Service Level Agreements (SLAs) need to specify and adhere to such estimates. In this paper we present novel cost formulae for estimating the end-to-end response time for distributed data mining (DDM) web services.

1. Introduction

Umesh Dayal [2] predicted that "...data analysis and mining functions themselves will be offered as business intelligence e-services that accept operational data from clients and return models or rules". The growing number of Web Service Providers (WSPs) like digiMine™ (<http://www.digimine.com>) and Information Discovery™ (<http://www.datamine.aa.psiweb.com>) who offer commercial data mining web services are testimony to this statement [8, 11, 4]. The increasing focus on data mining web services can be attributed to the recognition of data mining as an important technology in aiding strategic decision making coupled with the commercial viability of the WSP paradigm. The option of Internet-delivery of data mining services is emerging as attractive for small to medium range organisations, which are the most constrained by the high cost of data mining software, and consequently, stand to benefit by paying for software usage without having to incur the costs associated with buying, setting-up and training. While the primary focus of the commercial arena has been the delivery of data mining as a web service, there is an emerging research focus on providing data mining models as services on the Internet [14]. Thus rather than the hosting of a data mining system and delivering the results as a service, the aim is to be able to sell data mining models, which can be bought, for example, by start-up organisations operating in a given vertical domain.

In general, the operational cornerstone for WSPs is the contractual agreement between the client and the service provider, known as the Service Level Agreement (SLA). The SLA is a legally binding document and specifies the contractual obligations of the WSP with respect to the guaranteed level of service and the penalties associated with failure to comply with the contract. In the specific context of WSPs, which are governed by SLAs, QoS metrics have a direct bearing on the success in monetary terms. Therefore, the ability to accurately predict the level

of service that can be guaranteed is of immense value to WSPs. It is in this context that motivates [13] to state quality of service has "...a lot to do with a cost-benefit analysis and prediction for SLAs". The need for such predictive estimates of the quality of service that can be ensured is also clearly indicated by qualitative studies presented in [1] which surveyed user behaviour and the criteria users applied to assessing network services and pricing. One of the outcomes of this study was that "...users value predictive feedback over feedback concerned with current statistics". While predicting the quality of service a priori is an important requirement for WSPs as discussed in [1, 13], it has not been addressed by the web services community. This can be attributed to several reasons. The focus has been on system level metrics that are the key to load balancing and resource utilisation and not on application centric metrics such as the waiting time, probability of successful completion and end-to-end application response time [16, 19]. It is difficult to formalise the semantics of application centric metrics since characteristics vary from application to application. Prediction is challenging in a dynamic environment such as the Internet, where WSPs operate. This challenge is considerably increased by the consequences and pitfalls of inaccurate estimates, because of the direct relationship between prediction accuracy and revenue/loss.

In summary, WSPs require the development of techniques to estimate the quality of service that can be ensured by the service provider. This need is driven by SLAs, which have a direct bearing on the revenue of WSPs and is increasingly being stated as an issue that must be addressed [1, 13]. In this paper we present techniques for estimating the response time of data mining application services.

2. Response Time of Distributed Data Mining

In this section, we present techniques for estimating the end-to-end response time in data mining web services. At a conceptual level, the response times for different scenarios is as illustrated in the example scenario illustrated in figure 1. The client has two data sources ("Data 1" and "Data 2") and two computational resources ("Server 1" and "Server 3") that it can make available for mining. One of the datasets (Data 1) is located on Server 2 that is not available for mining. The service provider has three high-performance servers. The three servers on the service provider's side may be geographically distributed, thereby making the

communication costs variable.

Figure 1 Data Mining Web services

There are three possible options that the client can choose:

1. The mining should be done locally using only the client's computational resources. In this case a mobile agent based approach will have to be employed in order to perform the task at the client's site.
2. The mining should be done remotely using only the service provider's computational resources. In this case, a client-server approach will have to be used and the data has to be transferred to the service provider's servers.
3. The client has no preference for the location. In this case, a combination approach of mixing the client-server and the mobile agent models can be used.

The estimation requires the identification of the cost components and formalisation of a cost model for response time in the context of distributed data mining (DDM) web services. We now formalise the cost components of the DDM response time and present estimation techniques for these cost components.

2.1 Cost Components of the DDM Response Time

In this section we specify the different cost components of the response time in distributed data mining web services. The response time of a task in a distributed data mining web service broadly consists of three components: *communication*, *computation* and *knowledge integration*.

Communication: The communication time is largely dependent on the operational model. It varies depending on whether the task is performed using a client-server approach or using mobile agents. In the client-server model the communication time is principally the time taken to transfer data from distributed servers to a high performance machine where the data mining is performed. In the mobile agent model, the communication time revolves around the

time taken to transfer mobile agents carrying data mining software to remote datasets and the time taken to transfer results from remote locations for integration.

Computation: This is the time taken to perform data mining on the data sets and is a core factor irrespective of the operational model.

Knowledge Integration: This is the time taken to integrate the results from the distributed datasets.

The response time for distributed data mining is as follows:

$$T = t_{dm} + t_{com} + t_{ki} \quad (1)$$

In Eq. 1 above, T is the response time, t_{dm} is the time taken to perform data mining, t_{com} is the time involved in communication and t_{ki} is the time taken to perform knowledge integration. The modelling and estimation of the knowledge integration (t_{ki}) variable is dependent on the size and contents of the results obtained from the distributed datasets. Given that the primary objective of data mining is to discover hitherto unknown patterns in the data [3], we consider the a priori estimation of the time taken to perform knowledge integration to be outside the scope of this paper (since knowledge integration depends on the characteristics of the results of the data mining process). Having identified the cost components of the DDM response time, we now formalise the overall estimation cost for different models and scenarios.

2.2 Cost Matrix for Representing the Composite Response Time

We now present a cost matrix for computing the composite DDM response time estimates for different strategies. The response time for distributed data mining as presented in Eq. 1 consists of three components including communication (due to either transfer of mobile agents and/or transfer of data), computation (performing data mining) and knowledge integration. The following discussion focuses on the communication and computation components and does not consider the knowledge integration component. The strategy is to compute estimates for the individual cost components and then uses the estimates to determine the overall response times for different strategies. The cost matrix to calculate the composite response time for different DDM strategies is denoted by CM and is represented as a two-dimensional $m \times n$ matrix, where m is the number of available servers and n is the number of datasets. A fundamental feature of the cost matrix that makes it applicable for both the mobile agent and client-server models is that we incorporate location information on the datasets and servers.

The elements of the cost matrix represent the estimated response time and are defined as follows:

1. Let m be the number of servers.
2. Let $S = \{S_1, S_2, \dots, S_m\}$ be the set of servers. A server S_i can either be located at the service provider's site or at the client's site. Therefore, let S^{SP} be the set of servers located at the service providers site and let S^C be the

set of servers located at the client's site. The following properties are true for the sets, S , S^{SP} , S^C .

- $S^{SP} \cup S^C = S$; the set of servers available at the client's site and the set of servers available at the service provider's site summarily constitute the total set of available servers. The obvious corollaries are $S^{SP} \subseteq S$ and $S^C \subseteq S$.
- $S^{SP} \cap S^C = \emptyset$; thus a server either belongs to the client or the service provider. It cannot belong to both.
- $S^{SP} = \emptyset$ is valid and indicates that the client is not willing to ship the data across and $S^C = S$ is also valid and indicates that the client's computational resources are unavailable or inadequate.

In order to specify the location of a server we use the following notation: $S_j \in S^{SP}$ and $S_j \in S^C$ where, $j = 1, 2, \dots, m$. This distinction is necessary for specification of how the response time has to be estimated in the cost matrix.

3. Let n be the number of datasets and let $DS = \{ds(1), ds(2), \dots, ds(n)\}$ represent the labelling of the datasets.
4. Let $ds(i)_{S_j}$ represent the location of a dataset labelled $ds(i)$, $i = 1, 2, \dots, n$ at server S_j , where $ds(i) \in DS$ and $j = 1, 2, \dots, m$. Thus datasets are uniquely identified and multiple datasets at locations can be represented.

Let $cm_{ij} \in CM$ be the estimated response time for taking a dataset located at the server j and mining it at the server i , where $1 \leq i \leq m$ and $1 \leq j \leq n$. The value of cm_{ij} is computed as follows:

$$cm_{ij} = \begin{cases} MA_{S_X \rightarrow S_i} + TR_{S_i \rightarrow S_i}^{ds(k)_{S_i}} + W_{S_i} + DM_{S_i}^{ds(k)_{S_i}}, & i \neq j, S_X \in S^{SP}, S_i \in S^C, S_j \in S^C \\ MA_{S_X \rightarrow S_i} + W_{S_i} + DM_{S_i}^{ds(k)_{S_i}}, & i = j, S_X \in S^{SP}, S_i \in S^C, S_j \in S^C \\ TR_{S_j \rightarrow S_i}^{ds(k)_{S_j}} + W_{S_i} + DM_{S_i}^{ds(k)_{S_j}}, & i \neq j, S_i \in S^C, S_j \in S^{SP} \end{cases}$$

In the above equation:

- $MA_{S_X \rightarrow S_i}$ is the time to transfer a mobile data mining agent from server S_X (which is a server of the service provider) to server S_i
- $TR_{S_j \rightarrow S_i}^{ds(k)_{S_j}}$ is the time to transfer a dataset $ds(k)_{S_j}$ located at server S_j to server S_i
- $DM_{S_i}^{ds(k)_{S_i}}$ is the time to mine dataset $ds(k)_{S_i}$ located originally at server S_i at server S_i
- W_{S_i} is the wait time at server S_i required for the completion of previous tasks and is generally more significant when $S_i \in S^{SP}$ (i.e. server S_i is located at the service provider's site).

As presented above there are three formulae for estimating

the response time for different scenarios in the cost matrix. The first one is for the case where the server S_i where the mining is to be performed is at the client's site but does not contain the dataset $ds(k)_{S_j}$ (which as indicated is located

at the server S_j). Hence there is a need to transfer the data from its original location S_j to the server S_i to perform the data mining. Further, the client's site would not have the data mining software and a mobile agent needs to be transferred from the service provider's site (represented as S_X). The second formula is for the case where the server where the mining is to be performed is at the client's site and the dataset is located on the same server (i.e. $i = j$). In this case, the mobile agent needs to be transferred but there is no need to transfer the data. The third formula is for the case where the server where the mining is to be performed is located at the service provider's site (i.e. $S_i \in S^{SP}$) and therefore the data has to be shipped across from the client's site to perform mining. The three formulae map to the three scenarios outlined earlier, namely, that of mining at the client's site, mining at the service provider's site and using both sites. The cost matrix has been designed to determine the response time for mining the datasets at the different available servers. The location of the servers and the datasets determine the cost formula that has to be applied for computing the response time. We now present cost formulae for estimating the individual cost components.

3. Estimating Individual Cost Components of Response Time

As discussed, we now present strategies for estimating the individual components of the DDM response time.

3.1 Estimating the Communication Cost

The communication cost in the DDM process varies depending on whether the client-server strategy is followed or the mobile agent model is used.

3.1.1 Mobile Agent Model

In general, the mobile agent model for DDM involves dispatching mobile agents carrying the mining algorithms to the locations of the data to perform data mining. Thus, the model is characterised by a set of mobile agents traversing the relevant data servers to perform mining. This can be expressed as m mobile agents traversing n servers (that contain datasets). In the context of data mining web services, the mobile agent model is applied when the client specifically requires the task to be performed using the client's computational resources (e.g. where the client does not want the data to leave the site). This model can also be used in cases where the client has no preference, but applying this model results in better response time. Therefore it can be seen that the mobile agent option primarily involves the servers located at the client's site. In order to estimate the transfer times for mobile agents,

consider the following:

Let N be the total number of servers at the clients site.

Let n be the number of servers where the mining is performed.

Let S represent the n servers in question i.e. $S^C = \{S_1, S_2, \dots, S_n\}$.

Let m be the number of mobile agents dispatched from the service provider's central server CES to perform mining at the set of servers S^C .

Let $t_{ma}(x, y) = MA_{x \rightarrow y}$ refers to the time taken by the agent ma to travel from node x to node y .

In order to compute the estimates in the cost matrix, we need to estimate the transfer times of the mobile agents from CES to the servers of the set S^C (i.e. we need to estimate $MA_{CES \rightarrow S^C}$).

Given that there are n servers that have datasets for mining and m agents, there are three possible alternatives within this scenario and they are:

1. $m = n$, where the number of mobile agents is equal to the number of servers. This implies that one data mining agent is sent to each server involved in the distributed data mining task.
2. $m < n$, where the number of mobile agents is less than the number of data servers. The implication of having fewer agents than servers is that some agents traverse more than one server. This option is not used often, but is modelled to allow for cases where there is an imposed ordering in the traversal. For example, a scenario where an agent must first visit server r to obtain background knowledge necessary to perform data mining at server s . This knowledge can be in the form of a concept hierarchy [5] or a database schema that defines the attributes of the database located at server s . In such cases, it is necessary to have one agent traverse several servers.
3. $m > n$, which we do not explicitly consider since this is in effect equivalent to the case 1 above with respect to travel time where there is a mobile agent available per server. That is, having modelled the travel time for a single mobile agent from one server to another it is implicit that we can estimate the travel time for several agents that have to be sent between the same servers. A possible scenario for sending more than one agent to a server may be if there are several datasets that need to be mined at the server and different agents are required to process the various datasets.

Each of the above cases has a cost function and the cost models for estimating the response time. However, in this paper, we focus on the scenario of equal number of mobile agents and data servers, since this is the most common.

This case, where data mining from different distributed data servers is performed in parallel and there is one mobile agent per server (i.e. $m=n$). The algorithm used across the different data servers can be uniform or varied. The service provider dispatches a mobile agent encapsulating the data mining algorithm (with the relevant parameters) to each

data server participating in the distributed data mining task.

In order to derive the cost function for the general case involving n data servers and n data mining mobile agents (since $m=n$), we first formulate the cost function for the case where there is one data server and one data mining agent. Let us consider the case where data mining has to be performed at the i^{th} server $S_i \in S^C, 1 \leq i \leq n$. The overall cost function for the response time to perform distributed data mining involving the i^{th} data server is computed from the formulae presented in section 3.2.3 and consists of the time to transfer the mobile agent to the server, transfer the data to the server (if the data is not originally located at the server) and perform the mining subject to any Wait time imposed. Each of these components have to be estimated in order to derive the overall estimated response time. In this section we focus on estimating the communication time for the transfer of a single data mining mobile agent $dmAgent$ from server CES to server S_i , that is $t_{dmAgent}(CES, S_i)$.

The time taken for a mobile agent to travel depends on the following factors: the size of the agent, the bandwidth between servers and the latency between the servers. The travel time is proportional to the size of the agent and is inversely proportional to the bandwidth (i.e. the time taken increases as the agent size increases and decreases as the bandwidth increases). The latency is the delay, typically expressed in Round Trip Time (RTT) and is added to obtain the transfer time. The latency has higher impact on the transfer time, when the amount of data that is transferred is small, whereas the bandwidth has a higher impact when the amount of data is large. This can be expressed as follows:

$$t_{dmAgent}(CES, S_i) \propto \text{size}(dmAgent) \quad (2)$$

$$t_{dmAgent}(CES, S_i) \propto 1 / (\text{bandwidth between } CES_i/S(3))$$

From (2) and (3):

$$t_{dmAgent}(CES, S_i) = \lambda (CES, S_i) + \text{size}(dmAgent) / \beta (CES_i, S_i) \quad (4)$$

In the above Equation 4, λ is the latency and β is the bandwidth. While bandwidth and latency can be measured, we need to determine the size of the $dmAgent$. In [StS97] the size of an agent is given by the following triple: $\text{size of an agent} = \langle \text{Agent State, Agent Code, Agent Data} \rangle$ where, *Agent State* is the execution state of the agent, *Agent Code* is the program that is encapsulated within the agent that performs the agent's functionality and *Agent Data* is the data that the agent carries (either as a result of some computation performed at a remote location or the additional parameters that the agent code requires). On adapting the above representation to express the size of the data mining agent ($dmAgent$), we now have, $\text{size}(dmAgent) = \langle dmAgent \text{ state, data mining algorithm, input parameters} \rangle$

We now extend the cost estimate for the general case characterised by n mobile agents and n distributed servers. Thus, n mobile agents encapsulating the respective mining algorithms and parameters are dispatched concurrently. Mining is performed at each of the sites in parallel and the results are returned to the central server. Thus, the transfer time per server from Eq. 4 above, is $t_{dmAgent}(CES, S_j), 1 \leq j \leq n$

n . The total transfer time is the time taken by the mobile agent that requires the longest individual transfer time. In case the agent is required to travel back to the server, the estimated travel time is computed as $t_{\text{Agent}}(S_j, \text{CES})$, $\forall j \leq n$.

We have modelled the scenarios for using mobile agents to perform distributed data mining and have presented cost formulae to estimate the mobile agent transfer times for each case. This addresses the *a priori* estimation of the communication mobile agent transfer time component in the cost matrix. The next section focuses on estimating the data transfer time, which is the second communication component.

3.1.2 Estimating Data Transfer Time

The transfer of data in the hybrid DDM model can be attributed to two reasons. Firstly, the hybrid model integrates both the client-server and mobile agent models. In the client-server model the data is transferred from the client's site to the servers of the service provider. Secondly, data transfer occurs when the data resides on a server that is not available for mining (e.g. because it lacks the necessary computational resources or it is dedicated for some other tasks) and has to be transferred to another server at the client's site. Typically, the transfer times in the first case would be more significant than the second where the transfer might occur within an organisation's intranet. In this section, we present the cost formulae for estimating data transfer times $TR_{S_j \rightarrow S_i}^{ds(k)_{S_j}}$ for transferring a dataset $ds(k)_{S_j}$ located at server S_j to server S_i . Server S_i is at the client's site and S_j may be at either the client's site or the service provider's site.

The cost formulae for transferring datasets are primarily dependent on the size of the data, the bandwidth between the servers and the latency or delay. Let $ds(k)_{S_j}$ represent the dataset that is located $S_j \in S^C$ and has to be transferred to S_i (where $S_i \in S^{SP}$ or $S_i \in S^C$). The data transfer time $t_{ds}(S_j, S_i) = TR_{S_j \rightarrow S_i}^{ds(k)_{S_j}}$ can be estimated as follows in equation 5:

$$t_{ds}(S_j, S_i) = \lambda(S_j, S_i) + \text{size}(ds(k)) / \beta(S_j, S_i)$$
 In the above equation 5, λ is the latency and β is the bandwidth between the servers S_j and S_i . Since typical dataset sizes tend to be very large, the effect of the bandwidth will be greater than the effect of the latency of the data transfer time.

We have modelled the cost formulae for the data transfer component of the DDM response time. The cost formulae presented are applicable to DDM systems irrespective of their architectural model and are unique in that, we propose to mathematically model the communication costs in distributed data mining. Further, the cost models developed also take into account the

different cases and options within each model, thereby facilitating comparison of different sub options within a given model. There has not been a comparison of communication times between the client-server and mobile agent models with respect to distributed data mining. The cost formulae developed in this section support the explicit comparison of the communication time between the client-server and mobile agent models for distributed data mining. Further, while previous costing techniques in distributed data mining have implicitly considered the communication cost in terms of the number of datasets [PaS01] or have assigned the cost in terms of bandwidth [TuG00], our approach is based on taking into account several factors including bandwidth, latency, dataset sizes and mobile agent sizes. Finally, the cost formulae proposed and developed in this chapter allow *a priori* estimation of the communication components in the cost matrix. Having modelled the response time for the communication component, we now present our technique for estimating the response time of the computational component (i.e. the cost of performing data mining).

3.2 Estimating the Data Mining Cost

In order to estimate accurately the computation cost of data mining tasks we have proposed and developed a novel rough sets based algorithm for application run time estimation [6, 9, 10]. It must be noted that considerations of space do not allow us to present an explanation of this algorithm here, however we present experimental results of applying this technique for estimating the run times of data mining tasks.

4. Experimental Results and Analysis

The viability of using these cost estimates depends on the accuracy of the estimation techniques. Thus, the estimated communication times and predicted data mining task run times must be close to actual run time for these cost formulae to form the basis for effective optimisation.

We have proposed a model for *a priori* estimation of the DDM response time by estimating the individual components. These estimates are used in the cost matrix to represent the overall response time for different strategies. As discussed, communication is an important factor in the response time for distributed data mining. We developed cost formulae for estimating the transfer times for both the models for performing distributed data mining, namely, mobile agents and client-server. In the context of data mining web services, the mobile agent model maps to the case where the task is performed at the client's site and the client-server model maps to the case where the task is performed at the service provider's site. In this section, we present experimental results of our cost formulae for estimating the transfer time for both data and mobile agents.

4.1 Estimating Mobile Agent Transfer Time

In this section, we present the estimated and actual transfer times for the data mining mobile agents implemented in our DDM system Distributed Agent-based Mining Environment (DAME) [7]. The mobile agents were developed using the Aglets™ SDK [12] and are used to carry the data mining software to remote data servers. The agents are provided with an itinerary of destinations and respective tasks to be performed in each server that it visits. The agent carries the data mining software as a serialised object. We note that while we use Aglets for experimental and implementation purposes, our cost formulae for estimating the transfer times of mobile data mining agents are not specific to any toolkit. The experimental evaluation consisted of estimating the transfer times for mobile data mining agents and comparing it with the actual transfer times to determine the mean error. The experiments were conducted using four distributed machines with the three machines connected through high speed communication links (two machines via a 100 Mbits link and one machine via a 10 Mbits link) and one machine connected via a 28.8 Kbits modem link. Two machines were located on one campus of Monash University and one machine was located in another campus and was on a different domain. The size of the information carried by the mobile agent was different in each run by varying the software that it carried and the tasks that it was required to perform. The comparative difference in the estimated and the actual results obtained from the tests are shown in figure 2.

Figure 2 Estimation Accuracy for Mobile Agent Transfer Times

In summary the experimental scenario used mobile agents carrying algorithms and data varying from approximately 0.5 MB to 30 MB over connections where the highest bandwidth obtained was 7.3 Mbits/s and the lowest bandwidth was 24 Kbits. The latency was a factor only when the slow links were used. The mean error of the estimates is 10.84 sec, which shows that our strategy for estimating the transfer times is accurate. We obtained the highest accuracy for an error of 1 sec and the lowest accuracy for an error of 33 sec. It must be noted that the lowest accuracy was obtained when the network link was a 28.8 Kbits modem connection, which should be viewed in the context of comparing modem speeds with T1 speeds. Furthermore the mean error as a percentage of the mean

run-times is 23.59 percent, which is a good indicator of accuracy.

4.2 Estimating Data Transfer Time

In this section we present experimental results for the accuracy of the cost formulae for estimating the data transfer times. The data transfer times are primarily dependent on the size of the data and the network characteristics such as bandwidth and latency. In the implementation of the DAME system the data transfer is done using FTP, which we note is also used among commercial data mining service providers such as digiMine™ (<http://www.digimine.com>). The experiments were conducted by measuring the latency and bandwidth in real time between the two servers involved in the data transfers and then transferring the datasets required for mining. We conducted experiments using file sizes varying from 5 MB to 65 MB. We used two different connections—a high speed link (where the average bandwidth ranged from 6.5 – 8.3 Mbits and the latency was negligible) and a modem link (where the average bandwidth ranged from 41–45 Kbits due to internal modem compression and the latency varied from 2 to 3 sec). The comparative results between the estimated and actual transfer times for the three different bandwidth and latency characteristics shown are illustrated in figures 3 and 4.

Figure 3 Experiments with Bandwidth Varying from 6.7 – 8.2 Mbits

Figure 4 Experiments with Bandwidth Varying from 41 – 45 Kbits

The mean error for the experiments conducted using a high speed connection was 3.56 sec and the mean error as a percentage of the mean transfer time was 12.05 percent, which are both low indicating the high accuracy of the cost formulae. The mean error for the experiments conducted using a low speed link was 20.5 sec. However, the mean error as a percentage of the mean transfer time was 1.3 percent, which shows that the estimates are accurate. The combined mean error was 6.95 sec.

The difference in the mean error as a percentage of the mean transfer times between the two types of connections can be attributed to the fact that overall transfer times were very low with the high speed link. We have thus far presented experimental results validating the cost formulae for a priori estimation of the communication component of distributed data mining.

4.3 Estimating the Run Times of Data Mining Tasks

In this section, we present experimental results obtained by using our rough sets based application run-time estimation algorithm on data mining tasks. We compiled a history of data mining tasks by running several data mining algorithms on a network of distributed machines and recording information about the tasks and the environment. We executed several runs of data mining jobs by varying the parameters of the jobs such as the mining algorithm, the datasets, the sizes of the datasets, the dimensionality of the datasets and the machines on which the tasks were run. The algorithms used were from the WEKA package of data mining algorithms [18]. We generated several datasets of sizes varying from 1MB to 20MB. The data mining jobs were executed on four distributed machines with different physical configurations and operating systems. Three machines had Windows 2000 and one machine had Solaris 5.8. Two of the Windows machines were Pentium III with 833 Mhz processor and 512 MB memory, while the other was a Pentium II with 433 Mhz processor and 128 MB memory. The third machine was a Sun Sparc with 444 Mhz processor and 256 MB memory. The history provides the data for the estimation algorithm to predict the run time of a given data mining task. The rationale for building a history using a distributed network of nodes was two-fold. Firstly, we wanted to obtain a diverse history and test the estimation accuracy given a varied history. Secondly, it represents a realistic scenario where data mining web service providers and clients would typically operate using a distributed network of servers and would use the estimation for each node in the allocation of jobs.

For each data mining job, the following information was recorded in the history: the algorithm, the file name, the file size, the dimensionality of the data, the operating system, the version of the operating system, the IP address of the local host on which the job was run, the processor speed, the memory, the status of the server (whether it was

dedicated or not), the start and end times of the job. The history was used to conduct experiments using the run-time estimation process described in chapter 4. We used histories with 100 and 150 records and each experimental run consisted of 20 tests. The performance accuracy is illustrated in figure 5, which presents the actual and estimated run-times from one of our experimental runs.

The mean error is approximately one minute and the error as a percentage of the actual run-times is 26.4%. The result that our algorithm selected as a similarity template included the following attributes: algorithm, file size, dimensionality and available memory. It must be noted that our application run-time estimation technique like other techniques that rely on historical data [15,17] is limited by the initial need to collect a history.

We have presented experimental results that demonstrate the performance accuracy of our rough sets algorithm for estimating application run-times of data mining tasks. Thus far, the experimental evaluation has validated our technique for a priori estimation of the DDM response time. This facilitates service providers to commit to service levels that can be ensured in SLAs.

Figure 5 Performance of Run-Time Estimation for Data Mining Tasks

5. Conclusions and Future Work

This issue of estimating QoS in application services is important and one that needs to be addressed. This paper takes a first step in estimating the response time for data mining web services. The model presented in this paper is applicable to distributed, data intensive application services in general. The current focus is experimental evaluation of this work with other application services and focusing on additional QoS metrics.

An Analysis of E-Business Systems Impacts on the Business Domain

Norazlin Yusop, Didar Zowghi, David Lowe

University of Technology, Sydney

PO Box 123 Broadway 2007, NSW, Australia

norazlin@it.uts.edu.au, didar@it.uts.edu.au, david.lowe@uts.edu.au

Abstract

In e-business systems, the business environment and processes not only drive the identification of system needs, but also are in turn fundamentally changed by the introduction or evolution of a system. This means that an e-business system that is under development will be highly volatile with a complex set of impacts on the various domain characteristics (and conversely, the changes in the domain impact on the nature of the desired system). We report on a detailed analysis of the literature related to these impacts. From this analysis we show how different facets of the domain of a system are impacted in different ways. As the scale and immediacy of these impacts increase we need to become more predictive of these impacts in taking them into account during the development. Our analysis will provide organisations with the basis for moving towards this increased level of predictiveness.

1. Introduction

A key characteristic of e-business is that the introduction of the system has a fundamental impact on the nature of the business processes and business models which are being supported by the system. In other words, the business environment and processes not only drive the definition of the system needs, but are in turn fundamentally changed by the system. These changes are such that not only are the system requirements changed, but the very nature of the problem that was being addressed is changed. In effect, the business "problem" defines the nature of the technical system "solution" that is desired, but the solution itself changes the characteristics of the problem space. This can be described as solutions and problems being "mutually constituted" – a concept well understood in the area of social informatics [40] and requirements engineering [9].

Whilst this concept of mutual constitution – or its expression as a technical solution leading to significant changes in the problem space – is typical of almost all systems development, it is particularly significant with e-business systems. This is because of the scale and immediacy of the impacts that e-business systems can have on their domain. Whilst most IT development exhibits these characteristics, either the process impacts are sufficiently obvious to be able to be taken into account easily, or their scale is sufficiently constrained to allow them to be initially ignored and to then be addressed once the system has been implemented. As the

scale of the impacts increases, we need to become more predictive of these impacts and take them into account during the initial development. Whilst there has been a significant body of work looking at specific impacts of e-business systems, these impacts have not been analysed in the way they impacted the organisation. This paper presents an analysis that encapsulates the dimensions of impact of both the domain of mutual influence and the domain of context. This analysis will provide the organisations with a framework for developing strategies for joint development of e-business systems and business processes. It will also serve as value-added knowledge for the companies in understanding the strengths, weaknesses, opportunities and threats that may affect their system, organisation and stakeholders (e.g. trading partners). These dimensions and their characteristics are derived from a comprehensive analysis of the literature across a wide range of disciplines.

In essence this analysis of the literature provides a basis for addressing the following research questions:

Question 1: In the development of an e-business system, what are the characteristics that impact on the organisation's business environment (system and organisation)?

Question 2: Are different facets of the domain impacted in fundamentally different ways by the introduction of e-business systems, and if so then what are the differences?

In the next section, Section 2, we will be discussing the e-business system types, the characteristics of the domain of mutual influence, domain of context and the taxonomy which we have developed from the analysis of the literature. In Section 3, we will be evaluating the facets of the domain that are being impacted by the development of e-business systems. In Section 4, we will conclude this paper and briefly present our future research plan.

2. Existing Literature

In analysing existing work on e-business systems impacts, we undertook a broadly-focused analysis of literature from diverse disciplines including: marketing, management, logistics, engineering, information systems, information technology, and manufacturing. Content analysis is used to identify web related factors and elements that impact organisations, the type of e-business systems they are related to, the extent of impact, what is being impacted and whether the impact is positive or

negative. Content analysis technique is used as it is a research method that uses a set of procedures to make valid inferences from the text, which in this paper is the literature [34]. In this paper, we have identified e-commerce systems and e-business systems as being a subset of the web systems.

2.1 Web system types

From the literature, there are several studies which identify various types of impacts and the applicability of these impacts to different types of web systems. Whilst the definition of Web system varies, a useful working definition is a system that is designed and developed using a web based technology. "Web systems are different from conventional software systems. They are developed in shorter timeframes, and with smaller budgets, meet a more generic set of requirements, and generally serve a less specific user group. They are often developed very quickly from templated solutions, using coarse-grained authoring tools, and by the efforts of a multi-disciplinary team" [31].

There is significant number of articles, which have discussed E-commerce and E-business systems. E-commerce is defined "as the buying and selling over digital media" [29]. E-business definitions often encompass e-commerce and include both front-and back-office applications that form the engine for modern business. E-business is not just about E-commerce transactions; it's about redefining old business models, with the aid of technology, to maximise customer value. E-business definition refers to a broader definition of E-commerce, which includes collaborating with business partners, and conducting electronic transactions within an organisation [46]. As there are various trading partners, e-business trade activities are categorised under business-to-business (B2B), business-to-consumer (B2C), consumer-to-business (C2B), consumer-to-consumer (C2C), people-to-people (P2P), government-to-citizen (G2C) and intra-business (organisation unit to organisation unit) [40]. Essentially these systems facilitate the inter- and intra-organisational flow of goods, services, information, coordination and collaboration.

2.2 Domain of Context vs. Domain of Mutual Influence

The domain of the system under development can be separated into two distinct sub-domains. The Domain of Context is those aspects of a systems (or organisations) which provide a context for (i.e. affect) the system, but which are not directly and immediately affected by the system (e.g. legal regulatory frameworks). The Domain of Mutual Influence is those aspects of the domain which affect the system, but which are in turn directly and immediately affected by the system (e.g. business processes, or – for most e-business systems – the external customers).

Table 1 outlines the characteristics of the Domain of Mutual Influence and the characteristics of the Domain

of Context that impact on e-business systems and the literature sources, which discuss these impacts. Characteristics identified in the Domain of Mutual Influence are characteristics that are impacted by e-business systems and organisations. Examination of existing literature highlights several facets of the domain that are impacted by the introduction or modification of e-business systems. These typically relate to the business processes, systems, operations, structure and communication between the organisation's employees and with the various trading partners, such as customers, suppliers and manufacturers. Within an organisation, e-business systems have a more direct impact. Studies that have been undertaken typically characterise impacts as either positive or negative (or strengths and weaknesses) for the organisation, depending on the types, effect and level of impact each has on the organisation.

2.3 Taxonomy

From the e-business systems discussed in the literature (and summarised in Table 1) it can be observed that the development of e-business systems have different impacts on the business environment. There are five dimensions of these impacts that form the taxonomy that we propose in this paper, which is discussed in detail in [49]. In table 1, characteristic which affect (labelled alphabetically) is identified as characteristic of a particular domain that affect the system or organisation domain. Characteristic that are affected (labelled numerically) is identified as characteristics of the system or organisation domain that are being affected. Let us illustrate the taxonomy with an example. As depicted at the top of Table 1, time and speed (of business operations) is a characteristic of the business environment that is affected by the introduction of an e-business system. This type of impact is typically most evidenced in e-business systems and most commonly affects the facets of the domain, which in this example, is the organisation and the system domain. The impact on time and speed has a generally positive effect and high level of impact on the organisation [8] [46].

3 Facets of the domain which are impacted by e-business systems

In this paper we have identified four different facets of the domain which can have impacts: the domain of mutual influence, the domain of context, the system itself and the organisation which hosts this system. In the facets of the domain column of Table 1, the facets are categorized according to the facets of the domain that is impacted, which are System, Organisation, domain that is Mutually influenced and the domain that form the Context. We explain these facets and their characteristics in detail below. For System and Organisation facets, we also discuss some of the characteristics that are mutually influenced, hence categorized as characteristics of the domain of mutual influence.

Table 1. Characteristics of the organisation and its environment that impact and/or are impacted by e-business system

Characteristics which affect	Characteristics that are affected	Facets of the Domain Impacted	Effect of Impact	Level of Impact	Sources
Goods and services delivery to market (A) Cycle time of product ordering and delivery (B) Ordering process (C)	Time and speed of org. decision-making process (1) Time of workflow process Speed of workflow process	OS/M	Positive Positive and Negative Positive	High (all aspects) High (all aspects) High (all aspects)	Byrne (2000) Jones and Kochtanek (2002) Golcic et al (2002)
Supply chain intermediation and disintermediation (D) Access levels differentiation (E) Customer value (F)	Value Exchange (2)	OS/M	Positive Positive	Medium for all aspects EXCEPT High for value offering	Gordijn et al (2000) John et al (2002) Turban et al(2000)
Service personalisation (G) Robots to monitor promotion activities (H) Multiple response generations (I)	Scalability (3)	SS/M	Negative	High for System	Arlitt et al (2001), Arlitt and Jin (2000), Challenger et al (1999), Fielding and Taylor (2000)
Work processes streamlining (J) Spread of network infrastructure use (K)	Customer Expectation (4)	OS/M	Positive	Medium (all aspects)	Gaedke and Turowski (2000)
Real time access, easy to use interfaces (L)	Usability (5)	SS/M	Positive	Medium (all aspects)	Hansen (2002)
Collaboration and communication support (M) Interface between systems (N) Linking various stakeholders (O)	Communications interface (6)	OS/M	Positive	High (all aspects)	Peng (2002) Fielding and Taylor (2000)
Unspecified system characteristics	Navigation structure (7)	S-S	Positive and Negative	Medium (all aspects)	Scharl (2001), Conklin (1987), Schwabe et al (2002)
Security threat to org. proprietary data (P) Internet infrastructure security threat (Q)	Security (8)	OS/M	Negative Negative Negative	High (all aspects)	Osmonbekov et al (2003) Chakrabarti and Manimaran (2002)
Unspecified system characteristics	Intra-organisational communication & collaboration (9)	S-S	Positive	High (all aspects) Low for all aspects EXCEPT Medium for organisation	Tang (2000) Michael (1996), Ciborra (1996)
Unspecified system characteristics	Business Process (10)	S-S	Positive	Medium (all aspects)	Fowler (1998) Coltman et al (2002) Giaglis (1999) Scheer and Habermann (2000) Swatman et al (1994)
Document routing, retrieval and approval process (R) Process of ordering (S)	Workflow process (11)	OS/M	Positive Positive Positive and Negative	Medium (all aspects)	Miers (2001) Ames et al (1997) Cunningham (1999)
Change from mass production manufacturing to demand-driven manufacturing (T)	Material purchase method (12)	O-S	Positive	Medium (all aspects)	Turban et al (2000)
Information accuracy, currency, output timeliness and relevance (U)	Information Quality (13)	S-S	Positive	Low for all aspects	Negash et al (2002)

Continued from previous table

Characteristics which affect	Characteristics that are affected	Facets of the Domain Impacted	Effect of Impact	Level of Impact	Sources
Dynamic data, complex web page design (V)	System Performance (14)	S-S	Positive	High (all aspects)	Challenger et al (2002), Challenger (2000)
Management and improving org.'s relationship with customer and supplier (W)	Relationship Management (15)	OS/M	Positive Positive	Medium (all aspects) Medium (all aspects)	Dignum (2002)
Data accuracy, reliability, system flexibility, ease of use (X)	System Quality (16)	S-S	Positive	Medium for all aspects EXCEPT High for System	Negash et al (2002)
Web adoption cost, System acquisition cost (Y) Transaction cost (Z)	Cost (17)	OS/M	Positive	Medium (all aspects)	Osmonbekov et al (2002) Kalakota and Whinston (1996) Ardagna and Francalanci (2002)
Customers' need of viewing orders on own system (AA)	Integration of front and back-end office system (18)	C-S	Positive and Negative	High for System (medium organisation)	Dignum (2002)
Web applications and tools interoperability problems (AB)	Integration of different web system applications (19)	OS/M	Positive and Negative	High for System medium for organisation)	Bohner (2002), Jin et al (2002), (Bussler et al, 2003), Gaede and Turowski (2000)
Web application customisation and personalisation (AC)	Personalisation of service and product offering (20)	C-S	Positive	Medium for System	Schwabe et al (2002) Schwabe and Rossi (1998), Rossi et al (2001)
Competition from existing and new firms (AD)	Competition (21)	C-S	Negative Negative	Medium (all aspects) High (all aspects except System)	Wheelen and Hunger (1998), Chan and Peel (1998) Ing et al (2000)
Unidentified characteristics	Legal, ethical, govt regulation (22)	C-S	Positive and Negative	Low (all aspects)	Turban et al (2000), Mason et al (1995)
Unidentified characteristics	Web Technology Adoption (23)	C-S	Positive	Low for all aspects EXCEPT Medium for organisation	Jones and Kochtanek (2002)
Information visibility facilitated by speed and connectivity, evolving and changing business process (AE)	Uncertainty of business environment (24)	C-S	Negative Negative	Medium (all aspects) Medium (all aspects)	Golicic et al (2002) Achrol (1997)

Facets of the Domain Impacted explanations:

- 'S': System characteristics that impact or are impacted
- 'O': Organisation characteristics that impact or are impacted
- 'M': Characteristics identified in the Domain of Mutual Influence are characteristics that are impacted by e-business systems and organisations. The Domain of Mutual Influence is those aspects of the domain which affect the system, but which are in turn directly and immediately affected by the system (e.g. business processes, or – for most e-business systems – the external customers).
- 'C': Characteristics identified in the Domain of Context are those aspects of a systems (or organisations) domain which provide a context for (i.e. affect) the system, but which are not directly and immediately affected by the system
- OS/M: Organisation characteristic that impacts on the System characteristic but which is in turn directly impacted by the system. Hence the organisation and system characteristics are mutually influenced, thus identified as being the characteristic in the Domain of Mutual Influence
- SS/M: System characteristic that are mutually influenced by another system characteristic
- O-S: Organisation characteristic that impact on System characteristic
- S-S: System characteristic that impact on another system characteristic
- C-S: Characteristic that provides the context for the system which impact on the system.

Figure 2: Impact and Domain Boundary

3.1 System

Dynamic data, insufficient network bandwidth and poor network design impact on the system's performance [11]. Performance is a critical factor and impacts significantly on the organisation's system efficiency, particularly for websites that receive hundreds of thousands of hits per minute. It may also impact on websites that receives a moderate amount of traffic if most of the requests are for dynamic data, which are expensive to create. In improving performance of a Web site, multiple processors can be used to scale the CPU capacity of the system [11]. System developers need to be selective of the types of web servers deployed so as to service a high request rates and techniques for routing requests to servers. Web pages should be designed to convey useful information in a limited number of pages so that clients do not have to navigate through too many pages to obtain information that they looking for. Table 1, shows that dynamic data and complex web page design is a characteristic of a system that impact on the performance of the organisation's system (S-S). In Figure 2, it shows that System Performance (labelled 14) is being affected by the organisation's initiative to use dynamic data and complex web pages for its e-business systems (labelled 'V').

Security has a significant impact on e-business functions as the systems interfaces into business functions of a corporation. As a result of this, security of the business transactions and process need to be safeguarded. Security poses a high impact on the organisation and the system development as there is no security technology that can secure the system effectively. Limiting access to proprietary data and controlling the scope of information retrieval are major issues that organisation need to focus on [37]. Currently, web-based selling and purchase tools have yet to fully address the security concerns. Replacing paper documents with electronic documentation has an undesirable impact on the organisation security. This is due to the possibility of permitting open links to proprietary data, and that electronic document lacks permanency and legal legitimacy of paper. In Table 1, it shows that Security is a characteristic that is mutually impacted, hence is labelled as OS/M (refer to the Facets of the Domain Impacted column). This explains that security is a characteristic of the organisation which impacts on the system and in return it directly impacts back on the organisation.

Another critical characteristic is integration of front and back-end office system, and integration of different web applications and tools. It is critical that e-business system developers integrate processes and operations, such as integrating the catalogue with internal databases, the order information with users' profiles, and integrate the ordering process with the back office of the customer's system [18]. In Table 1, it shows that customers are a characteristic of the domain of context that affects the integration of front and back-end office system (labelled as C-S in the Facets of the Domain Impacted column). This explains that customers may

indirectly affect the organisation's system. This impact drives the changes within the organisation; hence indirectly influence the organisation to integrate its processes with the customer's back office systems. Integration of different web applications and tools can lead to significant problems for an organisation and its external stakeholders. It is therefore important that different systems are able to interoperate with each other. B2B e-business integration is a complex issue; hence web services are used as a solution for many significant integration problems [7]. There is currently little research or lessons learned that report on the deployments that could advance web services technology functionality and integrates different e-business systems. As shown in Table 1, deployment of web applications and tools (labelled 'AB') is a characteristic initiated by the organisation's that affect on the e-business system. Deployment of web applications and tools create interoperability problems. The system therefore needs to be able to effectively integrate the different web applications to determine that the organisation's and external stakeholders' system can seamlessly interoperate with each other. This characteristic mutually influence on the organisation and system domain, hence labelled as OS/M in Table 1.

The need to personalise service and product offering to customers, trading partners and employees lead to the system designer to personalise link, structure, content and behaviour of the web page [43]. E-business initiatives have a significant impact on the organisation's stability, as it increases competition thus pressuring system developers to develop web applications that offer distinct competitive advantage. The challenge is to build customisable Internet applications, such as developing a personalisable Internet application [43]. The result of this is that it might provide different navigation topologies to different users, recommend specific products according to a user's preferences, or implement multiple policies.

These personalisation tasks have an impact on the requirements of the system. An application is required to model the user and user preferences, build profiles, and find algorithms for best linking options and others. The critical issue is however, to integrate all the personalisation features into a single design. Link personalisation for example, is useful for an electronic store such as Amazon, who may wish to provide customers personal recommendations of products that they prefer. A result of this personalisation is that the product directly accessible for one user may be different from those available to a different user and that certain users will have more direct access to certain information than the others [43].

3.2 Organisation

In terms of the organisation, facets of the domain include things such as the organisational structure, communication process, operations and matters relating to people who work within the organisation context.

One of the characteristics of the organisation that is impacted by the e-business system is business process, where the e-business system is being integrated into the process. Business process performance is dependent on the optimisation of core and support business processes. It is fundamental that due attention should be paid to the core business processes, their linkages, which add value to customer's service and product delivery. In relation to this, both organisational and technical aspects are important for effective transformation by describing a synergistic method for integrating EDI (electronic data interchange) by means of Enterprise Analysis [47]. Enterprise Analysis has taken the shape of ERP (enterprise resource planning) and is being integrated with e-business concepts [42]. After various BPR (business process reengineering) and ERP lessons learned, organisations have a better understanding of the limitations of intra-organisational improvement and play an active role in the global e-business community.

Organisations have shifted their mindset in thinking that e-business is only about creating a web site. It is critical that the back-office processes are designed according to the new requirements of ERP. With e-business concept, ERP cannot remain inside organisational boundaries. Technically, ERP vendors are forced to move from a traditional client/server to browser/web server architecture so as to deliver e-business capabilities. This has direct impact on the systems used by the vendors. On the conceptual side, ERP vendors face a greater challenge to provide instruments for managing the increasing e-business complexity [42].

In Table 1, it shows that business process (labelled 10) is a characteristic that is affected by unspecified system characteristics (not identified by the literature). This unspecified system characteristic affects the way business process functions and operates on the e-business system. Business process, in turn impact on the unspecified system characteristics itself, hence business process is identified as a characteristic that is mutually influenced.

In terms of the impact of web systems on time, employees increasingly feel the pressure to get breakthrough ideas to market first [8]. Internet is a tool, whose most significant impact is speed. This is a positive impact to an organisation but have a profound impact on the employee as shrinking time demands may caused increased problems in other areas, for example employee stress. In an e-business system environment, orders will be fulfilled electronically and the 'virtual financial close' put real time sales and profit figures at fingertips via a wireless phone or voice command to a computer. By taking orders from customers online, orders can be quickly routed to the appropriate order-processing site [42]. This process has a positive impact on the organisation and work productivity of the employees as this saves time and reduces expenses so sales staff have more time to sell. In Table 1, time and speed is a characteristic of the organisation that impacts on the system, which is in turn impacted back (labelled as

OS/M). This explains that time and speed is a characteristic that have mutual influence on the organisation and system domain.

E-business generates a new way of managing customers and suppliers' relationship (refers to as Relationship Management in Table 1). This means a transformation from a company that is geared towards production excellence or innovation excellence into a company that is geared towards customer intimacy [18]. In e-business, there is no unique successful business model for companies. Just as in traditional business, e-business model depends on the products and services that the company delivers and also on the market structure [18]. The Internet and the WWW is used as a tool by companies to track the traffic through the sites for their marketing and promotion purposes. This type of tracking allows the companies to collect customers' data, such as their purchases, purchase intent, IP address, email address and others.

In a customer relationship management project embarked by a trucking company in Eindhoven, Netherland, DAF trucks use the Internet to get feedback from their customers on the product and on the transaction of performance [18]. This means that the feedback from a customer can be processed together with the customer's profile by the departments of the company that are most affected by the feedback. This has significant impact on the system, whereby the organisation's information systems that are used internally have to be connected and synchronised, for example through the use of an enterprise resource planning system throughout the company. In Table 1, it shows that Relationship Management is a characteristic that is mutually impacted, hence is labelled as OS/M. This explains that Relationship Management is a characteristic of the organisation which impact on the system and in return it directly impacts back on the organisation.

Value exchange is a characteristic that impacts on system as well as the organisation. In e-business, process of intermediation and disintermediation presents specific e-business risks for traditional sellers. For example, intermediaries such as brokers might easily disappear or re-appear in an e-business environment. This is because buyers might decide to use a middle person (intermediary) to increase their combined buying power and seek better negotiations with the sellers. Due to this issue, it is important to show who is doing what with whom as e-business is more flexible than traditional business. Actors in e-business can be of different entities but their value offerings may coincide. This will have significant impact on the e-business project if there is no differentiation in the value offered by the different entities [24].

E-business systems offer the customers a distinct customer service value, compared to traditional business systems. The types of customer service offered via the e-business systems include answering customer enquiries, providing search and comparison activities, providing technical information to customers and allowing

customers to track order status [46]. Most banks and financial institutions allow their customers to view their account balance, status of stock portfolio, loan application anywhere and at any time. FedEx for example allows their customers to track their packages. Amazon on the other hand, notifies the customer by e-mail the acceptance of their order, the anticipated delivery dates, and later on, the actual delivery date.

3.3 Domain of Context

As discussed in Section 2.2, domain of context has an indirect impact on the organisation, system and external stakeholders (eg. trading partners). The decisions and e-business initiatives have strong implication on how business activities will be conducted between the organisation and the external stakeholders. From the analysis of the literature (refer to Table 1 and Fig.2), the characteristics of the domain of context that impact on the domain of context are external competition, market structure, legal and ethical issues, web technology adoption and uncertainty.

Competition is a characteristic that impact on the industry. In a hypercompetitive industry, such as the computer software industry, competition plays an important role and has a strong impact on the corporation strength and existence in the marketplace [48]. In this industry, competitive intelligence comes from an up-to-date knowledge of environmental trends and competitive activity and a willingness to risk a current advantage for a possible new advantage. A company in current market needs to compete with domestic and global competitors in order to survive [13].

Competitors in the Internet evolve rapidly over night and this makes it difficult for organisations to keep developing and changing its competitive intelligence. It is therefore critical that organisations capture the value from customers [26]. In e-business, the value that the organisation creates and controls changes over time. Organisations therefore need to be vigilant in determining that the value they provide is not being eroded as competitors introduce new business designs, restructure their business models, and offer new value propositions [48]. In Table 1, it shows that Competition from existing and new firms has an indirect impact on the organisation's system. This characteristic therefore forms the context for the organisation's e-business system initiative.

Another domain of context characteristic is legal, ethical and other public policy issues, which form the legal framework for the organisations and indirectly affecting the system. The legal issues that relate to the e-business are privacy, intellectual property rights (copyrights and trademarks), free speech, consumer protection, and other legal issues (includes topics such as validity of contracts, jurisdiction over trades, encryption policies) and ethical issues [46] [32]. Ethical issues particularly are difficult to define as it is a branch of philosophy that deals with what is considered to be right and wrong [46]. In Table 1, it shows that an unidentified

characteristic affect the legal regularity framework of e-business system. The legal regularity framework is therefore identified as a characteristic that provides the context for the e-business system.

Web technology adoption impact on how suppliers and customers interact and do business with the organisations via the Internet. The network effect of e-business systems allows the suppliers and customers to interconnect and rely on the "system-to-system connection". The Internet also allows the companies to communicate and share information across the supply chain. Companies use Internet adoption as part of their business model to bring other companies to their network, which then let them achieve critical mass quickly. Web systems allow e-business technology to provide information visibility throughout the supply chain. The system allows supply chain members to view real time data via the Internet and it offers value for someone who can deploy solutions effectively, link someone to their trading partners, and allow them total visibility to the supply chain [23].

Dynamism of markets and the increased information visibility facilitated by the speed and connectivity of e-business present an uncertain environment [23]. With the Internet, every business process is evolving and changing. This leads to companies having to make decisions without complete information, thus making outcome more uncertain. Advances in technology leads to increased external uncertainty faced by firms [1]. This is due to the environments, which are being affected by an increasing pace of technological change, motivated by explosion of growth and the availability of knowledge. All these elements lead to the world moving towards a borderless marketplace. The impact of technological change is strengthened in global environments that are tightly interconnected and interdependent.

3.4 Impact and Domain Boundary

From the analysis of the literature, characteristics of domain of mutual influence and domain of context may impact on the same facet of domain. This explains that some of the identified characteristics do not belong exclusively to one domain. In order to identify where these characteristics lay in the boundary of different domains, we have developed the Impact and Domain Boundary Diagram (refer to Fig.2). The alphabets or numbers at the end of each arrow are characteristics that listed in Table 1 (not in any order of significance). Let us illustrate the diagram with an example.

Integration (characteristics labelled 18 and 19) is a characteristic that impact on both domain of context and domain of influence. For example, in developing an e-business system which manages customers' complex transactions, Dell Computer's customers' need their orders to be integrated to their own system. The customer therefore forms the domain of context, which impact on Dell's e-business system development initiative. This also impacted on the organisation as document management processes, which were previously managed solely on a

local database system by the employees, will now need to be fully integrated to the network and delivered to the customers via the Internet. As such, integration is a characteristic of domain of mutual influence as in this example, integration of different applications are system and organisation-related characteristics, which impact on each other.

With this e-business initiative, Dell made this database available to its customers' through customised Premier Web Pages, constructed and posted on the Internet by Dell [37]. As a result of this, the number of employees handling customers' transactions will also be significantly reduced. The Premier Web Pages are password-protected and are updated regularly to reduce the complexity of every purchase by showing detailed specifications of the customer's previous transactions. This function impacts on the e-business system itself, due to several factors, such as integrating the front and back-end systems, ensuring system security and providing and delivering fast information and services. As the transaction information is available mainly on the Internet, it is very critical that the e-business systems are reliable and has high system performance. Dell's readily accessible transaction information streamlines the procurement process thus increasing the ease and speed of the purchase [37] [18].

Conversely, system-related failure, such as network or server problems, change in government regulations and change in organisational structure may also impact on the e-business system that is in development within the organisation's function. The e-business system that is in development is therefore considered volatile whereby it is impacted by most of the characteristics, which also impact on other domains [37] [18].

4. Conclusions and Further Work

The data that was collected from the literature will become the basis of questions to be used in the next stage of our research, which is a case study. This case study will be conducted in an organisation that has recently developed an e-business project. The questions for the case study will be formulated from the literature. It is the goal of the study to reaffirm from practice the type and level of impacts that are found from the literature. In addition, there may be more specific and fine-grained impacts and characteristics that will be discovered from the organisation that could complement the literature survey. Hence, the survey of the relevant literature provides a basis for focusing on developer and client attention on the characteristics that were found from the literature. From this study, we will also be able to discover which impacts are the ones that are most likely to need careful consideration

Online Marketing: Enthusiasm, Disappointment, and Academic Responsibility?

Suzan Burton

Australia
Suzan.Burton@mq.edu.au

Abstract

From the late 1990s up to the collapse of Internet stocks in April 2000, the professional and popular marketing press carried a stream of articles that were enthusiastic about the potential of Internet marketing for all the components of marketing; selling products and services, building brands and relationships and providing individualised information to customers. With the benefit of hindsight, and in view of the many well-publicised losses of Internet based companies, much of this enthusiasm was unjustified. This paper analyses the pattern of growing interest in, and changing assessment of, Internet marketing from both marketing and professional writers, as revealed by a retrospective study of one of the most common data bases. Academic interest in the Internet, as measured by growth in the number of articles, is seen to have lagged behind professional interest. Of more concern, however, is the apparent failure of marketing academics to have given advice which might have tempered managers' investment in what proved, for many, to be a very risky area.

1. Introduction

From the late 1990s, the academic and marketing literature, like the more general media, suggested optimistic predictions for the impact of, and future of, Internet marketing. Early predictions for the Internet suggested that it could "...transform the way we build brands and communicate them to consumers" [1]. Exhortations such as 'Catch the wave or drown' were said to be the 'advice of industry experts to retailers resisting the onslaught of the Internet' (Chain Store Age, 1998). While there is no doubt that the Internet has created many business opportunities, the most common business experience has been one of failure, particularly in the highly promoted area of Internet retailing [2]. As the realisation grew that selling directly to consumers online was a high risk, competitive market for most companies, interest grew in the potential of B2B, where, it was claimed, the Internet would have its largest impact [3]. In particular, B2B exchanges were said to be the 'killer application in the B2B Internet revolution' that 'changes everything in B2B' [4]. The growth of a number of B2B exchanges, strongly backed by powerful business buyers, seemed to justify that claim, yet we have now in turn seen the failure of many high-profile online

exchanges, with one recent study finding that only 43% of independent B2B exchanges survived in the two years following Spring 2000 [5]. Given this pattern of enthusiasm, frequent business failure, with associated falling share prices and decreased investment, it is instructive to look back and examine the extent to which articles published in the peer-reviewed literature represented, reflected, or perhaps challenged the prevailing optimism before the 2000 crash, and the extent to which this pattern has changed since the collapse of Internet stocks.

2. Early enthusiasm

There is no doubt that managers were under severe pressure to invest large sums of money in the uncertain world of Internet business. In 1996, marketing scholar and Wharton Professor George Day wrote in Harvard Business Review "For those companies whose managers write - and exploit - the new rules of the game, the evolution of interactive marketing in an electronic medium will be exhilarating" [1]. Day went on to say that the chances of incumbent established, large companies prevailing in the new electronic marketplace were small, because "such companies are prone to falling into several common traps". Day lists these traps as:

- 1) Deferring participation
- 2) Picking the wrong technology
- 3) Unwillingness to commit
- 4) Lack of persistence.

Day states that "large companies have little patience for continued adverse results" and he suggests that "pulling out of an endeavour without giving it a fair shot...wastes time and money and erodes morale". However his 'traps' appear to endorse a strategy of early and sustained investment in an uncertain technology, and persistence in the face of continued failure. This strategy has much in common with the problems of escalating commitment, but Day's conclusion was that "for many companies, the question is not whether they should participate in interactive marketing, but whether they can afford not to prevail". In the words of Yogi Berra, "predictions are difficult, especially about the future" and it is easy to be wise after the event, but with such an enthusiastic endorsement from one of the foremost marketing scholars, could a reasonable manager not invest, and continue to invest, in online marketing?

Day's encouragement to managers to invest in online ventures is perhaps extreme, but the question as to what extent academics were influential, if at all, in the discussion of Internet marketing when interest was at its peak, before April 2000, has not been addressed. To what extent, if at all, would a perusal of the academic literature have warned managers of the risk of investing in what turned out to be a risky strategy for many organizations?

3. Method

The frequency of publications covering the topic of 'Internet Marketing', as represented in the business data base ProQuest ABI Inform, was investigated, from 1993 to 2002, the last full year for which full yearly data are available. Articles were selected as being relevant to Internet marketing by a search using the terms 'Internet' and 'marketing'. The study thus uses the 'bibliometrics' approach discussed by Nisonger [6] and Jacso [7]. While this approach may cause some misclassification by neglecting some articles without these key terms which do discuss Internet marketing issues, the error is expected to be relatively constant, and hence is not anticipated to bias the results. The first part of the analysis separated articles into 'scholarly and peer-reviewed', using the Proquest classification of that type, and general articles, and assessed the pattern of growth for each type of article.

For the second part of the analysis, a research assistant blind to the purpose of the study was asked to rate all articles published in the peer-reviewed journals from 1997 using the question "How would you rate this article's attitude to the impact of the Internet on business?" Articles were rated on a seven point scale from -3 'extremely pessimistic' to 3 'extremely optimistic' with a neutral rating of zero "neither pessimistic or optimistic".

4. Results

Results for the first part of the analysis are given below, in Table 1 and Figure 1, showing the changing proportion of peer-reviewed and general articles.

Table 1: Peer-reviewed and general articles, Internet marketing, 1993-2002

Year	No Peer reviewed	Number Others	Total number	% Peer reviewed
1993	0	2	2	0.00
1994	3	58	61	0.05
1995	29	307	336	0.09
1996	35	440	475	0.07
1997	36	614	650	0.06
1998	35	637	672	0.05
1999	33	1097	1130	0.03
2000	67	1606	1673	0.04
2001	82	640	722	0.11
2002	66	347	413	0.16

In the second part of the analysis, mean scores on the average rated optimism of the article were analysed. Overall, academic articles were rated as significantly more optimistic than zero, a 'neutral' rating ($p < 0.001$). Moreover, there was an upward trend in the mean optimism rating from 1997 to a peak in 2001, shown in Figure 2.

Figure 1: Number of Internet Marketing articles

Figure 2: Mean rating of optimism of peer-reviewed articles concerning internet marketing

5. Discussion

Based on a simple count of articles, the academic literature appears to have reflected the enthusiasm of the general business press for Internet marketing to only a limited degree. The increase in numbers of Internet marketing articles in the academic literature was much less than the increase in non peer-reviewed articles. This could be interpreted in both a positive or a negative way. On the positive side, the growth in numbers of articles in the academic literature was far less dramatic, possibly reflecting less unquestioning enthusiasm for the impact of Internet marketing. On the other hand, the relatively small proportion of articles in the peer-reviewed literature, and the increasing percentage after the dot-com crash, suggests that marketing academics may have had relatively little impact on business decisions, and may instead have reflected business practice. Perhaps most worrying for academics who would like to believe that they influence business practice, the fact that the proportion of academic articles peaked in 2001, after the Internet collapse, and the absolute number of academic articles continued to

increase in 2002, when the number of articles in the general press had fallen steeply, suggests that academic publications tend to follow, rather than influence, business practice.

An examination of the level of optimism of the articles published in the peer-reviewed literature suggests that academics were not immune from the hype of the Internet boom. For every year except 1997, articles appearing in the peer-reviewed journals were rated significantly higher in optimism on the impact of internet marketing than a neutral rating of zero. A comparison of average optimism in the peer-reviewed and other literature is under way. However the results do not suggest that perusal of the academic literature would have given managers substantial cause to question the overwhelming optimism of the share market and popular press about the likely impact of the Internet on business.

6. Conclusion

The partial results available suggest a trend that should perhaps be of concern to academics. In the case of Internet marketing, articles published in the peer-reviewed press seem to lag well behind the level of interest and discussion in the general press. While this is not perhaps surprising, given the often long lead times involved in publication in academic journals, it does question the extent to which academic writing influences business decisions, or instead reacts to business decisions.

In addition, the results suggest that the peer-reviewed literature, based on a rating of optimism expressed in the articles, failed to sound a significant warning that the impact of the Internet would not be profitable for many companies. If academics hope to influence, rather than follow or reflect business practice, then attention may need to be given to decreasing the lead time on

peer-reviewed publications. However, the optimism shown by rating of the content of articles published in the peer-reviewed sources suggests that in the case of Internet marketing, authors failed to provide timely warning of the substantial risks for businesses in investment in this uncertain technology.

Abstract

Business Process Reengineering, a hot issue in modern management, is a significant and creative idea on administration based on a series of management theories and successful carry-outs. All along, people have been used to defining and studying it in view of management, overlooking its intimate affiliation with division theory of economics. Here, the author tries to analyze the economic background and academic basis of Business Process Reengineering from a new point of view. While, the business process of any corporate is quite complicated. Here, through the case of books borrowing, the author makes an analysis of its division of labor, and probes into the relations between the four factors which are division of labor, the extent of market or throughputs, information technology and business process, and attempts to explain this administration issue by the combination of administration and economics knowledge.

1. Introduction

According to Adam Smith's theory of division of labor, the division of labor is limited by the extent of the market and throughputs, and appropriate division of labor helps to meet the demand of market. For a worker to do a series of different activities, there must be a sequence; with the emergence of division of labor, the work formerly for one worker is then disintegrated into different parts, which are taken up orderly by different workers. Such a sequential series of activities may be called as a process. It can be said that the business process exists together with the division of labor., and the process bases itself on division. However, Adam Smith's theory of division of labor overlooks technology's impacts on division of labor and business process. Under the condition of new technology, the division would not remain the same, and a simple automation or informationalization of former working manner is not enough.; at the same time, the progress of information disposal influences the changes on division as well ,with the existence of information exchanges between various activities and divisions. Accordingly, a timely and appropriate process should be created after a drastic reengineering, instead of any imitation or technical improvement of former process. In this way, the process efficiency would be largely improved, and the corporate capabilities would be strengthened.

2. The background and significance of BPR

As a creative and significant idea on administration, Business Process Reengineering has wiped over a great number of countries, and is always taken as promising. It is a fruit in management field that goes well with the times.

2.1 The pressure and challenges that corporations are facing appear as the impetus for BPR

In the world of fierce competitions, corporations are in the face of piles and piles of pressure and challenges ,from both of the outside, which features“3 C”, and the inside. The corporations are beginning to realize that , for a better survival and development, not only the advanced technology is needed, but also a flexible administration mechanism and organizational structure which responds to the circumstances promptly and suitably, is in great demand. This calls for a new management innovation cored “Business Process Reengineering”.

2.2 The rapid development of information technology provides BPR with substantial conditions

The innovation of management ideas is based on new technology possibility. The rapid development of information technology provides substantial conditions and advantageous technology support. It not only enlarges the space for process reengineering, but carries forward the realization of process management and the organizational reform as well. Just through utilizing information technology creatively and organizational management in accompany does process reengineering bring corporations a great improvement of performance.

2.3 The realistic significance of BPR

There are several elements which help to strengthen the competitive power for corporations, such as organizational structure, staff, technology, etc. Business process is only part of them. However, it covers a great deal :logistics, money flow, information flow, etc. In this way , we take business process as the life line of the whole corporation. Only by regarding and managing business

process as a systemic engineering can we strengthen the accommodation and competitive power of corporations, settle the problems and help to realize the continuous development of corporations.

3. The theoretical basis of Business Process Reengineering

As a management idea, process reengineering grows from piles of management ideas and technology methods. It is a combination of administration thinking and information technology. However, people have always ignored its intimate affiliation with division theory of economics.

3.1 The deepening of division of labor is the practical basis of Business Process

Business process comes into being and develops with the deepening of division of labor. As the demand gets bigger and bigger, the market extent and throughputs increase. The division of labor comes into being in order to promote the efficiency and meet the great market demand. The process is full of information delivers and exchanges. In correspondence with books borrowing activity in library, under various technology circumstances, the continuous progress of information technology influences the division of labor and process development.

3.2 The progress of information technology pushes on the corresponding changes of division of labor and business process

Because of the changeable economic environment and increasing amount of information, the division of labor in corporations varies. To ensure the efficient operation and effective fulfillment of the task, it is demandable for corporations to further the division of organizations and functions, which will surely lead the process to change and reform constantly. The progress of information technology provides powerful ways and means for process reengineering. With the support of advanced information technology, the regulated division and correspondent organizational management can cut the costs, elevate the resource setup efficiency, and win credits for corporations.

4. The research on books borrowing process of library

Adam Smith's theory of division of labor tells that the division of labor is limited by the extent of the market and throughputs, and appropriate division of labor helps to meet the demand of market. Under the condition of new technology, the division would not remain the same, and a timely and appropriate process should be created after a drastic reengineering, instead of any imitation or technical improvement of former process.

We will take books borrowing as an example to

analyze its division of labor, studying the information technology's impact on throughputs, division of labor, and process, and also the relations between these three factors under new technology circumstances.

First, we can summarize the general steps of books borrowing and division of labor through the analysis of the following case.

4.1 The books borrowing process between two persons

In the mutual communications, one person may raise the idea of borrowing the needed books after the other one's introduction. It is clear that the lender supplies the information of books, and the borrower catches it. This tache needs a positive participation and cooperation of the two sides. Then, the borrower raises the demand for book to the lender, waiting for the response. This is always done orally. After consideration, the lender admits the borrower's request, picks the book and hands it to the borrower, which ends the books carrying process. At this moment, the lender has memorized all the information in mind, or a receipt for a loan can also be used. When the borrower returns the book to the lender, the lender deletes the information in mind, or expires the receipt.

From the above depiction, we are able to divide the whole course of books borrowing into seven steps generally: (Chart 1)

Chart 1

Here is a figure of the books borrowing process between two persons. (chart 2)

Chart 2

From the above chart, we can see that the whole process is shared by the borrower and lender. On account of the small quantity of books- throughputs and participants, there's no need to divide any sectors, and the division of labor and the process here are rather simple. In the following, let's take the case of library as an example, and analyze how the division of labor and the business process change when the throughputs grow bigger.

4.2 The books borrowing process of library

As for the books borrowing process of library, due to the variety of sizes, storages, throughputs, etc, the organizational structure and division of labor of different libraries vary, and the corresponding books borrowing process is being adapted and improved. In the following, we'll make an analysis of the corresponding adaptation of division and process as the throughputs are getting bigger and bigger.

4.2.1 The analysis on the books borrowing process of Beijing Jiaotong University's Library

Beijing Jiaotong University's Library covers an area of 12065 square meters, and has a collection of over one million books, including over 3500 types of publications home and abroad, and forty thousand internal documents, special type literature and non-book documents. It has a faculty of 70 persons, who serve the ten thousand readers of the whole university. Due to the reality, the library has a division of Office, Acquisition and Cataloging department, Circulation department, Reading department, Information consultation department, and Literature research department. How do these departments come into being and cooperate to serve the readers?

As a university library, the collection of it is so rich that it's impossible for one or only several persons to fulfill the task of collecting and cataloging all the materials. So, Acquisition and Cataloging department, with now a faculty of 12, is set up, which is one of the fundamental sectors, and also the headstream of the library's operation. Here, the Acquisition and Cataloging department, which acts as the information supplier, selects and catalogs the materials, makes sorted record cards or inputs the information into the computer (computer local net based on Dancheng DT-1000). The readers can search for the needed book's information through either the cards or the local net.

When the readers get the information of the books, they will go to the Circulation department for the books. The service manner of this department is open-shelf. The Circulation department of Beijing Jiaotong University's Library is made up of open-shelf hall, where the readers can select the books, and service counter, where the borrow-and-return procedures are carried out.

The borrower gets to the entrance of the open-shelf hall and hands the library card to the librarian for the replacing board, which in fact means raising the demand for borrowing books. After the validation of identity, the librarian admits the reader's entrance into the hall. The library has a collection of more than one million, and the throughputs of readers everyday are up to 700 persons. So, it's impossible for the librarians to carry books for each reader. In this case, within the effective supervision, the borrowers are permitted to fetch the books by themselves in the hall. At the entrance, after the librarians scan the information into the library cards, the borrowers can then leave with the books. And when the readers return the books, a similar scan on the card will be made to affirm the return.

The above process can be illustrated by the following chart. (Chart 3)

Chart 3

Compared with the activity between two persons, here at the library, as the increase of the readers and books, the division of labor between borrower and lender has been adjusted: the task of "books carrying" is passed over to the borrower within the effective supervision, which has offered more efficiency and convenience. At the same time, in order to meet the big demand of the readers on campus and deal with the complicated information more efficiently, it's necessary for the library, as the borrower, to specify the division of labor, which means to set up some specialized sectors as Acquisition and cataloging department for "information supply", and Circulation department for "request admission", "books hand-over" and "books return".

4.2.2 The analysis and comparison on the books borrowing process of National Library of China

As to different amounts of throughputs, how do the division of labor and process of National Library of China differ from those of Beijing Jiaotong University's Library? Let's make an analysis of the two reforms of its books borrowing process.

4.2.2.1 The comparison of the two books borrowing processes of National Library

The Library has the total floor area of 170,000 square meters, ranking first in the national libraries in Asia, and fourth in those of the world. It is a comprehensive research library, a national repository of the home publications, a national bibliographic center, a national center of library information networks, and the library research and development center. The Library serves for central legislature, government, key research institutions, academy, education, business and the general public. The Library has a rich collection of 22,400,000 volumes, ranking fifth in the libraries of the world. In the collection there are 270,000 volumes of rare books; 1,600,000 volumes of general ancient books; 35,000 pieces of the scripted turtle shells and animal bones. The Library opens to the public 365 day a year and its on-line services are available 24 hours a day via its linkage with various multimedia networks and on Internet. It offers a reception of 7000-8000 everyday, and the daily books throughputs are up to over ten thousand. Due to the huge size, also the rich collection and large throughputs, for better management, the library furthered its division into more specialized sectors, including both of the main operation sectors, such as Acquisition & Cataloging Department, Stack Management & Reading Service Dept, Rare Book Department, Information Service Center, etc, and management sectors, such as human resource section, finance section, office, international section, security sections, etc.

Similar to the Beijing Jiaotong University's library, Acquisition & Cataloging Department acts as the information supplier. With the improvement and popularity of information technology, the Library has introduced computer into daily work. The faculty of

Acquisition & Cataloging Department input the information on books into computer, and store it in the database to show the states of the books. And the reader can enter the local net and search for the information about the books. Then, the reader fills in the book sheet and hands it to the librarian to raise the demand for the books. The librarian inputs the information into the online database to notify the faculty who work in the place where the books are stored. As the collection of books is so rich and the throughputs are so big, for the safety of books, the readers are forbidden to enter the open-shelf hall themselves to fetch books, because it's beyond effective supervision and control of the Library. At the same time, it's impossible for the librarians at the counter to fetch books for each of the readers because of the limitation of faculty number and working intensity. To solve this problem, a special sector was set up to carry books. The faculty where the books are stored receive the demand from the counter through online database, and send the demanded books through mechanic convey belt to the counter. In this way, the working efficiency is promoted and the valuable time and human resource is saved, and the security of books is guaranteed.

The above process can be illustrated by the following chart. (Chart 4)

Chart 4

From the above we can see that this process differs from that of Beijing Jiaotong University's Library in two main points. First, on account of the large market size and the immense throughputs, the library furthered its division of labor, and established a specialized sector for books carrying, which ensured the safety of books and elevate the efficiency. Second, a sector for "passing message" was set up to connect the "request admission" sector and "books hand-over" sector. It is noted here that the process took advantage of the automation technique (two examples: mechanic convey belt for books carrying, local net for passing information). All these help to save time and resources, and meet the demand of readers better.

However, these measures are only some kind of automation on the original system, going by the former division style and process mode. It's only an improvement on the traditional process, saving some time by technical skills. Overlooking the crucial principles in process management, it cannot help to realize the integral qualitative flit.

With the development of information technology and wider popularity of internet, the National Library introduced the updated technological outcome to the foreign language books borrowing process by utilizing a software system from Israel. Through a thorough redesign of process, it leads to more rational and effective division and process, which embody high profits and high return.

The following is the depiction of the foreign language

books borrowing process.

With the support of information technology, the faculty of Acquisition & Cataloging Department dispose and offer the information of books by making ferret system on internet. The readers can log in the Library's website anytime and anywhere to search for the needed books information. All that a reader needs to do is clicking the names of the books, making a reservation "request" and clicking "confirmation".

In this way, the moment the readers confirm the information of books, the demand request has been submitted to the Library. Then, the readers get to the counter for the prepared books which are conveyed by the mechanic convey belt, and after the validation of identity, the readers may get away with the books.

The above process can be illustrated by the following chart. (Chart 5)

Chart 5

Compared with the former books borrowing process, the information supplier is still Acquisition & Cataloging Department. But here, it has put all the information of books on the internet database for the readers to share anytime or anywhere with the support of information service sector. "Request for borrowing" and "request permission" can be finished in seconds by the readers themselves anywhere after the "information seek", instead of getting to library's counter in person for the faculty's help. When the readers' request for books is submitted on internet, it immediately reaches the "books carrying" sector, where the faculty can easily keep up with the readers' demand through online database, with no need for the information convey by the faculty at counter. This saves time and human resource effectively, and helps to avoid the possibility of error. "Books carrying" here is taken on by the lender. Since the first four steps have been finished by the borrower on internet, so, when the borrower comes to the counter, the faculty have already got the book ready for the borrower, which is also on account of the relative small number and high value of the foreign books. When the record is made by computer, the borrower may leave with the books. On return, the record is deleted by computer, which saves time and offers convenience.

Through the above analysis and comparison, we may see that, with the continual increase of throughputs, the efficiency of the Library's past division and process has been far behind the development of Library and failed to meet the demand of readers, which has caused a waste on resources.

With the support of advanced technology, in order to fulfill the task effectively and ensure the high efficient operation of the activity, the functions between the readers and the Library, also the division of the Library's internal sectors have all been continually adjusted: the activity

shared only by several persons formerly has been organized by further specialized posts and divisions; the task that belongs to either of the lender or the borrower has been creatively transferred to the other side, taking great advantage of information technology; meanwhile, according to the reality, certain procedures have been either combined or deleted, and the process has been redesigned to make use of the resources to the most degree.

How does of the foreign language books borrowing process of the National Library of China realize a successful reengineering? In my point of view, it is mainly focused on the following four principles:

Firstly, to “have those who use the output of the process perform the process”. With the development of Library and the increase of the books collection, throughouts of the readers and books, the former service condition cannot meet the increasing demand, and a simple augment of faculty will not solve the problem virtually. With the support of information technology, the readers can log in at the National Library’s website and reserve the interested books. As the people who use the output, they themselves perform the process of “information seek”, “request for borrowing” and “request admission” in a very short time, which simplifies the process, saves time and offers much convenience to the readers. As for the Library, it saves human resource, saves the working space for faculty and waiting space prepared for the readers, and the frictions between original working interfaces (the readers and the faculty, the faculty themselves, the administrators and the staff) can be more effectively avoided, which results in cutting down the management costs and winning the credits as immaterial assets. The most importantly, the working efficiency is promoted, and the resource setup efficiency is optimized.

Secondly, to “treat geographically dispersed resources as though they were centralized”. The Library has the total floor area of 170,000 square meters, with 19 floors above ground and 3 floors under ground. The Library has 38 reading rooms, and a rich collection of 22,400,000 volumes, ranking fifth in the libraries of the world. With such a huge collection in such a huge area, it’s not easy for both the internal management and the external service. With the help of database, tele-net and information distribution management system, all the information of books collection was put into database, and embodied in the instant tele-net and information distribution management system. For both readers and librarians, they can get the detailed information and states of books easily and precisely. It not only keeps the scale benefit of the library, but also offers flexible and exact service for the customers.

Thirdly, to “subsume information-processing work into the real work that produces the information”. There are mainly two ways today to solve the problems of delay or error during the information convey: one is to improve the speed and quality of information convey with the popularity of computer and internet; the other is to optimize the linking ways between the information

production and convey by reengineering the process. The National Library of China just combines these two ways into the books borrowing process reengineering, and not only saves time and resource, but also ensures the exactness and opportuness of information.

When the readers finish making the reservation for books, the library admits their requests meanwhile. In this way, as the information producer, the readers process the information the moment it is produced. It not only avoids the possible delay or mistake during the convey of message, but also improves the efficiency and convenience. Processing the information where it is produced means service in time, and the process efficiency is greatly improved, which certainly satisfies the customers. At the same time, to ensure the reliability and authenticity of the information, a set of measures are carried out, such as validation of identity, penalty on the readers who delay or fail to fetch the reserved books.

Fourthly, to “capture information once and at the source”. This is embodied in the following three cases:

First, the management of documents. In the past, the information about books was managed by the Acquisition & Cataloging Department in paper, and the faculty in other sectors had to ask them for information. The information was disposed by many times according to different needs, which wasted a great deal of time and energy, not ensuring the veracity of information. At the utilization of online database and internet technology, the information about books is input into the online database at one time and being adjusted according to the reality, showing the updated and truest states of books. In this way, both the borrowers far away and the faculty inside the library can acquire the needed information and take advantage of it.

Another one is the utilization in the books hand-over and return. In the past, the information of books borrowing and return was captured many times by the readers and the librarians, which caused many man-made mistakes and a waste of time. In the new process, when the borrower succeeds in submitting the request on line, the personal record has been input into the database. When the borrower comes to fetch or return the books, the librarian may output the borrower’s record from the database immediately, and handles it easily. This simplified process not only saves time and resource, but also ensures the veracity of information.

The third case is the convey of books information. In the past, the librarian input the information on the book sheet which had been filled out by the borrower himself into the computer to notify the “books carrying” department. In this way, the information was disposed twice, which easily caused mistakes and wasted time and costs. The obvious reason is that it didn’t obey the principle of “capture information once and at the source”. While today, the manner of “request convey” has greatly changed. When the borrower submits the reservation request on line, the faculty at “books carrying” department immediately know about the information about the needed books, and send them to the counter by

the convey belt in no time, with no need for the counter to notify them. This not only reduces the errors, but also promotes the efficiency and cuts the costs. And the most above all is that it really offers convenience for the borrowers to log in for books any time and anywhere.

4.2.2.2 The existing problems that need to be improved

Although the process reengineering here is effective, there are still some problems in practice:

For example, there's a blind point of internet ferret on books state. Because the actual software system can only memorize whether the books are carried out of the library, not whether they are on the shelves, ignoring the case that the books may be taken to the reading room by the readers. This brings on the incoincidence of states caused by the off-shelf browse. So, it always happens that the readers get to the library for the reserved books, but the books are not prepared. Then, is it possible for us to find out the storage of books for outward borrowing the moment we submit the reservation information on internet by strengthening of technology?

Another example is the problem caused by the lack of logistics for books. It's quite convenient and time-saving for the readers to log in the Library's ferret system and reserve the needed books anytime and anywhere, but the point is that the readers have to get to the Library in person for the books, which really adds a lot of inconvenience of books hand-over. This has raised another problem on the perfection of books borrowing process: Is it necessary to supplement a tache of "books borrowing logistics" which matches with the "online books reservation"?

In my point of view, only by rigorous scientific demonstration in consideration with the feasibility in technology and economy, the applicability in environments, and the matchness of the actual resources, can these kinds of problems be settled step by step.

5. Conclusion

From the above all we can see that, in economics, the Adam Smith's theory of division of labor illustrates the affiliation between division of labor and the extent of

market, emphasizes that division brings efficiency, but ignores the importance of technology development in the changes of process as powerful tools and manners, and its driving force on the division and process change; in management, the information technology and administration ideas are creatively utilized, and the idea of process management, organization and human, also the impacts of information technology on organization are focused on, but the decisive significance of market extent and throughouts on division of labor and process is ignored. The author here, by this simple example of books borrowing, attempts to explain this administration issue by the combination of administration and economics knowledge. It means a great deal not only to corporations, but also to any organizations' division of labor and business process.

Abstract

This paper examines how Internet Cafes (I-Cafés) in New Zealand can enhance their services in the market typified by growing competition both within the industry and from other industries. I-Cafés in the North Island were studied to provide the background material. Along with interviews these observations were used to derive the constituents of I-Cafés. Selected I-Cafes were benchmarked against these constituents. I-café users were surveyed to rank these constituents on their performance as well as their importance Connection speed, experience and values that include atmosphere, type of customer, pricing, friendly service and seating were found to lead to satisfaction.

1. Introduction

The Internet has “created a new way of doing old things, rather than being a technology that changes the manner in which people live their lives” [10]. The world is becoming increasingly reliant on Internet connections for business and personal communications; having Internet access is becoming a necessity, especially while traveling [3]. The Internet has provided us with a new channel of communication and keeping in touch in businesses, with friends and family. We have moved from the age of physical letters to virtual mails, from talking over the phone to virtual chatting, with such products as ICQ. The Internet has created a new dimension for traditional tasks; a way of doing things quickly and immediately. This explains the wide adoption in the use of the Internet, and thus I-Café is rapidly growing in popularity [7].

The Internet has become a major component in our daily life; some people have even become addicted to the Internet [5]. Entrepreneurs saw this as a good business opportunity and developed the concept of I-Cafés. The concept of the European style café had been successfully adopted into the New Zealand culture. Cafés are places where people gather together and chat or just simply read newspapers. More recently millions of people have begun to use the Internet to communicate at home, school or the workplace. The concept of an Internet Café or Cyber Café (referred for convenience in this paper as I-Café) is given to those cafés that provide a means of Internet access to people.

I-cafés are facing a competitive market, not just from those in the same industry but also from other businesses that provide access to the Internet. There are many issues that influence the adoption and penetration of I-Cafés in

New Zealand. The format of providing Internet access in a café environment has evolved and there are many different forms of I-Cafés. The concept of I-Café has shifted due to shifts in user groups and their changing needs. Competition has also strengthened, as other businesses want a share of this market by providing Internet access. Internet access has been made easier. You can now find standalone computers in shopping malls where you can surf the net and check email simply by putting money into the slot. Backpackers are also a market rival, providing Internet access to guests. Advances in technology, such as broadband and wireless technology will also influence the I-Café Industry. Additionally, with the increase in households that own computers and the lower costs of high-speed connections, more and more people are able to afford Internet access at home. The latest study conducted by Statistics New Zealand indicates that 47% of New Zealand households have a computer at home, and 37% of households have access to the Internet [9]. With all these factors influencing the use of I-Café, survival of individual I-Cafés is threatened. They must be competitive. To remain so, they must understand what the customers want and to define the priorities, given the limited resources available [1]. Thus the objective of this research is to discover “what are the determinants of user satisfaction?”

2. Study Methodology

A multi-methodology approach [6] [8] was used in this study: observation, interview and survey. Observation and interview were used to create the set of constituents, the survey were used to rank these constituents in terms of their importance.

2.1 I-Café Satisfaction Constituents

The collection of data was done in three distinct stages. The first stage was unstructured observation. This was conducted in the Auckland region. Prior to this the interviewer had not formulated definitive ideas on the particular aspects on which the study should focus. The second stage was the interview stage. A semi-structured interview was conducted with Interviewee A to elucidate the preliminary issues so that in-depth investigation could be designed on the variables needing further attention. The third stage was structured observations. These were conducted on 25 I-Cafés in Auckland; 5 in Wellington; 4 in Rotorua; 3 in Taupo and 2 in Hamilton to gain a deeper understanding on the I-Café industry and on the variables

that emerged in the Interview stage.

Table 1 provides a summarised version of the findings from the literature, interviewee and from researcher participation. The “+” denotes the variables considered relevant for customer satisfaction as derived from each source.

Table 1 Sources of Customer Satisfaction Variables

Constituents	Literature	Interviewee	Researcher
Speed	+		+
Service Variety	+		+
Games Variety	+	+	+
Software Variety	+		+
Atmosphere	+		+
Type of Customer			+
Price	+	+	+
Friendly Service	+		+
Payment Variety	+		+
Computer Availability		+	
Food/Drink Variety	+		+
Personal Space			+

The literature list is available in Tsui [11].

All these variables are said to influence the level of satisfaction. Thus, it is critical that they be tested.

2.2. Survey

Literature and field observation identified the measurement variables of this study; questionnaires will therefore be used to capture the user perspective for these variables. A questionnaire is the most cost effective and efficient way to obtain data from large samples.

Convenience sampling was used for this study as a complete sampling frame from the population of all I-Café users and non I-Café users would be costly to implement. Questionnaires were either administered personally or distributed in class by the instructor. Both these methods ensure a fast response rate and can be collected within a short period of time. The format of the questionnaire was based on Chung [2]. Sekaran’s [8] guidelines for developing questionnaires were followed to ensure minimal bias. Wording, categories and scale were carefully considered. A pilot questionnaire was used to check the understandability.

SPSS was used to analyse the survey data. Factor analysis [4] was used to test and reduce the operational variables. Multiple regression was used to test the significance of the operational factors to user satisfaction.

3. Analysis

The importance of each element as measured in the survey is shown in Table 2. The average importance element is measured in a 7-point scale, from 1 indicating very unimportant to 7 indicating very important. Speed has the highest mean (6.16), followed closely by price (5.97), comfortable atmosphere (5.69), personal space (5.63), availability of computers for use (5.62), friendly staff service (5.5) and seating (5.43). The range of services available (4.96), type of customer (4.8), range of software available (4.78), payment option (4.7), range of food and drinks available (4.5) and range of games available (4.5) tend to be close to neutral. None of the elements appeared to be unimportant. Factor analysis was conducted to reduce and group these variables, as the number of variables is quite large. Table 3 shows how the 13 variables loaded into 5 factors. The factors are named based on the set of variables that they contain. These factors will be used in the regression model to test against satisfaction.

Table 2 The Importance of Each Element

Variable		
Speed	6.16	88%
Range of Services Available	4.96	71%
Range of Games Available	4.46	64%
Range of Software Available	4.78	68%
Comfortable Atmosphere	5.69	81%
Type of Customer	4.8	69%
Price	5.97	85%
Friendly Staff Service	5.5	79%
Payment Option	4.7	67%
Seating	5.43	78%
Personal Space	5.63	80%
Range of Food and Drinks Available	4.5	64%
Availability of Computers	5.62	80%

Regression analysis is used to understand which factors predict the satisfaction of I-Café users. These five factors were used as independent variables and satisfaction was used as the dependent variable. Table 4 denotes the result from regression analysis.

Table 3 Factor Label

Factor Label	Factor	Variable	Loading
Experience and Value	1	Atmosphere	0.752
		Type of Customer	0.658
		Price	0.721
		Friendly Service	0.648
		Seating	0.637
Gaming Related	2	Game Variety	0.602
		Payment Option	0.803
		Personal Space	0.684
Work Related	3	Service Variety	0.886
		Software Variety	0.867
Fundamentals	4	Food/Drinks Variety	0.618
		Availability of Computer	0.798
Speed	5	Speed	0.920

The variables that seem to be related to Satisfaction are Experience and Value, and Speed. Examination of the correlation matrix in Table 4 indicates that Speed is most closely correlated with Overall Satisfaction because it has

the greatest correlation coefficient (0.399). Notice that there are no correlations between independent variables because orthogonal rotation was used in the factor analysis. This ensures that all independent variables in the regression analysis are appropriate.

Stepwise regression was then used on the 5 variables. Stepwise estimation starts by selecting variables for inclusion in the regression model by selecting the best predictor of the dependent variable. Additional independent variables will be selected in terms of their incremental explanatory power they add to the regression model. By choosing this method, only significant variables are included. Under the Stepwise Regression method, we will choose model 2 because model 2 has the largest adjusted R² (0.236) (Table 5). This means that model 2 is able to explain the most variance in the dependent variable. Model 2 refers to Speed and Experience and Value. All the other variables were removed because they are not significant at the 0.05 level. Table 6 shows that the regression model with 2 variables is significant at the 0.05 level. This indicates that the two I-Café factors are related to Overall Satisfaction, namely: Speed and Experience and Value.

Table 4. Correlation Matrix between Overall Satisfaction and I-Café variables

	Overall Satisfaction	Experience and Value	Gaming Related	Business Related	Fundamentals	Speed
Overall Satisfaction	1.000	.278	.192	.092	.187	.399
Experience and Value	.278	1.000	.000	.000	.000	.000
Gaming Related	.192	.000	1.000	.000	.000	.000
Business Related	.092	.000	.000	1.000	.000	.000
Fundamentals	.187	.000	.000	.000	1.000	.000
Speed	.399	.000	.000	.000	.000	1.000

Table 5 Regression Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.399 ^a	.159	.144	.638
2	.486 ^b	.236	.209	.613

a. Predictors: (Constant), Speed

b. Predictors: (Constant), Speed, Experience and Value

c. Dependent Variable: Overall Satisfaction

Table 6 Significance of Regression Model**ANOVA^a**

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	4.381	1	4.381	10.775	.002 ^a
	Residual	23.178	57	.407		
	Total	27.559	58			
2	Regression	6.512	2	3.256	8.663	.001 ^b
	Residual	21.048	56	.376		
	Total	27.559	58			

a. Predictors: (Constant), Speed

b. Predictors: (Constant), Speed, Experience and Value

c. Dependent Variable: Overall Satisfaction

Table 7 Regression Coefficients of I-Café Variables**Coefficients^a**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	3.797	.083		45.732	.000
	Speed	.270	.082	.399	3.283	.002
2	(Constant)	3.797	.080		47.568	.000
	Speed	.270	.079	.399	3.414	.001
	Experience and Value	.188	.079	.278	2.381	.021

a. Dependent Variable: Overall Satisfaction

Since the assumptions behind the regression variate were met, so we can proceed with the interpretation. Table 7 shows that Speed and Experience and Value are all significant at the 0.05 level. The best predictor of Overall Satisfaction is Speed. Experience and Value are significant but are insubstantial compared to Speed. We conclude that both variables explain Overall Satisfaction. Gamer Related, Business Related and Fundamentals do not relate to overall satisfaction.

4. Conclusions

I-Cafés' resources are limited, hence they need to concentrate on resources that would generate the greatest satisfaction. While improving all the operational factors would have a positive affect on satisfaction, the affects of these different elements differ significantly. I-Cafes should only focus on the operational factors that would lead to greatest satisfaction to avoid wasting resources on those that would not generate as much benefit.

I-Café users consider connection speed as the most important element of an I-Café. Price, comfortable atmosphere, personal space, availability of computers for use, friendly staff service and seating were all consider relatively important as opposed to the remaining operational factors. However, not all of these elements lead to a significant increase level of satisfaction. In other words, although the elements may be considered important, the improved provisioning of these elements may not significantly satisfy users.

The experience and value of the visit; price, comfortable atmosphere, type of customer, friendly staff service and seating are the second set of elements that indicate a moderate increase to satisfaction. This indicates that customers are price sensitive so charging a premium is not an effective strategy, but yet customers still want a premium experience.

The other operational factors; variety of games, variety of payment options, variety of service, variety of software, variety of food and drinks, personal space and availability of computers do not significantly improve overall satisfaction.

A Collaborative Framework For Collaborative Commerce

Ta-Tao Chuang

Abstract

This article proposes a collaborative framework for the process of collaborative commerce (c-commerce) through which prospective partners could employ and configure c-commerce technologies according to the needs of different stages to realize potential benefits promised by the next generation of enterprise application software. This framework details pre-conditions that lead prospective partners to establish a collaborative relationship, including structural, social-psychological, and technological factors. This framework also describes how collaboration in c-commerce is unfolded following a teamwork problem-solving model. Furthermore, the framework discusses a variety of possible outcomes resulting from an initiative of collaborative commerce. Those components of collaborative commerce are structured in the format of the input-process-output model.

1. Introduction

In the past few years, the business press has constantly reported successful stories of collaborative commerce (c-commerce) that companies in a variety of industries employed to realize potential benefits from the use of collaborative technologies. For example, Boeing improved its production productivity from 228 airplanes per year in 1992 to 620 expected in 2002 by using collaborative e-marketplace [9]. In order to build a new family of supersonic stealth fighter planes that it was bound to deliver in four years, Lockheed Martin Aeronautics Co. used collaborative technologies to link more than 80 suppliers located at 187 locations to design and build components of the Joint Strike Fighter [15]. A recent report on c-commerce [2] indicated that software for creating c-commerce would be the next stage of growth in the enterprise application software business. The report estimated that the size of the c-commerce market would grow from \$5.8 billion in 1999 to \$36.5 billion in 2004 (estimated by AMR and IDC). Another report [8] showed that about 60 percent of 356 survey respondents considered c-commerce as critically important to their businesses in the year of 2001 – 2002 and 78 percent of companies planned to implement c-commerce to improve supplier and customer interaction. As many firms start adopting c-commerce, issues surrounding c-commerce have intrigued researchers' interests. For example, Welty and Becerra-Fernandez [31] investigated the issue of managing trust and commitment in collaborative relationships. Kumar [16]

delineated the features of information and communication technologies for supporting c-commerce. Based on the type of inter-organizational relationship and the level of organizational computing, Chuang and Nakatani [5] propose a classification of c-commerce.

The majority of existing c-commerce literature was anecdotal, although sporadic research about c-commerce has been published. The focus of extant literature has been on reporting the benefits realized by those pioneers and on the architecture of information technology for c-commerce. C-commerce applications are generally described with what business processes c-commerce systems may support. For example, Bellini, Gravitt and Diana [2] classify the c-commerce market into three categories: supplier relationship management, knowledge management, and product lifecycle management.

Not much, if any, research has been done to examine the phenomenon from the perspective of collaborative process, let alone the interactivity of the process. Furthermore, even though it is indicated that the value proposition of c-commerce should be derived from the development of collaborative relationship [7], how c-commerce could be used to facilitate the development of such a relationship is not clear. Fou [10] defined c-commerce as "commercial relationships carried out over a collaborative framework to integrate enterprises' business processes, share customer relationships and manage knowledge across enterprise boundaries." [9, p. 1] Although the target of c-commerce might not be limited to the items listed by Fou, his definition indicates an important element in c-commerce: a collaborative framework through which prospective partners obtain mutual benefits and share common risks. Nevertheless, his definition raises a few interesting questions that are unanswered by the extant literature. For example, what is a collaborative framework for c-commerce? How could it facilitate the achievement of goals of c-commerce initiatives? How are c-commerce technologies used in such a framework? We believe answers to those questions are critical to understand the phenomenon of c-commerce. Furthermore, answers to those questions would provide guidance for determining and configuring the features of c-commerce applications and for sustaining collaborative relationships. Consequently, the objective of this article is aimed to answering those questions by proposing a collaborative framework for the process of c-commerce at the project level. By drawing research in organizational collaboration, organizational cooperation, group dynamics, and information systems,

we developed such a framework to address the above issues.

2. Literature Review

Even though c-commerce is an emerging business phenomenon, collaboration between trading partners / stakeholders has long been a research topic among researchers in the areas of business and public policy disciplines. In the field of marketing, for example, researchers examine the factors that affect the development of collaborative relationships between buyers and sellers [27], and the means to develop and sustain collaborative supply chain relationships [26]. Also, research in the field of social services has been done to investigate into how business, government, and stakeholders form collaborative alliance to generate constructive solutions to social problems [11]. However, only limited research studies have been conducted in c-commerce. With very few exceptions, such as Welty and Becerra-Fernandez [31], Kuma [16], and Chuang and Nakatani [5], existing studies are focused on two themes: (1) reporting successful anecdotes and potential benefits of adopting c-commerce (2) proposing IT infrastructures for building c-commerce. Examples of successful stories [9] [15] are available in companies in various industries, such as Boeing Co. and Lockheed Martin Aeronautics, Co., General Motors Corp., Juniper Networks Inc., and Toshiba Canada Office Corp. Alexander [1] gave a more general discussion about the benefits of c-commerce and barriers of deploying c-commerce from a practitioner's point of view.

The emphasis of IT infrastructure prevails in the extant literature of c-commerce. For example, Bellini, Gravitt and Diana [2] classify the c-commerce market into three categories of enterprise application software: supplier relationship management, knowledge management, and product lifecycle management. Fou [10] considers c-commerce as a continuum of application of enterprise application software and classifies the evolution of c-commerce into three stages: (1) web-enabled single-dimensional and single-process c-commerce, (2) B2B exchanges-based, single-dimensional and multiple-process c-commerce, and (3) Web service-based, multiple-dimensional and multiple-process c-commerce. Fou asserts that the ultimate aim of c-commerce is to maximize return on intellectual capital investment, improve business agility, and provide better quality of customer experience. In order to achieve the objective, Fou believes that the next stage of c-commerce must be built on Web services, and he proposes a Web service-based collaborative architecture that consists of four tiers: c-commerce vendors, web services, business rule engine, and multi-dimensional c-commerce enterprise web portal.

Derome [7] believes that c-commerce capabilities should be depicted from a functional standpoint and downplays the importance of state-of-the-art technologies in developing collaborative relationship. For example, according to him, e-mail is a c-commerce tool, as are

Electronic Data Interchange (EDI) and extensible Markup Language (XML). He segments the c-commerce capabilities into three categories: Free-form collaborative services, process collaboration layer, and the structured data exchange category. The IT environment, duration of collaboration, and goal of collaboration vary from category to category. Although Derome suggests a variety of technologies for each of the three categories, he emphasizes the importance of deriving value propositions from the development of a collaborative relationship.

Li and Williams [19] examined the impact of previously established transaction-focused application one the cooperative relationship and found that companies that had established a successful cooperative relationship at the transactional level by creating interfirm network (via proprietary or open systems) tended to develop new and collaborative partnership at the strategic level. Their studies show that further developed collaborative relationship could occur in the existing transactional application or a new application devoted to the new partnership.

As it is generally accepted that trust and commitment are the premises for establishing and developing a collaborative relationship, Welty and Becerra-Fernandez [31] presents a business interaction model in which interaction technology (i.e., collaborative commerce software) is used to develop and enforce the development of trust and commitment between cooperative partners. Welty and Becerra-Fernandez's article highlights an important element of sophisticated c-commerce: interaction between cooperative partners over four different phases of business transaction process. Besides, they assert that the difference between traditional enterprise resource planning systems and collaborative commerce lies in that the latter integrate customer satisfaction into business processes. In other words, it is customer satisfaction rather than the delivery of goods or the submission of payment that closes a business transaction loop. The importance of trust and commitment in c-commerce is also addressed by Chuang and Nakatani [5]. Chuang and Nakatani assert that existing inter-organizational relationship (IOR) and trust level among prospective collaborators might affect the establishment of a c-commerce. Different types of IOR and different levels of trust might dictate the structure and conduct of a c-commerce. Based on the combinations of types of inter-organizational relationships and the stages of organizational computing, Chuang and Nakatani [5] propose a classification of c-commerce applications.

As shown by the above review, research studies of c-commerce are rare. Reporting successful cases and IT infrastructure for c-commerce dominate the extant literature. Although the selection of appropriate IT infrastructures is critical to develop successful c-commerce, yet they are not sufficient. The decision over the choice of an IT infrastructure for c-commerce should be made taking into account factors surrounding collaboration per se. Those factors should be identified and organized as parameters of a collaborative framework

through which collaboration would grow, develop, and sustain.

3. Collaborative Framework For C-Commerce

To serve the purpose of the study, we believe that a collaborative framework for c-commerce should include the elements that explain why firms enter into IT-enabled inter-organizational relationship, the process that describes how collaboration is unfolded, and what is expected to produce from such a collaborative effort. Hence, the structure of the collaborative framework we proposed will be in the format of precondition, process, and outcomes. By integrating research in inter-organizational cooperation, inter-organizational collaboration, group dynamics, and information systems, we propose a collaborative framework as shown Figure 1. In the following paragraphs, we will discuss how those factors come together and affect each other.

3.1 Pre-conditions of C-Commerce

Although the practice of collaboration is part of human life and might be as old as the history of human being, due to the concern with anti-trust law, not until early 1980s was the necessity and conduct of inter-organizational collaboration gradually recognized and accepted [17]. Since then, issues in inter-organizational collaboration and relevant areas have caught researchers' attention and research has been reported, though a comprehensive theory is still not available [32]. Based on different theoretical perspectives (e.g., resource dependence or political perspectives), researchers in relevant areas have identified several factors that may facilitate the development of inter-organizational collaboration. Those factors are presumably applicable to c-commerce, which we consider a special case of inter-

organizational collaboration. In addition to those factors identified by research in inter-organizational collaboration, we also consider other factors unique to c-commerce. We classify those antecedents into three broad categories: structural, social-psychological, and technological.

3.1.1 Structural factors

Structural factors refer to those related to the structure of prospective partners in the industry or in the supply chain. It is generally accepted that high interdependence between organizations is an important antecedent to the development of an inter-organizational collaboration [20] [12] [27]. Nowadays, because of the complexity of business activities and high level of division of specialization, no one single company can solely assume all kinds of roles in the industry. As a result, an essential aspect of today's business activities is the coordination of activities performed by different companies. While interdependence is widely acknowledged as an important factor to the formation of a collaborative alliance, the definition of it in most research studies is vague. It is generally referred to task interdependence, which can be defined as the extent that tasks performed by one party are related to those performed by other parties. However, according to Tjosvold [28], task is one of many facets of interdependence and he proposes an integrated model of interdependence in organizations in which he differentiates objective interdependence from subjective interdependence. Objective interdependences include tasks, rewards, and assignments, while subjective interdependence means the link between goals expectation. The importance of interdependence is that the extent and the manner that prospective collaborators are interdependent of may affect how they collaborate and the performance of the alliance.

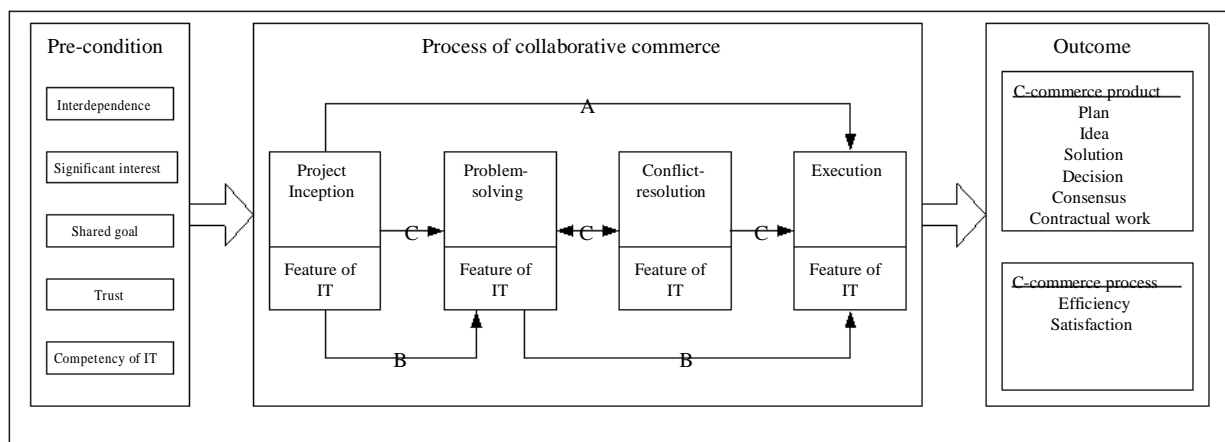

Figure 1. A collaborative framework for c-commerce

Another pre-condition of c-commerce is the significance of interest of the collaborative business in

question. Logsdon [20] argues that high stake and high interdependence are two premises to collaboration. She defines interest broadly, including long-term interest and

legitimacy status of an organization. In other words, she asserts that an institute would not engage in collaborative relationship with others because of short-term efficiency. Instead, just as Kanter indicates, "Successful partnerships manage the relationship, not just the deal." [13, p. 96], prospective collaborators will consider the significance of each transaction in the context of long-term perspective and decide whether to collaborate. In one study, Sriram, Krapfel, and Spekman [27] obtain similar results and their research shows that the importance of transaction (collaborative business) affects the propensity to collaborate through perceived buyer dependence and transaction costs.

3.1.2 Social-Psychological Factors

Structural factors such as task interdependence might warrant the necessity for collaboration, but they are not sufficient for organizations to collaborate. Social-psychological factors, such as mutual trust, might play an even more important role in the decision on collaborative relationship. Trust and commitment are generally considered as premises for establishing a collaborative relationship [25] [26]. Trust could be broadly defined as the belief that others will act or react in a predictable way [21]. Trust is important for the creation of collaborative partnership because it could reduce uncertainty and provide certain extent of assurance for managers' decisions. The level of trust one party has on the other party in a relationship might determine how strong the first party is committed to the relationship. Just like relationship between individuals, relationships between companies begin, grow and develop [14]. The level of trust and commitment grows following the development process of relationship between two parties. The level of trust might have impacts in three aspects of an alliance of c-commerce: First, it might affect the willingness of prospective collaborators to join the alliance. Second, the level of trust might determine the amount of resources (e.g., time and effort) collaborators would invest in the relationship. Third, the level of trust and commitment influence the interaction between collaborators. Impacts in those aspects will not only affect the outcome of c-commerce, but also influence sustainability of the alliance. For example, previous studies [19] indicate that those companies that had already developed routine applications between them are more likely to develop interfirm collaboration than those had not, because trust and commitment had been nurtured.

Another social-psychological pre-condition is shared goal expectation. As indicated previously, Tjosvold [28] classifies interdependence into broad categories: objective and subjective interdependence. By subjective interdependence, he means the link between goals expectation, which means that the goals of collaborative initiative expected to achieve by prospective collaborators must be related or shared. The importance of shared goal expectation in c-commerce initiatives is twofold: One is that shared goal expectation could help direct efforts from different parties toward the

same direction and the result would be a truly synergetic outcome. Second, shared goal expectation would confine conflicts, when arise, to the category: choice of means. According to Daft & Lengel [6], conflicts in organizations may occur in two different ways: one is conflict in ends and the other is conflict in means. Conflict in ends means that organizational units have different viewpoints regarding what goals or objective the organization should pursue, while conflict in means implies that organizational units share organizational goals but have different opinions regarding how to achieve the shared goal. In general, conflict in means could be resolved by providing more data to parties in questions. Thus, shared goal expectation is important in that it may affect the way collaborators interact in the process of c-commerce.

3.1.3 Technology Competency of Prospective Collaborators

Technologies underpinning c-commerce vary considerably. As Derome [7] indicates, c-commerce technologies may range from free-form interaction tools, such as email and secure chat, to structured data exchange, such as electronic data interchange (EDI) and XML. Although proprietary c-commerce package is available, it is generally accepted by practitioners that c-commerce technologies should be integrated with existing commerce systems, such as ERP and CRM. As a result, at least, there are two reasons that organizational competency of information technology is an important factor affecting the establishment of a c-commerce: First, as other studies [7] [24] show, a c-commerce system usually consists of many different technologies, each of which could be chosen from a wide range of technologies. Without a decent level of IT competency, a prospective collaborator might not be able to make informed decisions over the choice of proper technologies. Second, organizational IT competency, to certain extent, reflects the sophistication level of the company using commerce systems. Previous studies [19] show that developing routing applications between partners is an important step of developing interfirm collaboration.

3.2 Process of C-Commerce

At the project level of a collaborative alliance, the practice of a c-commerce is teamwork in nature. Although a c-commerce initiative is initiated, sponsored, sustained, and supported by participating organizations, implementation and on-going activities are carried out by a group of people representing their own organizations who electronically work together in order to achieve a specific objective, such as developing a new product, forecasting product demand, or improving customer services. From this point of view, the on-going process of c-commerce is a teamwork process. Depending on the nature and purpose of the collaborative alliance, the duration and the structuredness of collaboration may significantly vary. For example, Procter & Gamble, Co.

developed a Collaborative Planning, Forecasting, and Replenishment (CPFR) system with which it could receive input from its partnerships with retail customers to determine when, what, and how much to produce so it would be able to meet demands from its retailers [30]. Although the implementation of a system like this may take time, once it is in place, the planning and forecasting process is relatively structured and each session could be relatively short. In contrast, a c-commerce for developing new products might not be so structured as CPFR systems. For example, Lockheed Martin Aeronautics Co. used collaborative technologies to link more than 80 suppliers located at 187 locations to design and build components in order to build a new family of supersonic stealth fighter planes that it was expected to deliver in four years [15]. The c-commerce case in Lockheed Martin Aeronautics Co. is much more unstructured than the CPFR system in Procter & Gamble. As a result, the prescribed process of a collaborative commerce should take into account the possibility that different c-commerce scenarios could have different routes.

3.2.1 Paths of C-Commerce Process

Based on the above discussion, we borrowed McGrath's model of stages of group project activity [22] to describe the on-going process of c-commerce. According to McGrath, groups perform three different functions: production function, member-support function, and well-being function. Production function means that groups perform a variety of activities to generate results, which make contributions to their embedding systems (e.g., participating companies in a c-commerce). Groups also make contributions to their components (member-support function) and to themselves (well-being function). For a long-term c-commerce relationship, sustainability of the collaborative alliance obviously is an important objective (i.e., well-being function of the alliance). However, for the purpose of this study, the production function is the major process that we should focus on. Here, we detail the stages of production function and, when appropriate, illustrate those stages with real cases.

McGrath [22] proposes that the stages of group activities are the inception and acceptance of a project (goal choice), the resolution of technical issues (means choice), resolution of conflict (police choice), and the execution of the performance requirements of the project (goal attainment). In the first stage, the inception and acceptance of a project, members of the collaborative alliance recognize the opportunity or the need for collaboration. The purpose or goal of the particular project for the group is articulated in this stage. McGrath indicate that there are three routes through which groups acquire projects: a project proposed by one of members of the group, a project assigned by an outside agent, or a recurrent project of long standing for the group. It is the third route that most of c-commerce sessions acquire their projects. For example, a manufacturer may regularly use a Collaborative Planning, Forecasting, and

Replenishment (CPFR) system [30] with its retailers to forecast the demand for products. The second stage is the choice or design of a logically correct or best means for solution to achieve the articulated goal, when such a means is not readily available. In the context of c-commerce, the second stage could be extended to include general problem-solving issues, not just the choice of means. The third stage, the resolution of conflict of interests or of viewpoints, might be needed when members of the group possess different, or even conflicting, interests or viewpoints. Finally, the last stage is the execution of the project, carrying out the procedure for achieving the articulated goal.

McGrath claims that those stages should be "regarded as a logical template for potential project activities, rather than an endogenous set of inevitable developmental phases." [21, p. 29]. This statement suggests that the process of c-commerce is not a linear or rigid process. Instead, members of the collaborative alliance may "shift gear" from one stage to another, whenever the need arises or the situation warrants. As a result, there are several different paths through which one session of c-commerce may pass.

Execution path: When the activities required to achieve the articulated goal are available, the first stage of inception might directly lead to the last stage of execution (Path A in Figure 1). For a well-defined and recurrent c-commerce system, path A might be the most frequently visited path. Under such a circumstance, the execution stage would be the heart of the c-commerce because for a c-commerce system characterized by recurrent activities (e.g., forecasting demand for products), the inception and acceptance of the goal would gradually become a routine.

For example, IBM developed a c-commerce prototype system for a fictitious company selling power tools [22]. This system would allow the user (i.e., buyers or purchasing agents) to perform transactional activities, such as create requisition lists and issue an order (or reorder) using a requisition list, and non-transactional activities, such as contract negotiation and collaborative product design. Once the user logs into the system, the system will greet him/her with a welcome menu in which the projects that the user is participating are displayed (i.e., configuration of membership in different projects) and the user could choose the project that he/she intends to create a session and carry out the necessary activities to achieve his/her objective for that particular session. In most of the time, the user might be able to carry out his/her business by following the straightforward procedure and finish the session without a glitch.

Problem-solving path: In a c-commerce system designed to support a less structured business process, the procedure or activities for achieving the goal might not be readily available. In such a case, users of the c-commerce system will enter into the second stage, the problem-solving stage, in order to identify or agree upon a feasible procedure to achieve the goal. When the choice of the procedure or the means is made, the group could move

ahead to the last stage of execution. This is path B in Figure 1. McGrath [22] indicates, “[For] path B, sometimes the problem-solving activities of Stage II are the heart of the matter, and Stage IV is pro forma once the correct procedure or appropriate algorithms has been determined.” [21, p. 32]. In the context of c-commerce, although for path B, Stage IV is not completely a formality, Stage II could be the major part of the whole process. For example, in a project of joint product development, the problem-solving activities are essential for product conception and development, not just only for the choice of means to conduct the product development.

An example of the problem-solving path is that of the prototype system developed by IBM [22]. In addition to functions introduced above, the system features an awareness function. This function allows the customer service agents of the prototype to offer assistance and proactive help to customers by giving an immediate context of what page they are on, and how long they have been there. Whenever the customer requests for assistance, this system would open a window for communication and allow customer service agents to provide live help. In terms of the process of c-commerce, the customer and the customer service agent enter into the problem-solving stage.

Conflict-resolution path: On some occasions, members of the group may attempt to enter the execution or problem-solving stages and found that they might need to address the issue of difference in viewpoints or interests among them before they can identify or carry out the procedure. As a result, instead of entering into the execution stage, members of the group need to enter the conflict-resolution stage. When this occurs, the path the group travels is path C in Figure 1. Because the impact of unresolved conflicts of viewpoints or interest in the process and the result of group activities could be detrimental, the management of conflicts is very critical to the success of teamwork. Consequently, McGrath [22] claims that on certain occasions, the conflict-resolution stage might be the heart of the matter and Stage II or Stage IV could be a matter of formality or even trivial.

The prototype system developed by IBM [23] offers several functions, such as contract negotiation, with features of real-time and asynchronous collaboration. Those features could partially facilitate the resolution of conflict of viewpoints. For example, the feature of real-time collaboration introduced above for problem solving could be used to present and discuss issues in the process of negotiation. If and when issues cannot be resolved in real time, the feature of asynchronous communication could be used to create a “forum” equipped with necessary contents and functions to facilitate group processes. Several functions of group decision support systems (GDSS), such as brainstorming, voting, and ranking, could be added on the c-commerce systems and used to resolve conflicts of viewpoints.

The significance of specifying different paths in the process of c-commerce is twofold: One is recognizing the

need for coordinating activities performed by different organizations or their representatives in different stages. Second, features of technology required for supporting different coordination mechanisms or activities in different stages would be accordingly different.

3.2.2 Features of Collaborative Technologies

Different technologies that offer different capabilities could be adopted to implement c-commerce. For example, in a highly structured partnership, EDI might be sufficient. However, more sophisticated technology will be needed for a less structured project, like joint product conception, in which partners usually need technology that supports real-time interaction. In these two cases, one type of technology might be sufficient for supporting the whole process. However, as we discussed above, when a group of people work together, the path they may take could be quite different from another group of people or perhaps, even different from the path they take in another session. Consequently, we assert that passing along with different paths and different stages will need support with different technologies. Here, we borrow Derome’s classification of technologies (which he called Collaboration over Internet Protocol, CoIP) to discuss how collaborative technologies could be used to support different stages.

Derome [7] classifies c-commerce technologies capabilities into three categories: Free-form collaborative services, process collaboration layer, and the structured data exchange category. Those categories differ in delivery model, suitable environment, duration of c-commerce, expected goal, and applicable business functions.

Structured data exchange is most suitable for a stable environment in which the goal of c-commerce is to precisely and accurately transport data from one location to another. As a result, the less human intervention, the better. Furthermore, the data format, data sources, corporate relationships, and quality of data are all well defined. Explicit rules and standards are necessary for the definition, movement, and representation of data. Technologies for this category are fairly mature and are available from major software vendors. Furthermore, technologies for this category pave foundations for paths A, B, and C. However, they are particularly important for path A. For example, in a c-commerce system based on Collaborative Planning, Forecasting, and Replenishment (CPFR) standard, most of communication could be accomplished with structured data, even though technologies for free-form interaction might be needed occasionally for resolving the difference in forecasting between buyers and sellers.

Process collaboration provides less structured, yet more flexible solution to the alignment of processes between companies. Process collaboration enable partners to share information, synchronize activities and execute shared processes. Because this category requires the synchrony between partners’ business activities, it is

usually integrated with existing back-office systems. The integration to back-office systems and the process-oriented focus dictate the requirement of technologies for this category. The capabilities of technology for process collaboration include process modeling, workflow management, document management, graphical analytics, and content aggregation technology. Additionally, process-specific capabilities, such as planning and scheduling optimization technologies, CAD/CAM design capabilities, project management, might be needed. Since the focus of CoIP networks is not on data transportation, but on the support of business functions, systems in this category are usually more flexible and less structured. Also, systems in this category are not so isolated from human intervention as those in structured data exchange. Technologies in this category could be delivered either as a stand-alone network or an add-on to e-marketplace system. Early systems are mainly focused on joint product development or joint-production planning and scheduling. Combined with structured data exchange, technologies for process-oriented collaboration could be used to support path A and partially support path B.

The third segment of c-commerce technology capabilities is free-form CoIP services, which is the most flexible in that participation is not pre-defined in this type of environment. Instead, goals of collaboration, governance rules for interaction, and information access are all defined by participants. The primary function of this category is to augment structured data exchange or process collaboration by offering ask-and-responses conversation, initiating and managing discovery processes, and interactively creating plans, strategies, and partnerships. CoIP technologies widely range from online whiteboard technology, secure chat, file sharing, and analytical tools. Those free-form CoIP services could be available on subscription basis, ("snapped on") part of enterprise applications, or via a web browser free of charge. As the prototype developed by IBM [23] shows, technologies for free-form interaction could be used to in

Stage II and Stage III. In other words, those technologies could be employed to support paths A and B.

3.3 Outcomes of C-Commerce

Although a c-commerce could be a short-term establishment, most of them would be long-term agreement among collaborators and collaboration will be recurrent processes. For a long-term collaborative relationship, the outcome of the c-commerce is more than that resulting from one session of c-commerce. The sustainability of the collaborative alliance might be a desired result. While what factors affect the sustainability of a c-commerce needs further investigation, we postulate that the more satisfied with the process and the result of c-commerce the collaborators are, the more likely the alliance would sustain. Consequently, we consider two broad categories of the outcomes that should be measured for evaluating the performance of c-commerce: the product and the process of c-commerce.

Information sharing is one of major targets of c-commerce; however, many reports show that sharing information is one small portion of and limited value-added activity in c-commerce. In order to direct the target of c-commerce to high value activities, we make an attempt to conceptualize the product of c-commerce by employing task classification of McGrath's Task Circumplex, in which McGrath classifies the types of tasks into four broad categories: generating alternatives, choosing alternatives, negotiating issues, and executing works. Because the execution type is mostly about physical activities, such as performing psycho-motor tasks, we don't consider it here. Under each of the other three categories, McGrath further classifies into two subcategories, as shown in the second column in Table 1. In Table 1, we add a few c-commerce examples from Phillips and Meeker [24] to demonstrate the applicability of the classification.

Table 1. Products and examples of c-commerce (Source: Adapted from [22] and [24])

Category	Type	Definition	Examples in c-commerce
Generate	Planning tasks	Generating plans	Planning, scheduling and forecasting
	Creative tasks	Generating ideas	Product conception and development
Choose	Intellective tasks	Solving problem with a correct answer	Payment reconciliation, or complex pricing, route optimization
	Decision-making tasks	Dealing with tasks for which the preferred or agreed upon answer is the correct	Collaborative promotion planning, campaign management
Negotiate	Cognitive conflict tasks	Resolving conflicts of viewpoint (not of interests)	Resolving difference in forecasts of demand for products
	Mixed-motive tasks	Resolving conflicts of motive-interest	Contract negotiation and management

Each type of the products of c-commerce could be measured and evaluated in terms of objective dimensions that are appropriate for that type. However, because c-commerce generally involve more inter-personal and inter-organizational interaction than transactional commerce, stakeholders' satisfaction with the product might be, if not more important, as important as objective measurements. Those measurements are directly related to the product of one session of c-commerce. It is obvious that those dimensions of the result of c-commerce will have impact on stakeholders' assessment over whether the establishment of the c-commerce achieves its objectives and expected benefits.

Many c-commerce initiatives are intended to improve the efficiency of business processes. For example, shortening the lead-time of product delivery or product development cycle time. As a result, the efficiency of c-commerce process is an important factor for the survival of the c-commerce. With the same token as satisfaction with the product of c-commerce, the level of stakeholders' satisfaction with the c-commerce process is important for the retention of stakeholders in the c-commerce.

4. Conclusion
