C-commerce creates a new form of commerce. Extant literature has focused on the development of IT infrastructure for c-commerce and reporting realized benefits in those companies adopting c-commerce. In this article, we proposed a collaborative framework that depicts the pre-condition, interactive process, and possible outcomes of collaborative commerce. Interdependence, significant interests, mutual trust, shared goal expectation, and sufficient IT competency are factors that lead companies to initiate and join the establishment of collaborative commerce. The proposed framework indicates that the collaborative process is an interactive process in which participants may "shift the gear" and take different paths when the situation warrants the necessity. It is our position that different technologies should be employed to support different stages and paths of c-commerce. Furthermore, we take the first step toward conceptualizing the product of c-commerce and briefly discussed the issue of sustainability of a c-commerce initiative.

Abstract

This paper discusses research that has been conducted in relation to online learning websites. Initially, the current situation of Online Learning will be discussed. Results of the analysis of a number of Online Learning websites (such websites include both international and New Zealand websites) will then be discussed in depth. This paper will describe the basic requirements of Online Learning websites, and will provide the reader with website design principles, in order to assist in increasing the effectiveness of an Online Learning website. The benefits and drawbacks of the creation of, and use of an Online Learning environment will also be discussed. In the end of the paper, a few future trends of online learning will be indicated. This paper will provide the reader with a general overview of the current status of Online Learning.

1. Introduction

As one of the most significant technologies created during the last century, computer network has been changing people's lives dramatically. The way we live, we work, we entertain and even we think are likely changed by the spreading computer network. This paper is going to talk about another change made by computer network---the change on our way to learn.

The way in which our learning is conducted can be expected to be vastly different to that of our forbears. Such new technologies will have a dramatic impact on learning aspects such as where an individual learns, when they learn, and who will be assigned the role of the teacher. Recently, exponential growth of information becomes the driver for people to be a lifelong learner, continuously engaged in some form of learning activities. Therefore education becomes a lifelong process rather than being taken in a short period of time in the first twenty years of life.

In order to assist in the fulfillment of individuals new learning requirements, a new education strategy merged, that is online learning. Online Learning utilizes computing technologies to achieve educational goals. It provides people a much more flexible learning environment to learn what they want to learn with their own class schedule.

In order to harness the global trend towards Online learning, educational institutions and private corporations have and will continue to invest significant amounts of capital in online learning capabilities. It is estimated that the portion of online learning market devoted to technical

training alone will grow from \$1.7 billion in 2000 to about \$5.3 billion in 2003 [1].

Whether these investments could get satisfactory payoff?

How we can improve the learning process so that the benefits can be sustained?

In order to provide explanation for such questions, this paper will discuss the findings of research that was conducted on existing online learning programs. The key elements of the implementation of an Online Learning system will then be discussed, taking into consideration the principles on how an Online Learning site should be built and managed.

2. Research Background

2.1 What is Online Learning?

Before this paper provides further discussion of the Online Study undertaken, it is felt necessary to clearly define what is indicated by the term "Online Learning", and the relationship that it has with other learning networks.

Online learning refers to all learning strategies, which use Internet/Intranet as learning environment. Computerworld magazine defines it as online learning is the delivery of remote training over the Internet or a corporate Intranet via a Web browser. The program which implements online learning is called online learning system. The network supporting online learning is called online learning network (OLN), which is "a system that enables students learning via the Internet. OLN facilitates interaction of professor-to-students, student-to-professor and students-to-students communication via asynchronous learning tools, including anytime, anywhere learning or synchronous learning tools, i.e., real-time communication, or any combination of these two" [2].

A broader concept is online learning system (OLS), which includes learner, instructor, class, technological and system configuration, and management of OLN. Online learning systems can be mainly divided into two parts—synchronous and asynchronous online learning systems. Figure 1 shows a hierarchical relationship of different learning systems.

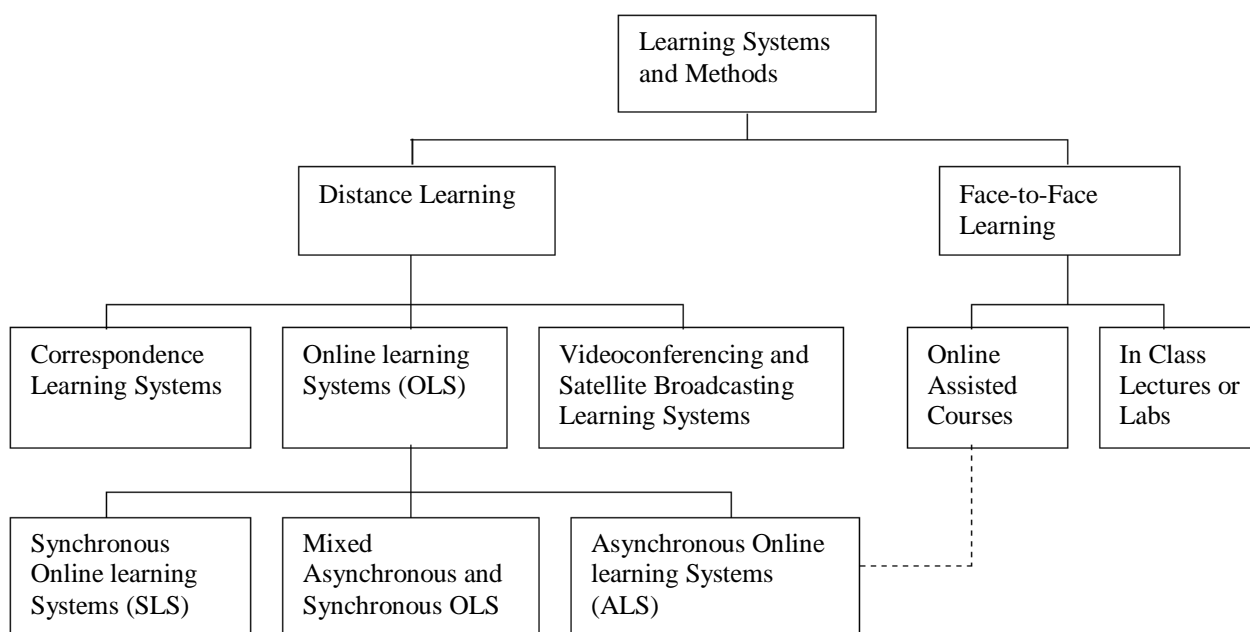

Figure 1: Different Learning Systems Hierarchy

2.2 History of Computers in Education

The popularity, the wide use of computer makes the merge of online learning. The use of computers during learning was first hypothesized approximately four decades ago. Such computer-based learning applications were referred to as computer-assisted instruction (CAI) or computer-based instruction (CBI). The main idea was that computers could provide individualized learning experiences, including interactive sequences consisting of problems or questions with appropriate feedback [3].

In the early stages of computer-assisted learning, the aforementioned idea was only used on some courseware within some specific course programs. Later, some CAI/CBI systems merged, like PLATO. Such integrated systems incorporated email and BBS functionality. Such functionality is currently widely utilized within Universities nowadays.

But the real bloom did not occur until the World Wide Web appeared in the early 1990. The Web makes it easier to create and access networked information. It also supports the collaboration of the major forms of learning interaction (email, chatting, threaded discussions, and conferencing). The form of computer assisted learning, that utilizes the Internet as its platform will now become the basis of this paper – referred to as “Online Learning”.

2.3. Infrastructure Required for Online Learning Networks

It is obvious that an online learning system heavily involves the use of computer networks. Different forms of OLS may be built using computer networks from large-scale public networks such as the Internet to small local networks (LANs). For most institutions and organizations, LAN is the basis for their learning systems. In general, such LANs will also be connected to public

networks, making differences in location transparent to individual users.

Connections to public networks are mainly dependent on moderns and existing telephone lines, whereas LAN connections are normally facilitated through the use of cable. School and college systems with many locations are likely to lease high-speed data communication lines using fiber optics or microwave transmission. Large corporations and government/military agencies utilize satellite technologies for data transmission and network communications. It is also possible (and increasingly common) for people to connect to public networks or LANs using wireless technologies.

Regardless of the underlying technologies of a network, a considerable technological infrastructure is always required, in order to develop, and support a given network. A network infrastructure is comprised of hardware, software and support personnel. It is thought that the hardware and software required to support an Online Learning system are no more complex than that required in a general-purpose computer.

With the rapid growth of computer industry and spreading use of computer in education, such infrastructures will not be a problem any longer. Nowadays, most countries are ready for adapting online learning as a new education strategy.

2.4 Literature Review

A number of studies have been conducted associated with online learning. Each study discusses the status of one given aspect of Online Learning. Studies performed include the following:

2.4.1 Online Professional Interactive Network: Virtual Professional Learning Communities for Teachers

Supported by different types of professional interactive network examples, this paper summarises the functions of professional learning networks, the way to achieve information for meeting the goals of working professionals and the reasons of using electronically mediated networks. Also it gives examples of teacher support networks in New Zealand and compares them with international counterparts.

2.4.2 Internet Use in Schools: Legal and Ethical Issues

Internet gives children and young people access to the same information as adults, which causes a series of legal and ethical problems. When schools decide to get Internet connection, it is very necessary to consider these issues and make the Internet exactly be used for educational purposes. This paper discusses these legal and ethical issues and gives suggestions for schools on how to use Internet to its best advantage.

2.4.3 Designing Web-Based Learning Environment

This paper discusses some questions and provides some resources as to how to design a website for an online learning program. It provides the procedure of website designing and implementation with the principles of online learning website design.

2.4.4 Toward a Value Framework for Online Learning Systems

This paper queries the student concerning the features of these systems that add value to their learning experience. A questionnaire is utilized for gathering student values associated with online learning systems and organization supporting these technologies. Results from the survey and a literature review are organized in a proposed value framework for online learning course effectiveness.

3. Web Site Analysis

The major research method in this paper is website analysis. In subsequent chapters, the research results are gotten from the analysis made in this chapter. After reviewing a number of Online Learning websites, it has become apparent that such sites should be categorized, and discussed independently. In the field of online learning, websites serve for the following multi-dimensional topics and sub-topics [4].

Higher Education

K-12

Corporate

Health Care

Informal Learning (Museums, Communities, Homes)

Government

Military Training

Professional Associations & Non-Profits

In this paper, three main segments of online learning websites will be discussed in detail, including their unique features and an example will be provided as to a website that facilitates the defined category of Online Learning applications.

3.1 Online Learning Applications

3.1.1 Higher Education – University of Auckland

It is apparent that online learning methods are most extensively facilitated within Colleges and Universities. Due to the wide availability of computers, and the provision of basic computing education, within the Tertiary Education sector, Online Education can be widely implemented within their course offerings.

Currently, Online Courses offered by Tertiary Institutions rely on a web-based database for the storage of course materials and information (such as lecture notes, student grades, hyperlinks).

A relevant example within this category is Cecil (www.cecil.edu). Cecil can be viewed as the University of Auckland's Online Learning System. Students have the ability to access course materials, and course related information, from anywhere. Cecil provides a majority of the previously discussed online learning functions (namely, group email, a discussion forum, course information, and file downloading). Cecil accommodates all courses that are offered by the University of Auckland. The degree of utilization of Cecil appears to differ between departments and papers. Cecil also allows for the checking of coursework marks, and online testing functionality. It helps greatly for providing high quality education.

3.1.2 K-12 Education – The Global Lab (<http://global.terc.edu>)

For K-12 schools, online learning websites' major function is to provide an online library system. With the help of these online libraries, searches for books, journals, and other relevant sources of information become much easier. This indicates that schools are no longer constrained by the information contained within their limited number of textbooks, and library books.

Another popular application incorporated into Online Learning Systems within K-12 Schools, is the facilitation of collaborative projects. Collaborative projects may be implemented solely within one class, or spanning a number of schools. Students utilize the network to collect relevant information, and prepare documents in small-sized groups. A majority of such projects also require interaction with students at different schools (via email).

Other functions of OLS at this level include: linking to the outside world; storing curriculum resources and providing interaction.

An example of an implementation of an Online Learning System in Middle Schools is the Global Lab. The Global Lab is a large-scale science project that

involves in excess of 100 schools internationally. Students within participating schools must agree to collect, and analyze data that relates to some aspect of their local environment. Such analysis results are then placed on the Global Site website, in order to allow for the determination of global trends in each given aspect.

3.1.3 Corporations – Cisco Network Academy (<http://www.cisco.com/edu/academies>)

Corporate training is the largest among online learning market segments. In early 2002, it was estimated that as many as 350 companies were marketing learning-management systems (usually server-based software), educational content or online learning hosting services. Investment was put into the U.S. online learning market at \$2.2 billion last year [5].

Information technologists who have an in-depth understanding of networks are in high demand and are likely to remain so in the future. As a result, a number of networking companies play a pivotal role in the provision of such training. Cisco Systems is an example of such an organization. Cisco provides training through the Cisco Networking Academy. This academy is comprised of high schools and colleges internationally, that have been authorized by Cisco to teach a four-semester course in networking that will be examined at the conclusion of the course. If an individual is successful in passing the Cisco examination, then they are considered to be a Cisco Certified Network Associate or Professional. This academy is partitioned into regional and local sites. The regional sites have responsibility for training, supporting, and quality control of the course offerings at the local sites.

The Cisco Networking Academy can be considered to be a relevant example of an industry-educational partnership, which is beneficial to all involved.

Also based on the self-assessment survey completed by 3,560 Cisco partners, the online training program has improved their productivity significantly. For example, 74 percent reported an improvement in the ability to sell or service clients and 76 percent said that customer satisfaction jumped 50 percent or more [5].

3.2 NZ Online Learning Websites

A large number of OLN's serve the purpose of the provision of additional resources for teachers, as well as allowing for the exchange of information, and utilization of new technologies. Like other countries, online learning has been developing fast in recent years. New Zealand Learning Network can be considered to be a relevant example of New Zealand online learning websites.

3.2.1 New Zealand Learning Network

<http://education.otago.ac.nz/NZLNet/home.nclk>

The New Zealand Learning Network was established in 1998 and is being continuously developed and maintained by the University of Otago School of Education. The purpose of this information, service, and

discussion network is to provide an online teacher-centered resource that will support and assist New Zealand teachers in the process of integrating the Internet in the classroom. It does this by providing links with colleagues and other professionals locally and nationally, access to Internet information and resources for classroom use, and professional background material relevant to New Zealand teachers. Interaction online includes computer conferencing areas, online chat room, and news boards for posting of educational news.

The service facilities allow for contribution from members, in a number of ways. This includes the hosting of school web pages, and collaborative projects, organized by teachers, for other classes. Teachers are encouraged to contribute ideas to the site, and such ideas may be archived online. Members also have the ability to post news items of educational interest.

4. Results

4.1 Unique Features of Online Learning

Unlike any other training form, online learning promises to provide a single experience that accommodates the three distinct learning styles of auditory learners, visual learners, and kinesthetic learners [5]. By the advent and development of online learning more efficient training is provided to a globally dispersed audience. As Web-based training becomes a standard, publishing and distribution costs have been reduced.

Online learning also offers individualized education, which is impossible for print media. Under the wave of personalization, individualized learning form is more welcomed by adult learner and working people. Besides its individualized instruction, online learning can target specific needs. And by using learning style tests, online learning can locate and target individual learning preferences.

Additionally, synchronous online learning is self-paced. Advanced learners are allowed to speed through or skip instruction as needed.

In these ways, online learning can serve simultaneously for a maximum number of participants with a maximum range of learning styles, preferences, and needs. The experience and value of the visit; price, comfortable atmosphere, type of customer, friendly staff service and seating are the second set of elements that indicate a moderate increase to satisfaction. This indicates that customers are price sensitive so charging a premium is not an effective strategy, but yet customers still want a premium experience.

4.2 Basic Elements of Online Learning

Online learning requires some basic elements to support its functions. In the sequent paragraph, I will discuss such elements.

4.2.1 Email

Email is the foundation for all forms of online leaning and teaching. Indeed, it is quite possible to use nothing more than email in a course and still have a highly valuable leaning experience. Email is also a very cost-effective application in terms of computing and network resources required; it works with a minimum amount of equipment, software, and facilities. Furthermore, since web-based email is free, there is no need to purchase email software.

4.2.2 Threaded Discussion

Threaded Discussions are the second most commonly used element in online learning. It may also be referred to as asynchronous conferencing, a forum, or a bulletin board.

These systems work as: topics and subtopics are created, and people post messages under topics. Messages include the sender's name, a subject title for the message and the text of message. To read messages, an individual must select the topic of interest and choose the message available. Finally, a reply message can be posted below the topic.

4.2.3 Real-time Conferencing

Real-time conferencing covers any form of online synchronous interaction, the simplest form of Real-time conferencing is a chat session. A chat session enables participants to communicate with each other through the exchange of typed messages. Each participant has the ability to view the typed messages. Each message is preceded with the name of the message sender.

4.2.4 MUDs/MOOs

MUDs (multi-user domains) and MOOs (MUDs object-oriented) are an interesting category of real-time conferences used in some education settings. MUDs/MOOs

Allow many people to share a virtual world, usually set up as "rooms" containing objects that can be viewed or manipulated. People can interact with others by sending chat messages as well as performing simulated actions.

4.2.5 Desktop Video

The most advanced forms of real-time conferencing are desktop video systems. A desktop video system is mainly a chat system that uses video images instead of text messages. The video images (including audio) are captured by a small digital camera that is connected to the PC.

4.2.6 Audio-graphics

Audio graphics allows for audio interaction, and the sharing of graphical images, or applications. Conference participants have the ability to hear others comment, and view the graphical images or program screens.

4.2.7 Groupware

A relatively new category of software are groupware programs, which are specifically designed to facilitate group interaction. The MUD/MOO systems mentioned before are a specialized case of groupware for shared worlds..

4.3 Website Design Principles

When designing an online learning website, there are some principles needed to be followed:

4.3.1 Interactivity

One of the most important reasons for using the Internet as a learning environment is its capability to enhance interaction between teachers and students, and among students. In the online course, teachers can employ a range of synchronous and asynchronous tools in such a learning environment. The activities in such a learning environment should be interesting and stimulating.

4.3.2 Collaboration

All collaborative learning theory contends that human interaction is a vital ingredient to learning. Consideration of this is particularly crucial when designing online learning websites, realizing the potential of using web medium to isolate learners. With well-delivered synchronous distance education, and technology like message boards, chats, e-mail, and video-conferencing, this potential drawback can be reduced.

4.3.3 Social and Interpersonal Interaction

As the best environment for learning is a social setting, a Web-based course site should be designed to promote social and interpersonal interaction as well. The course website should be viewed as a virtual meeting place shared by all the students. Social interaction was a significant factor in contributing to knowledge construction in this environment.

4.3.4 User Control

In designing a user interface, we should follow Lai's five criteria [6]: easy to learn; easy to use; easy to remember; pleasant to use; and allowing for feelings of user ownership.

4.3.5 Structure and Management of the Learning Environment

A Web-based learning environment should be a flexible learning environment. A good management structure should include clear and explicit information on the assessment tasks, as well as just in time feedback on their assignments.

4.4 Benefits of Online Learning

By combining the new technology of the Internet with new thinking of how people learning, online learning brings a new era to traditional education. Some of the most outstanding benefits have been indicated [7].

4.4.1 Online Learning Lowers Costs

Despite appearances, online learning is often the most cost-effective way to deliver instruction (training) or information. It cuts travel expenses, reduces training time, and eliminates costs [8]. The elimination of costs associated with instructor's salaries, meeting room rentals, and student travel, lodging, and other infrastructures. When deployment is based on a sound business case, the significant startup investment can be quickly recovered through delivery savings.

4.4.2 Online Learning Enhances Business Responsiveness

Online learning can reach an unlimited number of people virtually simultaneously. This can be critical when business practice and capabilities are rapidly changing.

4.4.3 Messages are Consistent or Customized, Depending on Need

All can get the same content, presented in the same way. Meanwhile the programs can also be customized for different learning needs or different groups of people.

4.4.4 Content is More Timely and Dependable

Because it's web-based, online learning can be updated instantaneously, making the information more accurate and useful for a longer period of time.

4.4.5 Learning is 24/7

People can access online learning anywhere and any time. It's "just in time – any time" approach makes an organization's learning operations truly global.

4.4.6 No User "Ramp-Up" Time

With so many millions of people already on the Internet and comfortable with browser technology, learning to access online learning is quickly becoming a non-issue.

4.4.7 Universality

Online learning is Web-enabled and takes advantage of the universal Internet protocols and browsers. Concern over differences in platforms and operating systems is rapidly fading. Everyone on the Web can receive virtually the same material in the same format.

4.4.8 Builds Community

The Web enables people to build enduring communities of practice where they can come together to share knowledge and insight long after a training program ends. This can be a tremendous motivator for organizational learning.

4.4.9 Scalability

Online learning solutions are highly scalable. Programs can move from 10 participants to 100 or even 100,000 participants with little effort or incremental cost (as long as the infrastructure is in place).

4.4.10 Leverages the Corporate Investment in the Web

Executives are increasingly looking for ways to leverage their huge investment in corporate intranets. Online learning is emerging as one of those applications.

4.4.11 Provides an Increasingly Valuable Customer Service

Although not internally focused, a business e-commerce effort can be enhanced through the effective and engaging use of online learning that helps customers derive increased benefit from the site.

4.5 Drawbacks of Online Learning

Despite its benefits, online learning is still in its nascent stages. It does have limitations.

4.5.1 Technology Issues

This include whether the existing technology infrastructure can accomplish the training goals, whether additional tech expenditures can be accepted, and whether compatibility of all software and hardware can be achieved. For learners, these issues include commonly technophobia, unavailability of required technologies and inability of grasping the computer techniques.

4.5.2 Reduced Social and Cultural Interaction

The impersonality, over-dependence of computer techniques, suppression of communication mechanisms such as body language, and elimination of face-to-face communication are part of the potential disadvantage brought by the advances in communications technologies.

4.6 Summary

The pros and cons of online learning vary depending on their business goals, target audience and organizational infrastructure and culture. But it is apparent that online learning is rapidly growing as form of training delivery and it is clear that benefits to online learning will guarantee it a position in the overall learning strategies.

5. Future Trends

Online learning is the most rapid growing learning form in recent years. There was an evolution that technology-enabled learning and distance education changed to online learning. By now, more and more people agree that online learning is here to stay. So we need to examine some trends of this new learning strategy.

5.1 Online Learning as a Business Strategy

For smart companies, it's no longer a question of if, but when to use online learning. These organizations see online learning as a strategic solution that must be deployed to all employees. Enterprises consider online learning as a guarantee to increase sales effectiveness, improve organizational competency, and build rich customer relationships. Consequently, online learning will continue to be a part of organizational infrastructure, similar to email packages and other product suites used to increase staff productivity.

5.2 Blended Learning

This trend involves blended learning programs, designed to integrate online learning with traditional training methods to increase overall effectiveness. A single delivery method is no longer sufficient to handle new training needs. The construction of true blended learning programs pushes learning into a new age. Blended learning preserves the necessary consideration of how people learn while offers options for learning and can still produce measurable savings promised by online learning.

5.3 Moving from Discrete to Integrated Learning

There is an increased desire for a seamless transition from one learning activity to another. Rather than stand-alone learning activities, the trend is towards the integration of these activities. The trend is looking for seamless transitions from live group activities to individual exercises, from self-paced learning activities to synchronous instruction, from activities in smaller groups to activities in a larger learning community.

5.4 Online Learning Beyond the Corporation

Early adopters of online learning consisted mainly of corporations, which were trying to enhance face-to-face meetings, demonstrations, training classes, and lectures. Nowadays, government agencies, colleges, universities, and non-profit organizations are now followers. These organizations are using online learning to address their learning and communication needs, as well as expand their business opportunities.

6. Conclusion

Rapidly expanding network technologies increase the possibilities of online learning. It is, however, difficult to predict what technology will be the dominant driving force in online education delivery in the future. It is expected that, in this new century, tremendous advances in computers and networks will have dramatic effect of altering individuals' lives and the learning experience as well.

Abstract

This paper discusses research that has been conducted in relation to online learning websites. Initially, the current situation of Online Learning will be discussed. Results of the analysis of a number of Online Learning websites (such websites include both international and New Zealand websites) will then be discussed in depth. This paper will describe the basic requirements of Online Learning websites, and will provide the reader with website design principles, in order to assist in increasing the effectiveness of an Online Learning website. The benefits and drawbacks of the creation of, and use of an Online Learning environment will also be discussed. In the end of the paper, a few future trends of online learning will be indicated. This paper will provide the reader with a general overview of the current status of Online Learning.

1. Introduction

As one of the most significant technologies created during the last century, computer network has been changing people's lives dramatically. The way we live, we work, we entertain and even we think are likely changed by the spreading computer network. This paper is going to talk about another change made by computer network---the change on our way to learn.

The way in which our learning is conducted can be expected to be vastly different to that of our forbears. Such new technologies will have a dramatic impact on learning aspects such as where an individual learns, when they learn, and who will be assigned the role of the teacher. Recently, exponential growth of information becomes the driver for people to be a lifelong learner, continuously engaged in some form of learning activities. Therefore education becomes a lifelong process rather than being taken in a short period of time in the first twenty years of life.

In order to assist in the fulfillment of individuals new learning requirements, a new education strategy merged, that is online learning. Online Learning utilizes computing technologies to achieve educational goals. It provides people a much more flexible learning environment to learn what they want to learn with their own class schedule.

In order to harness the global trend towards Online learning, educational institutions and private corporations have and will continue to invest significant amounts of capital in online learning capabilities. It is estimated that the portion of online learning market devoted to technical

training alone will grow from \$1.7 billion in 2000 to about \$5.3 billion in 2003 [1].

Whether these investments could get satisfactory payoff?

How we can improve the learning process so that the benefits can be sustained?

In order to provide explanation for such questions, this paper will discuss the findings of research that was conducted on existing online learning programs. The key elements of the implementation of an Online Learning system will then be discussed, taking into consideration the principles on how an Online Learning site should be built and managed.

2. Research Background

2.1 What is Online Learning?

Before this paper provides further discussion of the Online Study undertaken, it is felt necessary to clearly define what is indicated by the term "Online Learning", and the relationship that it has with other learning networks.

Online learning refers to all learning strategies, which use Internet/Intranet as learning environment. Computerworld magazine defines it as online learning is the delivery of remote training over the Internet or a corporate Intranet via a Web browser. The program which implements online learning is called online learning system. The network supporting online learning is called online learning network (OLN), which is "a system that enables students learning via the Internet. OLN facilitates interaction of professor-to-students, student-to-professor and students-to-students communication via asynchronous learning tools, including anytime, anywhere learning or synchronous learning tools, i.e., real-time communication, or any combination of these two" [2].

A broader concept is online learning system (OLS), which includes learner, instructor, class, technological and system configuration, and management of OLN. Online learning systems can be mainly divided into two parts—synchronous and asynchronous online learning systems. Figure 1 shows a hierarchical relationship of different learning systems.

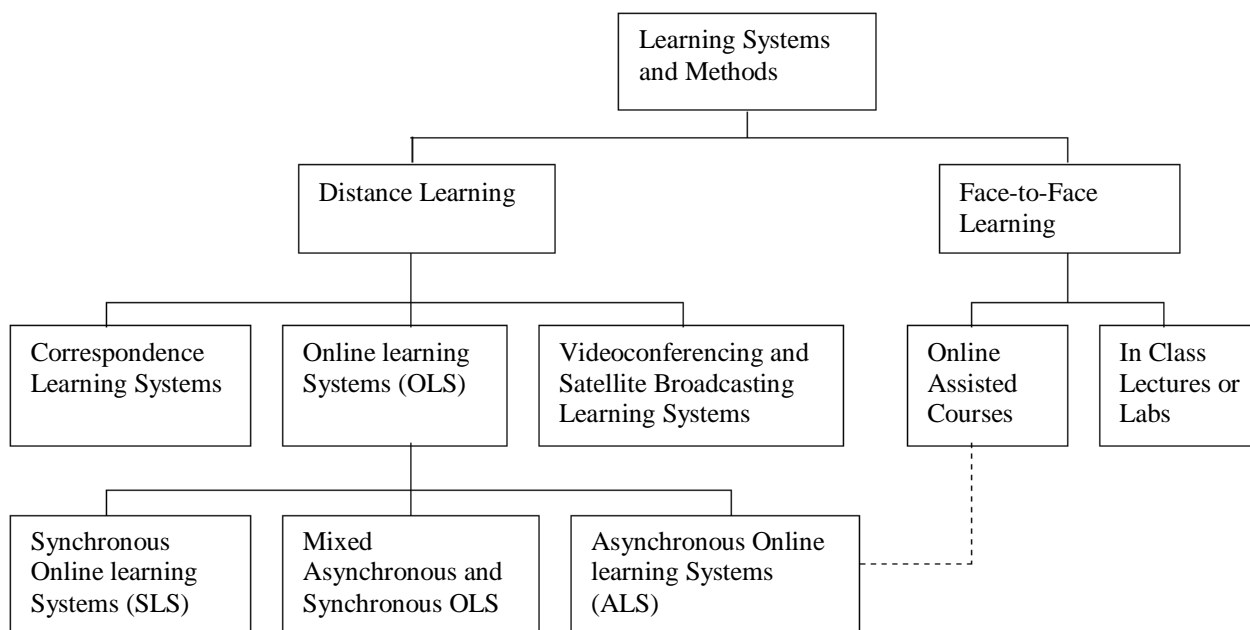

Figure 1: Different Learning Systems Hierarchy

2.2 History of Computers in Education

The popularity, the wide use of computer makes the merge of online learning. The use of computers during learning was first hypothesized approximately four decades ago. Such computer-based learning applications were referred to as computer-assisted instruction (CAI) or computer-based instruction (CBI). The main idea was that computers could provide individualized learning experiences, including interactive sequences consisting of problems or questions with appropriate feedback [3].

In the early stages of computer-assisted learning, the aforementioned idea was only used on some courseware within some specific course programs. Later, some CAI/CBI systems merged, like PLATO. Such integrated systems incorporated email and BBS functionality. Such functionality is currently widely utilized within Universities nowadays.

But the real bloom did not occur until the World Wide Web appeared in the early 1990. The Web makes it easier to create and access networked information. It also supports the collaboration of the major forms of learning interaction (email, chatting, threaded discussions, and conferencing). The form of computer assisted learning, that utilizes the Internet as its platform will now become the basis of this paper – referred to as “Online Learning”.

2.3. Infrastructure Required for Online Learning Networks

It is obvious that an online learning system heavily involves the use of computer networks. Different forms of OLS may be built using computer networks from large-scale public networks such as the Internet to small local networks (LANs). For most institutions and organizations, LAN is the basis for their learning systems. In general, such LANs will also be connected to public

networks, making differences in location transparent to individual users.

Connections to public networks are mainly dependent on moderns and existing telephone lines, whereas LAN connections are normally facilitated through the use of cable. School and college systems with many locations are likely to lease high-speed data communication lines using fiber optics or microwave transmission. Large corporations and government/military agencies utilize satellite technologies for data transmission and network communications. It is also possible (and increasingly common) for people to connect to public networks or LANs using wireless technologies.

Regardless of the underlying technologies of a network, a considerable technological infrastructure is always required, in order to develop, and support a given network. A network infrastructure is comprised of hardware, software and support personnel. It is thought that the hardware and software required to support an Online Learning system are no more complex than that required in a general-purpose computer.

With the rapid growth of computer industry and spreading use of computer in education, such infrastructures will not be a problem any longer. Nowadays, most countries are ready for adapting online learning as a new education strategy.

2.4 Literature Review

A number of studies have been conducted associated with online learning. Each study discusses the status of one given aspect of Online Learning. Studies performed include the following:

2.4.1 Online Professional Interactive Network: Virtual Professional Learning Communities for Teachers

Supported by different types of professional interactive network examples, this paper summarises the functions of professional learning networks, the way to achieve information for meeting the goals of working professionals and the reasons of using electronically mediated networks. Also it gives examples of teacher support networks in New Zealand and compares them with international counterparts.

2.4.2 Internet Use in Schools: Legal and Ethical Issues

Internet gives children and young people access to the same information as adults, which causes a series of legal and ethical problems. When schools decide to get Internet connection, it is very necessary to consider these issues and make the Internet exactly be used for educational purposes. This paper discusses these legal and ethical issues and gives suggestions for schools on how to use Internet to its best advantage.

2.4.3 Designing Web-Based Learning Environment

This paper discusses some questions and provides some resources as to how to design a website for an online learning program. It provides the procedure of website designing and implementation with the principles of online learning website design.

2.4.4 Toward a Value Framework for Online Learning Systems

This paper queries the student concerning the features of these systems that add value to their learning experience. A questionnaire is utilized for gathering student values associated with online learning systems and organization supporting these technologies. Results from the survey and a literature review are organized in a proposed value framework for online learning course effectiveness.

3. Web Site Analysis

The major research method in this paper is website analysis. In subsequent chapters, the research results are gotten from the analysis made in this chapter. After reviewing a number of Online Learning websites, it has become apparent that such sites should be categorized, and discussed independently. In the field of online learning, websites serve for the following multi-dimensional topics and sub-topics [4].

Higher Education

K-12

Corporate

Health Care

Informal Learning (Museums, Communities, Homes)

Government

Military Training

Professional Associations & Non-Profits

In this paper, three main segments of online learning websites will be discussed in detail, including their unique features and an example will be provided as to a website that facilitates the defined category of Online Learning applications.

3.1 Online Learning Applications

3.1.1 Higher Education – University of Auckland

It is apparent that online learning methods are most extensively facilitated within Colleges and Universities. Due to the wide availability of computers, and the provision of basic computing education, within the Tertiary Education sector, Online Education can be widely implemented within their course offerings.

Currently, Online Courses offered by Tertiary Institutions rely on a web-based database for the storage of course materials and information (such as lecture notes, student grades, hyperlinks).

A relevant example within this category is Cecil (www.cecil.edu). Cecil can be viewed as the University of Auckland's Online Learning System. Students have the ability to access course materials, and course related information, from anywhere. Cecil provides a majority of the previously discussed online learning functions (namely, group email, a discussion forum, course information, and file downloading). Cecil accommodates all courses that are offered by the University of Auckland. The degree of utilization of Cecil appears to differ between departments and papers. Cecil also allows for the checking of coursework marks, and online testing functionality. It helps greatly for providing high quality education.

3.1.2 K-12 Education – The Global Lab (<http://global.terc.edu>)

For K-12 schools, online learning websites' major function is to provide an online library system. With the help of these online libraries, searches for books, journals, and other relevant sources of information become much easier. This indicates that schools are no longer constrained by the information contained within their limited number of textbooks, and library books.

Another popular application incorporated into Online Learning Systems within K-12 Schools, is the facilitation of collaborative projects. Collaborative projects may be implemented solely within one class, or spanning a number of schools. Students utilize the network to collect relevant information, and prepare documents in small-sized groups. A majority of such projects also require interaction with students at different schools (via email).

Other functions of OLS at this level include: linking to the outside world; storing curriculum resources and providing interaction.

An example of an implementation of an Online Learning System in Middle Schools is the Global Lab. The Global Lab is a large-scale science project that

involves in excess of 100 schools internationally. Students within participating schools must agree to collect, and analyze data that relates to some aspect of their local environment. Such analysis results are then placed on the Global Site website, in order to allow for the determination of global trends in each given aspect.

3.1.3 Corporations – Cisco Network Academy (<http://www.cisco.com/edu/academies>)

Corporate training is the largest among online learning market segments. In early 2002, it was estimated that as many as 350 companies were marketing learning-management systems (usually server-based software), educational content or online learning hosting services. Investment was put into the U.S. online learning market at \$2.2 billion last year [5].

Information technologists who have an in-depth understanding of networks are in high demand and are likely to remain so in the future. As a result, a number of networking companies play a pivotal role in the provision of such training. Cisco Systems is an example of such an organization. Cisco provides training through the Cisco Networking Academy. This academy is comprised of high schools and colleges internationally, that have been authorized by Cisco to teach a four-semester course in networking that will be examined at the conclusion of the course. If an individual is successful in passing the Cisco examination, then they are considered to be a Cisco Certified Network Associate or Professional. This academy is partitioned into regional and local sites. The regional sites have responsibility for training, supporting, and quality control of the course offerings at the local sites.

The Cisco Networking Academy can be considered to be a relevant example of an industry-educational partnership, which is beneficial to all involved.

Also based on the self-assessment survey completed by 3,560 Cisco partners, the online training program has improved their productivity significantly. For example, 74 percent reported an improvement in the ability to sell or service clients and 76 percent said that customer satisfaction jumped 50 percent or more [5].

3.2 NZ Online Learning Websites

A large number of OLN's serve the purpose of the provision of additional resources for teachers, as well as allowing for the exchange of information, and utilization of new technologies. Like other countries, online learning has been developing fast in recent years. New Zealand Learning Network can be considered to be a relevant example of New Zealand online learning websites.

3.2.1 New Zealand Learning Network

<http://education.otago.ac.nz/NZLNet/home.nclk>

The New Zealand Learning Network was established in 1998 and is being continuously developed and maintained by the University of Otago School of Education. The purpose of this information, service, and

discussion network is to provide an online teacher-centered resource that will support and assist New Zealand teachers in the process of integrating the Internet in the classroom. It does this by providing links with colleagues and other professionals locally and nationally, access to Internet information and resources for classroom use, and professional background material relevant to New Zealand teachers. Interaction online includes computer conferencing areas, online chat room, and news boards for posting of educational news.

The service facilities allow for contribution from members, in a number of ways. This includes the hosting of school web pages, and collaborative projects, organized by teachers, for other classes. Teachers are encouraged to contribute ideas to the site, and such ideas may be archived online. Members also have the ability to post news items of educational interest.

4. Results

4.1 Unique Features of Online Learning

Unlike any other training form, online learning promises to provide a single experience that accommodates the three distinct learning styles of auditory learners, visual learners, and kinesthetic learners [5]. By the advent and development of online learning more efficient training is provided to a globally dispersed audience. As Web-based training becomes a standard, publishing and distribution costs have been reduced.

Online learning also offers individualized education, which is impossible for print media. Under the wave of personalization, individualized learning form is more welcomed by adult learner and working people. Besides its individualized instruction, online learning can target specific needs. And by using learning style tests, online learning can locate and target individual learning preferences.

Additionally, synchronous online learning is self-paced. Advanced learners are allowed to speed through or skip instruction as needed.

In these ways, online learning can serve simultaneously for a maximum number of participants with a maximum range of learning styles, preferences, and needs. The experience and value of the visit; price, comfortable atmosphere, type of customer, friendly staff service and seating are the second set of elements that indicate a moderate increase to satisfaction. This indicates that customers are price sensitive so charging a premium is not an effective strategy, but yet customers still want a premium experience.

4.2 Basic Elements of Online Learning

Online learning requires some basic elements to support its functions. In the sequent paragraph, I will discuss such elements.

4.2.1 Email

Email is the foundation for all forms of online leaning and teaching. Indeed, it is quite possible to use nothing more than email in a course and still have a highly valuable leaning experience. Email is also a very cost-effective application in terms of computing and network resources required; it works with a minimum amount of equipment, software, and facilities. Furthermore, since web-based email is free, there is no need to purchase email software.

4.2.2 Threaded Discussion

Threaded Discussions are the second most commonly used element in online learning. It may also be referred to as asynchronous conferencing, a forum, or a bulletin board.

These systems work as: topics and subtopics are created, and people post messages under topics. Messages include the sender's name, a subject title for the message and the text of message. To read messages, an individual must select the topic of interest and choose the message available. Finally, a reply message can be posted below the topic.

4.2.3 Real-time Conferencing

Real-time conferencing covers any form of online synchronous interaction, the simplest form of Real-time conferencing is a chat session. A chat session enables participants to communicate with each other through the exchange of typed messages. Each participant has the ability to view the typed messages. Each message is preceded with the name of the message sender.

4.2.4 MUDs/MOOs

MUDs (multi-user domains) and MOOs (MUDs object-oriented) are an interesting category of real-time conferences used in some education settings. MUDs/MOOs

Allow many people to share a virtual world, usually set up as "rooms" containing objects that can be viewed or manipulated. People can interact with others by sending chat messages as well as performing simulated actions.

4.2.5 Desktop Video

The most advanced forms of real-time conferencing are desktop video systems. A desktop video system is mainly a chat system that uses video images instead of text messages. The video images (including audio) are captured by a small digital camera that is connected to the PC.

4.2.6 Audio-graphics

Audio graphics allows for audio interaction, and the sharing of graphical images, or applications. Conference participants have the ability to hear others comment, and view the graphical images or program screens.

4.2.7 Groupware

A relatively new category of software are groupware programs, which are specifically designed to facilitate group interaction. The MUD/MOO systems mentioned before are a specialized case of groupware for shared worlds..

4.3 Website Design Principles

When designing an online learning website, there are some principles needed to be followed:

4.3.1 Interactivity

One of the most important reasons for using the Internet as a learning environment is its capability to enhance interaction between teachers and students, and among students. In the online course, teachers can employ a range of synchronous and asynchronous tools in such a learning environment. The activities in such a learning environment should be interesting and stimulating.

4.3.2 Collaboration

All collaborative learning theory contends that human interaction is a vital ingredient to learning. Consideration of this is particularly crucial when designing online learning websites, realizing the potential of using web medium to isolate learners. With well-delivered synchronous distance education, and technology like message boards, chats, e-mail, and video-conferencing, this potential drawback can be reduced.

4.3.3 Social and Interpersonal Interaction

As the best environment for learning is a social setting, a Web-based course site should be designed to promote social and interpersonal interaction as well. The course website should be viewed as a virtual meeting place shared by all the students. Social interaction was a significant factor in contributing to knowledge construction in this environment.

4.3.4 User Control

In designing a user interface, we should follow Lai's five criteria [6]: easy to learn; easy to use; easy to remember; pleasant to use; and allowing for feelings of user ownership.

4.3.5 Structure and Management of the Learning Environment

A Web-based learning environment should be a flexible learning environment. A good management structure should include clear and explicit information on the assessment tasks, as well as just in time feedback on their assignments.

4.4 Benefits of Online Learning

By combining the new technology of the Internet with new thinking of how people learning, online learning brings a new era to traditional education. Some of the most outstanding benefits have been indicated [7].

4.4.1 Online Learning Lowers Costs

Despite appearances, online learning is often the most cost-effective way to deliver instruction (training) or information. It cuts travel expenses, reduces training time, and eliminates costs [8]. The elimination of costs associated with instructor's salaries, meeting room rentals, and student travel, lodging, and other infrastructures. When deployment is based on a sound business case, the significant startup investment can be quickly recovered through delivery savings.

4.4.2 Online Learning Enhances Business Responsiveness

Online learning can reach an unlimited number of people virtually simultaneously. This can be critical when business practice and capabilities are rapidly changing.

4.4.3 Messages are Consistent or Customized, Depending on Need

All can get the same content, presented in the same way. Meanwhile the programs can also be customized for different learning needs or different groups of people.

4.4.4 Content is More Timely and Dependable

Because it's web-based, online learning can be updated instantaneously, making the information more accurate and useful for a longer period of time.

4.4.5 Learning is 24/7

People can access online learning anywhere and any time. It's "just in time – any time" approach makes an organization's learning operations truly global.

4.4.6 No User "Ramp-Up" Time

With so many millions of people already on the Internet and comfortable with browser technology, learning to access online learning is quickly becoming a non-issue.

4.4.7 Universality

Online learning is Web-enabled and takes advantage of the universal Internet protocols and browsers. Concern over differences in platforms and operating systems is rapidly fading. Everyone on the Web can receive virtually the same material in the same format.

4.4.8 Builds Community

The Web enables people to build enduring communities of practice where they can come together to share knowledge and insight long after a training program ends. This can be a tremendous motivator for organizational learning.

4.4.9 Scalability

Online learning solutions are highly scalable. Programs can move from 10 participants to 100 or even 100,000 participants with little effort or incremental cost (as long as the infrastructure is in place).

4.4.10 Leverages the Corporate Investment in the Web

Executives are increasingly looking for ways to leverage their huge investment in corporate intranets. Online learning is emerging as one of those applications.

4.4.11 Provides an Increasingly Valuable Customer Service

Although not internally focused, a business e-commerce effort can be enhanced through the effective and engaging use of online learning that helps customers derive increased benefit from the site.

4.5 Drawbacks of Online Learning

Despite its benefits, online learning is still in its nascent stages. It does have limitations.

4.5.1 Technology Issues

This include whether the existing technology infrastructure can accomplish the training goals, whether additional tech expenditures can be accepted, and whether compatibility of all software and hardware can be achieved. For learners, these issues include commonly technophobia, unavailability of required technologies and inability of grasping the computer techniques.

4.5.2 Reduced Social and Cultural Interaction

The impersonality, over-dependence of computer techniques, suppression of communication mechanisms such as body language, and elimination of face-to-face communication are part of the potential disadvantage brought by the advances in communications technologies.

4.6 Summary

The pros and cons of online learning vary depending on their business goals, target audience and organizational infrastructure and culture. But it is apparent that online learning is rapidly growing as form of training delivery and it is clear that benefits to online learning will guarantee it a position in the overall learning strategies.

5. Future Trends

Online learning is the most rapid growing learning form in recent years. There was an evolution that technology-enabled learning and distance education changed to online learning. By now, more and more people agree that online learning is here to stay. So we need to examine some trends of this new learning strategy.

5.1 Online Learning as a Business Strategy

For smart companies, it's no longer a question of if, but when to use online learning. These organizations see online learning as a strategic solution that must be deployed to all employees. Enterprises consider online learning as a guarantee to increase sales effectiveness, improve organizational competency, and build rich customer relationships. Consequently, online learning will continue to be a part of organizational infrastructure, similar to email packages and other product suites used to increase staff productivity.

5.2 Blended Learning

This trend involves blended learning programs, designed to integrate online learning with traditional training methods to increase overall effectiveness. A single delivery method is no longer sufficient to handle new training needs. The construction of true blended learning programs pushes learning into a new age. Blended learning preserves the necessary consideration of how people learn while offers options for learning and can still produce measurable savings promised by online learning.

5.3 Moving from Discrete to Integrated Learning

There is an increased desire for a seamless transition from one learning activity to another. Rather than stand-alone learning activities, the trend is towards the integration of these activities. The trend is looking for seamless transitions from live group activities to individual exercises, from self-paced learning activities to synchronous instruction, from activities in smaller groups to activities in a larger learning community.

5.4 Online Learning Beyond the Corporation

Early adopters of online learning consisted mainly of corporations, which were trying to enhance face-to-face meetings, demonstrations, training classes, and lectures. Nowadays, government agencies, colleges, universities, and non-profit organizations are now followers. These organizations are using online learning to address their learning and communication needs, as well as expand their business opportunities.

6. Conclusion

Rapidly expanding network technologies increase the possibilities of online learning. It is, however, difficult to predict what technology will be the dominant driving force in online education delivery in the future. It is expected that, in this new century, tremendous advances in computers and networks will have dramatic effect of altering individuals' lives and the learning experience as well.

Abstract

The New Zealand mortgage market is undergoing tremendous change with more lenders, more offers, and more options available to the borrower to structure home loans to suit their needs. The rapid growth in use of the Internet by mortgage operations is both a consequence and a symptom of the rapid development of the mortgage market as well as of the underlying information and communication technology. Given the increasing number of online mortgage service providers and increasing advertising to promote awareness of their websites, it is important to evaluate the effectiveness of the Internet solutions. A multi-method approach (including website content analysis, two surveys, and interviews) was adopted for this study.

1. Introduction

As in so many other fields, the advent of the Internet has provided opportunities for doing old things in new ways. According to 2001 Census statistics, 1,368,204 dwellings were owned in the country, with 31% of dwellings owned with a mortgage. The mortgage broker who serves as the intermediary between the bank (mortgagor) and the customer (mortgagee) can play an important role in the daily lives of New Zealanders. A mortgage is typically a household's biggest expense. The Internet has already demonstrated its ability to be a critical competitive advantage for organisations that can provide better services for customers. With high Internet penetration in New Zealand and the local penchant for adopting new technologies, the possible market for e-mortgages is substantial. It is therefore worth studying the effectiveness and trends of Internet mortgage services in New Zealand.

The main objective of this research project was to evaluate the effectiveness of the mortgage provider and broker websites in New Zealand. The current situation and performance of all identified e-mortgage services were explored. Questions such as "Does e-mortgage provide a better service than the traditional way?" and "Will e-mortgage change the way New Zealanders arrange, and/or pay, their mortgages in the future?" were addressed.

A multi-methodological approach was used. Websites and other electronic communications were analysed, the institutions offering e-mortgages and brokering were interviewed, and potential and current clients were surveyed.

2. Study Methodology

Due to the exploratory character of this research, data collected using multiple methods and from multiple sources were considered necessary to add rigour to the study [10]. This suggestion was affirmed by Mingers [4] within the context of information systems research; he asserted that a multi-methodological approach by combining different research methods would produce more reliable and richer research results. A multiple-methods approach was therefore adopted to provide a more complete picture of the online mortgage industry. The research methods utilised and their primary purposes are as follows:

Content analysis, which focuses on the characteristics of the online mortgage services websites, was used to assess and rank site capabilities against the model proposed to serve as a benchmark.

Two *surveys* were used to investigate the industry's Internet usage and to obtain consumer perceptions about online mortgage services capabilities, respectively. One survey was targeted at online mortgage brokers, the other at customers.

Interviews were conducted to gain an in-depth understanding of online business operations from the perspective of the mortgage market players.

2.1 Content Analysis

Berger [1] described content analysis as a communication media research technique based on quantitative means, for example, counting the amount of the presence of identified elements used to measure the concept in the study. To conduct such an analysis, a predefined model is required to serve as a benchmark. Therefore, content analysis in this study consists of two steps. Tailored online mortgage site evaluation models were developed, followed by a process of systematic analysis of websites. Before starting with the content analysis and the survey, an online mortgage website evaluation model was initially developed to provide the fundamental background to the study.

Based on a literature review of items relevant to website evaluation, in particular to measurement of online financial operations [3] [5], and preliminary observations of the New Zealand online mortgage websites, standards for measuring the mortgage sites were established. The primary ideas of the model are the components in Hersey's e-commerce website evaluation model and the categories in the abstract site usability model [7]. Due to

the unique features of each industry some of the components and /or categories considered to be inappropriate were tailored to meet the requirements of the online mortgage services market. The same approach was adopted by Satitkit [8] and Chung [2], who developed the adjusted models for measuring travel industry websites and Internet banking services, respectively.

2.1.1 Evaluation Model Components

This general online mortgage website evaluation model has six dimensions used to measure the concept of an effective online mortgage website, with each dimension consisting of several elements. Due to differences in their types of business operations, the model for online mortgage lending evaluation varies slightly from the model for online mortgage broking websites. The online mortgage broking model is depicted in Figure 1. In general, the online mortgage site evaluation model consists of six categories. These categories are:

- ¾ Information
- ¾ Mortgage transactions
- ¾ Trust
- ¾ Ease of use
- ¾ Marketing and customer focus
- ¾ Non-functional requirements

Content analysis should be a multistage and systematic process [9]. This point is also illustrated by Neuendorf's flowchart [6] for the typical process of content analysis research. The description of the process employs three main steps, sampling, coding, and analysis.

2.1.2 Sample Identification

The mortgage sites came from various sources:

1) 35 mortgage lenders' sites were collected from two websites located at: <http://www.nzherald.co.nz/money/ratetables/html/mortgagerates.htm> and <http://www.interest.co.nz/mortgages.html>, respectively. The New Zealand Herald online edition was ranked as among the top twenty by Hitwise (at <http://www.hitwise.co.nz>), the industry leader in comparative website monitoring and analysis. Interest.co.nz serves as a guide for the best options of interest rates derived from almost all professional organisations in the money market, including both banks and other financial institutions.

2) 40 mortgage brokers' sites were identified via the NZSearch search engine (a well-known web directory in New Zealand), via the Yellow Pages online edition finance section (at www.yellowpages.co.nz), and from the first survey conducted at the preliminary stage of this study.

The list totalling 75 online mortgage service websites in New Zealand, all that could be identified, constitutes the sample population of this study.

2.1.3 Coding

All of the sample sites were evaluated by using the same coding scheme. Binary scores (0 or 1) were used to

record the appearance of the characteristics on the sites against the two predefined models. A score of 1 is assigned to the elements identified while looking at the websites. In contrast, a score of 0 reflects the absence of such an element. It should be noted that some elements, such as page loading speed, and page presentation could not be simply scored by establishing their occurrence. Attitudes to such elements differ from person to person, therefore judgment of these elements tend to be somewhat subjective. To attempt to limit the subjectivity rules in terms of a range or a list of acceptable requirements are defined. The elements with performance within the accepted range or meeting the requirements were judged as 1, otherwise they were scored as 0.

The major advantage of this coding is that it maintains objectivity. Each site was assessed three times in order to minimise or eliminate judgment variance. Microsoft Excel was used for coding, which took place on 20 March 2002.

2.2 Surveys

Two surveys were carried out in the study, targeting industry players and consumers respectively.

The first survey outlines Internet usage in the mortgage broking industry. Members of the New Zealand Mortgage Brokers Association (NZMBA) were selected as a representative sample. The survey was administrated via e-mail. A list of the email addresses was collected from the New Zealand Mortgage Brokers Association website located at <http://www.nzmba.co.nz>, section "locate a member." The emailing list there is arranged on an organisation basis. Some organisations such as Mortgage Link Ltd, which is a co-operative of selected 35 offices and 65 mortgage brokers throughout New Zealand, Mike Pero Mortgages and Mortgage Choice with a franchise model are deemed as one single organisation specified in the study. They and their members share the same site. The survey was distributed twice within a period of ten days due to the limited response of the first survey.

The second survey was a web-based survey. It was created and published using WebSurveyor Corporation's online survey software and hosting services. It is ranked highest by PC Magazine for ease of use in America and located at <http://www.websurveyor.com>. The online mortgage web survey was published at <http://websurveyor.net/wsb.dll/8390/online-mortgage-websurvey.htm> on 26 March 2002 for a period of three months. In addition, this site was posted online on 24 April 2002 through link at <http://www.propertyinvestor.co.nz/>, a Residential Property Investor Magazine in New Zealand. Other means such as university staff and postgraduate students mailing list and newsgroup sites in New Zealand were used for the site promotion.

2.2.1 Pilot Test

Prior to publishing the mortgage web survey online, a hard copy version of the questionnaire was pilot tested by seven people including lecturers and postgraduate students. They were chosen because they are mortgage

borrowers and/or experienced Internet users. Inappropriate expressions of items or scales were modified to make sense and be logical. A revised questionnaire was tested again to assure the reliability and validity of the survey. Due to the characteristics of a web survey's presentation, four staff and postgraduate students in the MSIS department of the University of Auckland tested the final online version of the online mortgage survey.

2.3 Interviews

Interviews were conducted to gain an in-depth understanding of online mortgage operations from a mortgage market player perspective. The main emphasis was on strategy issues of online mortgage solutions in the mortgage industry. Major players who use the Internet for doing online mortgage business and /or the top 15 sites, ranked as the most innovative online mortgage sites in website content analysis in this study were invited to participate. Three organisations agreed to participate in the study. They are as follows, in the order of our obtaining permission to conducting interviews.

Mortgagenet Investments Ltd www.mortgagenet.co.nz

Wizard Mortgage Corporation www.ewizard.net.nz

Cains Lockie Mortgage Banker www.emortgage.co.nz

3. Analysis

3.1 Survey Results

3.1.1 Industry Survey

The data in this survey were gathered from the mortgage broking industry survey emailed (except one which was required to sent by post) to the NZMBA members. There were 120 unique sites of which 110 took delivery of the email (i.e. 10 messages failed). Twenty-four responded via email; four dropped out for reasons of company voluntary liquidation, duplication, enquiry, and unwillingness to be involved. Therefore, the response rate of 18% resulted from 20 completed and returned valid questionnaires. Fifteen replies were collected via email, four via fax, and one by post. The three key findings from the industry survey are:

(1) There has been a rapid growth of Internet presence in the mortgage broking industry in New Zealand, accounting for 40% of those studied. Although the adoption of the online mortgage service lags by several years compared with other financial services, such as banking, the entire mortgage broking market has been experiencing an increase in online mortgage operations in recently years.

(2) The field of online mortgage broking in New Zealand is relatively new. The Internet is mainly used as an advertising and brand-building tool; the majority (87.5%) of the mortgage broking sites are information-based rather than providing transactional facilities.

(3) The effectiveness of the web operation is still a major concern. First, the current online mortgage broking

service is considered to be less effective, as the majority of mortgage brokers (70 percent) surveyed indicated feeling neutral on the degree to how satisfied they are with their web presence. Second, brokers have not been convinced an increased amount of business has been generated from an online service, therefore they are watching, waiting for market trends, and then planning, rather than making decisions in a rush. Third, the effectiveness of investment in time, cost, and effort versus returns is taken into account. Finally, a personal touch is considered to be critical in the mortgage business.

3.1.2 Consumer Survey

People in their 30s and 40s are more likely to use an online mortgage service to arrange their mortgages. 49 out of 65 respondents (75.4%) were aged from 30 to 49. Increasing educational levels have contributed to the ability of customers to accept the online services. Half (33 out of 65 or 50.8 %) of customers are property investors, followed by first home buyers, accounting for 26.2% (17 out of 65). This would be a useful guide for developing a mortgage website, particularly the content design, when considering the target audience.

Mortgage borrowers are still comfortable with traditional services to arrange their mortgages. Face-to-face is regarded as an essential component of a mortgage business. In addition, mortgage borrowers are more likely to make a mortgage application in a traditional way rather than taking an online application.

Customers primarily use mortgage websites as an information gathering medium and an educational tool. The majority of the respondents access mortgage websites for the purpose of information-related activities such as shopping for mortgage rates, making comparisons among mortgage options, and gaining market intelligence. This was reflected in comments made by the customers on desired future improvements, which mainly included a desire for more detailed information, more options for comparisons, more powerful functionality, and faster response. Interactive features received more attention among the site users. Facilities in the forms of a powerful mortgage calculator, enquiry email, and various e-forms such as comments, feedback and request forms gave customers a good sense of two-way interaction. The lower percentage of transactional facility usage may be attributed to the fact that they were not popular at this stage, as well as that the website itself was not fully geared for mortgage business transactions. The absence and or the lack of such facilities were also observed in the content analysis of the mortgage websites.

Timesaving, convenience and reduced cost are the major benefits experienced by the online mortgage customers. In fact, the Internet has already demonstrated its ability to have a powerful impact on changes in time, cost and service. The online mortgage service is simply one reflection.

Participants felt more strongly about the importance of certain elements. Like most e-business consumers, the mortgage consumers are concerned with security issues.

Safety of information storage and transaction was ranked as the biggest concern of the customers. Information attracts considerable attention from the customers. There is an increasing demand for more up-to-date, more accurate and more detailed information displayed on a mortgage website. It is interesting to note that online servicing and electronic advice on mortgage options were important to the customers this survey reached. This would imply an increased awareness of the benefits of using online transaction processing. Therefore, changes in the mortgage facilitation process are expected. Other important issues include response time, page loading speed, and interactive tools. In contrast, some issues related to site marketing such as site brand, site innovations, and site personalisation are not considered to be important factors for a mortgage website. The low importance of e-subscription as perceived by the customers was contrary to what the mortgage service providers thought.

Although there is tremendous room for more effective mortgage website operation in New Zealand, overall the customers were satisfied with the current online mortgage services and indicated a greater probability of future adoption of online mortgage services.

3.2 Content Analysis

Content analysis, used to evaluate the effectiveness of the online mortgage websites, is quantitative in nature. The content domain chosen for examination in the study is of the online mortgage websites in New Zealand. The sample includes thirty-five mortgage lender websites and forty mortgage broker websites. The content analysis process followed the Neuendorf [6] flowchart for the typical process of content analysis research. The websites surveyed were evaluated based on the benchmarking models developed. Two evaluation models in terms of mortgage lending sites and mortgage broking sites consist of six dimensions, namely information, mortgage transaction, trust, ease of use, marketing and customer focus and non-functional requirements, but they differ in a few elements.

3.2.1 Lender Site Content Analysis

According to <http://www.interest.co.nz>, which also has a link from <http://www.nzherald.co.nz/money/>, there were fifty-six institutions providing their mortgage rates and products through the observation conducted on 18 March 2002. These included eleven banks, four trustee companies, nine building societies, five insurance companies and twenty-seven finance companies respectively. Out of the 56 mortgage lenders, 35 were found to have an Internet presence, via the web directory at <http://www.nzsearch.co.nz> by entering key words such as institution name. This gives an Internet usage of 62.5% for the mortgage lending industry in New Zealand.

The average score of each site, or the average number of elements used by a selected mortgage lender site was 15.8 per website, less than 17, the 'pass' or 50% mark for

representing all the 34 elements required in the evaluation model. Therefore, this figure reflects a fact that the overall adoption of elements measured on mortgage lender sites was low.

Additionally, the average numbers of elements utilised per website for different kinds of organisations was calculated. They are 21.3 (213/10) for the banking sector, 15 (60/4) for trustee companies, 13.75 (55/4) for insurance companies, 13.5 (162/12) for finance companies, and 12.4 (63/5) for building societies respectively. These average scores provide for comparisons among the different types of mortgage lender organisations. Other than the banks, which have a higher adoption of the elements required in the mortgage lender evaluation model, the others have a low occurrence of the identified elements.

3.2.2 Element Score Analysis

The same method as described above was applied to the calculation and the presentation of scores gained by each element across the selected population of the mortgage lender sites. The elements with higher scores illustrate their importance and / or usage in developing mortgage lender websites. The dashed line shows the maximum value obtainable for an element. The sample population of 35 mortgage lender sites determines this maximum value.

The average score for all elements, or the average number of organisations using an element, was 16.3 (553/34). The averages for each element were also calculated across the six dimensions classified in the evaluation model. They are 32.3 (97/3) for the information dimension, 9.1 (91/10) for mortgage transactions, 18.7 (56/3) for trust issues, 18.75 (75/4) for ease of use, 12.0 (132/11) for the marketing and customer focus dimension, and 34 (102/3) for non-functional requirements. These average scores show that the elements adopted by the organisations vary significantly with respect to the different dimensions to which the elements belong. Non-functional requirements and information received the most attention by the lender organisations, accounting for 97.1% and 92.3%, respectively. In contrast, the usages of the capabilities in terms of marketing and customer focus and mortgage transaction were low, accounting for 34.3% and 25.7%, respectively.

3.2.3 Broker Site Content Analysis

The average score of each site, or the average number of elements used by a mortgage lender site, was 14.1 (564/40) per website, which was less than 17.5, the fiftieth percentile for all the elements required in the evaluation model. Therefore, this figure indicates that the adoption of the elements measured in the model was below what may be expected. The overall standard of the online mortgage service website design was relatively low; they provide limited facilities at the online mortgage sites. The result is consistent with the observation of the lender sites.

The average scores for each element, or the average number of the organisations that use a specific element was 16.1 (564/35). The averages for each element were also calculated across the six dimensions classified in the evaluation model. They are 30.2 (151/5) for the information dimension, 10.25 (82/8) for mortgage transactions, 12.75 (51/4) for trust issues, 10 (40/4) for ease of use, 12.73 (140/11) for marketing and customer focus dimension, and 33.3 (100/3) for non-functional requirements. These average scores show that the dimensional average scores varied considerably. The information and non-functional requirements dimensions were considered essential parts in mortgage broker website design, accounting for 75.5% and 83.3% respectively. In contrast, the remaining four dimensions have an unacceptable level of organisational adoptions, accounting for only 25.6%, 25%, 31.9%, and 31.8% respectively.

The interviewees represented small organisations that had been in the mortgage lending and/or broking business for between 3 to 6 years. They used a combination of DIY and outsourcing to develop and maintain the site. Having up to date information was considered to be essential by all of them.

What are the factors that contribute to a successful website? "It must be easy to use; it must be very clear, (clear with the content), nice straight letters, you know, clear like that (show me a white paper with black letters on it). It's going to be quick down loading, very quick down loading, easy to navigate, Yes, very easy to navigate, easy to use."

3.3 Interview Results

All three interviewees stressed that the business could not just be electronic, but would be one component of an overall strategy "I think it's an ideal way to transact mortgage business, um, there are a couple of blockages, people have to sign mortgage documents, and also people still like talking to people, so the human factor is still evident, I think the Internet is going to be a helpful strategy, it's a part of your strategy. Here, we are not totally to rely on the Internet, the Internet is an important channel, and also an important marketing mechanism, but it's integrated with all the other marketing." Another found "You have to have the face-to-face to support the Internet presence"

The Internet site was seen as a communication channel, one that could allow the broker to make the initial contact and allow people who were overseas to invest in property in New Zealand and to take up a mortgage to do so. "I've got clients living all around the world now - Sweden, Japan, the USA, the Philippines, France, England. I could have never got without the Internet, too hard to find them, I can find them, now they can find me which is nice." The development of a mailing list or similar strategy was also seen as the major selling point of their business, although each had their own unique way of promoting this. "I've got a database now, it's actually close to 5000 subscribers

I've built up, and it's taken me five years to build that database. But it's good target marketing because ... most are property investors, because that's whom my site is designed to attract."

4. Discussion and Conclusions

In general, the online mortgage service sites that scored in the high category are considered fairly good with respect to the design and implementation of the six dimensions identified in this study. On one hand, they are informational in nature; on the other hand, they have a sophisticated web presence, not only offering a wide range of capabilities such as online transactions, online tools, and e-marketing incentives, but also taking advantage of new IT technologies to enable an interface with site navigability and media richness. Most of the high scoring online mortgage provider web sites represent leading players in the mortgage market in New Zealand.

Both mortgage lender and mortgage broker organisations represented multiple strategic business considerations on their websites, covering six dimensions in this study. This is consistent with findings from the literature. However, the performance of each dimension differs quite significantly. Six dimensions surveyed in the content analysis comprised information, mortgage transaction, trust, ease of use, marketing and customer focus, and non-functional requirements. Figure 1 provides statistics on specific site characteristics (elements) for the Broker sites. Information and non-functional requirement were the most frequently implemented elements. Most sites did fairly well with in terms of page loading, the use of graphics and animation, and the content organisation and presentation. Websites examined did not make heavy use of the site for marketing and customer focused activities. Activities such as mortgage glossary, site personalisation and e-subscription, were used by few of the responding organisations. Only two of the mortgage lenders provide site customisation, and none of the mortgage broker organisation applied this function to their websites. On the mortgage transaction side, the performance was considerably poor. The online tools used to process a mortgage arrangement were provided by very few organisations. About 31.4% of the mortgage lender and 40% of the mortgage broker offer an online application. None of the online mortgage service providers offer online mortgage approval. When we consider ease of use, although the overall navigability of the sites was considered good with the use of navigation tools, location indicator, and internal and external links, other facilities such as site map, online help and search function appear at relatively few online mortgage service sites.

The results of the content analysis allow a comparison between lender sites and broker sites (Table 1). The mortgage lender sites outscore the mortgage broker sites in terms of the overall capabilities and performance of the online services provided satisfaction.

Figure 1: Scores for each element on mortgage broker sites

Table 1. Online mortgage websites score summary

	Lender Sites (Total 35)			Broker Sites (Total 40)		
Site Scores	Low (17 or lower)	Medium (18 to 24)	High (25 to 34)	Low (17 or lower)	Medium (18 to 24)	High (25 to 35)
Percentage	22 (62.9%)	9(25.7%)	4 (11.4%)	30 (75.0%)	7 (17.5 %)	3 (7.5%)
Summary	$\frac{3}{4}$ Most of the sites providing online mortgage services received low scores $\frac{3}{4}$ Bank sites dominated the high scores with 7 in the top 10 $\frac{3}{4}$ Three non-bank sites also were ranked in the top 10 $\frac{3}{4}$ Overall, online mortgage lending sites are of poor performance			$\frac{3}{4}$ Most of the broker sites received lower scores $\frac{3}{4}$ The sites ranked in the top 10 included the most visible mortgage broker sites and primarily those among the medium and leading players in the market $\frac{3}{4}$ Overall, online mortgage broking sites performed poorly		

ACKNOWLEDGMENTS

We would like to thank the mortgage brokers who replied to the survey and the banks and brokers who made themselves available for interviews. We also would like to record our appreciation of the industry sites that allowed links to our survey to be maintained at their site.

Abstract

1. Introduction

Recent research has been carried out investigating the integration of e-commerce in major industries such as travel agency [12], e-mortgages [6] and banking [9]. Most of this research indicated that e-commerce potentially plays a major role in the business process of these organisations. This paper examines real estate agencies in the same way, as e-commerce redefines how the intermediary between seller and buyer may operate. The impact, benefits and implication of Internet on real estate agency have been investigated in the literature review. This study seeks to explore current situation and performance of the online real estate agency website in New Zealand, and to determine crucial web elements for this industry and to propose a tailored model that will serve as a benchmark for evaluating online real estate agency websites in New Zealand.

2. Background

2.1 Electronic Commerce

Rapid development in information technology, such as the Internet, broadband communications, networking and digitalisation of households, creates new forms of collaboration between seller and buyer. Peffers [11] and Turban et al [14] identify such collaboration as electronic commerce (e-commerce). With growing globalisation and deregulation, competitive strategies such as differentiation and cost leadership start to lose their effect [2]. Firms must now take advantage of the new technology and expand theirs into the e-commerce environment, in order to compete.

2.2 Real Estate Agency

The role of real estate agency is to facilitate the property transaction between buyer and vendor. This includes aiding the buyer to buy the property, aiding the vendor in selling their property and advising both parties best interest. A broker, who has license that can legally convey property, heads the agency. Within the real estate agency there are several agents, they have a contractual relationship with the agency [3]. The roles of real estate agent involve acting for the buyer and vendor, and maintaining interpersonal interaction with them in different roles.

Typically, real estate sales usually involved five stages. There are listing, prospecting, servicing, negotiation and agreement, and closing as identified by Wofford and Clauretie [16] (cited in [1]). These stages are essential for a real estate transaction to occur.

2.3 Internet Penetration in NZ Real Estate Agencies

The two vital real estate websites in New Zealand are REINZ (<http://www.reinz.org.nz/>) and RealENZ (<http://www.realenz.co.nz/>). REINZ is the official website of the Real Estate Institute of New Zealand (REINZ). RealENZ is associated with REINZ, which is the official property directory of REINZ. RealENZ list all the properties from different real estate agencies that submit the properties to them.

A list of 467 real estate agencies based in Auckland District was obtained from the REINZ website on 31st October 2002. This list is believed to be exhaustive given the fact that all real estate agencies in New Zealand are required to register with REINZ. 73% of the 467 real estate agencies in Auckland have their email address included in their contact detail. This suggests that most real estate agencies have access to the Internet. 32% of the 467 real estate agencies include a website in their operations. However, only 21% of the real estate agencies with a website have their own domain and website content, while the majority of them provide content through REINZ website, implying that the penetration of websites in the real estate industry in Auckland is relatively weak.

2.4 Potential Property Buyer and Internet Real Estate Agency

This section attempts to understand the relationship between the consumer, the property buyer, and online real estate agency. To understand such a relationship, we begin by exploring the classical decision-making process. Classical decision-making consists of five stages, namely problem recognition, information search, evaluation of alternatives, purchase decision and post purchase behaviour. According to McGaughey and Mason [7], the Internet can successfully influence all the stages of the decision making process from stimulating problem recognition to supporting post purchase behaviour.

However, in the real estate industry, the Internet serves as a mechanism to enhance the information search stage of the decision making process. Littlefield [4] reported that a significant proportion of consumers tend to use the

Internet to enhance the information search phase of the home purchasing process. This is because one transaction in the real estate industry usually involves a large sum of money. Littlefield indicated that the Internet enables the consumer to purchase houses conveniently and efficiently through obtaining online real estate information. Such information includes information relevant to the property such as prices and features, and also information irrelevant to the property such as real estate agent information, demographic information of the areas. Thus, the information-intensive Internet has proven to be a very powerful tool for such an information-intensive and information-driven industry.

2.5 Impact of Internet on Real Estate Sales

The Internet has brought significant impact to the real estate. The impacts are translated in terms of changes in the real estate processes. According to Alberts and Townsend [1], the Internet affects all five stages in the real estate sales as mentioned previously. In the listing stage, the Internet allows vendors to list properties online through a real estate agency website. These properties are then available for a potential buyer to search and browse on the agency website, this is the prospecting stage.

In the servicing stage, technology such as 'virtual tour' eliminates the need for the buyer to view the house physically. Instead, the buyer is able to inspect the property with 360 degrees panoramic view throughout the property, using the Internet. The Internet also enhances the negotiation and agreement stage such as allowing the buyer to apply for a loan [6] or contact a lawyer online. The Internet could also give the real estate agent the ability to communicate with the buyer and vendor through e-mail, thus the agent could facilitate negotiation between vendor and buyer through e-mail. Unfortunately, the Internet is currently unable to close a transaction online. However, there are websites such as Property Transaction Network (<http://www.theptn.com>) that offers a secure environment in which to exchange documents privately between vendor, buyer and other parties involved in the transaction [1].

In general, the Internet enables firms to increase revenue through increased sales and reduced expenses by cutting administrative and operating expenses [5] [13]. It provides another alternative channel for real estate agencies to market their properties. Traditionally, agencies would incur expenses in marketing their properties through intensive distribution of property brochures, or other costly activities that would distinguish themselves from their competitors. However, with the use of the Internet, smaller agencies can afford to market their properties to a wide audience.

3. Study Methodology

Content analysis is employed to evaluate and analyse web site content in order to determine crucial elements for this industry as well, as determining their strategy. We

start by proposing a tailored website evaluation model for real estate agency websites. This involves gathering dimensions and elements of the website contents; and then evaluation of real estate agency websites with the tailored model. This requires selecting websites from the 151 found, coding to obtain data and conduct analysis on the data. The web sites selected all had to have their own site (rather than be a part of others e.g. Yellow Pages TM or RealENZ, or a branch of a parent site), and deal in residential property in the Auckland region. We reviewed all 31 that fitted these criteria to identify the crucial elements for this industry. Elements that are perceived to be important are noted down, while elements that are common in a number of websites will also be noted down. As indicated in the literature review, the real estate website serves to augment consumer information search phases, thus it is important to focus on the element that reinforce quality of information. Through this exercise, a handful of elements are identified.

Due to the nature of the real estate agency operation, some elements from Hersey's model (as cited in [15]) are deemed inappropriate and inapplicable. Such elements will be omitted. The following indicate the list of elements that will be omitted from the Hersey's model along with an explanation.

[Negotiation], [Order], [Payment] and [Delivery]: These elements are not applicable to real estate agency website because face-to-face negotiation is still required and essential. This is due to the fact that the nature of the transaction in the real estate industry, particularly in change of ownership, always involve large sum of money.

[After-sales] and [Community]: These elements are not applicable to the study mainly because they are usually supported through email communication. However, email communication does not constitute a website element. Therefore, these elements will be omitted from the study.

The selected elements from Hersey's model are shown in Table 1.

Table 1. Elements from Hersey's model

Search	Company	Customer	Product
Performance	Ease of Use	Aesthetic Effect	Innovation

3.1 The Tailored Model

The elements obtained from site observations will be used in conjunction with the selected elements in Hershey's model to form the tailored model. Eight categories are defined as crucial elements for capturing the elements of quality for the tailored model. These eight categories are shown in Table 2.

Table 2. Elements for the tailored model

Property Search Criteria	Property Information	Relevant Information	Organisation Information
Price range	Photo tour	Job opportunity	Agent
No. of bathrooms	Virtual tour	Featured home	Branch
No. of bedrooms	Rigorous	Open home	News
House type		Sponsorship	Contacts
Suburb		New information	About us
Region		Local/Community	
Sales type		Tips for seller	
		Tips for vendor	

Appearance	Ease of Use	Relevant Features	Trust
Innovative	Help with website	Property appraisal	Legal disclaimer
Aesthetic effect	Site search	e-subscription	Privacy statement
Presentation	Sitemap	Other language	Other
	Navigation	Feedback	
	Favourite property	Useful links	
		Cookie	
		Mortgage	
		Calculator	
		Sell property	
		Performance	

All the elements indicated above are relevant to the real estate industry. However, it is clear that transactions that occur in the real estate industry involve three parties, namely buyer, vendor and real estate agency. The real estate agency, thus, has to ensure itself to function efficiently to satisfy both the buyer and vendor market.

The second part of content analysis involves a series of simple processes that include selecting the sample for evaluating, coding and analysis. These processes are generalised from the Neuendorf's [8] flowchart for typical process of content analysis research. When the sample is obtained, the coding process begins by evaluating the pool of sample website with the tailored website evaluation model for real estate agency through the process of assigning binary of 1 (the element is present) or 0 (absent), which is then analysed. Of the sample of 31 real estate agency websites, only 26 websites were analysed, as the other 5 websites remained inaccessible throughout the coding period.

4. Results

Under the 'Property Search Criteria' dimension, very few sites provide search criteria for 'Sales Type', while half the sites provide search for 'No. of bathrooms'. However, the elements 'Region', 'Suburb', 'House Type', 'No. of Bedroom' and 'Price Range' are very common to most websites, (ranging from about 50%-70%) of the websites. This may suggest that the sites that have search features usually provide all these five elements together. Under the 'Property Information' dimension, only 34% of websites provide rigorous information on a particular property while 38% of websites use both 'Virtual tour' and 'Photo tour'. The 'Virtual Tour' capability usually provides 'Photo Tour'. Thus sites supporting any of these elements tend to have these two elements together. 58% of the websites provide the element 'Featured Home', making it the most common element in the 'Relevant Information' dimension. 'Tips for Vendor', 'Local/Community', 'New Information' and 'Market Report' all have the same proportion of websites using these elements at around 30%. The element with the lowest proportion is 'Sponsorship', with only 23% of websites providing it.

The most significant findings for Organisation Information dimension are that over 90% of the websites have the 'About Us' and 'Contact' elements, an indication that they are the basic elements for real estate agency website. 'News' and 'Branch Information' are the least used elements at websites, at about 38% and 46% respectively.

'Navigation' has the highest proportion with 80% of websites scoring such an element, which suggests that many websites identify the need for good navigation. However, under this section, a significant proportion of websites did not hold any one of the elements apart from 'Navigation'. 96% of websites scored on 'Presentation'. Only about 58% and 27% of the websites have the elements 'Aesthetic effect' and 'Innovative'. This suggests that real estate agency perceive 'Presentation' as more important than 'Innovation'. Good 'Presentation', in general, is cost-effective and easier to achieve than being 'Innovative'. The common elements in the 'Relevant Features' dimension are 'Performance' and 'Useful Links' with about 77% and 70% respectively of the websites having such elements. Elements such as 'List property', 'Cookie' and 'Property Appraisal' have the same proportion of websites at 19%. The proportions of websites that use elements in the 'Trust' dimension are relatively low, 35% for 'Legal Disclaimer' and 27% for 'Privacy Statement'.

The overall performance of each dimension from our web evaluation model of Auckland real estate agency websites is shown in Figure 1. It shows that most websites in our study focus on Property Search Criteria, Organisation Information and Appearance, while Ease of Use and Trust appeared to be two of the lowest. The scoring for each of the elements can be found in Appendix 1.

Fig. 1 Overall performance of each dimension

There has been a rapid growth of Internet presence in the mortgage broking industry in New Zealand, accounting for 40% of those studied. Although the adoption of the online mortgage service lags by several years compared with other financial services, such as banking, the entire mortgage broking market has been experiencing an increase in online mortgage operations in recent years.

5. Discussion

The elements found in New Zealand real estate agency websites reflect an informational basis. That is to say that none of the sites could facilitate or perform a transaction through the website. Most of the sites managed to provide a majority of the elements in the 'Property Search Criteria' dimension.

Features such as virtual tour require considerable resources to implement, which usually involve a process known as object modelling that can capture 360-degree panoramic views from a standing point. Although less than half the real estate websites in the study provide features such as virtual tour, the proportion of the websites that provide this feature do so via third party websites. Two major third parties that provide virtual tour primarily for real estate agencies in New Zealand are Open2view (<http://www.open2view.co.nz>) and Virtualtours (<http://Virtualtours.co.nz>). Agencies such as Bayleys or Harcourts are an example of real estate agency websites that optimise the use of such a feature.

Some of the elements in the 'Relevant Information' dimension require a significant amount of resource. It is unlikely that smaller real estate agency can support this. Thus, large international real estate agencies such as the Professionals and Bayleys benefit from this dimension by providing elements such as 'Market Report' and 'Sponsorship' those smaller real estate agencies might not provide. Large real estate agencies tend to have the resource to update their website regularly too. The smaller real estate agency websites that score well in this dimension tend to take advantage of the elements that require fewer resources. Sawyer Real Estate is among the list of small local-based real estate agency that has the same score as the majority of the large international real estate agencies by providing elements such as 'tips for buyer and vendor' and 'local information' that require less resources.

Once again, the websites that top these dimensions are mostly the large real estate agency or ones that operate internationally. The smaller agencies tend to under-perform in elements such as 'News'. The reason is that 'News', such as newsletter, maybe costly for smaller real estate firms to produce. Another reason why smaller real estate firm score less in this dimension is because smaller real estate agencies usually only have a single branch, thus they automatically miss out the score for element 'Branch Information'.

Over 80% of the websites in the study scored in the element 'Navigation'. This suggests that most websites grasp the importance of navigation to the user. The only websites that score over 60% of the elements in this

dimension are Barfoot and Thompson and Wrightson Ltd, both of which are large firms with considerable resources. The element 'Favourite Property' is also found mostly in large real estate agency websites.

The findings suggest that not most websites score high in this dimension, they include both large and small real estate firms. Good 'Presentation' proved to be common to most real estate websites. However, a large proportion missed out in element 'Innovative'. Once again, the proportions of websites that include 'Innovative' in their websites are mostly large real estate firms.

The top four websites that top this dimension are, again, large real estate firms. Most websites take advantage of the element 'Performance' and 'Useful links'. Others benefited from providing 'Mortgage Calculator' directly from their website, which is reasonably easy to implement. Interestingly, the websites that provide the 'List Property' feature for vendors are mostly moderate or small real estate firms. Likewise, only two websites provide 'Other language' capability suggesting that elements in this dimension do not require significant resources, and can be easily provided by small firms, even though websites that top this dimension are large companies.

The proportion of websites that have many of the elements in the 'Relevant Features' dimension is low. A number of the websites do not have the subscription feature. The elements in this dimension are usually associated with the subscription as this brings visitors back to the site. Thus, sites that do not have subscription feature tend to exclude such elements from their website.

5.1 Study Limitations and Future Research

The samples of websites used in the study are all based within the Auckland district, as defined in REINZ's website. Although, a majority of them are nationwide agencies, it does not necessarily give an accurate complete representation of New Zealand real estate agency websites.

The tailored web evaluation model generated from the study is subject to personal inference to some degree. The elements selected for the tailored model may hold different interpretations for different individuals. Thus, the coding process would have resulted in slightly different findings if performed by different individuals. It should also be noted that only one person did the coding, which is potentially error-prone. The tailored web evaluation model could be enhanced using a survey to capture user perception on the crucial elements for real estate agency websites. Likewise, an interview with some real estate professionals would aid to validate the model too.

This study only evaluates elements of real estate websites based on the tailored model, which indicates how

well the website captured these elements. However, it does not reveal how popular the websites are to consumers. The website could be evaluated based on user perception, such as the most frequently visited website and also determine certain aspects of the websites that tend to attract consumers i.e. good web elements versus good property. Research would determine whether there is a correlation between high web scores and the size of the firm or the number of years the agency has been operating. As all the websites in the study are based in the Auckland district, it might be useful to carry the study to other districts in New Zealand.

6. Conclusions

The web provides an opportunity for the real estate agency to move information to the potential buyer. For some buyers, the 'servicing' stage, i.e. open home, can be participated in 'cyberspace' as capabilities such as the 'virtual tour' are used by some agencies to the benefit of buyer, agency and purchaser. Websites can be so efficient that the first four stages in real estate sales could be performed without the physical contact with a real estate agent. Ultimately, the website presents a win-win situation for both the agency and the consumer of the agency's website, providing that the website utilises the appropriate web elements, such as the ones identified in the tailored model of this study. The agency, that stands to benefit from the website, can effectively cut costs through eliminating the traditional distribution of real estate brochures or magazines. In addition, the website provides added benefit to the agency as property information can be now accessed anywhere in the world by potential buyers [10]. This implies that the potential buyer can easily relocate himself or herself from one region to another through advanced property hunts.

However the potential property purchaser would need the knowledge and technology to search for properties. The purchaser would also lose the benefit of a quality relationship with the agent, one that is only possible through interpersonal contact.

It is evident that the websites provide immense convenience for the purchaser in this information-driven industry. This, in effect, may attract a pool of non-current purchasers to the website. The website is so convenient that it might attract the attention of potential consumers who have no intention to purchase a property to use the website. Ultimately, while browsing the website, the consumer might be tempted to purchase the perfect property that they have found or indeed to list their own property.

Abstract

Many recruiters use the web for job placements, to help organisations quickly reach the correct audience by posting available positions on the Internet and providing a way for candidates to submit resumes electronically. Recruitment agencies find this an efficient and effective way to establish a connection between employer (client organisation) and job seeker (candidate). It is a fast, flexible, inexpensive way to find potential organisations/candidates. Content analysis is used in this study to evaluate recruitment agency web sites. The online recruitment agencies web sites are categorised into two groups: IT specialists, and the more general recruitment agencies web sites covering a wide range of industries. We evaluate and compare the New Zealand web sites of seven IT specialist recruitment agencies and eleven general ones. The fundamental elements for a fully functional electronic evaluation model based on the Hersey model (as cited in [5]) were defined. The results showed that although the sites scored well on the Information and Trust dimensions, they performed relatively poorly in transaction capability and in providing promotional elements.

1. Introduction

The Internet has become a medium, a channel between two independent parties. In this study, they are the client organisations and job candidates. The Internet not only brings the potential for much more marketing opportunities for both entities, but also provides the way both could communicate with each other more efficiently and effectively. The Internet has a great impact on the process of the traditional recruitment industry evaluation, so a new business model is built, and the recruitment environment is changed as well. In addition, organisations and customers are facing potential opportunities and challenges.

The global economy is entering a slowdown stage; this phenomenon affects not only NZ economics but also the employment market. In this environment, people are not passively seeking jobs any more. They know in the world where everything is fast moving, employers and employees want to make quick decisions. Recruiting through the Internet allows them to do this. The Internet becomes an effective medium, providing a wealth of information in real time. Online job recruitment agencies provide a common ground for both client organisations and job seekers. As a result, candidates use it to attempt to

obtain new jobs. People are aware that online recruitment agencies web sites are an important and effective tool to both seek candidates and to place resumes that can match the job requirements of both parties.

2. Literature Review

This section will present a literature review on recruitment related topics. First, the Internet's influence on industry structure will be explored. Second the role of online recruitment agencies is described. Finally, web site evaluation models suitable for examining the effectiveness of recruitment web sites are reviewed. These include the infotainment model and usability evaluation model.

2.1 The Internet Influences Industry Structure

Strategy guru Michael Porter [3] states that the Internet's greatest impact has been to enable the reconfiguration of existing industries that had been constrained by high costs for communicating, gathering information, or accomplishing transactions. Particularly, for the online recruitment agencies, the Internet is used not only to connect the various activities and entities but to optimise its working in real time. In addition, the data the recruitment agencies can collect and maintain will be optimised and customised based on input not only from organisations and suppliers but also from customers. He also explains that the basic tool for understanding the influence of Internet on organisations is the value chain - the set of the activities through which a product or service is created and delivered to customers [3:74]. By enabling the new approaches to meet needs and perform functions, the Internet creates new substitutes. The use of the Internet also tends to expand the geographic market, bringing many more organisations into competition with one another.

2.2 The Role of Online Recruitment Agencies

The recruitment agency's job is to represent job seekers fairly to potential employers, and to explain in clear detail where the job seeker stands in the marketplace and the types of work one can expect to find, as well as the appropriate remuneration package. A good agency should be able to give you a timeframe for finding a job, as well as provide you with an idea of the type of organisations with whom you can expect to be deal.

Whitely [5] said that the advantages of the Internet on recruitment agencies are obvious. It is easy for everyone with a computer access. It is incredibly quick, and much cheaper than advertising in newspapers and magazines. He also predicted that in the future the standard way to apply for a job could be to send e-mail to an online recruitment agency and go through the whole interview and selection process over the Internet. However, David Fox, CIPS's recruitment database co-ordinator, says: "The Internet is not a replacement for traditional methods. It's an add-on."

From the job seeker's view, they can provide their resume to a number of locations much more quickly, and also can get up-to-the-minute information in terms of which jobs are available. Organisations are looking for people who are not necessarily located in their area or even in the country in which the organisation is operating.

Customers want a recruitment and selection system is not only fast, but also flexible, paperless, and inexpensive. At the same time, they want a system that can be tailored to their individual requirements, be customised to select for position-specific skills, and provide up-to-date, easily accessible candidate information. They want a system that would reliably produce high quality candidates and be fair and equitable to all applicants.

2.3 Web Site Evaluation Model

This section includes models for web site evaluation, particularly for online recruitment agencies.

2.3.1 Infotainment Model

The Infotainment model created by Chung and Paynter [1] is used to provide a framework in which business sectors should consider a strategy to attract revisits to a web site. The framework includes two main attributes on which to classify a web site, 'information' and 'interaction'. A two by two matrix develops it with the axes of degree of information and interaction. Chung and Paynter defined these four quadrants as passive, interaction-oriented, information-oriented and interactive-information. Based on the features of online recruitment agencies against the infotainment model, the recruitment agencies web site should fall into information-oriented quadrants, which is mainly associated with information rather than with interaction.

2.3.2 Usability Evaluation Model

There are many approaches have been proposed for web site effectiveness evaluation and design. Here, a general model for e-commerce evaluation and design developed by Ian Hersey (as cited in [5]) is introduced. The model consists of fourteen elements that respond to different aspects of an effective e-commerce web site. This model was designed for the usability of an entire e-commerce web site and served as a five point scale from the web site visitor perspective to assess and rank the site when designing and implementing an e-commerce web site.

Based on this model, Paynter et al. [2] proposed a usability evaluation model that measures web sites by three dimensions: effectiveness, efficiency and satisfaction. The model consist of four fundamental components to an e-commerce web site. These are information, transaction service, trust and non-functional requirements. Each component includes the number of elements that might vary based on a particular industry. Therefore, this model presents an abstraction level, ignoring the identification of each element. With this idea, the model can be regarded as a basic model to evaluate the usability of variable e-commerce industry sectors. This model can be applied to recruitment agencies web sites. Therefore, the elements for this particular industry can be defined for examining the web sites. The details are described in the next section.

3. Research Method

The research method mainly focuses on content analysis backed up with qualitative assessments of the individual sites. The aim to determine the characteristics of the online recruitment agencies services web site to assess and rank site capabilities against the model proposed to serve as a benchmark.

3.1 Content Analysis

Weber [4] defined content analysis as a research method that uses a set of procedures to make valid inference from text. Content analysis is a quantitative research method. In this project, content analysis consists of two main steps. An evaluation model for online recruitment agencies web site is developed, and then a systematic and objective procedure can be followed to evaluate the individual sites.

3.1.1 Online IT Recruitment Agencies Web site Evaluation Models

The main ideas for the recruitment model are derived from the combination of the components in Hersey's e-commerce web site evaluation model and the categories in the abstract site usability model [2]. Due to the recruitment agencies' unique features, some components and categories are not appropriate to meet the requirements of online recruitment web site services. Therefore, a model for online recruitment agencies was developed. Five dimensions are used to measure online recruitment agencies web sites. Each dimension consists of various elements. Although the model is specific to IT recruitment agencies, the model still can be used for other types of recruitment agencies web sites. The categories are: Information, Transaction Service, Trust, Non-Functional requirements and Promotion. These five categories are defined to effectively catch the elements of quality for each specific model.

The categories and the elements incorporated into each category will be discussed below in detail.

1.Information: Three are three elements are associated with this category, which are

³/₄Organisation information. The site provides the information on the organisation, including the organisational profile, history, team members, contact information and marketing plan and branch.

³/₄Customer information. Due to the unique feature of recruitment agencies, two kinds of customer are allowed to enter into the web site by registration and contract service. These are job seekers, local or overseas, and client organisations.

³/₄Vacancy. The site contains job vacancy (NZ and overseas) information. These last two categories are the “product” of the recruitment agency.

2.Transaction Service: This category is used to assess the industry-specific services offered on recruitment agencies web sites. The criteria components are:

³/₄Job search engine. The site has this function to help customers purposely and quickly search the job.

³/₄Candidate registration (profile detail). The site registers candidate information into the database

³/₄CV submission. The candidates apply a vacancy by CV submission

³/₄E-mail contact service. The candidates can also use the email to apply for a vacancy.

³/₄Contractor Login. The function allows candidates to view or edit their personal details in the database, or enter the employment database that is specially set up for registered candidates.

3.Trust:

³/₄Legal disclaimer. The site should provide the legal information such as organisation and position information

³/₄Privacy statement. The site makes sure that a customer privacy and personal information are protected

³/₄Security. The site ensures the security when personal data (CV) are stored and transmitted.

4.Non-Function Requirements:

³/₄Aesthetic effect. The site contains graphics or animations

³/₄Ease of use. The site provides effective navigation tool or site map to help customers use the site

³/₄Update frequency. As the feature of recruitment industry, the job market is constantly changing, up-to-date information is essential to customers.

³/₄Page loading speed. The page loads in less than 8 seconds.

³/₄Online help. The site provides additional information to candidates.

5.Promotion

³/₄CV and interview Tips. The site provides the CV format and interview guide.

³/₄Email Newsletter. The site provide current job marketing news and update organisational news

³/₄Link. The site can link to other relevant sites from which the customers can get other information, such immigration and NZ general

³/₄Online learning/training. The site offers online training, especially in the IT field.

³/₄Articles and case study. A range of subjects in articles and case studies is available.

³/₄Survey. The site offers an up-to-the-moment insight into salaries presently commanded in each market.

³/₄Feedback. The site can get feedback from customers about the site and recruitment information.

³/₄Job offers. When a vacancy is matched, the site can automatically inform candidates by e-mail.

The components and elements on effective recruitment web sites are summarised in Table 1.

	Job offers

3.2 Sample Selection

The main industry recruitment magazine, the New Zealand Computer World (www.computerworld.co.nz), and the New Zealand Herald (www.nzherald.co.nz) were scanned to look for recruitment agencies. The electronic yellow pages (www.yellowpages.co.nz) was used as an additional source to search for other recruiters. Surprisingly few recruitment organisations were found. It

seems that in the last few years there have been structural changes in the industry. There were few, if any, indigenous recruitment agencies. The existing ones had been dissolved on the retirement of their principals or had been absorbed into multinationals.

4. Data Analysis and Key Findings

This section presents an overview of the data and its analysis, including identification of the specific web sites examined, how the scores were obtained and coded, how each site scored, and how each item scored across sites.

Seven IT specialist recruitment agencies web sites were included in this study. The names of agencies and their URLs are listed in Table 2.

Table 2: IT Recruitment agencies

No.	Recruitment Organisation	URL (http://)
1	Candle New Zealand Ltd	www.candle.co.nz
2	DeWinter International Ltd	www.dewinter.co.nz

4.1 Coding of Recruitment Agencies Web Sites

Binary scores were used to record the appearance of each element in the evaluation model on each site, including both IT specialist and general recruitment agencies (Table 4).

Table 4: Site scoring by element

4.2 Scores on Recruitment Agencies Web sites

Scores for IT specialist recruitment agencies and general recruitment agencies web sites are shown in Figures 1 and 2, respectively. The bars labelled with the data value indicate how many elements were present in each specific recruitment agency web site. The longer the bar, the higher the site score. The recruitment agency web sites with a higher score have incorporated a greater number of elements identified in the evaluation model for effective web site design. The maximum value obtainable is 25, which represents the 25 elements defined in the evaluation model for the recruitment agency web sites.

Figure 1: IT specialist recruitment site scores

Figure 2: Generalist recruitment site scores

4.3 Site Score Analysis

The average number of elements by the seven IT specialist recruitment agencies was 15.4 (108/7) per site, more than 12.5, the 50% mark for representing all the elements identified in the evaluation model. The average number of the utilised elements per web site for the eleven general recruitment agencies web site was 14.5 (159/11). The two figures are not significantly different; they reflect that the overall adoption of elements measured on both IT specialist and general recruitment agencies was acceptable, but still of a moderate degree indicating low utilisation of the potential of the Internet for recruitment organisations.

4.4 Element Score on Recruitment Agencies Web Sites

The same method was applied to calculate the presentation of scores gained by each element across the recruitment agencies sites. Bars labelled with the data value indicated how many sites presented the specific element. The elements with higher scores reveal the importance accorded them by the agencies in designing their recruitment web sites. The selected sites (7 and 11 respectively) determine the maximum value.

4.5 Element Scores Analysis

Figures 3 and 4 indicate that there is wide variation across both categories of sites with respect to the use of the different elements of the model. Both categories paid relatively more attention to the information and trust categories. In contrast, the organisations did not pay much attention to transaction services and promotion.

4.6 Key Findings

Both the IT specialist and general recruitment agencies web sites received low and medium scores (Table 5). Overall, the findings show that the online recruitment agencies web sites are performing poorly, as measured by this model.

Table 5: Site classification as to effectiveness

Site Score	IT specialist sites (7)			General sites (11)		
	Low (0-13)	Medium (14-18)	High (19-25)	Low (0-13)	Medium (14-18)	High (19-25)
Count/ (Percent)	3 (42.9%)	2 (28.6%)	2 (28.6%)	4 (36.4%)	5 (45.5%)	2 (18.2%)

Table 6: Analysis of Dimensions

Type	Dimensions	Dimension Scores				
			Element			
	Information	21	3	7	7	100
	Transaction Service	24	6	4	7	57.1
	Trust	21	3	7	7	100
	Non-Function Requirement	21	5	4.2	7	60
	Promotion	21	8	2.6	7	37.1
	Information	30	3	10	11	90.9
	Transaction Service	33	6	5.5	11	50
	Trust	32	3	10.7	11	97.3
	Non-Function Requirement	40	5	8	11	72.7
	Promotion	24	8	3	11	27.3

Figure 3: IT specialist recruitment element scores

Figure 4: Generalist recruitment element scores

Both IT specialist and general recruitment agencies web sites contained elements of all five dimensions used in the study. However, the performance of each dimension varies significantly. Information and trust were the most frequently implemented elements. The findings indicate that the recruitment agencies web sites are informational rather than transactional. The recruitment agencies emphasise the information available at the site. It is also good to see that the trust dimension is considered as a high priority. This is a sound strategy as job seekers are highly concerned about the privacy of their applications. For instance, they might not want their current employer and colleagues to know that they are looking for jobs. In the same way, organisations might not want their employees to know that they are recruiting or if they are, what the remuneration packages might be. However, the lack of transaction service and promotion in both types web sites should be noted.

The requirements of candidates were considered in most recruitment agencies web site, such as job search, and candidate profile registration. Only one web site provided a function to allow client organisations to enter the candidate database. Most web sites have not realised that the web can provide more services for the organisations recruiting employees. The promotion dimension was implemented quite differently among all recruitment agencies web sites. For example, CV format and interview guide are offered by several sites. They are very attractive factors to candidates. The recruitment agency web sites with high scores tended to do well on the promotion dimension. Overall, the recruitment agency web sites did not provide many options for both candidates and client organisations.

5. Discussion

This section is divided into a discussion of the analysis of the web sites, and some recommendations for the organizations and their web site developers.

5.1 Recruitment Agencies Web Sites Assessment

As the online recruitment agency web sites play important roles in the organisation's business strategies, it is important to evaluate what has been achieved and what challenges are still to be faced. The previous section presented the findings based on content analysis. The evaluation results were based on the site scores and element scores across the IT specialist and general recruitment agencies web sites. The findings indicated the performance of both types of web site were similar.

When looking at the five dimensions - information, transaction services, trust, non-function requirements and promotion, both put the most attention on the information and trust. Sites did quite well on the organisation information and vacancies available, probably due to the fact that recruitment agencies are information-oriented. The organisations try to make a good and confidential impression based on the content of the information and the display of the conditions of the site. In contrast to that

achieved by the online recruitment agencies web sites to date, the challenges faced by the online recruitment services are severe. For example, the web sites evaluated did not make much use of transaction service nor for promotions.

Most recruitment web sites provide some services for job seekers, such as job search, candidate profile registration and login. As this key functionalities improve, the web sites become rich and effective, the candidates can get more value from them. However, the client organisations cannot do too many things by using the recruitment agencies, the reason probably is, the client organisations are more likely to have face-to-face communication with recruitment agencies. They are more passive entities. Only one recruitment agency web site examined offers a service to allow client organisations to enter the candidate database. This allows the clients to access candidates directly, and can seek more suitable people preventing the bias of recruitment agencies.

Performance in the promotion dimension varied significantly. Some sites did well with respect to this dimension, but some sites did little. The promotion dimension can attract the customers to visit the web site. For example, online training and learning, CV format and interview guide, newsletters and web sites link are very useful to candidates. By visiting the web sites that tend to have more promotional elements, the job seekers can get not only current job information but also future career advice. They are more likely to revisit and the agency retain their custom.

5.2 Recommendations

The focus is on the evaluation of online recruitment agencies web sites in New Zealand. The findings represented the recruitment agencies web sites as of poor performance. What should an effective recruitment agency web site contain? We should take into account the needs of the customers and the purpose of the web sites.

The customers want recruitment agency web sites with sufficient and timely information, confidential service and quick response. In order to interact effectively with the customers, the transaction services and promotion need to be enhanced on the recruitment agencies web sites. In addition, some elements, such as CV format, should become standard.

6. Conclusion

The focus of the study is on content analysis of online recruitment agency web sites. By examining the current achievement of these web sites, we may enhance our understanding of how to better develop an online recruitment agency web site. The evaluation of recruitment web sites in this study was based on a previously developed usability model featuring five major dimensions – information, transaction service, trust, non-function requirements, and promotion. Each dimension comprises different elements. The findings from scoring the sites and elements respectively indicate

that the online recruitment agency web sites studied do not perform in a uniform manner, and most are of poor presentation. Transaction services and promotion should be improved to enhance the effectiveness of the web site. However, the single evaluation method, and the small (although exhaustive) sample size may limit the generalisability of the study. The job recruitment industry's use of web sites for this purpose is in its infancy. A longitudinal study would provide a more comprehensive and thorough examination of the use of the Internet by this industry.

Abstract

The Internet has been a key to optimizing the supply chain, enabling real-time data to be shared between supply chain partners, which usually connect together as an e-business network. Nowadays the focus is on building-in value added products/services, thereby enabling the network to differentiate itself from its competitors in a more sustainable manner. In this context, outsourcing has provided significant cost reductions for businesses, with the use of third party logistics providers (3PLs). This is today only a 'qualifying criterion' for most businesses, and no longer a competitive advantage. The creation of a fourth party logistics provider (4PL) aims at moving the client to a more competitive position, by analysing relevant business risk, and monitoring relevant KPI's, and applying these within a 4PL providers efficient alliance network.

1. Introduction

Supply Chain Management (SCM) may be viewed as "the art and science of creating and accentuating synergistic relationships among trading partners in supply and distribution channels with the common shared objective of delivering products and services to the 'right customer' in the 'right quantity' and at the 'right time'" [25]. Demand Chain Management (DCM) [23], provides another perspective where the locus of control is moved from the supplier to the customer. This move from a 'push' (supplier driven) to a 'pull' (customer driven) system allows customer initiated ordering to drive the entire supply chain. DCM aims first and foremost at meeting the needs of specific customer segments, rather than concentrating on internal optimization [28]. DCM also allows the single business unit to instigate new sets of efficient, co-ordinated, customer-related, data-sharing practices across its entire supply chain.

The World Wide Web and the Internet, combined with linked, innovative, integrated networks sharing digital information up-and-down the entire supply chain, provides the basis for the development of supply chains (SC), or demand chains (DC). Both supply chain management (SCM) and demand chain management (DCM) still have their place.

SCM is particularly useful in delivering longer product life-cycle items such as commodities, or complex products with long lead times such as aircraft

construction. Here, all links in the chain are compared to the desired overall total performance of the entire chain, and each individual link is separately optimized. Thus the overall performance of the entire chain may be improved [5].

The Internet has been a key to optimizing the supply chain. It has enabled real-time data to be shared between supply chain members (or partners). The supply chain members usually connect together as an e-business network. They share information freely with participating partners: obtaining real-time updates of production line product positions; planning schedules; stock requirements etc.; shipping to a schedule; paying electronically; and managing individual processes for the benefit of the entire supply chain. SCM is a continuously evolving process. New strategies, methods, systems, ideas, and the like continue to drive additional learning-curve effect efficiencies. Hence SCM is a pathway towards competitive advantage and sustainability [19], but they can only ever be as efficient as the sales forecast [18].

DCM is similar to SCM, but it is customer driven. Here the customer expresses a desire for a product, with a variation to the original standard product. The aim is produce this product variation and deliver it whilst meeting the customer's expectations. It appears best suited to shorter life-cycle products such as software, computers and the like. However, even traditional, complex SCM businesses, such as automotive industry companies like GM, are moving towards the DCM model.

The Internet has enabled the customer to acquire product knowledge from a global perspective, and to do so at a rapid rate. The knowledgeable customer has become the decision-maker, and the influence of the supplier is greatly reduced. The customer now manages the performance of the total supply chain [15], and decides what they want, when they want it, and why they want it.

The DCM model has conceptualized the introduction of dynamic pricing models, make-to-customer order systems, and new lead time policies [26]. Make-to-customer order systems have typically been termed 'customized' orders. DCM models are moving towards one-on-one customized orders where the individual customer gets a variation of the product that closely meets their needs and wants.

The next level of customization is the true one-on-one approach where the customer receives a product that fits their needs and wants exactly. This one-on-one relationship is termed 'customerization' [12]. Customerization requires skilful strategic positioning of the e-business [13]. Numerous other factors must be considered, including knowledge of the customer's culture [16]. For example, e-business research indicates Japanese customers prefer detailed descriptions and little graphics on e-business web sites, whilst USA and Korean customers prefer brief text and more extensive graphical presentations - yet all groups showed a preference for a grid layout when compared to a dynamic, curved layout. Where close similarities occur between countries, for example where USA and Korean customers preferred a more visual and less text based approach, one web site design may provide satisfactory, cross-cultural usability. The individual country customers are then segmented. This segmentation does not follow traditional lines based on demographics. It is based on technographics [10] [13] [30], where the country's customer profile is segmented based on their technological ability - how techno-savvy they are. User groups are profiled, and studied, with a view to providing 'customized' web interfaces that best meet their demands. Web site visitors are tracked, and customer specific interfaces are matched to the on-line information seeker's preferences. This immense task is most cost effective at the larger or 'portal' web site level. It requires: a programmer(s)/program analyst(s) and web master(s); a database driven web site(s); quality software, hardware and communications; specific tracking tools working in conjunction with internal business intelligence and knowledge management systems; appropriate supply chains and value adds; and a system that continuously updates.

Currently, under Internet communications protocol system IPv4, the on-line customer has no fixed address, there is no performance manageability due to routing and demand issues, and it is not really 'plug and play' [4]. Consequently, there is no direct way, other than 'cookies' and competitions, of tracking the number of visits a user makes to an e-business web site. We can, however, see where the user came from, how long they visit a page, where they go within the site (and the time they spend), and from where (and to) they exit. The user's mouse clicks can be tracked along with associated actions, and the time-interval between clicks. Thus some data collection (and subsequent analysis) is possible, especially if cookies can be deposited on the user's computer.

The new flexible, agile, demand chain driven/supply chain supported, dynamic e-businesses are also stretching out to build-in value added products, thereby enabling them to differentiate themselves from their competitors in a more sustainable manner. These e-businesses, being more agile, are more likely to survive against the lowest 'selling price' pursued by many on-line customers.

The entire e-business driven-supply chain is moving towards a new level of quantifiable information sharing and collaboration. To measure such intangible assets, the

'Cap Gemini Ernst and Young Centre for Business Innovation' has developed a 'Value Creation Index' (VCI) [6] [17]. The Index assesses (through regression and other advanced statistical tools) the non-financial value drivers. These drivers must be exploited in order of importance to maximize value. When applied to e-commerce businesses, strategic alliances, investments in innovation, and number of users are of high importance as drivers of market value. This in contrast to brand awareness, minutes per page, change in usage, and change in percentage reach, which do not display a statistical association with market value. The VCI model demonstrates that 90% of an e-commerce company's value is based on these intangible factors [6]. Thus e-business alliances should be established based on the firm's ability to: add value to customers; eliminate unnecessary and uneconomical complexity in creating value adding propositions; and consideration of the total customer experience [29].

Within the services arena the current, highly-competitive global business environment requires businesses to provide value to their business offerings [22]. For example: to remain agile, and compete effectively, IBM focuses on four drivers - globalization, value creation, the extended enterprise, and operational excellence. It has redefined its supply chain as 24 hours by 7 days access with immediate or same day delivery. This data centric corporation works with real-time information from smart data capture and analysis systems.

The 'services' industry has readily adopted the Internet based e-business environment. It has linked its supply chains to web interfaces, and has offered additional 'value-adds' to move its entire supply chain to more optimal positions. For example: the real estate industry, in addition to its property listings, offers financial calculators, mortgage and loan comparisons, on-line purchasing, and the like. Other service providers - including solicitors - have out-sourced non-core areas of their business like office typing and mail rooms. As such, these service providers have embraced an outsourcing model denoted as "Third Party Logistic (3PL) providers" [27].

This notion of outsourcing is taking on a new strategic dimension, which is the focus of this paper, and which will be further elaborated.

2. Third Party Logistics Providers

First Party Logistics (1PL) providers, prior to 1980, were traditional logistics suppliers. In the early 1990's Second Party Logistics (2PL) network players like TNT and UPS commenced global operations, and in the late 1990's Third Party Logistics (3PL) providers emerged with many unexpected players (for example: integrated IT suppliers; management consultants; financial services) entering the market. The development of 3PLs was primarily due to the emergence of technology - enabling information exchange and facilitating communication between businesses.

3PL providers offered the e-business significant benefits. They play a substantial role in supply chain optimization and integration initiatives, by taking over out sourced 'non core' business functions and reducing costs, consolidating activities, and improving efficiency of the supply chain. For the demand chain, the results are: reduction of asset intensity; restructuring of distribution systems triggered by restructuring of production structures; and reduction of labour costs by switching to a non-unionized labour force provided benefits. In addition, the supply side is driven by declining profit margins in basic services (like freight and transport), and the tight availability of capital outsourced items such as shipping. 3PL providers have the potential to add value to e-businesses by sharing resources between their customers, sometimes outsourcing certain activities to second or third tier providers, (who join the value adding process as complementary providers), with the greatest impact in containing logistics costs [20]. Thus both horizontal and vertical integration develops between these optimized 3PL service providers, and the e-business benefits [2].

Table 1: 3PLP Value Creation Table

Taxonomy of Value Creation by 3PL Providers				
				
Descript ion	Operation al efficiency	Integration of customer operations	Vertical or horizontal integration	Supply chain management & integration
Driver	Factor costs	Scale	1.Asset reduction 2.Scale 3.Factor costs	Development of customer business process
Skills	1.Operation 2.(IT)	1.Operations 2.IT	1.Operation s 2.IT 3.(Conceptu al)	1.Operations 2.IT 3.Conceptual
Example	Run warehouse efficiently	Share warehouse among several shippers	Outsourcing to lower tier providers	Cross-docking or other new concepts

Note:

1. Operations and IT are the basis of value creation
2. Skills - use conceptual logistics skills to improve supply chains
3. Conceptual skills - include knowledge of competitive advantage aspects

Table 1 encapsulates the four ways of adding value. Complexity and associated skills requirement increases from left to right. Vertical and horizontal integration often follows operational and resource sharing value creation. It is rare to find all three skill sets (operations, IT and conceptual) maximized to create value [2].

A major deficit of 3PLs has been the missing ingredients of continuous improvement, strategic supplier relationships, and responsiveness. This is due partially to

the nature of the 3PLs - as their specialisation was provided in a narrow range of services – as well as their historical roots of a very functional operations and logistics-provider background. These skills allow incremental improvements of both cost savings and benefits in sectors of the supply chain (primarily logistics and procurement)- where 3PLs were able to profitably manage these functions - however there is usually a lack of flow-on effect of overall benefit to the whole supply chain.

Today, with globalisation, and a highly competitive marketplace, the narrow service provisions of 3PLs are no longer providing a competitive advantage as these are the entry qualifications for all businesses. 3PLs are also struggling with the narrow profit margins, where providers compete by bidding for tenders – the lowest bid often winning the contract. This is coupled with customer demands for new and innovative solutions for their supply chain [8]. Improvements for 3PLs would be found in significant investment in IT, research and development, and high calibre management that would foster an environment of continuous improvement – yet 3PLs often do not have the financial resources to provide these value adding services.

At this time 3PLs usually do not have either:

- the necessary profit margins to develop new services that would add value for their clients
- nor the internal influence with their business partners to implement changes and improvements if they were developed, as these would be broader than current areas of service. This limitation is due to industry attitudes towards the function and place of out-source providers, as much as due to the self-defined specialisation of 3PLs. Thus 3PLs are confined to operational excellence in specific areas of the supply chain, and are usually unable to implement changes across the supply chain due to restricted access to information and managerial input.

However some current advantages for 3PLs are [9]:

- a highly fragmented and high growth market
- possibility for 3PLs with multiple customers to gain by providing technological and expertise advantages to their customers
- potential for further differentiation.

Some 3PLs are actively expanding their service provision to include procurement, inventory management and financial services [20]). The opportunities are extensive in the area of e-business, where integrated solutions and tools, along with collaborative supply chain management is the key to competitive advantage. Occasionally, a competent group of 3PL's have banded together to become a leading solution provider, closely linked to their customers. They often manage the transport and warehousing networks for a large group of second tier 3PL's. These leading solution providers are the precursor to the latest key players.

3. Strategic Sourcing

Dunn and Bradstreet [7], report large, sustainable cost reductions are achievable when spending is aggregated across business units (and regions), and suppliers are rationalized (with those remaining striving to find new ways of removing costs). This is very different from traditional procurement, which focused on squeezing cost reductions out of an existing set of suppliers. They believe strategic sourcing must incorporate:

- Integrated procurement and accounts payable systems so details and entire spending patterns can be monitored
- Detailed understanding of the amounts spent with each supplier (leading to an integrated position of accounts payable across the supply chain)
- Performance at both ends of the supply chain (as some suppliers are also customers, or alliance partners)
- Mass services as a commodity (one global price for major items, especially with a global provider)
- Risk management allowing consolidation of purchases with fewer, quality suppliers (collected, collated and evaluated information is the key to monitoring and assisting suppliers in this less flexible environment)

Isolated bodies including Deloitte, Ernst and Young, and others have been delivering similar services at an industry specific level for several years, working with specific telecommunications companies, software providers and the like.

Although outsourcing has provided significant cost reductions for businesses - especially at first - the use of 3PLs is now only a 'qualifying criteria' for most businesses, and no longer a competitive advantage. Outsourcing is a method for a company to refine its business to concentrate on core competencies, differentiate customer service and increase operational flexibility [1]. Further cost reductions are required for businesses to gain a competitive advantage and this is potentially found in managing the complete supply chain enabled by increased visibility of information - as seen in successful e-businesses.

4. Fourth Party Logistics Providers

4.1 Characteristics

A new model of logistics service providers is emerging. This model, termed a Fourth Party Logistics (4PL) provider, is shown in Figure 1. The 4PL provider aims to assume responsibility for the entire set of a client's supply chain processes, and to manage, coordinate and drive this 'set' in a highly efficient, and cost effective manner. This approach is no longer aimed at improving the supply chain for an individual company, rather to enhance the 'value-chain' across businesses [26], www.viewlocity.com.

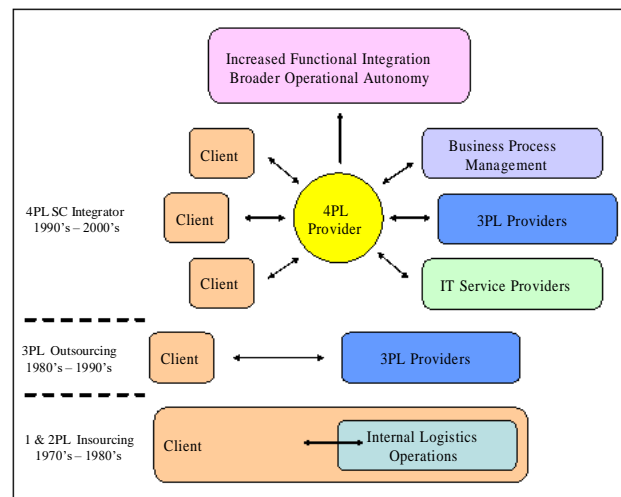

Figure 1: Evolution from 1 & 2PL to 4PL Models

A 4PL provider is a supply chain integrator that primarily provides technological capabilities to resolve a problem or opportunity for businesses [8]. The 4PL provider uses strategic sourcing to assemble and manage resources, capabilities, and technologies and assembles a conglomeration of other complimentary leading 3PL service providers for comprehensive supply chain solutions. It integrates these supply chain organisations into its 4PL structures, thereby creating unique new business models - tailor-made for the client's business or e-business, and its customer driven demand chain.

To be successful at the top of the supply chain, the 4PL provider must add value to its clients (e-businesses). It must deliver:

- Excellence in customer management, and do so in a manner that extracts maximum value. It must offer superior customer service, higher sales value, that focuses on delivering customer value and perceived value; operational excellence, that maximizes capital and human productivity; asset optimisation, that increases productivity and operational innovation; improved transparency and planning, thereby allowing visibility of forward orders across the supply chain; enhanced IT, network solutions and other business intelligence and knowledge management tools that allow lower transaction costs and world-class e-commerce solutions like e-procurement; and virtual inventory management with associated lower inventory costs.
- Corporate agility that maximizes the effectiveness of management by developing change management capabilities, teamwork, and alliance management with excellent people skills
- Strategic positioning that priorities and maximizes focus concerning relative market positioning and exploitation of the organization's capabilities within the

total supply chain, along with the related strategic choices of mode, geography, service and industry.

The success of a 4PL is dependent upon its ability to define top 3PL providers, enable technology providers to form alliances, and be extremely agile in all aspects of its operations. It has the added incentive to develop new cost reductions via leveraging integrated networks; exploring new ways to improve supply chain performance (for example, working with suppliers' external customers to improve and standardize their operations); aligning sourcing to strategic business unit needs (with CEO and CFO support); lead centrally but with local implementation (incorporating harmonious and skilled work teams); and provide excellent service to all its clients.

The 4PL provider may provide expert assistance to its alliance partners and create an extended enterprise. It must integrate ERP and gain/spend analysis data. Its IT systems must yield better information on spending and knowledge management (supplier performance knowledge, contract management, and the like).

4.2 Key Performance Indicators (KPI's)

To measure its success a 4PL must develop sets of key performance indicators (KPI). Measurable KPI's include:

- Availability of servers and applications
- Amount of work under backlog (tasks to complete eg help desk lists, IT/IS tasks)
- Utilization (database performance, resource allocation, personnel)
- Transactions per day (ordered by function, ease of payment, serviced level, responsiveness)
- Client customer satisfaction level with service
- Recovery time from disaster (business continuity metrics)
- Application functionality performance versus business requirements
- Number of problems per day
- Number of changes required per day
- Benefit realization
- Tracking and ordering (fill rates, on-time delivery, quality, rejections)
- Other (iitoolbox.com, haht.com, ncr.com and aeclever.com, 2003).

4.3 Risk Management

The 4PL must constantly assess risk. Risk-based management programs assess two key questions: what required assets are most at risk, and what constitutes risks to those assets? Risk is a relative term—an event or threat may be risky in one environment but not in another [3]. Therefore, a 4PL provider's risk management program will incorporate each strategic business unit's "worry radius" – where perceived risk and acceptable loss are defined. Effective risk management also requires determining the scope and value of assets. This cost must be considered against the estimated value of the assets

and the impact of their loss on operations and services[20].

There are numerous risk tools, risk guides, and risk services available on the Web. The 4PL's capital assets and digital assets management must be closely aligned with risk management developments. A typical progression of stages of risk management includes [14]:

- Risk identification
- Risk classification
- Risk assessment
- Risk analysis
- Risk management implementation

In addition to its KPI's, the 4PL must develop artificial intelligence methods, expert systems, knowledge management, business intelligence tools, profiles of itself, alliance partners, and its clients. The resulting tools and databases then provide evolving sources of information for analyzing potential risks.

Many decision-making and problem-solving tasks are too complex to be understood quantitatively, so 4PL's and others may succeed by using knowledge that is imprecise rather than precise. Any methodology or theory implementing "crisp" definitions such as classical set theory, arithmetic, and programming, may be "fuzzified" by generalizing the concept of a crisp set to a fuzzy set with blurred boundaries. Fuzzy logic allows these stratified sets to overlap (for example: an 85 kilogram man may be classified in both the "large" and "medium" categories, with varying degrees of belonging or membership to each group). Since fuzzy logic can handle approximate information in a systematic way, it is ideal for controlling nonlinear systems and for modelling complex systems where an inexact model exists or systems where ambiguity or vagueness is common. A typical fuzzy system consists of a rule base, membership functions, and an inference procedure. Thus the 4PL operation will generate perception-based decision analysis and decision support systems for risk analysis and management, uncertainty analysis, and new soft computing algorithms, making intelligent, semi-supervised use of large quantities of complex data to support its evaluation and management processes. When fuzzy logic and expert systems are applied to a customer's activities on an e-business web site, its database driven web site may be more responsive to the perceived demands of the user, thus enabling a faster, shorter path towards the customer's web site goals. Similar fuzzy logic processes may be applied across other areas of the supply chain. Thus performance against a 'business scorecard' can be established and monitored [24].

The next step for the 4PL provider is to use this business intelligence and determine the effect of changes on business effectiveness, competitive advantage, sustainability, and ROI.

5. Conclusion

The creation of a 4PL provider aims at moving the client to a more competitive position, at least until other

organisations either re-establish their competitive positions by copying such a system, or developing new innovative solutions. Analysing relevant business risk, and monitoring relevant KPI's, and applying these within 4PL provider's efficient alliance network may allow the 4PL to develop new, highly-efficient processes with added benefits to the client. These processes should increase the overall ROI of the system, and should benefit the client, the 4PL, its supply chain alliance partners, and most importantly, the client or customer.

The Formation Processes of an R&D Network: A Case Study

M. Sc. Marko Heikkinen and Acting Professor Jaana Tähtinen

Department of Marketing, University of Oulu, Finland

marko.t.heikkinen@oulu.fi and jaana.tahtinen@oulu.fi

Abstract

Because of fundamental changes in the competitive environment the amount of resources and knowledge needed in R&D activities has become overwhelming for a single organisation. Thus there is a strong need to perform R&D activities effectively in networks. This study increases the understanding about research and development networks by presenting an empirically grounded process model of formation processes of R&D networks. The model has three main elements; the initial conditions, the network webber and the cycle of sub-processes through which the formation proceeds. The process model highlights the importance of a single actor – the network webber – both in triggering the formation process and in managing the process. Moreover, the model suggests a view of the process that is cyclical – the sub-processes of enabling the network, joining, assuring continuity, formal structuring, learning and developing commitment – do not follow each other in a certain order.

1 Background of the Study

Nowadays both companies and research & training institutes share a strong need to perform research and development activities effectively in networks of many actors. There are several reasons that explain why the change from internal R&D activities to R&D networks has taken place. Firstly, fundamental changes in the competitive environment have resulted in a situation where the amount of resources and knowledge needed in R&D activities has become overwhelming for a single organisation. Technological fragmentation, the increased cost and importance of knowledge, developed information and transportation technology and positive previous experiences of co-operation are among the reasons that have increased the feasibility of external R&D activities [22]. Even in large multinational companies networks have replaced the traditionally market based and vertically integrated structures with more dynamic R&D networks.

Secondly, different companies and research & training institutes lack different resources or knowledge. Thus there is a need to form networks of actors with complementary resources and knowledge. Therefore, R&D networks often include different types of actors; competitors, suppliers, customer companies, research and training institutes, which perform R&D activities jointly [9]. Through intensive co-operation with research and training institutions companies can keep up with new technologies and the advancement of science. Companies gain an indirect contact with the international scientific

community, which provides them insights in latest basic research and an access pool of technically and scientific

sophisticated personnel [22]. Reciprocally R&D institutions receive vital external funding from companies as well as from national funding agencies. A network formation can even be a prerequisite for such external funding [12].

Thirdly, performing R&D activities in networks can also produce extra value for the participants. Formation of dense networks of contacts improves innovative capacity and fosters economic growth [22]. The result of this tendency is that the source of innovation is no longer a single actor or an inventor, but a network of interrelated actors. According to Easton [7, p.24] “inventions and innovations occur in networks not within but between firms”. This being the case, there is a great need for knowledge about how to manage an R&D network effectively, so that each actor in the network creates and receives value.

The question of managing in networks (see eg. [21]) can be approached from two different angles. A strong research tradition in strategic networks or strategic nets (e.g. [16][11][21]) endorses and accepts the idea of a single actor influencing the structure of the network and the positions of the companies within the network. From this perspective a network can be initialised (e.g. [4][3, p. 176]) or managed by single operating actor. In other words, one company can manage, in addition to its own actions, also the actions and reactions of all the other actors in the network.

A contradictory view is suggested by the Network Approach (see e.g. [7][8][13]). The approach argues that networks as such cannot be managed nor designed by a single individual or even by a single company. The argument is that networking is essentially acting, interacting and reacting and an actor cannot dictate the reactions of other actors in the network [8]. A company within network must accept that the outcome of networking is a synthesised result of all companies involved in network. The outcome of any action by a single actor is seldom restricted to actors’ original aims. Håkansson & Ford [8] claim that although a company may initiate change in the network, the achievement of the change is still dependent on approval and actions of others. Thus the actors within network have to adapt their goals to the goals of other actors in the network continuously [8].

When looking at the two above mentioned approaches on network management together, there is a major contradiction between them. The contradiction of networks’ inherent characteristics of being self-evolving

and unmanaged and on the other hand, the possibility to manage R&D networks forms the starting point of this research. Our research focuses on the early stages of network development, in other words on the formation of R&D networks. The model generated in this study relates strongly on strategic network literature and previous research on R&D network formation (e.g.[4][3]).

2 Purpose of the study

This study increases the understanding about managed formation processes of R&D networks. Thus we focus on engineered formation processes [4] and develop an empirically grounded process model of engineered formation of an R&D network. We build the model in three sections. The first part of the model describes the *initial conditions* of the engineered formation process. The second part discusses the role of a single actor, i.e. *a network webber* in managing the network formation process. The final part of the model describes the *activities* performed during an engineered formation process of R&D network..

In the following sections we first describe the method through which the empirical grounding of the model has been taken place. The empirical data is gathered from a members of a research and development network in Finland. Thereafter, we present the empirically grounded model of engineered R&D network formation and discuss each of the three parts of the model more thoroughly. The paper concludes with a discussion of the merits and demerits of the model that pave ways to further research.

3 A Case Study of Network formation

We conducted a longitudinal single-case study to provide data for the empirical grounding of the R&D network formation model. The existing research on R&D network formation is mostly retrospective. Therefore, we chose to conduct the data collection as a follow-up study, enabling us to analyse the whole formation process real-time.

The case is an engineered formation process of a R&D network. The focal network designs and develops mobile, context aware mobile multimedia services to end-consumer environment. The networks is financed from two main sources. The most remarkable stakeholder is the National Technology Agency of Finland, TEKES. The rest of the funding comes from the private companies that have joined the network. The network consists of technology companies, software companies, content providers, City of Oulu, local retailers (small ones through their joint non-profit organization), and research groups from the University of Oulu as seen in Figure 1. Each actor group is connected directly to the research groups and indirectly to other actors via the research groups. The dash line rectangle around the research groups points out the border between research and business consortium in the network.

The formation process of the network begun early 2002 among the researchers at the University of Oulu. The network can be roughly divided into two consortiums. The research consortium consists of researchers from faculties of Technology, Economics and Business Administration, and Education. The business consortium includes local, international and global companies. Thus the actors that form the focal network are versatile and heterogeneous both on their capabilities and their needs.

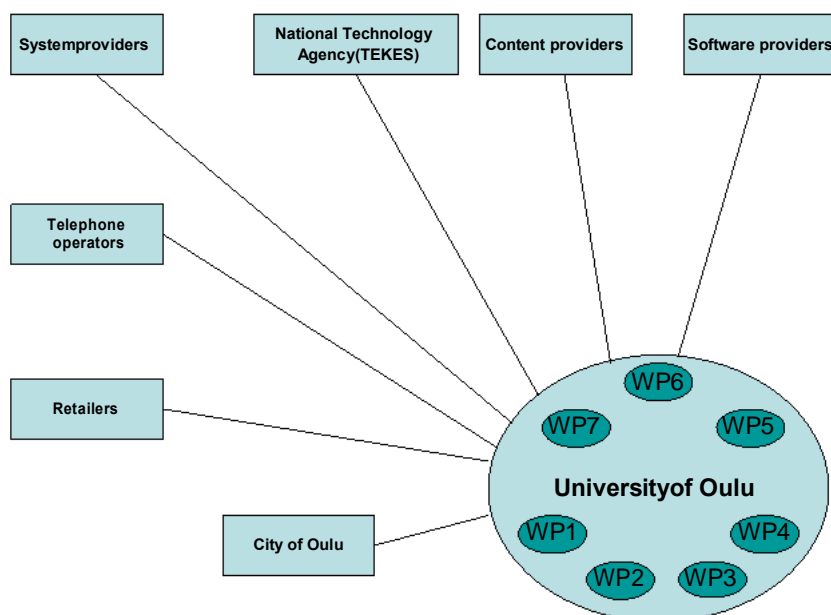

Figure 1. The overview of the case network

Gathered data consists of various types of information from the case network. Data were gathered through several personal focused interviews (see [20]) from different actors within the network under formation. The reason for utilising interview as a method for data gathering was the possibility to direct the focus of discussion during the interview. By interviewing it is possible to reveal the motives behind the actions of the interviewee. Focused interviews offer several advantages compared to other interviewing methods [20]. The interviewees can be selected among those that are knowledgeable of the issues under research attention. Secondly, the researchers have the opportunity to guide the structure of the situation with the use of theme lists. Focused interviews enhance the possibility to react to the responses of the interviewee and probe more deeply into interesting issues.

We selected four companies and two research groups to be interviewed on the basis of their membership in the network and the importance of their role in the network. The seven individuals interviewed were important contact persons of their company or research group, namely a CEO of a software company, a sales director of a software company, a sales manager of a global hardware provider, a CEO of a non-profit organisation representing the local retailers, a research director responsible of the whole research project (later referred to as PhD Timothy), and two research directors from different research groups (PhD Ann, PhD Philip), representing different scientific approaches and orientations. All interviews (in total 265 minutes) were tape recorded and transcribed producing in total 58 sheets.

In addition to the interview data we gathered empirical data through participation observations, as both authors took part in several official and unofficial meetings that took place between the members of the network. We also had access to all written material produced during the network formation, such as project plan, e-mails, PowerPoint slides, status reports, minutes of meetings, and press releases.

The nature of follow-ups study obscured the time span of data gathering for this study. The majority of data were gathered during 9 months, from August 2002 until the end of April 2003. Having said this, we have to admit that some important events took place a few weeks later and we have included them into the empirical data as well. We feel that, to restrict the data gathering tightly to certain dates would not have been the best solution in this case. The development of a network is never-ending continuous process and that is why any restriction to the dynamic process is always an artificial one. The ending of network formation or any other phase in network

development can not be stated exactly, hence the data gathering has to be flexible. This way the rich data enabled us to form a comprehensive picture of the initial conditions, formation processes, and the role of a single actor managing the network formation activities.

4 The Process Model of Engineered R&D Network Formation

Before introducing the model of R&D network formation, it is essential to discuss the approach this study applies when it refers to a process. Process refers to a sequence of events or activities, which describe the development over time [24]. In this study process is considered through a teleological perspective as we see the process of forming a network as a purposeful cooperation of the actors (see [24][25]). Applied in the focal case, a teleology process sees the network as a purposeful and adaptive entity, which has a jointly preferred end state towards which it reaches. The network thus pursues such actions that move it closer to the end state, which in this case is the formation of R&D network to produce an innovation. However, the process is seen as a multiple streams of activities, not as a continuous stream of sequences or phases. In addition, the network's recourses and environment may limit the process. This is why the outcome of the process is not known in advance, because the actions of the actors may also change the goal.

As pictured in Figure 2, the process model of engineered R&D network formation depicts the three main elements in R&D network formation; *the initial conditions* of the R&D network under formation process, *the role of the network webber*, and *the cycle of sub-processes*. The initial conditions, i.e. shared interest of the actors, interdependence among the actor, and the existence of a network webber influence each other as well as the network formation. The role of network webber is emphasised - the reason for doing this will be explained later in the paper.

The cycle of sub-processes contains six intertwined series of activities that take place during the network formation: enabling network formation, joining, assuring continuity, formal structuring, learning, and developing commitment. Together the sub-processes form the network formation process. Each sub-process is affected by the initial conditions and each sub-process may also influences other sub-processes. The intensity of a certain sub-process as a part the network formation process can vary from low to high. The higher the intensity, the more important the sub-process is.

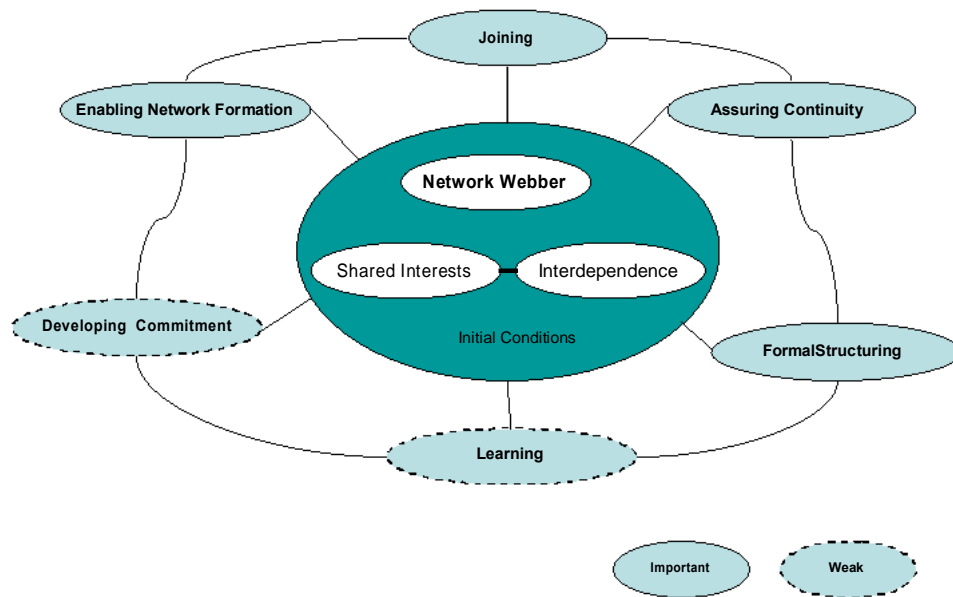

Figure 2. The Process model of engineered R&D network formation

The existing research (e.g. [4]) suggests that the sub-processes or stages of the network formation follow each other like steps in a staircase. We argue that this is not the case. Based on the empirical grounding, we are able to show that some of the sub-processes can take place at the same time, over a long time period and sometimes the process may return to previous sub-process forming loops within the process. Thus we suggest that there is no clear order of appearance in the sub-processes, they may take place simultaneously and partially, as well as that the network actors may repeat the sub-processes during the formation process. In the following sections each of the elements of the model will be discussed more thoroughly also in the light of the empirical data.

4.1 The Initial Conditions

According to existing literature on co-operative R&D processes (e.g. [4]) the network formation process is dominated by three sets of initial conditions. First initial condition is the actors' perception of interdependence caused by variety forms of change in the surrounding environment (e.g. [26][23]). Second initial condition is the existence and recognition of joint interests among the potential members of the network. Thirdly, the intervention of single energetic actor, which we call the network webber may trigger the formation process of R&D network.

4.1.1 Interdependence

Interdependence as initializing condition refers to the needs and willingness of single actors to perform R&D

activities with other members forming the potential network. Existing research (e.g. [4][24]) has also shown that companies tend to respond to their perceptions of interdependence by collaboration. The level of interdependence may of course vary significantly depending on the company. It is relevant to consider the level of interdependence, because the more the actors perceive their environment and the changes in the surrounding environment similarly the more willing they are to co-operate. If the changes of surrounding environment are not perceived the same way, the initialisation of network formation requires external influence typically provided by network webber.

In the case network, there are significant differences among the actors of the network. This diversity is related to the heterogeneity of the actors and their perceptions of their environment. Thus the incentive to join the network and the source of interdependency varies among the different type of actors. Small software companies seek marketing related benefits from co-operation. The companies have limited marketing resources and they expect to gain public relations benefits by operating jointly in nationally funded research and development network that attracts the public interests. University's research groups and technology companies' interests lie in the latest knowledge that the research project can provide. In addition, university research groups lack funding, and research networks are a way to attract outside funding, both from companies and from governmental sources. E.g. the National Agency of Technology (TEKES) requires co-operation with business life from any university research project for it to receive

funding. Research groups may also receive technological resources from companies. Scarcity of R&D resources combines both corporations and university research groups. University research groups can gain access to business context via technology companies. On the other hand, the companies need research groups to provide rigorous scientific research, which for the small companies is not possible because of the lack of resources. The following quotations illustrate how the actors perceive interdependence in their case.

PhD Timothy: *"Nowadays the persons that are responsible for R&D in certain companies receive so many project proposals...the change has been radical, if we compare to the past decade... they can compare and select only the ones they perceive interesting"*

PhD Ann: *"In fact we have... studied this area theoretically before this project and this is a quite logical extension to that. On the other hand, the mobility and mobile applications in our field are coming into the focus, but it is still quite shallow... which provokes severe criticism from a researcher. In a sense we have looking for this type of project earlier."*

In the focal case, the level of perceived interdependency was relatively low. Our view is that the reasons for this were the heterogeneity of the actors (e.g. high technology companies vs. small local retailers, international vs. local companies) as well as the task of the network, which is difficult to understand for the local retailers lacking the basic skills and knowledge in mobile systems. Our conclusion is that the level of interdependency was not high enough to alone initialise the formation of the network, but it was high enough to get the actors interested in the potential co-operation, once the opportunity was offered to them.

4.1.2 Shared Interest

The initialisation of R&D network requires also interest similarity between actors. The actors with pre-existing relationships, common industry origin, similarities with organisation structures and positive previous experiences in co-operation in R&D activities tend to recognise the interest similarities more effectively than the ones lacking similar experiences. The actors should be able to identify significant shared interest to initialise the network formation [4].

CEO of a Software Company: *"Actually we joined the project for the sake of interest. We like to be in a project, which in a certain way investigates the development of this business from customer's and service provider's perspective. Naturally, because we belong to this distribution chain we are interested to hear how the other members of the chain operate and what kind of expectations they have."*

4.1.3 Network webber

Third initialing condition in R&D network formation is the influence of the network webber. Network webber refers to a single actor in network, which proactively identifies even weak interdependencies and interest similarities among other potential members and

communicates these findings to the actors persuading them to join the network, in other words to perform the R&D activities jointly. It is very common that a central organisation or a central firm takes the role of the network webber (e.g.[18][5][14]) Also individuals or groups of individuals (e.g. [15], which potential actors find legitimate, justified and neutral initiators (e.g. [3]) can act as network webbers.

The network webber operates in a structure hole (e.g.[1]) combining relevant potential actors to form the network but also restricting irrelevant actors outside the network. The role of the network webber extends to also the later sequences of network formation, as the collaboration initiator may also possess an assuring role among network actors [3, p.177].

In the focal case, the heterogeneity of actors affected the relatively low level of interdependence joint perception of the surrounding environment. Thus an outsider was needed to point out the potential actors that they shared common needs and that they may expect certain benefits from co-operation. In other words, a legitimate network webber was needed to trigger the formation process. In the case, it was very clear that the research director, PhD Timothy took the role of the network webber, as the following quotation illustrates.

PhD Mary: *"Without a doubt - Timothy has been guiding the formation of this project and research consortium."*

The other network actors may perceive the strong position and influence of network webber as a threat towards themselves and the fulfilment of their own interests. Any change within network is always a result of joint acceptance among actors involved. (e.g.[13]) and therefore the actions of the network webber have to be accepted by the other actors in the network. A network provides almost endless possibilities of combining actor's resources. However, any innovation is created among those actors who perceive a useful combination and seize it. The network webber perceives opportunity and shares the notion with other actors, which seize the opportunity. The actors in the network accept the required change, as long as they perceive that the benefits from the change are mutual ones. Therefore, as long as the network webber acts benefit the joint goal of the network, the role is accepted. The role may also be perceived as an opportunistic behaviour, which would not be accepted by the other actors in the network.

In the focal case, the actions of the network webber were considered as a positive and the other actors accepted them. The network webber also allowed the other actors right to make decisions concerning their own preferred line of action, and then tried to fit and adjust these decisions into actions that guide the network towards its common goal, also shared by the network webber.

PhD Timothy: *"As a Responsible Director I have to make the final decision. Naturally we seek consensus and we have a conclave of research directors in which we discuss the decisions, but somebody has to take the final responsibility. Thus you receive the power to make*

decisions.”

PhD Timothy: *“We have had series of Research Group Directors’ meetings and everybody have had a possibility to contemplate also independently. Naturally the technical framework, which we have created, defines in a sense what can be done, but outside that, it has been their responsibility and in their interests to define what they want to do.”*

4.2 The Cycle of Sub-processes

The third element of the R&D network formation model is the cycle of sub-processes, which describes the activities undertaken during the formation process. The cycle consists of several series of activities: *enabling network formation, acquiring actors, formal structuring, assuring continuity, learning and developing commitment.*

4.2.1 Enabling network formation

By enabling network formation we refer to such activities that aim to develop the fundamentals of co-operative action. Through enabling network formation the potential network actors create a consensus of network domain. (e.g. [4][3]) The network domain consist number of mutual definitions among actors about performance expectations, goals, participants of the network and scope of co-operation. Prior positive experiences between actors and trust tend to lighten these activities. [6][10]

The effect of the network webber (i.e. PhD Timothy) was significant in the case that we analysed, since he took care of more than one task in enabling the network formation. The network webber was the main source of the original idea of forming the R&D network. Therefore his first role was to act as a representative of a R&D network, which did not exist at the time. The network webber set up all the meetings and discussions, chaired the occasions and communicated the basic goals of the network, the performance expectations, and the scope of co-operation as he planned them in his mind. During the first discussion with the potential actors the goals, expectations and the scope of co-operation were negotiated and the voice of the actors willing to joint in the network was incorporated to the original idea, as illustrated in the following.

PhD Mary: *“I would say that our goals remained quite the same, like they were at the beginning. Of course the restrictions related to the project, like the resources, timetables etc. had to be taken into account.”*

Some of the other actors counted on the network webber to enable the formation of the network and only wanted to react if the webber approached them. Some even considered the task of reaching a consensus over the basic elements of the network as a task solely for the network webber. These actors felt that it was not important for them to influence the basic premises of the research co-operation, since they were willing to accept them anyway.

PhD Ann: *“...of course I have maybe wanted to be a little bit ... or wished more just to follow from the*

background, than to be very proactive during the early phase, because the procedures follow more or less TEKES procedures, which define the rules or the game which relate more to the know-how of the Faculty of Technology than of ours.”

CEO of a retailers’ non-profit organisation: *“Entrepreneurs from different lines of business, like retailers, restaurants, service providers etc have been involved. They have provided pointers, but more like in basic issues of doing business.”*

PhD Mary: *“But maybe there is that MTeam (PhD Timothy’s research group) has already gone quite a long way, they have done a lot of work outside the project. We cannot influence that much what they present as their project.”*

However, there were many meetings where the University research groups had to discuss their goals and expectation related to the network, since there was a need to produce a common research plan to be presented to potential company actors as well as other funding agencies. The research plan included most of the definitions that the company actors as well as the funding agency accepted and therefore they perceived the network attractive and joined in. However, the research plan was deliberately left on a rather general level when addressing the co-operation of the company actors. This resulted in a situation that once the research plan had been presented to the funding agency and accepted by it, the network started to negotiate with each of the company members their specific role in the network. Thus the time span during which the network formation enabling actions were performed was rather long.

4.2.2 Joining

The sub-process of joining includes all the actions that the actors in potential network perform to seek and persuade other potential actors to join the network as well as the actions of actors wishing to join in. The sub-process consists of several activities of attracting new potential actors, selecting suitable actors among all the potential ones and restricting improper actors outside [4][3, p.177] The task in selecting potential members is not to find the best possible individual actors, but find the ones that perform best together. As Lundgren [19, p. 211] puts it, the challenge is to create policies that foster technological evolution on whole rather than of the parts. It is not difficult to find companies, research organisations or university research groups that are capable of performing R&D functions. The key is to find such actors that have the ability to joint decision-making concerning the task and goals of the network [3, p. 177][4].

In the focal case, the network webber made direct contacts to each and every actor that joined the network. However, the network webber was neither the only nor necessarily the first to take a contact. The actors joined to the network via three alternative routes. Firstly, network webber evaluated group of potential actors and contacted them directly offering them the possibility to join in. Secondly, actors willing to join in the network contacted

the network webber directly, since they had heard rumours about the project. Thirdly, some members of the network knew or found out about other potential members and contacted them directly. After the first contact, potential member was put into contact with the network webber. Also actors interested in the network contacted network members, which directed the potential ones to the network webber.

The webber was the main decision maker who accepted actors as members, if the actor itself was willing to join in. Thus the network webber had two roles during the sub-process of joining. The webber both persuaded potential members to join in and dissolved relationships with some actors willing to participate but not considered suitable. Although many of the network members took part in acquiring new members, only the network webber had the role of restricting actors.

PhD Ann: *"Timothy contacted Eric (another research director) and he knew us based on previous projects and he like knows what our research group does."*

Sales Manager of a hardware producer: *"Our co-operation started when PhD Timothy contacted us to discuss the opportunities our WLAN solutions would offer. We discussed and reached a successful agreement that enhanced the start of the co-operation."*

CEO of a Software company: *"Well, the joining the project was really an accident... I heard that there was a new professorship at the university... and I thought that since it was related our line of business I will contact him and ask if we he could share his views with us. He then told me that there is one project that is starting and it would be an opportunity for co-operation. The professor then asked me to contact PhD Timothy and we agreed that I will continue the discussion with him."*

PhD Timothy: *"In a way, Company X operated as a bridge to Company Y."*

Although the influence of the network webber in the focal case was considerable in acquiring the actors, there were also cases where the webber did not succeed. Some actors that were contacted by the webber and asked to join in refused to invest resources in the co-operation. There were also some environmental constraints restricting the acquisition of new members. A local department store was actively involved in enabling the formation of the network. However, the store did not join in the network since the local manager of the store had to get approval from the head office of the chain, which unexpectedly forbid the store manager from joining in. There were also other similar situations where the real decisions-makers were not local. Since the network webber could not get into contact with the decision-makers, the company did not consider joining the network useful for them and thus refused the invitation.

PhD Timothy: *"We even had a group from Organisation Z that developed a certain technology, but it did not lead to... And then the connection to Z became weaker and weaker. I wouldn't say that it broke down, but... At the moment it seems that the Organisation Z will not join the project. I am sure they will not."*

4.2.3 Assuring continuity

The sub-process of assuring continuity in the network formation process refers to all actions directed towards creating and communicating perception of the future benefits that the co-operation will offer as a reward for the investments of resources. Thus the members should share positive expectations of the co-operation in order to continue investing time and money into it ([3, p.177][4]). One essential element in the positive expectations is trust between the members of the network. Trust is gained through preventing opportunism either by sanctioning it in the contract [4], referring to a partner's reputation of being trustworthy [10], or referring to the history of successful past co-operation between the members [2]. The actors within network under formation may not have a history of co-operation and therefore the signs and conditions that raise the reliance on each other are vital for the network's future success [4]. The willingness to adapt and continuity of actor policies and priorities communicate credibility in joint operations [3, p. 178].

In the focal case, the most important precondition of continuity was the acceptance of the major funding organisation, TEKES. However, the acceptance is always based on the funding that other network actors, in this case the private companies and the city of Oulu provide for the network. Thus to assure major funding, the companies had to perceive that the network had a good chance of being accepted by TEKES, as all the funding from it is competitive and there is a large number of projects than do not receive funding.

In addition, in spite of the uncertainty of major funding the University research groups prepared for the project by investing their resources and setting up the infrastructure needed for the network. Thus the network webber was able to show concrete results of the network already during its formation. This way the University was perceived by the potential members of the network as a reliable research partner, that probably would also during the project deliver what it promises.

PhD Ann: *"Well of course the financial issues, as usual. Also, I think that everybody has pondered if and when we will reach the point of not understanding each other. This kind of multidisciplinary is always a possibility, but it is also a threat, since we have to respect the fundamentals of each discipline any way. We think that we know what the other work group is doing, but we cannot fully understand it, because it is a different discipline."*

4.2.4 Formal structuring

The last activity, which possesses a strong effect status in our model, is formal structuring. Formal structuring refers to actions designed to create structures that enhance co-operation, decision-making, communication, and learning [4]. Formal structure may consist of written or verbal agreements (e.g. a research agreement, a project plan) between actors, decision-making procedures or joint decision making organs. Formal structures can also include procedures through which conflict situations are resolved and exits from the network are accepted.

In the focal case the level of formal structuring was relatively low. During the nine months period that we followed the formation process intensively, the companies did not sign any agreements. However, the research groups needed to write a research plan and a project plan to apply for funding from TEKES. The documents also included plan of the formal structuring, namely designs for the steering groups, operative steering groups, project meetings, meetings of research directors, documentation procedures etc. All the companies that had orally agreed to join in and finance the network were listed in the documents, although they had not signed anything. Thus a high level of mutual trust was present and the members did not expect to meet any opportunistic behaviour from other members.

CEO of retailers' non-profit organisation: *"We have not made a written contract at the beginning... we have an oral agreement which divides our responsibilities between MTeam and our organisation. However, we have discussed our co-operation and ways of working together among our board members and internal committees."*

Since the network formation process took a long time, and there were no pressures to contribute financially until the national funding organisation accepted the application the companies could rely on oral agreements. After the acceptance from TEKES arrived during summer of 2003, all the involved actors had to agree on the terms of the research agreement and sign it officially. This process was still going on in the autumn of 2003. However, the plans to organise the project management that already appeared in the application documents were immediately put into practise once the funding was accepted. The steering group was set up (one member from each member) and in the first meeting, chairpersons were elected as well as individuals in other management groups.

As far as the research groups are concerned, their work became formally structured much earlier. Research directors meeting was the location where the groups co-ordinated their plans and efforts in the network.

PhD Timothy: *"In the research directors' meetings we have discussed work packages and the funding application as a whole. This means that everything that we have agreed on should be in the funding application and in the contents of the work packages. To the best of my knowledge, there were no discussions outside the meetings. It has progressed during the meetings."*

In the following sections we will discuss two of the sub-processes, learning and developing commitment that remained less important in our case example.

4.2.5 Learning

A company has to have an ability to learn from other actors if it wants to receive its share of the benefits that the co-operation in the R&D network brings. Inability to learn and adapt may even endanger the continuity of co-operation and lead to a dissolution of the joint activities [4][2]. The nature of any network is stable but, not static [7], meaning that even existing networks change, but the change is rarely quick and radical. Since the actors

joining an evolving network face a high level of change, e.g. new members joining in and thus changing the network, the need to adapt is also high. Thus the inability to adapt may easily lead to re-evaluation of the position of the actor in network. The level of interdependence and shared interest as initial conditions of network formation also affect the actors' abilities to adapt and learn from other each other. The actors perceiving high levels of interdependence and similar interest tend to be more capable of learning than actors that have joined the network solely because of network webber's efforts.

The network actors' learning in the focal case was not extensive. We suggest that during the formation process, the co-operation between the members of the network did not reach such an intensive and concrete level that would enhance learning from each other. However, in the relationships between software companies and the research group that PhD Timothy is responsible of, we could find clear indications of learning, since they had reached a concrete level of co-operation already during the network formation phase.

Sales director of a software company: *"For us the co-operation has already given a chance to exchange knowledge on technology. We have received feedback concerning the bugs in our software and some new ideas for further development of the software."*

CEO of a software company: *"Indeed we have received some pointers and thoughts concerning the direction to which the services are planned to develop. Through that we have learned new visions for the future."*

4.2.6 Developing commitment

The last activity of the activity cycle is labelled as developing commitment. Commitment development includes all actions to increase the awareness of single actor about their significance as a member of R&D network under formation. Through increasing awareness among actors each individual actor notices the importance of other partners as well as their own significance in R&D network. Successful collaboration starts feeding itself. Through establishment of a common ground between actors over time and fulfilling the commitments it is also possible to increase the scope and duration of co-operation [3]. This can lead to a positively reinforcing circle, where the attitudinal commitment leads to behavioural commitment and when the goals of the behaviour are achieved, this enforces the attitudinal commitment.

Communication is an important antecedent to enhancing commitment. All the important events in the network, such as goals achieved, delays or obstacles in action, overcoming the obstacles should be openly communicated to the members since this increases the members' reliance in co-operation. Open communication increases commitment and investments into the co-operation. [17]

In the focal case, the actors showed various levels of commitment. The research groups became committed to the network even before the first company members

agreed to join in. The commitment lead to finding new and extended possibilities for co-operation, as the following quotation reveals.

PhD Mary: *"It really has led to something concrete. We were preparing an EU-project, to which our department and two other departments, which are members of the network had prepared a separate application each. Thus we combined the applications. Because, based on this network, we knew that the research groups address the issue a bit alike."*

The company actors' commitment was more in an attitudinal level, since most of the companies did not have to perform any concrete tasks before signing the research agreement. However, there were also such companies, e.g. software producers, who also acted upon their commitment and invested human resources even before the funding decision was announced. These were also the ones that showed signs of learning as discussed above.

Discussion

This research has put forward an empirically grounded model of engineered R&D network formation process. The model has three elements: the initial conditions, the network webber and the cycle of sub-processes. The model offers two contributions to existing knowledge on R&D network formation. The first contribution concerns the strong role of a single actor, the network webber, in managing the network formation process. The second contribution concerns the nature of the formation process – it is a cyclical process.

The role of a single actor - *the network webber* - emerged from the data as highly influential and more extensive than research has indicated so far. The network webber not only initiates the formation of R&D network but also affects all the sub-processes of R&D network formation. The network webber triggers the engineered formation process when the initial conditions are not strong enough to trigger the process. However, the role of the network webber does not end here. The study shows clearly that the network webber was very active during the most important sub-processes through which the network became existent. The network webber enabled the network formation by pointing out to the potential members that they share interests and that those interests could be served in co-operation. During the acquiring actors sub-process, the network webber attracted, approved and disapproved potential members. The network webber was also a main assurance for continuity, since based on previous experiences he enjoyed a reputation of being reliable and was able to orchestrate the compiling of the research and project plans, which earned the major funding for the network. Also, during the formal structuring, the network webber acted as a major designer of the organisation, which actualised itself once the funding application was accepted. Besides being a major actor in the most important sub-processes, the network webber also was active in providing opportunities for learning and the development of commitment.

The suggested model presents six sub-processes, namely enabling network formation, joining, assuring continuity, formal structuring, learning and developing commitment, through which the formation process proceeds. We argue that the network formation activities do not follow a predetermined path as suggested by existing research. On the contrary, the model presented in this paper suggests that the activities appear in cyclical structure. Based on the empirical grounding, there is no clear order of appearance in the sub-processes and they may take place both simultaneously and partially. Moreover, the members of the network may repeat the sub-processes during the formation process. For example, actor acquiring was a sub-process that was ongoing throughout the duration of the formation process.

As any research, this also involves restrictions that pave ways to further research. Our focus was on the engineered network formation process and therefore it is natural the role of the network webber is strong. R&D networks can also evolve without a strong network webber, if the initial conditions are strong enough. However, we do not know how often the networks start without the triggering actions of network webber.

The empirical grounding of the model was based on a case study on a network formation, which included members from both academia and business life. Although we can assume that whenever the task of the network involves developing new technologies, the network includes research organisations that are government funded, there are also R&D networks that consist of private companies only. Even if the private company networks would receive government funding, we expect that in cases where the role of a network webber is held by a private company or representatives of one, that alone influences the process. In the focal case, the network webber was considered as a neutral actor, who acted upon the behalf of the whole network and not only behalf of his or his organisation's interest. This of course, had an effect on the formation process. However, it is logical to assume that the sub-processes would be much the same, although the outcome of e.g. joining would be different. Thus it would bring us new knowledge to compare the formation processes of different kinds of R&D networks, to see in what was they differ, if at all.

Abstract

Many factors such as barriers, reasons, vendor consideration, success factors and challenges play important roles in implementing electronic-learning systems for e-business. In this paper, a questionnaire is used to collect respondents' attitudes toward those factors, and the result is analyzed.

The result of chi-square test indicates that the respondents who have e-learning systems in their organizations are mostly from industries, and for those who have not tend to emphasize more on "cost and unawareness" which scored under 0.4 (i.e. low internal consistency) in reliability. However, the variance of the respondents' attitudes toward the remaining six factors is not large.

Keywords: e-Learning, e-Business, barriers, reasons for implementation, vendor consideration, success factors, challenge factors.

1. Introduction[†]

Problems may be encountered when implementing e-Learning systems for e-business; however if barriers are known in advance, problems are easier to be solved. In addition, reasons for implementation from different stakeholders setup directions to be followed for e-Learning systems. If the expectation of an e-Learning system is known, corporations can be more confident setting up corresponding strategies (see Figure 1) and implementation can be started. Furthermore, suitable vendors can supply satisfactory e-Learning solutions to corporations. Suitable vendors which provide contents, technologies and services help shorten the implementation time, and guarantee a successful e-Learning system for e-business. Success and challenge factors are collected from related articles which suggest actions to be taken for a better implementation.

In sum, it is recommended to analyze the situation of the corporation as well as plan the expectations for e-Learning systems for e-business. Suitable vendors shall be chosen, and lastly success and challenge factors serve as references for their e-Learning systems.

2. Purpose

B2B e-Learning systems facilitate enterprises' (i.e. business-to-business) learning mechanisms via the Internet. Some research reports the factors of their implementations. However, the relationships among the responses toward these factors and whether respondents have e-Learning systems in their organizations are seldom observed. Why do corporations need to understand all these critical factors clearly? Because by doing so, corporations save time and avoid spending money on unnecessary places. If corporations know exactly what different stakeholders feel toward these items, the results will be valuable.

This research investigates implementation factors, and provides practical advices. It analyzes the collected data which is from the survey of "critical factors of an e-Learning system for e-business", and tests such as chi-square test, factor analysis and t-test are used to verify whether there are significant differences in respondents who have e-Learning systems in their organizations, and those who have not. Lastly, the differences and new findings are emphasized.

Figure 1 Strategy and Stakeholders

[†] This work was partially supported by the National Science Council in Taiwan, Republic of China, under Grant NSC 91-2623-7-009-016, NSC91-2416-H009-012 and NSC92-2416-H009-012.

3. Methodology

The research methodology consists of “select critical factors”, “questionnaire design”, “chi-square test”, “factor analysis”, “t-test” and “conclusions” (see Figure 2). The critical factors which collected from the related literatures (see Table 1) are categorized into barriers for e-Learning, reasons for implementation, vendor consideration, success and challenge. A questionnaire which includes nine demographic questions and thirty-eight questions of critical factors is thus designed.

Chi-square test, factor analysis and t-test are conducted to examine if there are significant differences among the responses toward these factors and whether the respondents have e-Learning systems in their organizations. Lastly, the results will be well examined and feedback to the survey for advanced research.

3.1 Designing Questionnaire

Three different types of questionnaires that are web-based, e-mail and hardcopy are provided. The majority of the respondents prefer the web-based questionnaire. The questionnaire consists of six sections. Section 1 identifies the demographic information of the respondents. Questions include gender, age, career, department, position and education. Section 2 focuses on the attitudes of respondents toward the identified “four barriers”. Section 3 emphasizes their attitudes toward “reasons for implementation”.

Section 4 focuses on “vendor consideration”. Section 5 weights their viewpoints toward “success factors”, and lastly section 6 examines the attitudes toward “challenge factors”. These factors are measured using Likert-type scale which ranges from 5 to 1 with the following equivalence, “5”: “strongly agree”; “4”: “agree”; “3”: “neutral”; “2”: “disagree”; “1”: “strongly disagree”.

3.2 List of Factors under Investigation

In this survey, five main items are observed, and each of them contains sub-items. They are listed below:

Factors of Four Barriers [9] [18]

- B1 Cost too high
- B2 Technology Immaturity
- B3 Solution Immaturity
- B4 Unawareness

Factors of Reasons for Implementation [14]

- R1 Increase Competence
- R2 Stay Innovative
- R3 Support 24 x 7 Training
- R4 Reduce Training Time
- R5 New Training Technology
- R6 Reduce Training Cost
- R7 Increase Revenue
- R8 Decrease Time Spending on Selling
- R9 Flexible Learning
- R10 Win-Win Situation
- R11 Customer On-Line Learning
- R12 Enhance Customer Satisfaction

Factors of Vendor Consideration [4] [15]

- V1 Content
- V2 Technology Integration
- V3 Service Quality
- V4 Implementation Experience
- V5 Implementation Cost
- V6 Reputation

Success Factors [2] [3]

- S1 Organizational Support
- S2 Virtual Project Teams
- S3 Measure everything
- S4 Include Independent Learners
- S5 Include Peer Interaction
- S6 Provide Mentoring
- S7 Offer Performance Feedback
- S8 Marketing

Challenge Factors [4] [9]

- C1 Correct Target Setup
- C2 LMS Configuration
- C3 Tutors and SMEs Integration
- C4 Content Creation
- C5 Multiple Modes of Learning
- C6 Back-End Systems Integration
- C7 Web Infrastructure
- C8 Online Access Capability Training

3.3 Conceptual Model

A qualitative phase of this research is conducted to identify possible factors leading to the implementation of an e-Learning system for e-Business [1]. Related literatures on e-Learning systems for e-Business are also reviewed in order to select the factors of interest. Figure 3 depicts the conceptual model of the six factors naming, “Barriers”, “reasons”, “vendor consideration”, “success” and “challenge” and “implementation”.

4. Analysis Methods

Information on the attitudes toward critical factors of e-Learning systems for e-business is gathered through survey. Four types of analysis algorithms are used for different factors. Percentage analysis is used for demographic information, and chi-square test examines the relationships among different demographic data as well as whether the respondents have e-Learning systems in their organizations. Factor analysis extracts new factors from those five critical items. New factors are verified using Cronbach’s alpha test to measure the reliabilities. T-test examines the differences among the extracted factors and whether the respondents have e-Learning systems in their organizations.

Excel 2002 and SPSS10.0 are used to compute those results. Detailed explanation and diagrams are provided and discussed in the following sections. Chi-square test contains the row and column variables of the test. Factor analysis and Cronbach’s alpha test are explained in Section 4.2 and 4.3. T-test contains one diagram of the test and grouping variables.

Figure 3 Proposed Models of Factors of Implementing E-Learning Systems for e-Business

4.1 Chi-Square Test

Figure 4 depicts the variables of chi-square test. The relationships among gender, working field, department, role, experience and whether the respondents have e-Learning systems in their organizations are carefully examined.

Gender consists of female and male. Field contains students and the respondents from industries. Department is divided into two groups: Non-IT and IT departments. Role consists of the respondents' experiences on implementation of e-Learning systems. Lastly, experience includes those who have or have not experiences of using e-Learning systems.

4.2 Factor Analysis

According to Foster [12], factor analysis is a technique or a family of techniques which aim to simplify complex sets of data by analyzing the correlations between them. A component or a factor explains the variance in the inter-correlation matrix, and the amount of variance explained is called the eigenvalue.

A factor loading is the correlation of a variable with a factor. If a loading is higher or equal to 0.3, it is frequently taken as meaningful when interpreting a factor. In this paper, principal components analysis is recommended as the method for reducing the number of variables. In order to obtain an orthogonal simple structure rotation, varimax method is used.

4.3 Cronbach's Alpha Test

According to Foster [12], reliability refers to the consistency of the results on different items in a test. Cronbach's alpha is one of the standard ways to express the reliability of a test. The value can be obtained by using SPSS10.0. A reliability coefficient of 0.8 or higher is considered as "acceptable" in most social science applications. The value should not be lower than 0.7. However, tests of personality often have much lower values, partly because personality is a broader construct.

4.4 T-Test

Figure 5 depicts the test and grouping variables of t-test. The differences among "Cost and Unawareness" and "Immaturity" in barriers factor, "Training Effectiveness" and "New Revenues" under reasons for implementation, "Vendor Consideration", "Success", "Challenge" and whether the respondents have e-Learning systems in their organizations are carefully examined.

5. Demographic Information

The survey was conducted from May 13th to May 27th, 2003. There is a total number of 142 respondents, including 56 females (39.44%) and 86 males (60.56%) respectively (Figure 6), agreed to participate in this research. Most of them were from Hsin-Chu Industrial

Science Park and National Chiao Tung University.

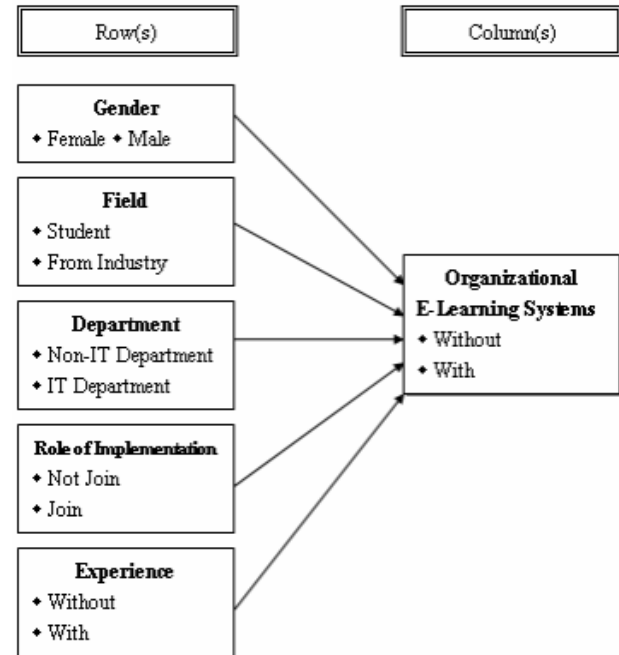

Figure 4 Variables of Chi-Square Test

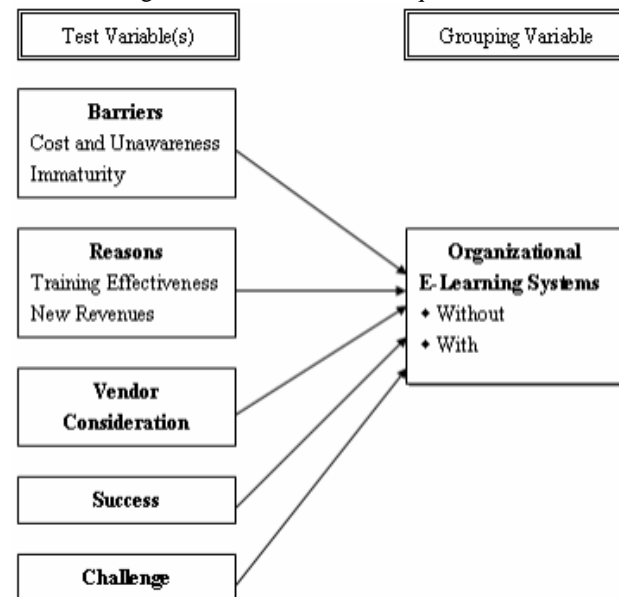

Figure 5 Test and Grouping Variables of T-Test

From figure 7, it clearly illustrates that 29.58% of the respondents were students, and 23.24% of the respondents came from the information technology industries, 16.20% were from electrical and electronics, and 15.4% were from military, government and academic. After the analysis of the departments' bar chart as shown in Figure 8, it is found that 21.13% of the respondents were from the departments of information technology, 11.27% were from management, 10.56% were from technical support, 8.45% were from research & design. 53.52% of the respondents have no e-Learning systems in their organizations (Figure 9). The respondents who have no experiences of implementing e-Learning systems accumulate 72.54% whereas the ones who have account for 27.46% (Figure 10). Lastly, Figure 11 illustrates their experiences of using

e-Learning systems.

Figure 6 Gender

Figure 7 Industry

Figure 8 Department

Figure 9 E-Learning Systems Implemented in Organizations

Figure 10 Joining the Implementations of E-Learning Systems

Figure 11 Experiences of Using E-Learning Systems

6. Chi-Square Test on Demographic Items

The chi-square test was conducted to test whether there were significant differences among different demographic data as well as whether the respondents have e-Learning systems in their organizations.

Gender

The chi-square value is 1.087 (df=1, n=142) and the p-value is .297 ($p > 0.05$) which means that there is no significant difference. Thus we concluded that whether the respondents have e-Learning systems in their organizations do not have significant difference in gender.

Working Field

The relationship between the respondents' fields and whether they have e-Learning systems in their organizations is shown in Table 2 (Note: WO/EL = Without Organizational E-Learning Systems; CW / EL = with Organizational E-Learning Systems). The chi-square value is 5.78 (df=1, n=142) and the p-value is .016 ($p < 0.05$) which means that there is a significant difference. When comparing the percentages of the two working field groups in Table 2, the percentage of the respondents who are students and have e-Learning systems in their organizations (19.7%) are smaller than those who are from industries (80.3%). It is obvious that the majority of the respondents who have e-Learning systems in their organizations are from industries rather than students. Figure 11 depicts the line chart of field * organizational e-Learning systems.

Table 2 Field * Organizational E-Learning Systems Cross Tabulation

Field	WO/ EL	W/ EL	Total
Students	29 (38.2%)	13 (19.7%)	42 (29.6%)
From Industries	47 (61.8%)	53 (80.3%)	100 (70.4%)
Total	76 (100.0%)	66 (100.0%)	142 (100.0%)
Chi-Square Value	$X^2=5.78$ $df=1$ $n=142$		

Figure 12 Field * Organizational E-Learning Systems

Department

The chi-square value is 2.642 ($df=1$, $n=142$) and the p-value is .104 ($p>0.05$) which means that there is no significant difference. Thus we conclude that whether the respondents have e-Learning systems in their organizations do not have significant difference in non-IT or IT departments.

Role in Implementation of E-Learning System

The relationship between the respondents' roles in implementations of e-Learning systems and whether they have e-Learning systems in their organizations is shown in Table 3. The chi-square value is 20.033 ($df=1$, $n=142$) and the p-value is .000 ($p<0.001$) which means that there is a significant difference. In order to find out which role group has more respondents, the percentages of the two role groups in Table 3 are compared. When comparing the respondents who have no e-Learning systems in their organizations, it is clear that the respondents who have no experiences of implementing e-Learning systems accumulate greater percentage (88.2%) than those who have (11.8%). However, if comparing the respondents who have e-Learning systems in their organizations, the percentages of respondents who have no experiences of implementing e-Learning systems (54.5%) and who have (45.5%) are very close. Therefore, we conclude that most of the respondents who have no e-Learning systems in their organizations also have no experiences of implementing e-Learning systems. Figure 13 depicts the

line chart of role * organizational e-Learning systems.

Experiences on Using e-Learning Systems

The relationship among the respondents' experiences on using e-Learning systems and whether they have e-Learning systems in their organizations is shown in Table 4. The chi-square value is 24.506 ($df=1$, $n=142$) and the p-value is .000 ($p<0.001$) which means that there is a significant difference. In order to figure out which experience group has more respondents among those who have e-Learning systems in their organizations, the percentages of the two experience groups are compared. It is obvious that the respondents with experiences show greater percentage (87.9%) than those who do not (12.1%). Thus we conclude that the majority of the respondents who have e-Learning systems in their organizations also have experiences of using e-Learning systems. Figure 14 depicts the line chart of experience * organizational e-Learning systems.

After the analysis of the chi-square test, we conclude that only working field, role and experience have significant differences between the respondents who have no e-Learning systems in their organizations and those who have. The respondents who have e-Learning systems in their organizations are mostly from industries and have experiences of using e-Learning systems. However, the majority of the respondents who have no e-Learning systems in their organizations also have no experiences of implementing e-Learning systems.

Table 3 Role * Organizational E-Learning Systems Cross Tabulation

7. Factor Analysis & Cronbach's Alpha Test

The following sections explain the results of factor analysis and Cronbach's alpha test, which are carefully calculated using SPSS version 10.0. It uses the extraction method of principal components and varimax rotation. Additional information regarding the results is also described, such as factor loadings, eigenvalues, percentages of variance and Cronbach's alpha values.

Every factor is labeled a new name which reflects the characteristics of the items it contains. Items are ordered according to their factor loadings (from highest to lowest) and grouped according to factors. However, if the difference between the item's highest and second highest factor loadings is less than 0.15, the item is eliminated.

7.1 Analysis of Four Barriers

The factors analysis result of barriers indicates that there are two factors with eigenvalues greater than 1.0. A two-factor solution is suggested after examining the results (see Table 5).

Component one is labeled "Cost and Unawareness" and accounted for 33.372% of the variance. It includes "cost too high" and "unawareness". The reliability (internal consistency) is 0.3702. Component two is labeled "Immaturity" and accounted for 30.031% of the variance. It includes "technology immaturity" and "solution immaturity". The reliability is 0.3848.

Table 5 Factor Analysis of Barriers

Item		Component & Factor Loading	
		1: Cost and Unawareness	2: Immaturity
B1	Cost too High	.811	-5.373E-02
B4	Unawareness	.682	.141
B2	Technology Immaturity	-9.541E-02	.900
B3	Solution Immaturity	.451	.606
Eigenvalue		1.335	1.201
% of Variance		33.372%	30.031%
Cronbach's Alpha		0.3702	0.3848

Note. Boldface indicates highest factor loadings.

Table 6 Factor Analysis of Reasons

Item		Component & Factor Loading	
		1: Training Effectiveness	2: New Revenue
R3	Provide 24 x 7 Full time Training	.834	6.830E-02
R5	New Training Technology	.830	.164
R9	Flexible Learning	.793	.289
R11	Customer On-Line Learning	.782	.132
R4	Reduce Training Time	.757	.228
R1	Increase Competence	.738	.385
R6	Reduce Training Cost	.547	.378
R10	Win-Win Situation	.538	.431
R8	Decrease Time Spending on Selling	-7.382E-02	.886
R7	Increase Revenue	.248	.672
R2	Stay Innovative	.464	.550
R12	Enhance Customer Satisfaction	.428	.507
Eigenvalue		4.796	2.457
% of Variance		39.964%	20.477%
Cronbach's Alpha		0.9033	0.5678

Note. Boldface indicates highest factor loadings.

Δ indicates the difference between two factor

loadings is less than 0.15.

7.2 Analysis of Reasons for Implementation

The factor analysis result of reasons indicates that there are two factors with eigenvalues greater than 1.0. A two-factor solution is suggested after examining the results (see Table 6).

Component one is labeled “Training Effectiveness” and accounted for 39.964% of the variance. It includes all the sub-items about training. The reliability is 0.9033. Component two is labeled “New Revenues” and accounted for 20.477% of the variance. It includes “decrease time spending on selling” and “increase revenue”. The reliability is 0.5678.

7.3 Analysis of Vendor Consideration

The factor analysis result of vendor consideration indicates that there is one factor with eigenvalue greater than 1.0. A one-factor solution is suggested after examining the results (see Table 7).

Component one is labeled “Vendor Consideration” and accounted for 62.289% of the variance. It contains all the items in vendor consideration. The reliability is 0.8658.

7.4 Analysis of Success Factors

The factor analysis result of success indicates that there is one factor with eigenvalue greater than 1.0. A one-factor solution is suggested after examining the results (see Table 8).

Component one is labeled “Success” and accounted for 65.314% of the variance. It contains all the items in success. The reliability is 0.9227.

7.5 Analysis of Challenge Factors

The factor analysis result of challenge indicates that there is one factor with eigenvalue greater than 1.0. A one-factor solution is suggested after examining the results (see Table 9).

Component one is labeled “Challenge” and accounted for 66.420% of the variance. It contains all the items in challenge. The reliability is 0.9274.

Table 7 Factor Analysis of Vendor Consideration

Component 1: Vendor Consideration		Factor Loading
V3	Service Quality	.911
V2	Technology Integration	.892
V4	Implementation Experience	.875
V1	Content	.840
V5	Implementation Cost	.723
V6	Reputation	.344
Eigenvalue		3.737
% of Variance		62.289%
Cronbach's Alpha		0.8658

Note. Boldface indicates highest factor loadings.

Eigenvalue		5.314
% of Variance		66.420%
Cronbach's Alpha		0.9274

Note. Boldface indicates highest factor loadings.

8. T-Test of Seven Extracted Factors

T-test is conducted to examine whether there are significant differences between the above seven factors and whether the respondents have e-Learning systems in their organizations. The seven factors are “Cost and Unawareness” and “Immaturity” under barriers, “Training Effectiveness” and “New Revenues” under reasons for implementation, “Vendor Consideration”, “Success” and “Challenge”.

8.1 Barriers

The t-test result of “Cost and Unawareness” ($t=-2.147$; $p<0.05$) from t-test shows significant differences between the respondents who have no e-Learning systems in their organizations and those who have. However, the result of “Immaturity” ($t=-.773$; $p>0.05$) from t-test does not have significant difference. The mean value of “Cost and Unawareness” from the respondents who have no e-Learning systems in their organizations is 6.8158; while from those who have is 6.2879. It is obvious that the respondents who have no e-Learning systems in their organizations emphasize more on “Cost and

Unawareness” than those who have (see Table 10).

Table 10 Group Statistics of Cost and Unawareness

Group	Mean	t-value	p-value
Without Organizational E-Learning Systems	6.8158	-2.147	0.034
With Organizational E-Learning Systems	6.2879		

8.2 Reasons for Implementation

The t-test results of both “Training Effectiveness” ($t=-.162$; $p>0.05$) and “New Revenues” ($t=.987$; $p>0.05$) do not show significant differences between the respondents who have no e-Learning systems in their organizations and those who have.

8.3 Vendor Consideration

The t-test result of “Vendor Consideration” ($t=-1.009$; $p>0.05$) does not have significant differences between the respondents who have no e-Learning systems in their organizations and those who have.

8.4 Success

The t-test result of “Success” ($t=-.683$; $p>0.05$) does not have significant differences between the respondents who have no e-Learning systems in their organizations and those who have.

8.5 Challenges

The t-test result of “Challenge” ($t=-.964$; $p>0.05$) from t-test does not have significant differences between the respondents who have no e-Learning systems in their organizations and those who have.

At the end, we conclude that only “Cost and Unawareness” have significant differences between the respondents who have no e-Learning systems in their organizations and those who have. Furthermore, the respondents who have no e-Learning systems in their organizations obviously consider it more important than those who have. On the contrast, regardless the respondents who have e-Learning systems in their organizations or not, they do not significantly differ in the attitudes toward other remaining factors.

9. Conclusion

9.1 New Findings

The following represents the new findings of this investigation. They are gathered from the results of chi-square test, factor analysis and t-test.

Results of Chi-Square Test

The results of chi-square test indicate that the majority of the respondents who have e-Learning systems in their organizations are mainly from industries. Most of the

respondents who have not e-Learning systems in their organizations also have not experiences of implementing e-Learning systems.

Results of Factor Analysis

From the results of factor analysis, only the two factors in barriers have reliabilities lower than 0.4 which indicates low internal consistencies. However, the other five factors have reliabilities higher than 0.7 which represents high internal consistencies.

Results of T-Test

When examining the results of t-test, the respondents who have not e-Learning systems in their organizations emphasize more on “Cost and Unawareness” than those who have. However, whether the respondents have e-Learning systems in their organizations, they do not have significant different attitudes toward the other six factors which are “Immaturity”, “Training Effectiveness”, “New Revenues”, “Vendor Consideration”, “Success” and “Challenge”.

9.2 Contributions

The following represents the seven contributions of this investigation. They are approaches and considerations, advantages and disadvantages of e-Learning systems for e-Business, elementary concepts and understanding, useful information, examples of benefits, where corporations stand and references from other e-Learning stakeholders

Basic Approaches and Considerations

There are some basic approaches and considerations proposed to help the corporations who are just getting started with the implementations of e-Learning systems for e-Business.

Advantages and Disadvantages of E-Learning Systems for E-Business

It advises the decision makers what the advantages and disadvantages are. They shall balance from the situations they choose, and avoid the failures from other people’s experiences. Different stakeholders shall know their own responsibilities and jobs.

Elementary Concepts and Understanding

The elementary concepts and understanding about the implementations of e-Learning systems are introduced. It also gives a good e-Learning guide and roadmap. No matter the reader is a beginner or an expert, this paper can enrich his / her e-Learning knowledge.

Useful Information

All the analytical results in the study provide useful information on how the respondents rate on all the critical

factors proposed. The information leads corporations to have a successful e-Learning system for e-Business.

Ö Benefits

If corporations know respondents' attitudes toward the barriers, barriers are easier to be solved. By knowing the reasons for implementation, corporations can propose a sound e-Learning project. The results of vendor consideration can aid to choose an appropriate one. The rates of success and challenge factors undoubtedly give strong evidences for a better e-Learning system.

Ü Where Corporations Stand

With a clear understanding of these results, corporations know where they stand. Furthermore, they can setup corresponding strategies and objectives which lead them to a smooth implementation of e-Learning system for e-Business.

á References from other Stakeholders

The vendors of e-Learning solutions can figure out what end-users emphasize the most when choosing suitable vendors. Different stakeholders shall consider all the perspectives. By doing so, they can understand what others feel toward a better implementation of e-Learning systems for e-Business.

9.3 Limitations

There are five points of limitations must be acknowledged. All of them are listed and explained in the following. They are time, manpower, demographic, response rate, validity, flexibility and reliability limitations.

Á Time and Manpower Limitation

Due to the limited time and manpower, there are still spaces for further investigation.

Ç Demographic Limitation

Most of the respondents came from Hsin Chu Science Park and National Chiao Tung University, so the results are limited to these areas.

É Response Rate and Validity

As people tend to dislike questionnaires, thus a low sample size is gathered. Furthermore, the conditions under which the questionnaires are finished cannot be controlled.

Ñ Flexibility

Questionnaires are less flexible and therefore required more preliminary thought and preparation for their structures and contents.

Ö Reliabilities of "Cost and Unawareness" & Immaturity"

They are both under 0.4 which mean that their internal consistencies are low. Therefore, in the future study, new test items shall be developed.

Abstract

In this paper, we study a sea cargo mix problem that occurs in the context of container shipment planning and revenue analysis in ocean carriers. We describe structure and characteristics of the cargo mix problem, and formulate as a Multi-Dimension Multiple Knapsack Problem (MDMKP). In particular, the MDMKP is an optimization model that maximizes the total profit in several periods, subject to the limited shipping capacity and the limited number of empty containers in the origin port, etc. Algorithm is proposed to obtain the near optimal solution for the problem. Numerical experiments demonstrate the efficiency of the algorithm.

Track area: SCM & e-logistics/ Operations Planning & Control.

Keywords: sea cargo mix, container shipping industry, MDMKP.

1. Introduction and Problem Description

In the recent economic environment, it is often the case that profits can only be maintained or increased by improving efficiency and cutting costs. This is particularly proverbial in the shipping industry, where it has been seen that the competition is very intensive among container carriers, thus alliances and partnerships are resulting for cost effective services in recent years. In this scenario, effective planning methods are important not only for strategic but also operating tasks, covering their entire transportation business (see [2][4][13][18][19]). Sea cargo mix planning is an important part of the operations of container shipping lines. This paper addresses the problem of sea cargo mix planning for containerized cargoes, to achieve the most profitable, time definite and cost-effective services in a competitive ocean container

shipping market.

Shipping industry has started utilizing internet B2B exchanges, a marketplace where many buyer and sellers post buy and sell bids to make trades at dynamically determined market prices. Both shipping lines and shippers are moving towards e-logistics in all dealings. All documents can be received electronically, captured and processed directly into the e-logistics system seamlessly. Online booking request is made available 24 hours a day. Within the e-booking, shipper has to select the cargo from the commodity list provided, specify the size and type of container, and enter port of receipt or delivery on the latest departure and arrival date. For examples, Maersk-Sealand, Hanjin, APL and Hyundai are among the carriers offering such service (see their websites for details). Maersk-Sealand uses digital certificate to prove one's identity and enable access to protected area to make booking online faster and safer. The shipper suggests the most appropriate vessel sailing from global schedule system displayed on screen and finally save all information. The shipper's request will then be transmitted to the local Maersk-Sealand office, where confirmation of requirement together with the booking reference number will be sent back to the shipper.

For many containerized cargo carriers, the majority of their bookings are under long-term contracts with shippers. Such long-term agreements help carriers support requests for the large amounts of capital required to run their businesses. These long-term contracts are typically for one to three years. For some carriers, annual contracts all date to the same time of year and may cause a flurry of activity to re-negotiate terms and solidify the next year's business. Regardless of timing, these contracts form a significant part of the revenue stream for a container carrier and negotiating the right prices and terms can be a major contributor to overall profitability. In practice, booking requests are often made less than 14 days before the freight becomes available for shipment, in which case

the carrier may delay moving the freight if insufficient capacity is available. For example, the shipper may request a booking on a voyage that departs 9 days into the future, but if that voyage is already too fully booked, then the carrier may offer to transport the freight on a voyage that departs a week later, thus 16 days into the future. The shipper may then accept the booking offer, or decline the booking offer and request a booking with another carrier. Also, often shippers' cancel previously made bookings. It also happens that freight scheduled to depart on a voyage does not arrive at the port in time for the voyage. Approximately 30% of booked freight ends up not transported as originally booked. The booking control decision maker at the carrier has to decide, whenever a shipper requests a booking, what booking to offer the shipper. For example, the carrier may offer the shipper a booking on the voyage 9 days into the future, or on a voyage scheduled to depart a week later. The decision maker should take into account the revenue specified in the contract with the shipper, the probability of the shipper declining the booking offer, as well as uncertain future booking requests, cancellations and no-shows.

In practical situation, less-than-container-load (LCL) cargo orders come through telephone, email or website from established customers (these usually have their own shipping department), freight forwarders who act for customers or some new customers. Full-container-load (FCL) cargo orders are usually from big firms such as many electronics manufacturing companies. These big customers usually let the carrier know approximately the number of containers they will ship over the next three or four weeks (need to check if this practice still is in place). Agreement is loose and not legally binding.

The carrier will have the following priorities:

- 1) High paying FCL cargo (e.g., electronics)
- 2) Medium paying
- 3) Low paying (e.g., gypsum board)

If times are good and demand exceeds container space, the shipping company will rollover those low paying cargo (i.e. not ship on schedule but postpone shipment to a later date). Under the contract, customers cannot sue the shipping company. If times are bad, the shipping company will look for low-paying cargo to fill the vessel rather than ship empties.

FCL cargo usually has no weight/volume specification because customers always pack to the fullest. Because maximum weight of 20-foot and 40-foot container are 18 MT and 40MT, respectively, so if cargo is volume cargo, you can pick in something like 40 cu meters and yet the cargo weighs less 20 tons. For weight cargo (e.g., steel), 20 tons is easily reached when the container is 1/3 full. You just cannot pack in anymore (legal requirement). Most LCL cargo tends to be volume cargo and the shipping company prefers that because they charge by weight or volume. The shipping company takes all orders but those they can't ship, they will inform the customers after the ship sails.

Sea cargo mix problem arises when a liner operator wants to select cargoes in order to maximize his revenue for some particular trips. Optimal cargo mix technique

needs data from the online booking system and container tracking system to provide current status and location of container inventory as well as details of all costs associated with shipments. Historical data is gathered or built up over time to permit forecasting of container flows and inventory levels. From demands, bookings, available capacity and average contributions, it mathematically determines an optimal target contribution to determine whether to accept or reject a proposed booking, or to suggest a surcharge or alternate product or service at a higher/lower price. The result would be used to adjust contribution calculations to favor certain types of freight on certain routes and discourage others.

Each type of cargo has different volume/ weight characteristic, different freight rate and generates different revenue. For example, the tradeoff in FCL and LCL cargo mix is important operational issue for liner operators. Shipping companies offer customers priority, time-bound forwarding for LCL and FCL shipments with fast transits, reliable schedules and competitive price. A FCL of electronics pays higher than a FCL of gypsum board. Furthermore, if the inbound vessel is full, and if this is not balanced by a full outbound, then there is the need to ship empties necessitated by the need to re-position the empties for use by the destination port. This too has to be taken into account in the optimal revenue analysis. The repositioning of empty containers is one of the single largest expenses for most container carriers. Regarding container demand and supply it minimizes empty repositioning costs and maximize vessels utilization and it lead to a pro-active pricing mechanism for improved revenues and reduced costs. In order to optimally use vessels optimally matched where possible according to customer requirements to minimize empty repositioning costs. This takes into account excess empties and will result in optimal utilization of vessels while total transportation costs (for both full and empty containers) are reduced and trade imbalances will be compensated. Many different models have been proposed in the literature to obtain an optimal container repositioning planning. However, most of them did not consider it with transportation of laden containers and revenue management (see [1][3][9]).

In our work, we abstract the FCL and LCL cargo and the empty container as different type of cargo. Further more, in the model proposed in our paper, we consider more detailed information concerned with each type of cargo. Such information include the weight, volume, shipment price and shipment due date requirement, etc.

To our knowledge, up until now, there is no any description and formulation for the multi-period sea cargo mix problem in the literature. Single period sea cargo mix problem is proposed by [5] and it is formulated as linear programming model by [10], when all cargoes are separable for shipment. Literature on related mathematical programming models and algorithms see related Sections.

The rest of the paper is organized as follows. In Section 2, the multi-period sea cargo mix problem is formulated as the Multi-Dimension Multiple Knapsack Problem (MDMKP). Section 3 presents algorithm for the

model. The heuristic algorithm with effective gradient and its modified algorithm are given in this section. We demonstrate the algorithm with effective gradient by a simple example in this section, followed in Section 4 by numerical experiments of the algorithm with a wide range of problem instances. Section 5 concludes the paper.

2. Mathematical Formulation

There are several technical constraints relative to how a ship should be loaded. The obvious constraints are that cargo weight and volume should not exceed the ship's capacity. The operational objective is to select the loading parameters in order to maximize some profit criterion subject to the mathematical expression of the weight/volume constraints. If the freight rates are known and the operator can refuse or delay to carry cargoes, then the multi-period sea cargo mix problem can be formulated as MDMKP. The objective of the problem is to maximize a weighted sum of the quantities transported. The relative coefficients for the cargoes might reflect their unit profits.

In this section, we develop a mathematical model for the problem under consideration. For the ease of our discussion, we consider that one time period represents one day or one week and we use the term t to represent the t th time period.

In order to present the mathematical formulation of the model for a given planning time horizon, we introduce some notation:

Index Sets

\tilde{T} set of time periods $\{1, 2, \dots, t, \dots, T\}$

\tilde{J} set of ports $\{1, 2, \dots, j, \dots, J\}$

\tilde{K}_t set of all cargoes received in period t , i.e.,

$$\tilde{K}_t = \{1, 2, \dots, k, \dots, K_t\}$$

Parameters

r_{tkdj_k} per volume revenue of cargo k which is received in period t and shipped to port j_k in period d

c_{tkdj_k} per volume cost of cargo k which is received in period t and shipped to port j_k in period d

h_{tk} per volume inventory cost of cargo k which is received in period t and delayed to carry in next period

τ_k due date of cargo k

E_t total volume of available empty containers at origin port in period t

V_{tj} total available volume capacity of shipment to port j in period t

W_{tj} maximum allowable weight capacity of shipment to port j in period t

$v_{tk\tau_k j_k}$ volume of cargo k received in period t ready for shipment to port j_k before its due date τ_k

$w_{tk\tau_k j_k}$ weight of cargo k received in period t ready for shipment to port j_k before its due date τ_k

Decision Variables

x_{tkdj_k} binary variable, i.e., $x_{tkdj_k} = 1$, if cargo k is received in period t and is ready for shipment to port j_k in period d before its due date τ_k , 0, otherwise.

In this paper, we assume that there are one origin port and J destination ports. All cargoes are received at origin port in a certain period of time horizon T . The shipping company decide which cargoes carry in the current period and which cargoes are delay to carry in the other period within their due date and which cargoes are refused to carry in the time horizon T .

Let $\bar{r}_{tkdj_k} = r_{tkdj_k} - c_{tkdj_k} - (d - t)h_{tk}$, $\forall t \in \tilde{T}$, $k \in \tilde{K}_t$, $j_k \in \tilde{J}$, $t \leq d \leq \tau_k$, our multi-period sea cargo mix problem can then be formulated as follows:

$$(M1): \text{Maximize } z = \sum_{t=1}^T \sum_{k \in \tilde{K}_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k j_k} \bar{r}_{tkdj_k} x_{tkdj_k} \quad (1)$$

subject to

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k j_k} x_{tkdj_k} \leq E_d \quad \forall d \in \tilde{T} \quad (2)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d \\ j_k = j}} v_{tk\tau_k j_k} x_{tkdj_k} \leq V_{dj} \quad \forall d \in \tilde{T}, j \in \tilde{J} \quad (3)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d \\ j_k = j}} w_{tk\tau_k j_k} x_{tkdj_k} \leq W_{dj} \quad \forall d \in \tilde{T}, j \in \tilde{J} \quad (4)$$

$$\sum_{d=t}^{\tau_k} x_{tkdj_k} \leq 1 \quad \forall t \in \tilde{T}, k \in \tilde{K}_t \quad (5)$$

$$x_{tkdj_k} \in \{0,1\} \quad \forall t \in \tilde{T}, k \in \tilde{K}_t, j_k \in \tilde{J} \quad (6)$$

The objective function (1) maximizes the total profit in the time horizon T . Constraints (2) ensure that the demand for empty containers at origin port is less than the number of available empty containers at origin port in each period. Constraints (3) ensure that the total volume of cargoes which will be carried to port j in period d is less than the total available volume capacity of shipment to port j in period d . Constraints (4) ensure that the total weight of cargoes which will be carried to port j in period d is less than the total available weight capacity of shipment to port j in period d . Constraints (5)

impose that each cargo may be carried in a certain period before their due date or be refused to carry in the time horizon T . Constraints (6) assure that each cargo can be either accepted at its total quantity or be turned down.

We may notice that the inequality sign in (5) is replaced by equality, if all received cargoes have to be carried in the time horizon T . In this case, the MDMKP (M1) may have not feasible solution, because the total available capacity of shipment may be less than the amount of demands in the time horizon T . On the other hand, MDMKP (M1) always has the optimal solution, because it has a trivial feasible solution $x_{tkdj_k} = 0$, for all $t \in \tilde{T}$, $k \in \tilde{K}_t$, $d \in \{t+1, L, \tau\}_k$, and its LP relaxation optimal value is an upper bound of its optimal value.

3. Heuristic Algorithm for MDMKP

The 0-1 or binary integer programming is an integer programming whose all decision variables are 0-1 values. An important class of binary integer programming problems is the Knapsack Problem (KP). The Single Knapsack Problem (SKP) is one kind of KP where only one knapsack needs to be filled and each item may be chosen at most once; If the items should be chosen from disjoint classes and exactly one item from each class, we get the Multiple-Choice Knapsack Problem (MCKP); The Multiple Knapsack Problem (MKP) is also a kind of KP where several knapsacks are to be packed simultaneously. The more general kind of KP is the Multi-Dimensional Knapsack Problem (MDKP), also known as Multi-Constrained Knapsack Problem, where there are more than one limited resources, i.e. the resources are multi-dimensional for the knapsack. And the MDMKP is the combination of MDKP and MKP. All Knapsack problems belong to the *NP-hard* family (see [6]), therefore it is impossible that polynomial time algorithms can be devised for them.

There are different algorithms for solving variants of KPs (see [14][15][16][17][11]). Generally, there are two methods of finding their solutions: one is a method for finding exact solutions and the other is heuristic. Finding exact solutions is NP hard. Using the branch and bound with linear programming technique, Kolesar ([9]), Shih ([20]), Nauss ([12]) and Khan ([7]) presented exact algorithms for KP, MDKP, MCKP and MDPK respectively. A greedy approach has been proposed by Khan et al ([7]), Martello and Toh ([11]) and Toyoda ([21]) to find near optimal solutions of KPs.

3.1 Heuristic Algorithm with Effective Gradient

MDMKP (M1) is different with all kinds of KPs mentioned in the literature and it needs to develop efficient algorithms for it. In this section, we give an efficient heuristic algorithm with the effective gradient for it.

Let $\bar{v}_{tkdj_k} = v_{tk\tau_k j_k} / V_{dj_k}$, $\bar{w}_{tkdj_k} = w_{tk\tau_k j_k} / W_{dj_k}$, then we can rewritten (M1) as follows

$$(M2): \text{Maximize } z = \sum_{t=1}^T \sum_{k \in K_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k j_k} \bar{r}_{tkdj_k} x_{tkdj_k} \quad (7)$$

subject to

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k j_k} x_{tkdj_k} \leq E_d \quad \forall d \in \tilde{T} \quad (8)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d \\ j_k = j}} \bar{v}_{tkdj_k} x_{tkdj_k} \leq 1 \quad \forall d \in \tilde{T}, j \in \tilde{J} \quad (9)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d \\ j_k = j}} \bar{w}_{tkdj_k} x_{tkdj_k} \leq 1 \quad \forall d \in \tilde{T}, j \in \tilde{J} \quad (10)$$

$$\sum_{d=t}^{\tau_k} x_{tkdj_k} \leq 1 \quad \forall t \in \tilde{T}, k \in \tilde{K}_t \quad (11)$$

$$x_{tkdj_k} \in \{0,1\} \quad \forall d \in \tilde{T}, k \in \tilde{K}_t, j \in \tilde{J}_k \quad (12)$$

When each of the candidate items (i.e. cargoes) involves only one limited resource, it is easy to pick up more profitable items. When there exists more than one limited resource in the candidate items, it is difficult to evaluate the amount of limited resources used. Toyoda (see [21]) introduced the concept of penalty vector, which results in a single index based on the many limited resources. Toyoda's heuristic for MDKP starts with no items, and adds one item at a time iteratively as long as the solution is feasible. At any iteration, the heuristic picks the item which provides the maximum value per unit of aggregate resource or the effective gradient among the not-yet-picked items. Computational experiments show that this heuristic provides very good near optimal solutions to the MDKP using very short computation time, and it can be applied to large problem instances, such as problems with more than a thousand variables (see [21]).

In this section, we propose a heuristic algorithm HAEG to provide a near-optimal solution to MDMKP (M2) by means of concepts such as penalty vector and effective gradient in [21].

The heuristic algorithm for MDMKP can be presented as follows.

Algorithm HAEG

Step 1: Initialization.

Step 1.1: Let $K_U \leftarrow \emptyset$, where K_U is the set of accepted items.

Step 1.2: Assign all items to $K_D = K - K_U$, where K_D is the set of items not in K_U and $K = \{k : k \in \tilde{K}_t, t \in \tilde{T}\}$.

Step 1.3: Let $A_U^{dj} \leftarrow (0, 0)$, where A_U^{dj} is the total quantity vector of accepted items shipping to

port j in period d .

Step 1.4: Let the objective value be zero, i.e., $z \leftarrow 0$.

Step 1.5: Let $x_{tkdj_k} \leftarrow 0$, for

$$\forall t \in \tilde{T} \quad k \in \tilde{K}_t \quad d \in \{t+1, \tau_k\}$$

Step 2: Let $K_C \leftarrow \{k : k \in K_D, \exists d \leq \tau_k$

$$s.t. (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k}) \leq (1,1) - A_U^{dj_k},$$

$$v_{tk\tau_k j_k} \leq E_d - \sum_{\substack{k \in K_U \\ \tau_k \geq d}} v_{tk\tau_k j_k} \},$$

where K_C is the set of candidate items.

Step 3: Check K_C . If K_C is empty, the procedure terminates. Otherwise, proceed to the next step.

Step 4: Let $\bar{K}_C = \{(k, d) : k \in K_D,$

$$(\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k}) \leq (1,1) - A_U^{dj_k},$$

$$v_{tk\tau_k j_k} \leq E_d - \sum_{\substack{k \in K_U \\ \tau_k \geq d}} v_{tk\tau_k j_k} \}.$$

Compute effective gradients for the items in K_C as follows.

Step 4.1: If $A_U^{dj_k}$ is a zero vector, then we set

$$G_{kd} \leftarrow \frac{\sqrt{2} v_{tk\tau_k j_k} \bar{r}_{tkdj_k}}{\bar{v}_{tkdj_k} + \bar{w}_{tkdj_k}}, \text{ for } (k,d) \in \bar{K}_C$$

Step 4.2: Otherwise, we set

$$G_{kd} \leftarrow \frac{v_{tk\tau_k j_k} \bar{r}_{tkdj_k} \sqrt{(\sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}})^2 + (\sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}})^2}}{\bar{v}_{tkdj_k} \sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}} + \bar{w}_{tkdj_k} \sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}},$$

for $(k,d) \in \bar{K}_C$, where

$$K_U^d = \{k' : k' \in K_U, x_{tk'dj_{k'}} = 1\}.$$

Step 5: Find that item k whose effective gradient is the largest in a period, i.e.,

$$G_{kd} \leftarrow \max\{G_{k'd} : (k',d) \in \bar{K}_C\}$$

Step 6: Accept k . Let $K_U \leftarrow K_U + \{k\}$,

$$A_U^{dj_k} \leftarrow A_U^{dj_k} + (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k})$$

$$z \leftarrow z + v_{tk\tau_k j_k} \bar{r}_{tkdj_k}, K_D \leftarrow K_D - \{k\},$$

$$x_{tkdj_k} \leftarrow 1. \text{ Then, goto step 2.}$$

We may notice that the solution of HAEG is a feasible solution of MDMKP (M2) and the objective function value is a lower bound of the optimal solution value of it. The numerical experiments in Section 4 show that the solution of HAEG is very close to the optimal solution of MDMKP (M2).

3.2 A Simple Example

$$\text{Let } \hat{r}_{tkdj_k} = v_{tkdj_k} \bar{r}_{tkdj_k}, \tilde{T} = \{1, 2\}, \tilde{J} = \{1, 2\},$$

$$\tilde{K}_1 = \{1, 2, 3, 4, 5\} \quad \tilde{K}_2 = \{6, 7\}; \quad j_k = 1, \text{ for}$$

$$k = 1, 3, 5, 6; \quad j_k = 2, \text{ for } k = 2, 4, 7; \quad \tau_1 = 1 \quad \tau_k = 2,$$

$$\text{for } 2 \leq k \leq 7; (E_1, E_2) = (40, 32),$$

$$k = (V_{12}, V_{22}) = (13, 21) \quad (V_{11}, V_{21}) = (39, 30),$$

$$k = (W_{11}, W_{21}) = (35, 25) \quad (W_{12}, W_{22}) = (12, 38)$$

$$(w_{1111}, w_{1321}, w_{1521}, w_{2621}) = (10.13, 5, 9)$$

$$(w_{1222}, w_{1422}, w_{2722}) = (13.12, 8)$$

$$(\hat{r}_{1111}, \hat{r}_{1311}, \hat{r}_{1511}) = (340, 660, 60),$$

$$(\hat{r}_{1212}, \hat{r}_{1412}) = (182, 77),$$

$$(\hat{r}_{1321}, \hat{r}_{1521}, \hat{r}_{2621}) = (506, 70, 170),$$

$$(\hat{r}_{1222}, \hat{r}_{1422}, \hat{r}_{2722}) = (70, 231, 200).$$

We solve it by the heuristic algorithm with effective gradient HAEG given in Section 3.1. the procedure is briefly given as follows.

$$\text{Since } \bar{v}_{tkdj_k} = v_{tk\tau_k j_k} / V_{dj_k}, \bar{w}_{tkdj_k} = w_{tk\tau_k j_k} / W_{dj_k},$$

we have

$$(\bar{v}_{1111}, \bar{v}_{1311}, \bar{v}_{1511}) = (0.4359, 0.5641, 0.1282)$$

$$(\bar{v}_{1222}, \bar{v}_{1422}, \bar{v}_{2722}) = (0.3333, 0.5238, 0.8095)$$

$$(\bar{w}_{1111}, \bar{w}_{1311}, \bar{w}_{1511}) = (0.2857, 0.3714, 0.1429)$$

$$(\bar{w}_{1212}, \bar{w}_{1412}) = (1.0833, 1)$$

$$(\bar{w}_{1222}, \bar{w}_{1422}, \bar{w}_{2722}) = (0.3421, 0.3158, 0.2105)$$

$$(\bar{v}_{1212}, \bar{v}_{1412}) = (0.5385, 0.8462)$$

$$(\bar{v}_{1321}, \bar{v}_{1521}, \bar{v}_{2621}) = (0.7333, 0.1667, 0.3333)$$

$$(\bar{w}_{1321}, \bar{w}_{1521}, \bar{w}_{2621}) = (0.52, 0.2, 0.36)$$

Step 1. Let $K_U \leftarrow \emptyset$, all items be assigned to

$$K_D = K - K_U, z \leftarrow 0, A_U^{dj_k} \leftarrow (0, 0),$$

$$x_{tkdj_k} \leftarrow 0 \quad \forall t \in \tilde{T}, k \in \tilde{K}_t \quad \forall j_k \in \tilde{J}_k.$$

Step 2. Let $K_C \leftarrow \{k : k \in K_D, \exists d \leq \tau_k$

$$s.t. (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k}) \leq (1,1) - A_U^{dj_k},$$

$$v_{tk\tau_k j_k} \leq E_d - \sum_{\substack{k \in K_U \\ \tau_k \geq d}} v_{tk\tau_k j_k} \}.$$

Step 3. Since $K_C \neq \emptyset$, proceed to the next step.

Step 4. Since $A_U^{dj_k} = (0, 0)$, the effective gradients are calculated by formula:

$$G_{kd} = \frac{\hat{r}_{tkdj_k} \sqrt{2}}{\bar{v}_{tkdj_k} + \bar{w}_{tkdj_k}}, \text{ for } (k,d) \in \bar{K}_C,$$

$$\text{we have } G_{11} = 666.33, G_{31} = 997.7,$$

$$G_{51} = 313.04, G_{32} = 666.33, G_{52} = 269.99,$$

$$G_{62} = 346.75, G_{41} = 58.98, G_{22} = 146.56$$

$$G_{42} = 389.09, G_{72} = 277.28.$$

Step 5. The largest effective gradient is $G_{31} = 997.7$.

Step 6. Accept item 3. Let $K_U \leftarrow K_U + \{3\}$,

$$A_U^{11} \leftarrow A_U^{11} + (\bar{v}_{1311}, \bar{w}_{1311}) \quad z \leftarrow z + \bar{r}_{1311},$$

$K_D \leftarrow K_D - \{3\}$, $x_{1311} \leftarrow 1$. Then, go to step 2.

After it is repeated several times, K_C becomes empty and we obtain the final solution:

$$z = 1471, x_{1111} = x_{1311} = x_{1521} = x_{2621} = x_{222} = 1,$$

$$x_{1511} = x_{1321} = x_{1212} = x_{1412} = x_{2222} = x_{2722} = 0.$$

This solution is the same as the optimal one obtained by perfect enumeration.

3.3 Modified Heuristic Algorithm

In this section, we modify the effective gradient G_{ij} which introduced in Section 3.1 to increase accuracy of the heuristic algorithm.

Algorithm MHA

Step 1: Initialization.

Step 1.1: Let $l \leftarrow 0$, $\hat{z} \leftarrow 0$, $\hat{x}_{tkdj_k} \leftarrow 0$,

$$\forall t \in \tilde{T}, k \in \tilde{K}_t, t \leq d \leq \tau_k.$$

Step 1.2: Let $K_U \leftarrow \emptyset$, where K_U is the set of accepted items.

Step 1.3: Assign all items to $K_D = K - K_U$, where

K_D is the set of items not in K_U and

$$K = \{k : k \in \tilde{K}_t, t \in \tilde{T}\}.$$

Step 1.4: Let $A_U^{dj} \leftarrow (0, 0)$, where A_U^{dj} is the total quantity vector of accepted items shipping to port j in period d .

Step 1.5: Let the objective value be zero, i.e., $z \leftarrow 0$.

Step 1.6: Let $x_{tkdj_k} \leftarrow 0 \forall t \in \tilde{T}, k \in \tilde{K}_t$,

$$t \leq d \leq \tau_k.$$

Step 2: Let $K_C \leftarrow \{k : k \in K_D, \exists d \leq \tau_k$

$$s.t. (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k}) \leq (1, 1) - A_U^{dj_k},$$

$$v_{tk\tau_k j_k} \leq E_d - \sum_{\substack{k \in K_U \\ \tau_{k'} \geq d}} v_{tk'\tau_{k'} j_k}\},$$

where K_C is the set of candidate items.

Step 3: Check K_C . If K_C is empty, goto **step 7**.

Otherwise, proceed to the next step.

Step 4: Let $\bar{K}_C = \{(k, d) : k \in K_C, (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k})$

$$\leq (1, 1) - A_U^{dj_k}, v_{tk\tau_k j_k} \leq E_d - \sum_{\substack{k \in K_U \\ \tau_{k'} \geq d}} v_{tk'\tau_{k'} j_k}\}.$$

Compute effective gradients for the items in K_C as follows.

Step 4.1: If $A_U^{dj_k}$ is a zero vector, then we set

$$G_{kd} \leftarrow \frac{\sqrt{2} v_{tk\tau_k j_k} \bar{r}_{tkdj_k}}{\bar{v}_{tkdj_k} + \bar{w}_{tkdj_k}}, \text{ for } (k, d) \in \bar{K}_C$$

Step 4.2: Otherwise, let

$K_U^d = \{k' : k' \in K_U, x_{tk'dj_{k'}} = 1\}$, for $l = 0, 1, 2$ we set

$$G_{kd} \leftarrow \max\left(\frac{v_{tk\tau_k j_k} \bar{r}_{tkdj_k} \sqrt{\left(\sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}}\right)^2 + \left(\sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}\right)^2}}{\bar{v}_{tkdj_k} \sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}} + \bar{w}_{tkdj_k} \sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}}, \right. \\ \left. - \alpha \max\left(\sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}}, \sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}\right), 0\right)$$

for $(k, d) \in \bar{K}_C$, where $\alpha = 0, 0.2, 0.9$ respectively, for $l = 0, 1, 2$

for $l = 3$, we set

$$G_{kd} \leftarrow \max\left(\frac{v_{tk\tau_k j_k} \bar{r}_{tkdj_k} \sqrt{\left(\sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}}\right)^2 + \left(\sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}\right)^2}}{\bar{v}_{tkdj_k} \sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}} + \bar{w}_{tkdj_k} \sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}}, \right. \\ \left. - \left(\max\left(\sum_{k' \in K_U^d} \bar{v}_{tk'dj_{k'}}, \sum_{k' \in K_U^d} \bar{w}_{tk'dj_{k'}}\right)\right)^2, 0\right)$$

for $(k, d) \in \bar{K}_C$; we set

$$G_{kd} \leftarrow \frac{\sqrt{\alpha} v_{tk\tau_k j_k} \bar{r}_{tkdj_k}}{\bar{v}_{tkdj_k} + \bar{w}_{tkdj_k}}, \text{ for } (k, d) \in \bar{K}_C, \text{ where}$$

$\alpha = 0.125, 0.25, 2, 1.2, 1$ respectively, for $l = 4, 5, 6, 7, 8$.

Step 5: Find that item k whose effective gradient is the largest in a period, i.e.,

$$G_{kd} = \max\{G_{k'd'} : (k', d') \in \bar{K}_C\}$$

Step 6: Accept k . Let $K_U \leftarrow K_U + \{k\}$,

$$A_U^{dj_k} \leftarrow A_U^{dj_k} + (\bar{v}_{tkdj_k}, \bar{w}_{tkdj_k}) \quad z \leftarrow z + v_{tk\tau_k j_k} \bar{r}_{tkdj_k},$$

$K_D \leftarrow K_D - \{k\}$, $x_{tkdj_k} \leftarrow 1$. Then, goto **step 2**.

Step 7: If $z > \hat{z}$, then $\hat{z} \leftarrow z$, $\hat{x}_{tkdj_k} \leftarrow x_{tkdj_k}$,

$$\text{for } t \in \tilde{T}, k \in \tilde{K}_t, d \in \{t + 1, \dots, \tau_k\}$$

Step 8: If $l = 8$, then the procedure terminates.

Otherwise, let $l \leftarrow l + 1$, goto **step 1.1**.

From the steps of the modified heuristic algorithm, the solution of MHA is closer to the optimal solution than HAEG, because we take the maximum value among

solutions given by nine methods including the method used in HAEG. We may easily notice that the computation time of MHA is more than four times of HAEG.

4. Numerical Experiments

In this section, we implement the modified heuristic algorithm MHA and give comparisons among heuristic solutions and optimal solutions or LP optimal solutions (as the up bound of optimal solutions). The algorithm has been coded in C++ and run under Windows 2000 Professional using a notebook computer (Pentium IV with 1794MHz and 256MB in RAM). CPU times were obtained through the C++ function clock(). To conduct our experiments we used randomly generated instances. For simplicity of implementation, we assumed that destination port j_k of each cargo k is decided by:

$j_k = j$, if $\text{floor}(K/J) \times (j-1) \leq j_k < \text{floor}(K/J) \times j$,
for $j = 1, 2, \dots, J-1$;

$j_k = J$, if $\text{floor}(K/J) \times (J-1) < j_k \leq J$.

For each set of parameters J , T and K , we generated

10 random MDMKP instances. We tested heuristic solutions and optimal solutions or LP optimal solutions on all 10 instances, and tabulated the average relative gap and average computation time. In table 1, the relative gap between heuristic solution and optimal solution g_O is computed as

$$\frac{\text{total profit of optimal solution} - \text{total profit of heuristic solution}}{\text{total profit of optimal solution}} \times 100\%$$

In table 1 and table 2, the relative gap between heuristic solution and LP relaxation optimal solution g_L is computed as

$$\frac{\text{total profit of LP relaxation optimal solution} - \text{total profit of heuristic solution}}{\text{total profit of LP relaxation optimal solution}} \times 100\%$$

Table 1. Results for small test problems

T	J	K	Number of variables	Number of constraints	Instances tested	Average relative gap (%)	
						g_O	g_L
2	2	37	74	84	10	1.62	2.82
2	2	57	114	124	10	1.27	2.65
3	4	27	81	108	10	2.31	3.29
4	8	23	92	160	10	2.85	9.41

Table 2. Results for Medium Scale problems

T	J	K	Number of variables	Number of constraints	Instances tested	Average relative gap g_L (%)	Average CPU time (sec)	
							Heuristic	LP
2	2	271	542	552	10	5.79	0.54	5.02
4	8	800	3200	3268	10	6.18	26.43	1167.53
4	40	500	2000	2324	10	7.79	46.32	298.79
5	70	700	3500	4205	10	8.74	110.23	1982.67
5	9	900	4500	4595	10	7.65	41.58	2139.04
5	30	990	4950	5255	10	8.41	160.23	2531.45

Table 3. Computation Time for Large Scale Problems

T	J	K	Number of variables	Number of constraints	Instances tested	Average CPU time (sec)
5	70	1200	6000	6705	10	367.02
3	4	4000	12000	12027	10	273.46
6	7	2500	15000	15090	10	158.85
4	4	5500	22000	22036	10	503.49
5	10	5000	25000	25105	10	1310.34
6	8	4500	27000	27102	10	631.82

Table 1 shows the results obtained for a set of small test problems. Test problems 1-2 have 2 periods, 2

destination ports and 74, 114 items (cargoes) respectively; test problem 3 have 3 periods, 4

destination ports and 27 items; test problem 4 have 4 periods, 8 destination ports and 23 items. For comparison, the optimal solution has been computed using CPLEX 8.0. As can be seen from table 1, the obtained results seem to be encouraging. The gap between the optimal solution and the heuristic solution is small and the computation time is very short. Table 2 shows the results obtained for a set of medium scale problems. Table 3 gives the computation times for a set of large scale problem. It show that the computation time of the heuristic algorithm is very short even for very large scale problems with tens of thousands of decision variables.

We believe that heuristic algorithm will be a very good candidate for solving MDMKP in time critical or real-time applications such as sea cargo mix problems where a near optimal solution is acceptable, and fast computation is more important than guaranteeing optimal value.

5. Conclusions

We formulated the multi-period sea cargo mix problem as the MDMKP model and presented an effective heuristic algorithm for it.

The heuristic algorithm gives fast and near optimal solution for the multi-period sea cargo mix problem. We presented experimental results to evaluate the algorithm by a wide range of problem instances. The heuristic algorithm is a very effective for time critical operations level decisions where a near optimal solution is acceptable, and fast computation is more important than guaranteeing optimal value.

Abstract

With the rapid growth of the Internet and the subsequent emergence of Electronic Commerce, the importance of product promotion in electronic marketplaces has come into sharper focus in marketing theory and practice. One way to acquire customers and promote the products is to initiate a trial of the company's product. Traditional product sampling is been extremely costly and many firms tend to sell and promote their products via their own website or through other web sites. The concept of Online Product Promotion & Trial emerged as an alternative to the traditional product promotion methods. This study examined the effectiveness of Online Product Promotion & Trial industry in New Zealand. In particular, this study investigates how well Freesamples Ltd web site is performing and how New Zealand consumers react to the idea Online Product Promotion & Trial. The results show consumer satisfaction and willingness to participate towards Online Product Promotion & Trial is high, and most New Zealand organisations are willing to promote their products by giving out free samples through the Internet depending on the cost and budget. Recommendations for this industry in New Zealand and future research directions are also presented.

1. Introduction

Online Product Promotion & Trial is the new wave in promoting products and offering consumers free products to trial through the use of a web site. Surveys estimate that there are 605.6 million people using the Internet throughout the world [5]. Due to the rapid rise of the Internet as a vital channel of communications, the consumer perception of product promotion is changing. The Internet makes it easier for organisations to initiate promotions anytime.

Consumer behaviour about the marketing messages and how they respond to those messages have changed since the Internet has given them power to ignore messages they do not want to see and to find the ones they want. Marketing organisations can truly measure how many people view their messages since in traditional marketing promotions (for example, television advertisement) measurement of how many people have viewed their messages are unattainable. Consumers are not passively letting marketing messages pass by them, rather they proactively choose the messages they want to receive. One of the best ways to reel in consumers is with

promotional offers [3]. Companies can choose to do promotional offers online, offline or both.

No prior research exists on the online product promotion and trial industry in New Zealand. In this research, we focus on the online product promotional aspects that include free product trials for consumers. The objectives of this project are to explore the need of Online Product Promotion & Trial in New Zealand and to investigate the effectiveness of Online Product Promotion & Trial from the perspectives of consumer and company (client).

2. Literature Review

There is no doubt that Information Technology is fundamentally changing the way people communicate and do business, and is changing the choices consumers can make. Electronic Commerce opens up new opportunities to develop new products and services, create new networks and relationships, exploit new markets and to reduce the cost of doing business. The emergence of Electronic Commerce presents new opportunities for New Zealand businesses, including potentially larger markets in which to sell goods and services, and improved communication with customers and suppliers. A survey by Statistics New Zealand [12] reveals that 79% of New Zealand businesses regularly use the Internet and 79% of New Zealand businesses regularly use email for communication. 36% of New Zealand businesses operates a website while total sales generated through the Internet are estimated to be \$523 million in the year ended June 2001 [12]. The Internet was mostly used as a means of communicating with customers and suppliers, as most firms use their website to provide information about their business.

The Internet is the primary driving technology behind electronic commerce and gives marketers unprecedented capabilities. Due to the low entry barriers of the Internet such as low set up cost and easy to maintain information websites, businesses can bypass physical intermediaries and bring goods and services directly to consumers. The Internet is fast becoming part of everyday life for many New Zealanders. AC Neilson Media Research [10] showed that in December 2002, three quarters of New Zealanders aged 10 onwards (2,469,000 people) have access to the Internet.

Promotion encompasses all the various ways an organisation undertakes to communicate its products and to persuade target customers to buy them [7]. One way to acquire customers is to initiate a trial of the company's

product. Traditional product sampling has been extremely costly. Carmody [3] states that the waste factor associated with most product sampling programs is astounding; traditional marketers focus on the “direct” marketing program ends up more like a shotgun approach hitting only 2 percent of the targeted consumers. The Internet helps to solve the waste problem through consumer self-selection. Benitez [2] also says that the ultimate goal of online promotions is to get consumers to come back to the website again and again, to purchase more items and tell their friends about the website. Benitez posits that convenience is the main reason why online sweepstakes, contests and sampling are more effective than in-store, fill out a card or mail out sampling, because consumers do not need to leave their home to enter. Bannan [1] described online product sampling as “consumers go to the website, browse among a smattering of samples and choose products, which are mailed to their homes”. There are a number of advantages for companies to promote products via online free samples. Consumers are attracted to the free sites because there is no cost for them; thus they come to the site specifically to learn about and sample new products, so the companies do not pester consumers who are not interested. Companies can also select certain groups of consumers to whom they want to make the samples available based on their demographic information and product preferences provided on the consumer registration form (for example, they can limit sampling to female consumers). 62 percent of Internet users say filling out online surveys that offer incentives is worth the hassle and admitted to going online specifically to hunt for special offers or contests [11].

As with any giveaway, there are disadvantages for businesses tempted to try online free sample offers. Some consumers surf the Internet looking for as many free samples as possible and often take samples out of the hands of targeted consumers. Another disadvantage of online free samples offers is it is limited to people who know how to use a computer and have access to the Internet.

While there are disadvantages of the Internet promotion, there are still many advantages that marketers can trigger. Based on theories developed by Carmody [3], Table 1 summarizes the specific pros and cons of online promotion.

2.1 Examples of Online Free Samples sites

There are a number of websites offering free samples and free products. All free samples or free products sites have their own unique look and feel, since they rely heavily on offers and links.

Freesamples.com, launched in March 1999, is financed by Witt Capital and other institutional investors. The aim of Freesamples.com is to connect qualified consumers with marketers. Users of Freesamples.com can select up to four free samples at a time, which are shipped directly from the company’s fulfillment centre. The best feature of Freesamples.com is that users can get all of the samples requested within a week. This is an important

distinction between other online sample sites as it takes a long time to deliver the samples to consumers. After the users receive the free samples, Freesamples.com will email the users with follow up questions about the product by offering cash rewards for every response. The clients companies of Freesamples.com can then obtain information and feedbacks about their products

Table 1: Overview of Online Promotions Pros and Cons

Pros of Online Promotions	Cons of Online Promotion
Costs: <i>Cheaper than traditional / offline promotions</i>	Contact: <i>no face-to-face contact with customers</i>
Permission-based: <i>Consumers determine their own level of involvement and manage their own profiles</i>	Histories: <i>no research/case histories</i>
New: <i>Constantly changing with new technology, new ideas</i>	Risk: <i>Larger risk of technology failures</i>
Technology: <i>Allows for further innovations</i>	Reach: <i>Cannot reach audience that don’t have Internet access</i>
Research: <i>Can get feedback and response (both qualitative and quantitative)</i>	Customer Service: <i>Higher degree of customer services needed.</i>
Speed: <i>Faster for create, launch and manage an online promotion</i>	
Control: <i>Higher degree of control</i>	
Environmental: <i>Less paper and other waster on non-interested consumers</i>	
Follow-up marketing: <i>Using email is a fast and effective way to do follow-up marketing when consumers given permission</i>	
Mobility: <i>Consumers can participate from virtually anywhere</i>	
Ongoing: <i>Easier to keep consumers coming back to participate in daily programs</i>	

. While there are other free sample sites on the Internet, few engage in the kind of lengthy information gathering used by Freesamples.com [8]. Freesamples.com is not just a sample distribution system; they are focused on real research data.

Other similar sites include easy-freebies.com and StartSampling.com.

3. Case Background - Freesamples Ltd

Freesamples Ltd. is a New Zealand based company that offers consumers free product trial and helps companies promote product online. Its website (<http://www.freesamples.co.nz>) was launched in April 2000. The primary objective of the company is to promote consumer products and services online to New Zealand residents by offering respondents free products and services through the website. The opportunity to use the Internet as a cheap communication method to promote products and services through one-to-one communication with consumers stimulated Freesamples directors to start up this business. Freesamples offers a convenient way for consumers to pre-trial the products or services and give valuable feedback to improve the product. Freesamples also offers clients a cost effective way to promote their products and services online, research consumers preferences for products and services and distribute free samples. At December 2002 there were approximately 35,000 New Zealanders registered with www.freesamples.co.nz. Products and services listed on the Freesamples site are on behalf of the manufacturers and consumers need to register before they can receive any of the products at no cost. There are times that consumers might need to fill in a survey before they can get free samples. Once consumers have selected the products or services they wish to trial for free and answer the pre-trial research questions; free samples are either posted, couriered to consumers or alternatively, consumers can collect the free samples from retail outlets. After the free samples have been delivered to consumers, they are invited to participate in post-trial research survey and give feedback about the products they received. Freesamples only contact their members via email when there are free samples on board and will invite them to get free samples.

4. Methodology

This study collects responses through interviews, questionnaires and observation. Electronic questionnaires are becoming more common, replacing mail questionnaires. As this study is related to an online application, electronic questionnaire is the best way to learn about the consumers. The advantages of online questionnaires include being able to collect large numbers of survey results in a short amount of time at a low cost. It is important to understand the organisations' perspectives for this study. Two surveys utilising electronic questionnaires were run and two interviews were conducted to test the uptake and effectiveness of Internet trailing. The first electronic survey is targeted at consumers who are a member of Freesamples Ltd. The second survey is targeted at marketing organisations or organisations with a marketing department in New Zealand. The first interview was conducted to capture information about the operations of Freesamples with a director. The second interview was conducted with a marketing organisation. All interviews conducted in this

study are in face-to-face format to capture ideas from organisations and Freesamples Ltd. This helps us to explore and understand complex issues about Online Product Promotion & Trial and company's operations. Following the surveys and interviews, analyses were made to test the four research questions.

4.1 Web site Analysis

While web site content development teams has focused on the necessary components of effective website design, content is much harder to measure. In this study, web site content analysis will be carried out to measure the effectiveness of Freesamples Ltd's web site. This study will follow Myer's [9] guidelines for web site content analysis: audience analysis and web site goals, appropriateness of content, familiarity, skimming & readability and matching delivery with goals.

5. Results

5.1 Content Analysis: Freesamples Ltd Website

5.1.1 Audience Analysis

The first step in web site content analysis is to understand audience demographics and psychographics. In order to capture the audience demographics and psychographics of Freesamples Ltd, a questionnaire was distributed by Freesamples Ltd to its members in March 2003. 4961 registered members answered this survey. The survey was posted in Freesamples website as a requirement for registration to be a member from March 2003.

5.1.2 Web Site Goal

The ultimate goal of Freesamples Ltd is to help clients to promote products and taking research while offering consumers free product trial via the Internet. The goal of Freesamples website is to provide a cost-effective and convenient product promotion medium that benefits both organisations and consumers. It is important to align the web site content goals with the organisation's goal. Freesamples matches the web site goals with the organisation goals.

5.1.3 Appropriateness of Freesamples Web site Content

Appropriateness of web site content is defined as "knowing what content is appropriate for your audience and what content is appropriate for organisation to publish" [9]. Freesamples Ltd has taken both factors into account when they started to re-design their web site to suit audience needs. Freesamples Ltd carried out a research of their members in March 2003 to capture their demographics and psychographics.

5.1.4 Technical Aspects of Freesamples Web site Design

The Freesamples.co.nz web site is categorised as having: Easy Navigation, Excellent Access Performance, Error-free and no dead-links, and Provides password retrieval services.

5.1.5 Written Content

The Freesamples site presents information about the company, samples available and information regarding technical problems. The web site content is updated when there are free samples available or any changes to the website. The site is easy to read and when members login they do not need to enter their personal information again. The web site content is also appropriately tied in to the samples offered. It gives brief introduction of the samples and how this site works. The goal of Freesamples web site is to distribute free samples for consumers and conduct market research for organisations. The web site persuades the audience to participate by telling them there is no cost to them. The goal of the Freesamples web site clearly aligns with its company goal.

5.2 Results of the Consumer Survey

There were 204 responses from the electronic consumer survey. The consumer survey link was available at the Freesamples web for a period of 45 days. The electronic consumer survey was placed at www.informis.co.nz. Visitors to Freesamples could click on the link and be seamlessly taken to the exact survey url. 74% of the total respondents completed the entire survey. As there is no real concept of response rate for Internet surveys; the total of 204 consumer responses represents 3.4% of the 35000 Freesamples members.

The exposure of the industry web sites to New Zealanders is one factor that can be used to gauge the consumer awareness of Online Product Promotion & Trial opportunities. Figure 1 shows that a large group of respondents (cited 66% of total respondents) were not aware of any online product promotion & trial opportunities before they became a member of Freesamples, while 28% of respondents were aware of these opportunities. Only a small percentage of respondents (6%) were unsure about their awareness of online product promotion & trial opportunities.

Figure 1: Consumer awareness of Online Product Promotion & Trial Opportunities

Consumer preference to receive free samples has also gathered from this survey, specifically for permission based sampling and sampling without permission. A high percentage (70%) of consumers are willing to accept free samples without their permission while about 30% of consumers would reject them. A high percentage (72%) of surveyed members have received free samples from Freesamples Ltd in the past. This result corresponds to the distribution information held by the company, confirming that the survey sample was representative. Over half of surveyed members (52%) have received more than one free sample from Freesamples Ltd in the past and 25% of them received more than five samples. The results show that large majority of consumers are willing to participate in the online product trial through the use of Freesamples web site.

Figure 2: Consumer interest level on online product promotion & trial web sites

Three main factors were investigated to analyse the effectiveness of Freesamples web site from the consumer perspective. The three main factors were consumer opinions of the interest level, usability level and usefulness of the Freesamples web site. Figure 2 shows a large majority of respondents considered that Freesamples web site is very interesting. Only 2 respondents thought that such a web site was boring. A question on usability of the Freesamples web site was asked and the results showed that large numbers of participants in this study claimed that such web site are very simple to use, while a

very small number of participants in this study claimed that it is complicated (Figure 3). A simple and usable web site allows consumers to find their way around the site without difficulties and finding what they are after successfully.

Figure 3: Consumer Opinions on Usability level of Online Product Promotion & Trial Web sites

The third factor is usefulness of Freesamples web site. When a web site provides useful functions or information on the product or company, consumers will usually return. Most respondents rated Freesample's website as very useful, and notably, no respondent rated it not useful or not useful at all. A small number of votes were cast as neutral. Figure 4 is the distribution of these ratings.

Figure 4: Consumer Opinions on usefulness of Online Product Promotion & Trial web sites

From the consumer survey, one question was asked to find out how often did participants visit Freesamples web site. 37% of the respondents visit Freesamples web site only when notified there are new samples available and 32% of the respondents visit Freesamples web site occasionally. Only a small percentage (5%) of respondents visit Freesamples web site on an everyday basis (Figure 5).

Figure 5: How often did consumers visit Freesamples website?

Another pleasing result is that most respondents are either very satisfied or satisfied with Freesamples service (Figure 6). Although a number of respondents stated they are dissatisfied with Freesamples service, a high percentage (98%) of the total respondents claimed that they would go back to Freesamples web site in the future, while only 2% of the total respondents who are not unsure what they will do given the circumstances. No respondent claimed that they would not go back to Freesamples web site in the future.

Figure 6: Satisfy Level of Consumers on Freesamples Services

Consumer comments of how Freesamples could improve the quality of service provide were collated. Most consumers desired Freesamples to provide greater variety of samples, including more interesting samples and to increase the number of available samples. A number of consumers suggested that Freesamples should notify members when new samples are launched, deliver the samples faster, give description of samples and change the samples more often to improve their quality of service. This result reflects how Freesamples can increase consumer satisfaction and encourage potential consumers to visit their web site. Another question explored general comments about Online Product Promotion & Trial web sites. Some suggested that more promotion of such web sites is needed and the concept of Online Product Promotion & Trial is a great way for consumers to trial the products before purchase. Some respondents desired more of such web sites.

It is noted that demographics of this sample are very similar to those found by the member survey of Freesamples. It is almost impossible to know how this sample might differ from the total user population; however, the sample population demographics clearly matches with the members' survey demographics so we can say that this sample is representative sample of Freesamples members.

5.3 Organisation Survey Results

The organisation survey is targeted at or organisations that might be expected to promote products by giving out free samples. The organisation survey was sent to 50 marketing organisations in New Zealand, most of the businesses were in Auckland. The 50 marketing organisations were selected randomly from the electronic yellow pages in the beauty & health and food categories and to past clients of Freesamples Ltd. Out of the 50 surveys, 2 of them were received from marketing managers who had been contacted personally and 3 of them were distributed electronically. The remaining responses were received from the postal survey. Out of 10 returned postal surveys, only 8 were completed adequately. There were a total of 15 surveys returned achieving a response rate of 30%. As a rule of thumb, a 30 percent response rate is considered acceptable [4]. The response rate of the organisations survey was acceptable in this study. The possible reason that a majority of all surveyed organisations did not respond could be due to timing constraints, or having little interest in the subject area covered in the survey.

Most organisations that responded to the survey had been operating for a number of years. Another way to determine the exposure of the online product promotion and trial concept to organisations is to verify that organisations understand the meaning of this concept. Over half of the surveyed organisations (54%) claimed that they do not understand what Online Product Promotion & Trial means, while 31% of all surveyed organisations stated they are not sure about the meaning. Only 15% of all surveyed organisations claimed that they understand the concept.

The organisations were asked about the recently used methods to promote their products. The result showed that most of the responding organisations used newspaper or magazines advertising. A number used direct mail and/or mailed out free to promote their products. The data clearly shows that most of the surveyed organisations used traditional promotion methods instead of an online promotion method. 11 of the 13 organisations used more than one promotion method.

Only two of the 13 responding organisations were familiar with Freesamples Ltd and only 31% of surveyed organisations are familiar with free product trials. However, 7 (54%) of surveyed organisations would be willing to promote their products and offer free samples online, 2 (15%) would not, while 4 (31%) were unsure. As Online Product Promotion & Trial is a new concept, the

benefits of Online Product Promotion & Trial are not known by many organisations. 7 (54%) of the surveyed organisations are aware of the benefits of Online Product Promotion & Trial method, while one was not sure.

3 (23%) of surveyed organisations say they would determine this based on the cost.

6. Discussion

Willingness of consumers to participate is important for the companies that offer online product trial as it affects their survivability. The majority of survey respondents say they are willing to participate in online product trial promotion. Most consumers are willing to go back to Freesamples web site and get more than one free sample. This shows the revisit rate of such web sites is high.

It is interesting to find out that most New Zealand consumers prefer permission based marketing messages but some of them still accept marketing messages without permission. Permission based marketing allow consumers to be in control of how much and how often they want to hear from marketers. Unlike traditional sampling programs, free product sampling sites capture customers who are actively looking for a particular product or experiences. Consumers do not get unwanted samples that are of little or interest to them. Traditional sampling methods without gaining permission from consumers include letterbox drops, or giving out free samples in shopping malls or supermarkets.

The willingness of New Zealand organisations to participate in online product promotion will affect the survivability of the Online Product Promotion & Trial industry in New Zealand. At present, it is fair to surmise that not many organisations understand the meaning of Online Product Promotion & Trial. Even though most of the organisations were not familiar with Freesamples Ltd in particular and free product trial promotion methods in general, most would be willing to promote their products and offer free samples online in the future. That an increasing number of companies would prefer to advertise or promote products through the use of websites reflects the increasing trend of Internet usage in New Zealand.

The head of a medium sized marketing agency in Auckland was interviewed. He stated that 50% of their clients are willing to promote their products through the use of web sites. Most of their clients have their own web sites and most of them use both traditional promotional methods such as print advertising and direct mail to customers as well as using Internet to promote their products. Most New Zealand organisations are not aware of the benefits of online product promotion and offering free samples online. They tend to use traditional product promotional methods rather than online product promotion methods. Some the organisations use both traditional promotional methods such as print advertising, direct mail to customers, magazines, event sampling as well as using the Internet to promote their products. New Zealand organisations tend to use more than one promotion methods.

It is rare that organisations use only pure Online Product Promotion & Trial method to promote their products. Some marketing managers believe that some people use the Internet to just get free samples without purchasing after trying. By giving out free samples through the web site, some organisations consider that their conversion to sales is minimal. According to Freesamples Director, it is difficult to get organisations to appreciate the value and power of online product promotion and trial. Generally organisations prefer traditional methods; that is through the use of magazines, television advertisement without getting responses and feedbacks from consumers and any idea of effectiveness of the promotion cannot be measured.

However, there are promotional advantages offered by online product promotion and trials. Online sampling sites offer advantages for both consumers and organisations. Convenience is the main reason considered by consumers why online sampling is more effective than other traditional sampling methods. Consumers also appreciate permission-based marketing where they do not get messages foisted on them. Organisations can enjoy a cost effective way to distribute free samples because samples are only given away to people requesting them. Consumer feedback can be collected and organisations can carry out pre and post trial research. Moreover, organisations can also promote their brand and their distribution chain / retail outlets by using them as the collection points for free samples.

Achieving consumer satisfaction is important for online product promotion and trial companies as it is related to consumer retention. It is obvious that if consumer retention is high, they are more likely to re-visit the website. Apparently, most consumers are either very satisfied or satisfied with the service offered by Freesamples. Generally, consumers appreciate web sites that refrain from 'hard selling'. Freesamples gives them an opportunity to trial the product before buying. Consumers like to try the products before buying, especially expensive products such as cosmetics.

Approximately 150 promotion and trial campaigns have been launched successfully in the Freesamples site. According to Freesamples statistics, about 20% of their clients have repeat campaigns. Consumers stated that most of the free samples sites are based in United States or United Kingdom and they are hoping there will be more free samples sites launched in New Zealand.

6.2 Limitations of this Research and Future Research Directions

There are several limitations in this research. Survey respondents might not answer the surveys correctly. Some people give inaccurate information because they are motivated by the need for privacy and some people might honestly not remember the answers to such questions as "How often did you visit Freesamples website?" The consumer survey respondents are self-selected. The survey might be misleading because it has attracted specific audience or people with particular motivation. On

the other hand, this is exactly the target market of Freesamples Ltd. It should be noted that the consumer surveys are only distributed to members of Freesamples.

Future research can focus on how other factors such as gender, age and income level of respondents can affect consumer satisfaction and consumer willingness to participate in Online Product Promotion & Trial. For instance, the relative importance of the different drivers in consumer participation is worth investigating. Another dimension of future research in this topic deals with the measurement issues of effectiveness of Online Product Promotion & Trial campaigns. In this research, we measure this by the repeat samples campaign rate to Freesamples and the repeat samples requested by individual consumers. It is important to go beyond just the repeat campaigns by organisations and the repeat samples requested by consumers; effectiveness of the past campaigns should be also measure by the actual product sales before and after the product trial.

6.3 Recommendations

Privacy concerns may make consumers unwilling to give out information and technologies such as privacy programs allow consumers to prevent data from being collected. Currently, Freesamples did not provide a privacy statement in their web site. Some consumers may realise the value of their information and demand a premium for it [6]. Using consumer information to create substantial value for the consumer can solve these problems; for example, letting consumers know Freesamples will offer more samples to suit their interests. As consumers recognise the value of giving up information they will be more likely to share their information.

Promotion of Freesamples Ltd is all through "word of mouth". It is suggested that Freesamples needs to advertise to consumers to grow the membership as well as client companies. Statistics shows that 41% of web users find new sites through search engines and online shoppers are three times more likely to use search engines than advertisements to find what they want on the web [10]. Freesamples can register in popular New Zealand search engines such as Xtra MSN, Yahoo NZ, and Nzooom.

7. Conclusions

There are enormous opportunities for businesses and consumers to participate in online product promotion due to the explosive growth of the Internet. The concept of Online Product Promotion & Trial has emerged as an alternative to the traditional product promotion methods. This study provides a better insight into both existing and potential members of Freesamples Ltd by examining the Freesamples Ltd member database. Most of the Freesamples members are in the mid to high-socio economic groups.

Our results suggest that the willingness of consumers and organisations to participate in Online Product Promotion and Trial are potentially high. Most New

Zealand consumers are very satisfied with services offered by Freesamples and they show interest to participate in the online product trial. The satisfied and loyal consumer database will increase the likelihood of return visits to Freesamples.

On the other hand, our results indicate that the concept of Online Product Promotion & Trial is not clearly understood by many organisations in New Zealand. Many organisations are not aware of the benefits the Online Product Promotion & Trial. However, it is shown from the results of this study that most organisations are interested in participating in Online Product Promotion & Trial depending on the cost and budget.

The benefits of Online Product Promotion & Trial include convenience for consumers, cost effective and efficient sampling method for organisations, carry out market research for organisations, provides one-to-one and permission based marketing.

We cannot prove that Online Product Promotion & Trial method can replace the traditional promotional method as surveyed organisations tend to use traditional methods or a mix of both methods rather than online promotion methods. The results of previous Online Product Promotion & Trial promotions launched in New Zealand were a success. This is determined by the strong consumer satisfaction level of Freesamples services and the willingness of consumers and organisations to use Online Product Promotion & Trial.

Abstract

The financing field of Taiwan facing a violent variation in the recent years, a series of financing revolution and of lifting the ban of laws and decrees has brought forth a turning point of the existence for the line of finance. Only the financing unit may properly use the high-tech data, can an effective benefit be obtained, especially, the merger between financing units as well as crisscross sales, that reduce unnecessary expenditures of overhead for traders, and that transfer the saving cost and manpower into the product service corresponding with the demand of customer's design to enhance the clients satisfaction and loyalty.

In the year of Internet, CRM is the lifeblood to maintain the resource of customers for enterprises in the future; if an excellent relationship can be established with the customer, it shall be won their loyalties. The mobile communication with unlimited time and space, such a characteristic may develop the customer service into a maximum extent and let the users obtain the service easily.

A mobile bank cooperated by each bank to promote the value-added service may provide with an intelligent mobile-phone system for transfers, inquiries, and payment. Through the cellular phone, it can be directly to contact with the bank to proceed with the balance inquiry, checking the particulars of transaction and the payment and transfers, as if it has a potable, private, confidential, and secure ATM.

Research and development of the application with respect to the news flash provided by mobile bank, and taking the banking house loan as a topic to combine with wireless Internet tech, dealers and housing demanders are establishing a "Housing Loan Based upon the Protocol of Wireless Application", of which the specific researching content is comprised of wireless transmission protocol, instant order to buy a house on-line, transacting the trade on-line, and integrating the system of house loan on-line.

In conclusion, look forward to provide more conveniences of instant order to purchase a house through the substantial practice, and provide the service to transact the trade on-line to decrease enterprise's time and manpower's cost, combining with new high-tech development to enhance the service quality and competitiveness of the enterprise.

1. Introduction

The financing field of Taiwan facing a violent variation in the recent years, a series of financing revolution and of lifting the ban of laws and decrees has brought forth a turning point of the existence for the line of finance. Only the financing unit may properly use the Information, can an effective benefit be obtained, and that transfer the saving cost and manpower into the product service corresponding with the demand of customer's design to enhance the clients satisfaction and loyalty. [1]

The service quality is the hinge to determine if the financing service on-line is successful, so it has further to analysis it to enhance the industrial competitiveness with the relative contending superiority. The boundary of the network media in the future will be increasingly blurred, hence, developing the mechanism of various trading platform shall be the key-point for the future. The relevant dealer engaged in e-commerce has to orient toward easy use and compatibilities with the past habit for future development.

Following with the rise of e-commerce, the role acted by the bank of the cash-flow network becomes increasingly important, in which the network bank has to consider the issues of the enterprise demand. There is a obviously positive influence that the useful property for customer's perception to the innovating service versus the relationship for enterprise's client to an intimating extent. Provide an empirical research for mobile banks to reconsider their orientations, the function of which is not only a promoting web page of the substantial bank, but also a vital part of the e-commerce.

In the era of Internet, CRM is the lifeblood to maintain the resource of customers for enterprises in the future; if an excellent relationship can be established with the customer, it shall be won their loyalties. They are enthusiastically combining with communication dealers to provide an integral service recently, and helping the bank to provide more diversities and conveniences for clients.

In terms of the financing service, the promoted range may provide with a SMS of the payment in each current business for the bank and mobile bank, coordinated with the program of industrial automation advocated by the finance bureau of the Ministry of Finance and the Executive Yuan, reached to the target of a safe network, ensured the issues of consumer's privilege and verification in financing system, and controlled and administrated the trading risk by network.

Targeting at mobile communicating industries, a derivative issue caused by the competitions between that telecom operators acted as the communicating portal and that bankers held the status of transaction and liquidation in the e-commerce payment. The optimum model is to integrate most of telecom operators, banks and account-clearance centers, forming a MCSP (Mobile Commerce Service Provider) to provide the open and diverse mobile-commerce for traders and banks.

In conclusion, look forward to provide more conveniences of instant order to purchase a building through the substantial practice, and provide the service to transact the trade on-line to decrease enterprise's time and manpower's cost, combining with new high-tech development to enhance the service quality and competitiveness of the enterprise.

2. Related Works

In a score and half years, the social wealth is rapidly accumulated due to the incessant changes of industry and commerce, in which the level of nationals' income has substantially been increased as well as the money-managing movements are frequently operated in investment for various ranks in the society.

The operation of conventional bank is personally transacting the business through the banking staff, substantial shop-front, and counters, etc. The banking business is acting an important role in the cash-flow system of the service operation.

2.1 Information Technology Impacts on Banks

The financing environment of Taiwan in recent years has been transformed into liberalization and internationalization, which results in banking business getting more drastic competitions as well as the business of traditional bank becoming more and more difficult in operation. The banking business shall apply the characteristic of the network market to enhance the self-substantiality responding to environmental challenge and using the wisdom system to analysis the client behavior and the new benefit excavated by correlative data.

In the financial business, from ATM to unmanned bank as well as the network bank, the customer service is unceasingly enhanced by marketing conception of the network personalization. Only proceed with the one-to-one contact constantly with the consumer, can consumers' various demands and preferences be mastered further to provide individual service and client's satisfaction; the computerized "Call Center" may duly resolve customer's complains and telephoned promotion.

The large-scale mainframe may correctly record and transact the daily trading data; ATM is allowed the customer to engage in basic transaction during the off-duty; e-disbursement system can facilitate the customer having more payment modes besides the cash, check, and credit card; Internet is even expanded the trading range, with which clients may transfer his account, remit money, order

on line, and purchase insurances.

The financing units use the Information that many risks, hackers, or viruses will simultaneously be invaded, but it is only a small part among the multitudinous risks. A qualitative change will be produced by the data application to the floating risks. Only reduce the risk in the process of policy-decision, can the correct content be enhanced, and will the integral efficacy be increased in applications.[4]

Security Hole in WAP Legacy Stack:

1. At WAP gateway switching the WTLS to TLS, there is a loophole in safety due to the data is temporarily unencrypted.
2. It is incapable of reaching to a end-to-end security.

2.2 Mobile Banking Services

The tidal wave of Internet is still on its upward surge in recent years, how to reap profits and to enhance CRM's efficiency in the promotional operating movements is the most imperative and important target of the perspective for each enterprise.

Mobile Internet and Internet are blessed by network, communication and Information, achieving e-commerce to be developed prosperously, and subverting behavioral pattern of the traditional commerce. In the Internet world, despite the B2B, B2C, or multiple operating models, the network-foam is approved that genuine market value is based on the sufficient combination of the profitable business model and networking effect.

With the mobile communicating techniques getting mature day-by-day, the mobile commerce becomes another newly prosperous industry after the e-commerce. The development of mobile commerce, however, still not grows substantially as expectation to date. From the viewpoint of the practice to explore accepted behaviors of the consumer to mobile commerce is because the value of Information is derived from user's practicability.

Wireless communicating development has been changed the communicating model; by means of wireless communicating device. the needful data can be secured when we communicate with others from time to time [5] [10] [11] [12]. The network of marketing operation is not only provided with the promotion, advertisement, correct labor service, assisting merchandise confirmation, and orientation for Enterprise's runner, but also needed to seek out a distributing channel for consumers.

STK is a group of the mandate to develop the value-added business, as well as a small-scale programming languish software, solidifying in the SIM card to receive and send the data of GSM's SMS. SIM may use its own application software.

Mobile banking system of the STK at present time is mutually cooperated by each telecommunicating dealer and the financing unit, or by overseas dealer; all of the STK they established is adopted the One-to-One model, and its systematic frame is shown as Figure 1

Systematic Frame shown in Figure 1 specifies briefly process as follows:

¾ Users first must have the mobile phone with the STK

functions, simultaneously, apply the SIM card with the function of mobile bank to the telecommunicating dealer or the financing unit.

- ³/₄ Through the pre-recorded Applet in SIM card, users may browse and choose the financing service items of mobile phone to enter the necessary trading data.
- ³/₄ Through a dedicated line, the mobile banking system will be obtained the data by TCP/IP with interfaces, formatted by mainframe and transmitted the data to mainframe.
- ³/₄ After the disposition of mainframe either by this bank or by other banks, the trading result will fax back to the mobile banking system as a result to follow the original route fax back to users.

Figure 1. STK Mobile Banking Systematic Frame

The WAP mobile bank so far cooperated by domestic telecom operators and financing unit, and the functions of each components [13] and the process of integral transaction is specified as follows [14] [15]:

- ³/₄ Users use the WAP function of the mobile phone to connect with Internet access, entering the WAP website of the financing unit.
- ³/₄ The trading service content in WAP website of the financing units is using WML form through HTTP protocol being transmitted to WAP gateway.
- ³/₄ Received the WML, WAP gateway r uses WML encoder to shift it into binary code. If the WML received contains Script, use the WML script compiler to transfer it into executable code, and then transmit it to user's WAP mobile phone trough the GSM network by WSP (wireless session protocol) /WTP (wireless transaction protocol).
- ³/₄ Users browse and choose the financing service item at WAP website, and key in the necessary trading data through the key of mobile phone; the WAP web gateway then will transmit the trading data to web server of the financing unit.
- ³/₄ By CGI program or other techniques, the transaction server obtains the trading data from web server, and processes the operations of transferring the form of trading data and record with its transaction process modules, then, by mainframe connected with the interface to transmit the formed data to mainframe.

After the disposition of mainframe either by this bank or by other banks, the trading result will fax back to the mobile banking system as a result to follow the original route fax back to users.

In accordance with knowledge, Master Card, a heavyweight-financing unit, and its subordinate unit---Europe International, as well as the mobile phone

makers, intelligent card makers, and the application software company proceed with a strategic alliance. They present a wireless payment mechanism that users may use the WAP mobile phone to start up the SET [16] payment operation at the WAP-end of proxy server and remote wallet server, with which the existed Internet network trader and the payment gateway may continuously use this system. The payment mechanism, according to developing status of the market, identifies users' ID including:

- ³/₄ Dual-slot phone with full size chip Card : Use the intelligent card at once to identify the status and to provide the functions of basic code, certificates, and ciphers, which are necessary in the process of transaction.
- ³/₄ Multi-application SIM : Integrate the functions of basic code, certificates, and ciphers, into the SIM Card of mobile phone; it can be directly identifying users' ID in transaction, no need to insert the additional intelligence-card.
- ³/₄ ID-Password: Use the code name (e.g. MSISDN) and the code to identify user's ID, no need to provide the intelligent car; its security level is poor, not but that it is direct, convenient, and available to all.

STK (SIM Toolkit), the full-name read as "Subscriber Identity Module Application Toolkit", cooperates with SIM card maker through mobile phone company, recording or infilling the value-added servicing software into the microprocessor on user's ID card, select the value-added service he wants from the menu on the phone directly.

Only the banking business keeps continuously introducing the new service, can the predicament be settled, in which the wireless Internet and mobile commerce is a direction that banks, and that also is a successful operating model and key factor.

3. The Framework of the SMS Service

Domestic private-telecommunicating dealers recently are promoting in droves the service of wireless online, cellular phone with camera, and PDA, etc. Although it can be using the encrypted algorithms to protect the message transmitted, the operation ability and electric power of the cellular phone instead is only suitable for the symmetric-key algorithm of Symmetric-key to achieve the confidentiality and security rather than the complex and public one.

Hence, researching on the application development of the wireless Internet shall take the banking building loan as a subject to combine with the network technique of wireless Internet, traders, and building demanders to set up the "Housing Loan System Based on Wireless Application Protocol". With regard to its contents, it is comprised of wireless communication protocol, buying building with an instant order online, trading process online, and integration of housing-loan system.

In conclusion, look forward to providing more conveniences of the instant order to purchase a building, transacting the trade on-line and the data service,

decreasing the time and manpower's cost, combining with new high-tech development to enhance the service quality and competitiveness.

3.1 Characteristics of the SMS Service

Short Message Service (SMS): The bank currently provides the service of account management with an integral money-administration, with which it can cope with the integrated issues of different financing products. So, taken XML as a common standard for data exchange, the integrating issue may be avoided while the system data are involved with different forms.

Take the XML as a standard word for account data, further to set up an account platform frame to integrate individual money-management. Take the XML as a standard for documented data form in favor of the data exchange and transmission, so that target of the data integration can be reached. Based on the frame of individual money-management to integrate the account, achieving the purpose of the administration of individual money-management, and centralizing the asset to manage from time to time, and to dispatch nimbly the fund to procure the maximum profit.

3.2 Security Mechanism of the SMS Service

Common system of the STK mobile bank according to the transmitting feature to divide the trading message into two sections; the one is intervened between mobile phone users and common Center, and the other between common Center and financial units. The projected safety control mechanism, through the encryption and password, produce symmetric-key diversification, which may prevent the SMS cent or the message in transmitting process from encountering any security threat.

Table 1 Security Control Processes for Trading Message

Message Unit	Transmitting Process of the Message
Mobile Phone Users	Step 1: Select the trading item through the menu. Step 2: Input the data through the mobile phone Step 3: Enter user's cipher for the account transaction
Common Center	Step 4: Accept message of mobile phone users to decrypt and verify the password, transferring the cipher, and then shifting the message form.
Financial Unit	Step 5: The message received from common center, the password will be engraved transaction will be processed. Step 6: Responding disposition to the message.
Common Center	Step 7: Respond to the message of financing unit, verify the engraved code, and transfer the message form.
Mobile Phone User	Sept 8: Message of the common center, through mobile phone, prompts the user to read the result Step 9: Users of mobile phone read result through menu.

The message's security control measures, processes, and steps in transaction are specified as Table 1. The trading message transmitted by mobile phone will be transferred through common center, and this message will be sent back pursuant to the user of mobile phone after the financing unit has processed the message.

These trading messages are marked with account number, amount, and ciphers, the integrity of sequence, identification of the resources, and privacies of the message and cipher.

Another message of the account announcement is specified the security control measures and steps. Discovering user's account having inward remittance (I/R), not sufficient funds (n.s.f.), and expiry of C/D, etc. the system of financing unit will send the noticing message to the user of mobile phone through common center.

These notifying messages are likely carrying with data of the account number, amount, and etc. Therefore, the strictness in the security control has to be deliberately considered to protect the integrity of users' financial account, the integrity of sequence, the resources identification, and the message privacies.

It may decrypt the sensitive data due to the important data in storage protected effectively. The code system is the Symmetric-Key, e.g. DES (Data Encryption Standard), which is often used in decrypting algorithms with a considerable volume, exceeding the capability of the traditional chips---CPU can be loaded---thus the ALU has to be used for auxiliary purpose. Algorithms of the symmetric key is simpler, as same as the SIM and WIM, as the mobile station also used it.

3.2 Benefits of the SMS Mobile Banking Service

Anticipating to use the mobile banking service, the consumer primarily want to have the services of inquiries and transfer; and they have a positive relationship to the "Service Attitude of the SMS" and the "Service of Practical Using SMS". A convenience is the most noticeable factor to affect consumer's attitude to the service attitude of the SMS.

Scholar Brown (1989) had divided the convenient attribute into five formations as time dimension, place dimension, acquisition dimension, use dimension, and execution dimension. Functional Formation Conveniences in Mobile Phone Service) The mobile phone with the service of SMS has the merit of these five conveniences, and its servicing function is consistent with consumer's demand.

The banks have mostly adopted the specialized commissioner system to promote enterprise's financing business since a long time; the customer's commissioner runs the whole show of client's problem resolved and client's relationship maintained. Whether client's commissioner may properly arrange his working contents, and bring the benefit into a full play has become an important issue in banking operation.

4. A Case of SMS Mobile Banking Service

Bank is an important chain linked within the financing mechanism, dominating the indirect finance to act as an intervening role in funds. The resource of the bank deposit is to absorb the public unused-fund loaning to the demander, creating a revolving credit as the primary operating target to form a capital circulation, which is to play a decisive role in the trading behaviors of economies.

Banking business is a service business; in order to procure the optimum benefit of economic scale, the product is normally having the identical quality, traditionally; it is a blurred distinction between the different banks, so the service's convenience and security becomes the major variable of bank's distinction.

A mobile bank cooperated by each bank to promote the value-added service may provide with an intelligent mobile-phone system for transfers, inquiries, and payment. Through the cellular phone, it can be directly to contact with the bank to proceed with the balance inquiry, checking the particulars of transaction and the payment and transfers, as if it has a potable, private, confidential, and secure ATM. SIM card to collocate with STK cellular phone shall be having a higher security in confidentialities and verifications. Users may have the STK function if they own the SIM card issued by mobile bank.

The Internet application may help the bank to enhance the competitive superiority [6]. By means of the hyper-link feature of Internet, different industries have formed a strategic alliance such as the telecommunications, network communications, computers, securities, and insurances. Emome, as "e" is digital; "mobile" is action; and "me" is in the life, signifies the electronic and the mobile. Personalization is collective title of the value-added service of the mobile phone provided by the China Telecommunication Company. Emome website is a wireless portal. In order to procure the best profits of economic scale, the added value may provide more services, which is one of the important promoting strategies for banking business.

4.1 Alternative Operating Modes

The credit given is a major system of the commercial bank. The loan procedure for traditionally existed building made by banks is comprised of: client's negotiation, conditions discussion, acceptance of the application, collaterals appraisalment, credits investigation, analysis, and audits, etc. Should it be consistent with the bank would sign the contract with them, the mortgage arrangement of the collateral, and then the fund will be deposited into debtor's account [7] by transfers.

Internet's development signifies a breakthrough in the realm of information; the data can be received in any time and locations through the voice and words to make the communicating reciprocation, with which the commercial opportunity brought is immeasurable.

Owing to the Internet frequently being used, the computer becomes an indispensable partner in daily living. The Process Step Drawing of the Building Loan mad with

the SMS of Mobile Phone as shown in Table 2.

Table 2. Process Schedule for Mobile Building Loan.

Step	Process Schedule for Operation Building Loan Cellular Phone
1	Consumers use cellular phone to inquire the building type he likes.
2	Consumers use the cellular phone to order the building, and inquire the possible loan conditions.
3	The bank inquires the credit data by integrated database. A. If the client is having an account at this bank, investigate the credit grade and financial status data, and review his credit degree. B. If he is not, then, notify online and wish the client might visit the counter for negotiation.
4	When consumers inquire the possible preferential interest rate, the system will instantly inspect: A. If there is the data of credit's degree, give the good customer a preferential interest rate in accordance with the credit degree B. If not, the interest shall be in accordance with the normal loan condition.
5	Consumers based on the preferential interest rate provided by banks place directly an application for building loan [confirm]
6	A. Clients have to visit the counter to seal and affirm the identification, and both parties sign the contract of building loan. B. Banks will provide the league accountant to ensure the privilege for both parties. C. Banks will provide the league insurance company because their premium is absolutely reasonable
7	After banks and clients signed the contract, the sum can be deposited into consumer's account within 2~3 working days.
8	Deduct the principal and interest by the contract signed by both parties in accordance with terms.
9	When the building loan is expired, the client may apply to postpone the loan
10	When the building loan is expired, the client would not be continuously this loan; system will automatically cancel the debts.
11	If the building loan is not expired, this building loan shall be transferred into receivables on demand when the client failed to pay the interest with the demand many a time
12	If it is unable to communicate online, invite the client to pay a visit to the counter for negotiation.

The mobile bank cooperated with the telecom operator promotes the STK mobile bank service, adopting the GSM mobile phone with STK function to proceed with the order, transfers, and payment, etc of the financing service all year round through the service of SMS in SMS mode with the

menu function displaying on the screen of cellular phone. The features of STK mobile bank are specified as follows: 1). Adopt the menu function displaying on the screen, easy learning, and easy use. 2). 3DES is added the protections of decryptions and multiple ciphers. 3). Expandable, allow to deal simultaneously with many a security companies, and differ from WAP.

Financial card issued by mobile bank & emome money-managing card issued by the China Telecommunication Cellular-phone's function of the mobile bank, regardless of the where and the when, can use the cellular phone to accomplish lightly the transfer, payment, and inquiries of personal account data. In order to coordinate with various money-managing demand requested by clients, this card is integrated the service with the financing card of the mobile bank, or emome money-managing card of the China Telecommunication.

Building load of the mobile SMS, through the emome money-managing card of the China Telecommunication, is provided the menu function with a rapid operating mode. Emome is provided with the following functions except the normal conversation used by mobile phone, mobile online, and SMS.

³/₄ Mobile Bank – Clients may register maximum six banking accounts to provide the balance check, instant transfer, and free transaction service projected by each bank.

³/₄ Mobile Payment – Joining the emome money managing system and selected the merchandise at the contracted store, the client only needs to advise the store dealer of the payment number of the mobile phone issued by the China Telecommunication, then, the e-bill will be sent to the cellular phone with the SMS mode for client's reconfirmation while the financial card is processed the consuming transfer, or the credit card is signed for payment.

³/₄ Mobile Securities Firm – Clients may register maximum three securities accounts to provide the functions of orders (included stock buying, stock selling, loan purchase, loan selling, stock loan indent, stock loan venture, cancel the inquiry commitment, today's bargain status, inquire the stock inventory, free inquiries), profiles settings, profiles inquiries, and warming price setting, etc.

³/₄ Mobile Building Loan – Clients may, through the inquiry of SMS, determine the functions of building loan with cellular phone, which provides with inquiry to various types of building, and to the services of loan conditions, preferential interest rate, confirming the order to apply the building loan, account deposit, deducting principal and interests each term, and applying loan postponed online, etc.

The memory capacity of SIM card of the cellular phone helped with STK tech may expand the normal 2K to 32K, recording many executing program directly on the card, so consumers through STK of the cellular phone to place an order, the SIM card of which has the programming design. Set up directly on the screen, select and input the trading data, and exempt from the repeat listen and input while the

cellular phone is used as a voice order, enhancing the operating convenience and having an apparent improvement in efficiency.

Operate and input directly in accordance with the menu on screen, with which the correction and flexibility is better than voice order. The message is transmitted by the mode of SMS, and the charge is calculated by calls instead of by time.

The screen will be displaying the service of SMS and the normal communication; when the former is used, the keystroke on cellular phone will progressively select the necessary trading function according to the menu on screen, inputting various trading data, and pressing the confirm key to transmit with the SMS.

4.2 An Application Example

Use the cellular phone to determine the building loan, and place an order to operate the functions through the inquiry of SMS; the illustrative process of the cellular phone is simplified as follows:

Individual Inquiry to Buy Building:

³/₄ Step 1 first select [購屋個案查詢] item

³/₄ Step 2 Select the existed building located at County or City, which is distinguished by letters of the alphabet, e.g. Taipei County or City is A; Taoyuan City is B. When the selective items are more than one page, "next" shall be selected.

³/₄ Step 3 "previous" or "next" shall be selected.

³/₄ Step 4 Select the existed building located at County or City, distinguished by letters of the alphabet, e.g. Taipei County or City is A; Taoyuan City is B.

³/₄ Step 5 Select the existed building located at County or City, which is distinguished by figures, e.g. Hsinyi District of Taipei City is A1; Peitou District is A5. When the selective items are more than one page, "previous" or "next" shall be selected.

³/₄ Step 6 The inquiry of individual particulars has to input the inquired housing code (e.g. 1; 2; 3;...), inputting 1 means the individual case of code No.A51, Peitou District of Taipei City, irregularly updated by banking control center.

³/₄ Step 7 Pressing the [confirmed] key, it will show the "transacting is proceeded, please wait for responds", waiting for the center to respond the particulars data to each case.

³/₄ Step 8 Center responds the particulars to each case with following data; A51 Yu-Chuan Villa with Hot Spring, including the sector of the area, unit price, certificate, public facilities, available loan, and building-age.

Inquiries of Preferential Interest Rate:

³/₄ Step 1 first select [優惠利率查詢] item

³/₄ Step 2 Input the ID number to audit if it is the good customer of the bank.

³/₄ Step 3 Clients input the amount of loan, e.g. 130000000 signifies 13 millions.

³/₄ Step 4 Clients input the term of the loan (by year), e.g.

20 means 20 years.

³/₄ Step 5 Pressing the [confirmed] key, it will show the “transacting is proceeded, please wait for responds”, waiting for the center to respond the particulars data to each case.

³/₄ Step 6 Center responds particulars of the individual case with the following data: Building loan amount: 13,000,000; term: 20 years; preferential interest rate: 5.7%.

Applying an order for building loan:

³/₄ Step 1 first select [申請房貸下單] item

³/₄ Step 2 Input the ID number to audit if it is the good customer of the bank.

³/₄ Step 3 Placing an order is client’s personal money management, so it has to input the personal cipher to audit if the client has the authorization.

³/₄ Step 4 Clients input the amount of loan, e.g. 130000000 means 13 millions

³/₄ Step 5 Clients input the term of the loan (by year), e.g. 20 means 20 years.

³/₄ Step 6 Clients input the account number, e.g. 518551123451 signifies 5185-51-12345-1

³/₄ Step 7 Pressing the [confirmed] key, it will show the “transacting is proceeded, please wait for responds”, waiting for the center to respond the particulars data to each case.

³/₄ Step 8 Center responds particulars of the individual case with the following data: Building loan amount: 13,000,000; term: 20 years; preferential interest rate: 5.7%、A/C : 5185-51-12345-1.

4.3 Integrating with the Data Warehouse

To hold each customer is not a simple thing. Client’s data may be collectible through questionnaires or telephoned investigation though, the diversity of information resource and the increase of data volume are undeniable. Will a smooth operating mode be maintained, the demand of each customer shall be comprehended, and it shall be increasingly difficult on the merchandise and service.

Targeting information and data, different analyzing tools will produce various simple and complex analyzing outcome. Generally speaking, the functions of data all have the analyzing tools such as query and reporting, producing different analyzing report (shown as Table 3). Front Tools Including mainly various tools of reporting forms, data analysis, data development, develop tools based on the Data Warehouse.

In the process of a bank loan to the consumer, it is more valuing the various conditions at the consumer himself, banks, and external environment, as well as the factor research, loan-authorized contract, loan’s amount, and the reimbursing capability, than valuing the other request or restriction in the contract therein. As to the credit-authorized contract, manifest that bank often request the clause, which is neither agreeable nor incapable of scrutinizing the content of the contract, e.g.

the currently practical operating situation of immoveable collateral loan, immoveable evaluation, loan percentage, overdue loan, and bad debts, etc.

Table 3. Process Credit Control via Data Warehouse.

Step	Process of the Data Disposition
1	Providing user’s interface with a high affinity, the single window will be used for handling and integrating the storage function, control, and management to set up and maintain entire Data Warehouse.
2	Use unitary platform to control all accessing data of the inventory on entire network, and allow the manager of the Data Warehouse to manage easily the establishing program of Data Warehouse.
3	In the selective process, produce and manage relevant inventory frame and the metadata will automatically produce another metadata; vital data shall not be affected the inventory frame by the personnel variation
4	Provide interface to connect with OS, and time the scheduling software at a specific timing to execute the program automatically.

The commercial analyzing personnel in bank are exclusively using the tools of online analysis and multi-dimensional analysis, with which they might have the capability to analysis the original data, and to drill to understand the correlation among the different parameters in data[8].

Such analyzing report are mostly belonged to the property of system mode, that functional manager in relevant department is normally in charge, and that general analyzing subject is building loan in different phase, and the interest rated, etc.

Data mining is also having the preceding characteristic, the main discrimination of which is the data mining targeting at mass data to analysis and locate the hidden patterns in data. [9] Data mining is substantially differ from the statistic analysis and the online analyzing techniques; the former is only available for analyzing the minority of the data correlation or the different subject in statistics, while the latter is adopted to analysis the report for normal Data Warehouse, aiming at the system mode and the data with lower correlation in analysis.

Credit-authorization is one of the principle businesses, the quality of which is thus related to bank’s existence and development, especially within recent years, domestic economy was influenced by global depressions, the ratio of overdue loan has yearly been on the rise, further to stress on the importance that risk of the credit authorization shall be properly processed and managed from time to time. Nevertheless, owing to consumers’ building loan having

the features of small amount and high cost as per unit, it will be accept or not, and reaching the target to win the identical credit amount by quantities. Hence, to avoid of drawbacks, it is essential to reduce the audit time, decrease the risk of credit authorization, and establish a set of assessing model and system to measure the credit authorization.

5. Conclusions and Future Works

Succeeded by the upsurge of the network bank and the e-commerce, the wireless Internet access and finance has been becoming a newly burgeoning tropic. Developing the mobile bank may provide another sales channel and a more convenient service. As far as the service time is concerned, the mobile bank is 24 hours a day, and 365 days a year in operation, having no restrictions of traditional branches or ATM geographic influence, nor confining the customer to this bank, of which the service range may be included all network participants. Use the mobile phone and wireless transmitting tech to develop e-commerce to go across into a new realm. Promoting the mobile commerce, the banking dealer shall spare no efforts and walk towards the direction of easy use and the compatibility with old users habit in development.

The greatest contribution made by STK tech is to have provided an exploitable environment for the SIM card in value-added business as simply using easy operating and developing platform. Users exploit the SIM card through the coordination of server, with which it may present diversely rich and splendid business. SIM card may accomplish a given mission and the data storage, but its processing ability is inferior to that of computers. However, because it belongs to microcomputer system, it can be stored in the wallet or mobile phone, so SIM card also has an extensive application space. As far as the world scope is concerned, the application of Japan and Europe has gotten higher as well as the intelligent car is widely and rapidly spread out in US.

Devoting to develop the SMS service of the mobile bank, banks may effectively reduce the ratio of clients transact the business on counter. The employee of the bank would have more time to complete the higher value-added business (e.g. money-management projected, financing products promoted, and financing business process improved, etc.), further to benefit and enhance the banking competitiveness.

STK tech allows us directly to use cellular phone to place an order on stock and enjoy the financing service, it is, indeed, satisfied with modern's demands on pursuits of fast speed and on convenience as well as an extremely high security. So the entire transaction process is being protected as the relevant data is encrypted, from which we may see that securities of the data in the transmitting process is considerably conscientious and careful.

The SMS service combined with STK, it will be becoming a path to allow the system dealer to enhance individual service. STK tech is mainly being applied to the realms of mobile bank, stock transaction, foreign exchange

buying/selling, and money-management, etc. Although its service for is unitary, a considerable demand is requested to the use. For STK, it is still having a given technical defect such as the high difficulties in development, non-unified technical norm, confined to processor's tech development, narrowly technical developing space, etc. So it is still waiting for our unceasingly endeavors.

Abstract

Many problems in production planning and supply chain optimization can be modeled as Economic Lot Size problem (ELS). This paper first demonstrates forward and backward algorithms for the economic lot size problem with backlogging, and then applies the two algorithms to analyze the sensitivities of setup cost and demand. The result for setup cost sensitivity is the same as the one described in [8] for economic lot size problem without backlogging. These analyses are especially useful for online or real-time applications which are common in current E-commerce.

1. Introduction

Many problems in production planning and supply chain optimization can be modeled as Economic Lot Size (ELS) problem. For example, if we consider the single product production scheduling problem at the manufacturer's site, and also consider the same product's inventory control problem at the retailer's site, then it is a typical ELS provided the production and inventory cost have linear relationship with the production and inventory units. ELS is a classical problem and first proposed in [10]. After Wagner and Whitin provided and solved the economic lot size model without backlogging by an $O(n^2)$ algorithm, considerable research efforts have been made to extend the basic model. Two important extensions are the consideration of backlogging, and the improvement of computational complexity. This paper re-interprets the algorithms given in [12] and [7], and applies the forward and backward algorithms for conducting sensitivity analysis on setup cost and demand.

2. Previous Works

Zangwill [11] considered the inventory backlogging in the basic economic lot size model, and proved that there is an optimal solution that the production and inventory at every period satisfy the exact requirements. In the same paper Zangwill also developed an $O(n^3)$ algorithm to solve the model. Zangwill [12] expressed the economic lot size problem with and without backlogging as a network that has one entry with the demand summations and multiple exits with the demand of every period. He also developed an efficient $O(n^2)$ algorithm for the model where the production cost is fixed. It is worthy to notice

that the cost functions of every period in the Zangwill's works can be linear or nonlinear and the value can be computed in constant time. Blackburn and Kunreuther [3] developed a forward algorithm for the case where the production, holding and backlogging cost functions are linear. Some breakthrough was made at the beginning of 1990's. Wagelmans et al. [9] reformulate Wagner-Whitin model into a new model without holding cost, and employ a geometric method to reduce the computational complexity. Furthermore Hoesel, Wagelmans and Moerman [7] proved that the economic lot size problem with backlogging can also be solved with the same computational complexity as $O(n \log n)$ using geometric methods. Federgruen and Tzur [5] [6] also develop an $O(n \log n)$ forward dynamic algorithm to determine the optimal last setup period and minimum cost sequentially for the ELS with and without backlogging. Aggarwal and Park [2] identify the connections of the known fast array searching techniques in Monge arrays with the ELS, and obtain the same results.

Based on the geometric interpretation of the ELS developed in [9], Hoesel and Wagelmans [8] studied the variation scopes of setup, production, holding costs and demand respectively such that the optimal production schedule remained unchanged. If the setup cost for every period is constant and the unit production cost is also fixed, Chand and Voros [4] prove that the total cost of holding and backlogging is a non-increasing convex function of the number of setups for the ELS with and without backlogging, and develop an $O(n^2)$ forward algorithm to compute the stability region of the setup cost.

3. The Notations

Mathematically, economic lot sizing model with backlogging is to satisfy the known demands in a planning horizon at a minimum cost by a single commodity. ELS with backlogging permits to produce later to satisfy the demand of a former period. The following notations will be used through this article:

N : the length of the planning horizon,

d_i : the demand in period $i \in \{1, \dots, N\}$,

p_i : the unit production cost in period $i \in \{1, \dots, N\}$,

f_i : the setup cost in period $i \in \{1, \dots, N\}$,

h_i : the unit inventory cost $i \in \{1, \dots, N\}$,

h_i^b : the unit backlogging cost $i \in \{1, \dots, N\}$,

$$d_{i,j} = \sum_{t \in I} d_t, 1 \leq i \leq j \leq N$$

$$h_{i,j}^{\square} = \sum_{t \in I} h_t^{\square}, 1 \leq i \leq j \leq N$$

$$h_{i,j}^{\square} = \sum_{t \in I} h_t^{\square}, 1 \leq i \leq j \leq N$$

F(i): the minimum cost from period 1 to the end of period i, the demands are satisfied by the productions in these periods. The inventory at the end of period is zero (such period is defined as regeneration period).

F'(i) : the minimum cost from period 1 to the end of period i, the demands are satisfied by the productions in these periods. Period i is a production period (Such period is defined as production period).

B(i): the minimum cost from the beginning of period i to the end of period N, the demands are satisfied by the productions in these periods. The inventory at the beginning of period is zero.

B'(i) : the minimum cost from the beginning of period i to the end of period N, the demands are satisfied by the productions in these periods. Period i is a production period.

4. Forward and Backward Algorithms

Zangwill [12] gave a two-step expression to demonstrate ELS with backlogging. Hoesel, Wagelmans and Moerman [7] reformulated the formulas into the ones that can be explained in a geometric approach. Based on both the preceding works, this article re-formulates the backward and forward dynamic expressions with the parameters within the studied period scope, keeps the formulas' geometric meaning, and subsequently applies them in the setup cost sensitivity analysis and total demand variation.

4.1 Backward Algorithm

In [12] and [7], the backward algorithm of ELS with backlogging can be expressed as the following equations:

$$B(s) = \min_{s \leq t \leq N} \{ p_t d_{s,t} + \sum_{s \leq t \leq N} h_t^{\square} d_{s,t} + B'(t) \} \quad (1)$$

$$B'(t) = \min_{t \leq u \leq N} \{ f_t + p_t d_{t,u} + \sum_{t \leq u \leq N} h_u^{\square} d_{t,u} + B(u) \} \quad (2)$$

and define $B(N+1) = 0$, $B'(N+1) = 0$.

Define $M(s, t) = \sum_{s \leq t \leq N} h_t^{\square} d_{s,t}$ and

$$M'(t, u) = \sum_{t \leq u \leq N} h_u^{\square} d_{t,u}$$

The following equalities hold:

$$M(s, t) = M(s, N) - M(t, N) - h_{t,N}^{\square} d_{s,t},$$

$$M'(t, u) = M'(t, N) - M'(u, N) - h_{u,N}^{\square} d_{t,u}.$$

So the equalities (1) and (2) can be re-written as:

$$\begin{aligned} B(s) &= \min_{s \leq t \leq N} \{ p_t d_{s,t} + M(s, N) - M(t, N) \\ &\quad - h_{t,N}^{\square} d_{s,t} + B'(t) \} \\ &= M(s, N) + \min_{s \leq t \leq N} \{ B'(t) - M(t, N) \\ &\quad - (p_t - h_{t,N}^{\square}) d_{s,t} - (p_t - h_{t,N}^{\square}) d_{s,N} \} \quad (3) \end{aligned}$$

$$\begin{aligned} B'(t) &= \min_{t \leq u \leq N} \{ f_t + p_t d_{t,u} + M'(t, N) \\ &\quad - M'(u, N) - h_{u,N}^{\square} d_{t,u} + B(u) \} \\ &= M'(t, N) + f_t + h_{t,N}^{\square} d_{t,N} \\ &\quad + \min_{t \leq u \leq N} \{ B(u) - M'(u, N) \\ &\quad - h_{u,N}^{\square} d_{t,u} - (p_t - h_{t,N}^{\square}) d_{t,u} \} \quad (4) \end{aligned}$$

The geometric meaning of equalities (3) and (4) can be explained as follows: The lines passing through $(0, B'(t) - M(t, N) - (p_t - h_{t,N}^{\square}) d_{t,N})$ with slopes $(p_t - h_{t,N}^{\square})$ construct the concave lower envelope, the $B(s)$ can be obtained by maintaining this concave lower envelope; the points of $(d_{t,N}, B(u) - M'(u, N) - h_{u,N}^{\square} d_{t,u})$ construct a convex lower envelope, $B'(t)$ can be obtained by searching the point that the line passing through with slope $p_t - h_{t,N}^{\square}$ is tangent to the envelope. (Please refer to [7] for detail).

4.2 Forward Algorithm

The forward algorithm can be expressed as the following formulas:

$$F(s) = \min_{0 \leq t \leq s} \{ p_t d_{t,s} + \sum_{t \leq s \leq N} h_t^{\square} d_{t,s} + F'(t) \} \quad (5)$$

$$F'(t) = \min_{0 \leq u \leq t} \{ f_t + p_t d_{u,t} + \sum_{u \leq t \leq N} h_u^{\square} d_{u,t} + F(u) \} \quad (6)$$

and define $F(0) = 0$, $F'(0) = 0$.

Similarly, define

$$m(t, s) = \sum_{t \leq s \leq N} h_s^{\square} d_{t,s}, \text{ and}$$

$$m'(u, t) = \sum_{u \leq t \leq N} h_t^{\square} d_{u,t}.$$

The following equalities hold:

$$m(t, s) = m(1, s) - m(1, t) - h_{1,t}^{\square} d_{t,s},$$

$$m'(u, t) \leq m'(1, t) \leq m'(1, u) \leq h_{u,t} d_{2,u}$$

Equalities (5) and (6) can be rewritten as following:

$$\begin{aligned} F(s) &= \min_{0 \leq t \leq s} \{ p_t d_{t,s} \leq m(1, s) \leq m(1, t) \\ &\quad \leq h_{1,t} d_{t,s} \leq F'(t) \} \\ &= m(1, s) \leq \min_{0 \leq t \leq s} \{ F'(t) \leq m(1, t) \leq \\ &\quad (p_t \leq h_{1,t}) d_{1,t} \leq (p_t \leq h_{1,t}) d_{1,s} \} \quad (7) \end{aligned}$$

$$\begin{aligned} F'(t) &= \min_{0 \leq u \leq t} \{ f_t \leq p_t d_{u,t} \leq m'(1, t) \\ &\quad \leq m'(1, u) \leq h_{u,t} d_{2,u} \leq F(u) \} \\ &= f_t \leq m'(1, t) \leq h_{1,t} d_{2,t} \leq \\ &\quad \min_{0 \leq u \leq t} \{ F(u) \leq m'(1, u) \leq h_{1,u} d_{2,u} \\ &\quad \leq (p_t \leq h_{1,t}) d_{u,t} \} \quad (8) \end{aligned}$$

The similar geometric meaning of equalities (7) and (8) can be explained as follows: The lines passing through $(0, F'(t) \leq m(1, t) \leq (p_t \leq h_{1,t}) d_{1,t})$ with slopes $(p_t \leq h_{1,t})$ construct the concave lower envelope, the $F(s)$ can be obtained by maintaining this concave lower envelope; the points of $(d_{1,u}, F(u) \leq m'(1, u) \leq h_{1,u} d_{2,u})$ construct a convex lower envelope, $F'(t)$ can be obtained by searching the point that the line passing through with slope $p_t \leq h_{1,t}$ is tangent to the envelope.

Now we have the backward and forward dynamic algorithms that are expressed with the parameters within the study periods.

5. Setup Cost Sensitivity Analysis

In this section, two scenarios will be considered: setup cost at a period is decreased, or increased by a variation of Δ . The objective is to get the variation scope of the Δ such that the production schedule remains unchanged.

Scenario 1: Setup cost is decreased from f_i to $f_i \leq \Delta$.

First suppose period i is a production period in the original problem and we will prove the following proposition.

Proposition 1: If Period i is a production period in ELS model with backlogging, then period i will still be a production period if its setup cost is decreased.

Proof: Suppose the optimal production schedule S_1 for the new problem does not include period i . The minimum cost of the new optimal production schedule will not be less than that one for the original problem which period i is a production period. This contradicts that S_1 is the

optimal production schedule. \square

Lemma 1: If period i is a production period in the final optimal production schedule, then

$$B(1) = F(N) = F'(i) + B'(i) \leq f \leq p d.$$

Proof: Suppose the final production schedule is:

$1 \leq i_1 \leq i_2 \leq \dots \leq i_j \leq i \leq i_r \leq \dots \leq i_k \leq N$. If we can prove that the production schedule before and after period i in this final schedule is the optimal production schedule for $F'(i)$ and $B'(i)$ respectively, we prove the lemma. This can be proved by contradiction.

Suppose there is a better production schedule $i_1', i_2', \dots, i_j', i$ other than i_1, i_2, \dots, i_j, i for $F'(i)$ which the total cost for $F'(i)$ is smaller, then obviously $i_1', i_2', \dots, i_j', i, i_r, \dots, i_k$ will be a better production schedule than $i_1, i_2, \dots, i_j, i, i_r, \dots, i_k$. This is a contradiction to our supposition. In similar way, we can prove i, i_r, \dots, i_k is the optimal production schedule for $B'(i)$.

Because $f_i \leq p d_i$ is counted twice together in $F'(i)$ and $B'(i)$, so we have $B(1) = F(N) = F'(i) + B'(i) \leq f \leq p d_i$.

It is obvious to have the following lemma directly from equalities (4) and (8):

Lemma 2: If in period i , the setup cost is decreased from f_i to $f_i \leq \Delta$ (period i might not be a production period), then

(1) From period 1 to $i-1$, $F'(\cdot)$ remains unchanged; $F'(i)$ decreases by Δ ;

(2) From period $i+1$ to N , $B'(\cdot)$ remains unchanged; $B'(i)$ decreases by Δ .

From Proposition 1 and preceding analysis, we can get the following conclusion:

Proposition 2: If period i is a production period in ELS with backlogging, and its setup cost is decreased from f_i to $f_i \leq \Delta$, and the production schedule remains unchanged, then the optimal cost decreases by Δ .

Now suppose period i is not a production period in the original problem. Suppose period i becomes a production period in the new problem for its setup cost decreases from f_i to $f_i \leq \Delta$, then the optimal cost is $F'(i) + B'(i) \leq f \leq p d_i \leq \Delta$, and this value should be at least less than the original minimum cost. So:

$$F'(i) + B'(i) \leq f \leq p d \leq F(1),$$

$$\text{then } \Delta > F'(i) + B'(i) \leq f \leq p d \leq F(1)$$

So if $\Delta \leq F'(i) + B'(i) \leq f \leq p d \leq F(1)$, then period i will not become a production period in the new problem. So Δ is bounded by $\min\{f_i, F'(i) + B'(i) \leq f \leq p d_i \leq F(1)\}$. So the following

conclusion can be obtained:

Proposition 3: If Period i is not a production period in ELS with backlogging, and its setup cost is decreased from f_i to $f_i \square \square$, the variation of \square is bounded by $\text{Min}\{f_i, F'(i) \square B(i) \square f_i \square p_i d_i \square F(1)\}$.

Scenario 2: Setup cost is increased from f_i to $f_i \square \square$.

Opposite to Proposition 1, it is obvious that if a period is not a production period in the final production schedule, it is impossible for it to become a production period if its setup cost is increased. Thus, the period is a production period in the final production schedule can be considered only.

The idea here is to compute the optimal minimum value for problem that period i is not a production period from period 1 to N , the obtained optimal value is the upper bound for the problem that the setup cost of period i is increased and period i remains a production period.

Mathematically, the optimal minimum cost can be expressed as:

$$G = \min_{1 \leq j \leq i \leq N} \{F'(j) \square g(j, t) \square B'(t)\}, \quad (9)$$

where

$$g(j, t) \square \min_{j \leq 1 \leq t} \{p_j d_{j \square 1} \square p_t d_{1 \square t \square 1} \square \sum_{\square \square j}^{1 \square} h_{\square} d_{\square \square 1 \square 1} \square \sum_{\square \square 1}^{t \square} h_{\square} d_{1 \square \square \square}\}$$

In order to get the value of $G(\cdot)$ in equality (9), first we prove the following lemma:

Lemma 3: If a period is not a production period in the final production schedule, and its setup cost is increased, this period will still not be a production period in the final production schedule, and the final production schedule and optimal cost will remain unchanged.

Proof: Similar to proposition 1, the first part is obvious. The second part is proved as follows:

Suppose setup cost at period i is $f_i \square \square_1$ and $f_i \square \square_2$ respectively, and period i is not a production period in the final production schedule for both problems with different setup cost. Because the optimal total cost will only count the setup costs of final production periods, holding and backlogging costs between the consecutive production periods, and the other parameter values except the setup cost at period i are the same for both problems, so a feasible solution for one problem is also feasible for the other one. This proves the lemma. \square

Lemma 3 will be used in the following idea to compute the value of $G(\cdot)$: Because of increasing setup cost, it is possible that a production period i will be out of the final production schedule. So there is a break value of setup cost that period i is a production period in the final production schedule if its setup cost is less than this value (Proposition 1), and period i is not a production period in the final production schedule if its setup cost is larger than this value (Lemma 3). Also from Lemma 3, if setup cost is

larger than the setup break point value, the optimal final cost is the same no matter how big the setup cost is. So period i in equality (9) can be got if a big enough setup cost is assigned to period i such that period i will not be a production period in the final optimal solution.

Now it is clear that we can get the value of G in $O(n \log n)$ if the setup cost for period i is assigned a big enough value so that the period i is not a production period in the final solution. Of course we can start to solve the problem from $B(i+1)$ or $F(i-1)$. Such big enough setup value for period i exists, for example the new setup cost is:

$$f_i \square \sum_{j \square 1}^N f_j \square d_{1, N} [N * \text{Max}(h_1^{\square}, h_2^{\square}, \dots, h_N^{\square}) \square$$

$$N * \text{Max}(h_1^{\square}, h_2^{\square}, \dots, h_N^{\square}) \square \text{Max}(p_1, p_2, \dots, p_N)$$

If production occurs at such a period, the cost will be more than that for setup at every period, carrying and backlogging the total demands from the beginning to the end, and producing at the most expensive unit cost. Any production schedule other than including this period will definitely be smaller.

After value of G is computed, the period i will remain the production period if $F(n) + \square \square G$. So the upper bound for the value of \square is $G - F(n)$. So the following result holds:

Proposition 4: The maximal allowable increase of f_i can be calculated in $O(n \log n)$ time.

6. Total Demand Variation Analysis

It is also obvious to get the following lemma from equalities (4) and (8):

Lemma 4: If in period i , the demand is changed from d_i to $d_i \square \square$ then

(1) From period 1 to $i-1$, $F'(\cdot)$ remains unchanged, $F'(i)$ changes by $\square p \square$;

(2) From period $i+1$ to N , $B'(\cdot)$ remains unchanged, $B'(i)$ changes by $\square p \square$.

Here, we will study how the variation of the total demand affects the original optimal production plan.

Suppose the $\square \square$ units are increased or decreased at period i . The objective is still to let the whole costs minimum. Such minimum value can be expressed mathematically as follows for the case the products are increased or decreased:

$$VI(\square) \square \min_{1 \leq i \leq N} \{F'(i) \square B'(i) \square f \square p_i d \square p_i \square\} \quad (10)$$

$$V(\square) \square \min_{1 \leq i \leq N} \{F'(i) \square B'(i) \square f \square p_i d \square p_i \square\} \quad (11)$$

Let us discuss (10) first. Define l_i is the line which passes through point $(0, F'(i) \square B'(i) \square f \square p_i d)$ with slope of p_i . So lines of $i (1 \leq i \leq N)$ construct a concave lower envelop for the parameter of \square . Because

the values of $F'(i) \square B'(i) \square f \square p_i d_i$ are the same for all production periods, so only the period with the lowest p_i can be in the concave lower envelop for all production periods. Define such period as period A. The line A has the minimum value of $F'(i) \square B'(i) \square f \square p_i d_i$ due to A is a production period.

Figure 1

From Figure 1, we can see that if the increased \square is within $[0, B_1]$, which B_1 is the first break point of the concave lower envelop, then the production period A will produce the increased units; if the increased \square is not within $[0, B_1]$, then another period which is not a production period at the original optimal solution will produce the increased units, and therefore becomes a production period in the new solution.

Figure 2

Same logic can applied for (11) except that i is the line which passes through point $(0, F'(i) \square B'(i) \square f \square p_i d_i)$ with slope of $\square p_i$; and only the period with the biggest p_i can be in the concave lower envelop for all production periods due to the line gradient is negative. Figure 2 describes this case.

In [7], it is proved that time complexity of constructing such a concave lower envelop in Figure 1 and 2 will be $O(n \log n)$. They also proposed that balanced tree such as 2-3 tree [1] is the efficient data structure for supporting such a procedure.

From the preceding analysis, we can draw the following result:

Proposition 5:

(1) If the solution remains the same, the increased total demand is produced at the period with least production cost; and the decreased total demand is extracted from the period with largest production cost.

(2) The maximum increased (decreased) total demand

variation is the value of B_1 which is described in Figure 1 (2).

(3) The value of B can be computed at time complexity of $O(n \log n)$.

7. Conclusion

This article describes the backward and forward algorithms for the economic lot size problem with backlogging, and subsequently applies the algorithms to analyze the two main parameters of the model: variation of period setup cost, and total demand variation. Although the computational complexity of the algorithm for determining the sensitivity range of setup cost and demand is $O(n \log n)$, the complexity of solving the problem itself is not augmented by sensitivity analysis since these two can be implemented concurrently. Such analysis is very useful for online or real time ELS planning or scheduling problems which are very common in today's e-commerce applications.

Abstract

There are various types of trading behavior in the stock market. And the buying or selling activities in many investment strategies are influenced by numerous factors respectively, such as fundamental analysis, macroeconomic analysis, and news analysis. Consequently, various factors will reflect on market price. Random Walk in financial engineering is not the focus in this paper. Otherwise, the importance of the technique analysis about Taiwan Stock Index Futures will be emphasized in this research.

It is the intention of this paper to investigate the information content of Open, High, Low, Close prices in the previous trading day and relative higher and lower points in the prior period of the current trading day, as well as their prices in analyzing Taiwan Stock Index Future. The predictability of Learning Vector Quantization Network can clearly be seen from the empirical result.

Keywords : Neural Network, Learning Vector Quantization, Taiwan Stock Index Future

1. Introduction

From economic viewpoint, the prices of goods are determined by supply and demand. Buyers and sellers made their own trading decisions according to different view about the target goods. The price will rise if demand falls short of supply; On the contrary, if supply falls short of demand, price will decline. In other words, the price of goods is a common consensus for all participants about the value of goods itself. It is the same with financial commodities.

The prices of financial commodities are the trading results of buyers and sellers. Buyers and sellers made their own trading decision according to different trading rules, including fundamental analysis, macroeconomic analysis, and news analysis. Therefore, these factors have influence on determining stock prices as well. Figure 1 describes how these trading rules affect the stock prices continuously, such as fundamental factors, macroeconomic factors and etc. In this paper, we assumed that all factors are functions of time and will be continuous time relative data.

$$\text{Stock price} = \text{Real price} + \text{Effect price} \quad (1)$$

$$\text{Effect (fundamental)} = f_1(t) \quad (2)$$

$$\text{Effect(macroconomics)} = f_2(t) \quad (3)$$

Because of the restrictions on trading hours, the curve of market prices is discrete in time-axis. Therefore, it is impossible for market prices to reflect immediately the effect of all factors. After the market closing, all elements influencing market prices will be reflected on the Open prices in the next trading day. The non-cash-period represents expectation formation process.

For this reason, this research will focus on whether all factors between 13:45 and 08:45 (period T) from previous day will affect the Open price (point E) of next trading day. Furthermore, it is suspected that the sum of all factors will be the Open price of the next trading day.

$$\text{price}_{\text{Open}} = \sum_{e=1}^n \text{Effect}(e) = \sum_{e=1}^n f_e(T) \quad (4)$$

Open : open price

e : element influencing prices

n : number of elements

T : time period between two trading times

Figure 1. The factors influence the stock prices continuously, such as fundamental factors, macroeconomic factors and etc.

Figure 2. An illustration of the Open, High, Low, Close prices in the previous trading day as point A, B, C and D.

The relevance between the Open, High, Low, Close prices in the previous trading day, and relative higher and lower points in the prior period of the current trading day is discussed by using artificial Intelligence in this paper. The purpose is to make profits and to avoid risks by analyzing Taiwan Stock Index Future.

2. Literature

2.1 Literature Review

2.1.1 Literature in Stock Market Behavior

The overnight effect on the index future is discussed in this paper. Research on forecasting stock returns, such as Campbell and Shiller in 1988, and Bollerslev and Hodrick in 1992, have indicated that stock returns are predictable by using linear models.

Menkhoff (1998) indicated that changing order flows play an important part in determining market prices. Tian Shyue Lee and Nen Jing Chen [8] showed that the lead-lag relationship between the futures market during the non-cash-period and the cash market during its opening period does exist. The empirical results of the above research show that the prediction result of the model is better than random walk model. Therefore, this research is based on non random walk process.

2.1.2 Literature in Application of Artificial Intelligence.

Neural network has been widely applied in several financial areas, such as exchange rate prediction, bankruptcy forecasting and stock market prediction. For exchange rate prediction, Jingtao Yao and Chew Lim Tan [2] stated that a neural network model is applicable to the prediction of foreign exchange rates. For bankruptcy

forecasting, Moshe Leshno and Yishey Spector [5] stated that the prediction capabilities of neural network model in this bankruptcy case are clearly more accurate than other classical discriminate analysis model. For stock market prediction, Mary Malliaris and Linda Salchenberger [4] used neural network to forecast the S&P 100 implied volatility.

2.2 Candlestick Analysis

Open, High, Low and Close prices defined in candlestick analysis are used to be input factors in this research. Norbert M. Fiessa and Ronald MacDonald indicated that the difference between High and Low prices marks the intradaily trading range and measures volatility. The difference between the Open and the Close prices thus serves as a measure of the direction and the extent of intradaily trends. The academic survey on support and resistance levels by Curcio and Goodhart (1992), DeGrauwe and Decupere (1992) showed clearly that High and Low prices reveal information about shifts in the demand and supply structure. Therefore, Open, High, Low and Close prices are the inputs to the model in this research.

2.3 Learning Vector Quantization

Learning Vector Quantization of neural network is selected in this paper. Neural network is one part of Artificial Intelligence. It is an information-processing paradigm inspired by the way the densely interconnected, parallel structure of the mammalian brain processes information. The key element of the ANN paradigm to be differentiated from other methods of Artificial Intelligence is self-learning. Neural network is also well known for its ability to process nonlinear problem.

Ramazan Gençay[6] pointed out that strong evidence of non-linear predictability is found in the stock market returns by using the past buy and sell signals of moving average rules. Therefore, artificial neural network is applied in this paper to improve predictability of stock market and to raise the profitability.

Learning Vector Quantization is a competitive learning algorithm said to be a supervised version of the Self-Organising Map (SOM) algorithm by T. Kohonen[7].

Reference vectors are the weights of the connections leading from the input neurons to the output neurons. For each training sample, the reference vector that is closest to it is determined. Only the weights of the connections to this winner neuron are updated. The direction of the adaption depends on whether the class of the training sample and the class assigned to the reference vector identify or not. If the training sample is placed into the correct class, the reference vector is moved closer to the training sample; otherwise it is moved farther away. This

movement of the reference vector is controlled by a parameter called the learning rate [Christian Borgelt, 2000].

The algorithm of LVQ is listed as follows :

1. Initialize weights; initialize learning rate.
2. Do step 3-7 until stopping condition is true.
3. For each input vector X , repeat steps 4-5
4. Find node J so that $\|X - W_J\|$ is a minimum distance.
5. Update W_J according to follows :

 If X is classified to the correct class

$$W_J^{\text{new}} = W_J^{\text{old}} + \alpha(X - W_J^{\text{old}})$$

 If X is classified to the incorrect class

$$W_J^{\text{new}} = W_J^{\text{old}} - \alpha(X - W_J^{\text{old}})$$
6. Reduce learning rate.
7. Test stopping condition. It may be a fixed number of iterations or the learning rate reaching a sufficiently small value.

3. Architecture

3.1 The Research Process

First, data of Taiwan Stock Index Future is collected. The data of each trading day is processed as follows.

1. According to candlestick analysis, every Open, High, Low and Close prices are selected using daily minute ticks.
2. All apexes are found by the sign of multiple of two neighboring slopes, where these slopes are determined from each two neighboring points in daily minute ticks.

The input nodes of neural network model will be selected after completing the above steps. Then, the model will be trained with part of collected data. At last, there will be a performance validation with the rest of collected data. The research architecture is showed as Figure 3.

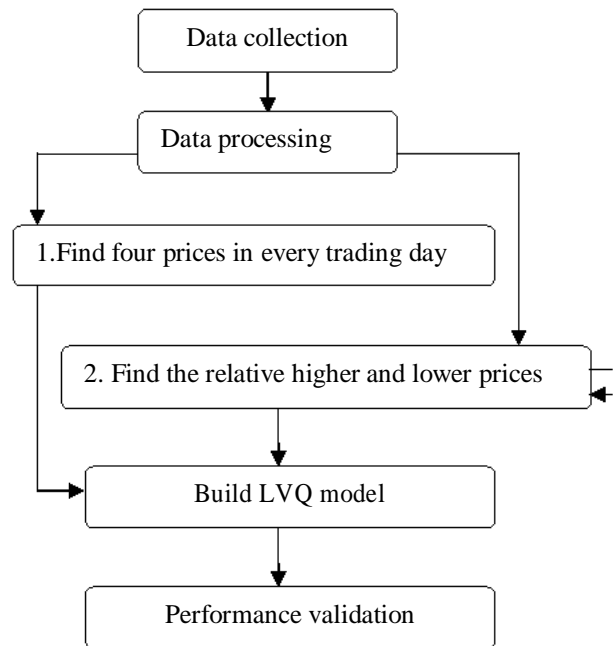

Figure 3. The research process of the study

3.2 The Neural Network Model

According to candlestick analysis mentioned in section 2.2, it is the belief that Open, High, Low and Close prices have a higher information content than other prices to extract featured prices of intraday trading. These four prices are used as input nodes in neural network model. The relative higher and lower points found after the opening of future market and stock market are also parts of the input nodes in neural network model. Hence, the Open, High, Low and Close prices in the prior period can be represented by these relative higher and lower points after future market and stock market opening. Based on fractal theory[3], pattern feature extraction is irrelevant to the length of period. Consequently, four prices in the previous trading day and four prices in the prior period after opening are considered as the factors to influence future prices. The input nodes and output nodes are listed as follows:

Table 1 Input nodes of neural Network model

1. True
2. False

Table2 Output nodes of neural Network model

1. The 1 st relative higher point after future opening
2. The 1 st relative lower point after future opening
3. The 2 nd relative higher point after future opening
4. The 2 nd relative lower point after future opening
5. The 1 st relative higher point after stock opening
6. The 1 st relative lower point after stock opening
7. The 2 nd relative higher point after stock opening
8. The 2 nd relative lower point after stock opening
9. Open price in the previous trading day
10. High price in the previous trading day
11. Low price in the previous trading day
12. Close price in the previous trading day

4. Experiment Result and Analysis

In this paper, the minute ticks of Taiwan Stock Index Future between 2001/04/13 and 2002/04/12 are used. Every minute price in one trading day is characterized as a record, totaling 204 records. 80% of records are taken as the training sample to build the neural network model. The remaining 20% records are tested for the accuracy of this model.

The first step is to process original data by computing the slope of every two neighboring points. The trend of stock market index could be determined by using the sign of slopes as formula (5).

$$m = \frac{p_2 - p_1}{t_2 - t_1} \quad (5)$$

m : slope
 t : time point
 p_t : future price at time t

By using the sign of the product of the two neighboring slopes, the apex is determined to be the relative higher point and lower point. The formula is listed as follows:

$$s = \text{sign}(m_t) * \text{sign}(m_{t+1}) \quad (6)$$

s : sign of product of two slopes

According to formula (5) and formula (6), relative higher and lower points can be found as Figure 4.

Figure 4. The relative higher and lower points

The slope of AB (m_t) is negative, and the slope of BC (m_{t+1}) is positive. So the product of m_t and m_{t+1} is negative. Because of a negative sign, point B is a relative higher and lower point.

This research takes relative higher and lower points and the four prices as the input nodes in this neural network model. The nodes are listed as Table 1 and Table 2. Nodes will be placed into True group if it is higher than or equal to the *higher price*, which is 0.5% higher than Open price calculated in formula (7), and the total number of True item will increase accordingly; otherwise, it will be placed into False group.

The formula to *higher price* is listed as follows:

$$h = O + 0.5\% * O \quad (7)$$

h : higher price

O : Open price

$$\begin{aligned} \text{If } H > h & \text{ then } T \\ \text{If } H < h & \text{ then } F \end{aligned} \quad (8)$$

H : High price

The ratio of success is the percentage of correct identification. The formula is listed as follows:

$$S = \frac{T}{T + F} \quad (9)$$

S : ratio of success
 T : the number of correct classification
 F : the number of incorrect classification

After data processing, Learning Vector Quantization is used to build a Neural Network model. The sequence of the input samples is randomly selected. This research also uses random weights and SOM (Self-Organizing Maps, SOM) to get the initial weights. After several runs, the representative results are listed in Table 3.

Table 3 Statistics of the experiment (iteration is 100)

experiment run	initial weights	learning rate	ratio of success
1	(W_1, W_2)	0.2	80%
2	(W_1, W_2)	0.2	35%
3	(W_1, W_2)	0.1	65%
4	(W_1, W_2)	0.1	37.5%
5	(W_1, W_2)	0.2	35%
6	(W_1, W_2)	0.2	30%
7	(W_1, W_2)	0.1	17.5%
8	(W_1, W_2)	0.1	27.5%

(W_1, W_2) are different initial weights in different runs of experiment.

$W_1 = \{w_{1i}, i = 1, 2, 3, \dots, 12\}$, $W_2 = \{w_{2i}, i = 1, 2, 3, \dots, 12\}$, (W_1, W_2) are showed as Figure 5:

Figure 5. The structure of neural network model

Table 3 shows that the first four runs used random initial weights, and the last four runs used SOM initial weights. When using random initial weights, success rate

can achieve 80% with learning rate of 0.2 and iteration number of 100. Hence, it is obvious that selecting random initial weights is better than selecting SOM weights.

This research is the application of classification in Neural Network. In this paper, there are two analytic methods, including BPN (Back-Propagation Network) and LVQ (Learning Vector Quantization). Figure 6 shows the result of BPN training process in this experiment, and also shows the unstableness of BPN. On the contrary, LVQ is more stable instead. Figure 7 describes the increase on success rate and stability of LVQ. Therefore, Learning Vector Quantization is chosen in this paper.

Figure 6. The result of BPN training process in this experiment, and also shows the unstableness of BPN

Figure 7. The increase on success rate and stability of LVQ

The relevance between the four prices in the previous trading day and the relative higher points and lower points in the prior period of current trading day is well analyzed using LVQ. The success rate of 80% represents the existence of behavior model, and disproved the unpredictableness of the stock market. In other words, this research emphasized analysis on behavior model. The phenomenon happened in the past can imply the occurrences of investment behavior in the future. This concept is a concept in behavioral science under conditional probability, not Random Walk Process stressed in financial engineering.

5. Conclusion

By using Learning Vector Quantization, this paper discussed about the gap of the market price between the two trading time. Furthermore, it showed that Open, High, Low, Close prices in the previous trading day and the relative higher and lower points are related to Taiwan Stock Index Future. The result can be applied to the strategy of arbitrage and speculation. As arbitrage between TAIMEX and SIMEX, arbitrageurs should have a short position on TAIMEX and have a long position on SIMEX or have a opposite position on SIMEX and TAIMEX. If the analysis on TAIMEX or SIMEX is correct, it is possible for investors to lower the trading cost of one. For example, Open price of TAIMEX is high, but the analysis shows that there will be a higher price in the trading hours. Arbitrageurs can offset the short position of TAIMEX, and repurchase the position back before closing. For arbitrageurs, this trading strategy can increase total profit by lowering the cost at the loss position. It can avoid the fluctuation of prices between the two trading times and make fixed profit.

Further research can focus on the application of Fuzzy system to judge amplitude of prices volatility and the application of trading volume to reflect momentum of buying and selling with the purpose to approve the accuracy of neural network model. In other words, it is intended to minimize the probability of loss and to increase profit.

Abstract

Web-based sharing of information across the supply chain can bring a host of advantages to the trading partners. lower cost, leaner inventories, and more efficient shipping are just the beginning. e-SCM is technology-enabled ability to concurrently manage high levels of complexity and multiple external relationships.

This study presents that the development of indexes for the performance evaluation of e-SCM should be given more priority by companies giving weights to each index. Deductive research is used for the development of evaluation items and AHP method for the development of weights of the items.

According to priority of each category - relationship between supplier and company, relationship between partner and company and relationship between customer and company- is as follows;

z Company driven type: relationship between customer and company, relationship between supplier and company, relationship between partner and company.

z Market portal type: relationship between supplier and company, relationship between customer and company, relationship between partner and company.

keywords : e-SCM, Relationship, Measure of Performance, AHP method

1. Introduction

Recent business environments of global firms are summarized by the globalization of competition, the advent of economic blocks represented in the European economic cooperation, the North American Free Trade Agreement, and the Pacific economic cooperation, and changes of competition advantage elements by developing of Information technology. International leading firms are taking a supply chain management (SCM) strategy in order to respond to these environment changes [6]. Furthermore, the development of digital technologies causes for leading firms to establish the Internet-based supply chain management (e-SCM) by changing business concept [3]. Therefore, the framework to evaluate whether the supply chains are operated well or not is requested.

As for the performance evaluation of an e-SCM, it is related deeply to business goal on all process of the chain --- growth, profitability, market share, and customer satisfaction [9]. Therefore, to evaluate the performance of a supply chain and to correspond to it could be a basis to secure competitive advantage of firms.

e-SCM is defined that to manage the flow of information, resources, and money on the supply chain, and to control all network between participants to achieve common goals using the Internet. This e-SCM is categorized into a company driven type and a market portal type. They have various differences. For the company driven type, the management flexibility is high and control on suppliers is

easy because the change of items is possible any time according to firms' own needs. Whereas, market portal type provides supplementary services such as purchasing guidance, payment guarantee, a risk management, a product delivery, payment, and storage. Besides, this type can provide more expanded services than the company driven type. However, it has a limit to provide the most suitable products that buyers want [5]. Therefore, this study finds weights of the performance evaluation items of the company driven type and the market portal type. And it suggests a guidance which items are more important, when the performance of firms is evaluated in both of the firms adopting company driven type and market portal type. Thus, the study provides the framework that can compare the performance before introduction of e-SCM with that after introduction of e-SCM

The research questions of this study are as follows:

- What is e-SCM and what kind of types are composed?
- What kinds of items are necessary to evaluate the performance of e-SCM? And what are weights of the performance of items in both of company driven type and market portal type?

2. Research Model

The purpose of this study is to evaluate the performance of e-SCM, and to draw evaluation items and its weights depending on its types. The research model is shown in Figure 1.

<Figure 1> Research Model

The study tries to evaluate the process performance among the objects on the e-SCM based on the Internet as shown in Figure 2.

<Figure 2> Scope of Evaluation Items drawn for Performance

Performance will be evaluated by three categories. These categories are composed of (1) Performance on transaction process between suppliers and firms, (2) Performance between partners and firms excluding suppliers, (3) Performance on transaction process between customers and firms. From all of these categories, performance evaluation items will be extracted.

Although the operating method is different between Company Driven Type and Market Portal Type, the core concept -- process among suppliers, firms, partners, customers -- is the same, so the management items are regarded as the same. But, the quantity and quality of objects on the process is different, so these two types of performance evaluation items cannot have the same level of importance. So this study will pay different importance level by weighing differently according to types and items. The purpose of this process is to apply different evaluation weight according to respective types.

3. Research Methodology

This study uses the Analytic Hierarchy Process (AHP) as a research methodology. The analytic hierarchy was composed of the evaluation items that were extracted by previous studies and interviews with experts based on the framework for the development of evaluation items.

The AHP, which enables the user to determine the relative importance of criteria sets underlying their choice behaviors [1], is selected as the appropriate analysis tool. The AHP of Saaty [10]-is theory and reality-an often used to solve strategic decision problems [2] [4] [7] [10] [11]

According to Saaty's original proposal, a complex system is decomposed into subsystems and represented in the hierarchical form. The element at the highest level is called the goal. The elements at each level are the criteria (factors) of elements at the level below. The elements at the bottom level are called the

alternatives. In this way, AHP organizes the basic rationality of the priority setting process by breaking down a multi-element complex system into its smaller constituent parts called components (or levels). The process can be divided into three phases, which are structuring a system, comparing pair-wise and synthesizing priorities.

The principle of comparative judgment is setting up a matrix to carry out the pair-wise comparisons of the relative importance of the elements in a component with respect to the criteria, elements in a dominating component at a higher level in the hierarchy.

Let the relative importance of each evaluation items ($a_1, a_2, a_3, \dots, a_n$) is $w_1, w_2, w_3, \dots, w_n$, and the pair-wise comparison of a_{ij} or a_{ji} can be replaced like equation (1).

$$a_{ij} = w_i/w_j \quad a_{ji} = w_j/w_i \quad (1)$$

The entry a_{ij} measures the relative importance of the impact on the criterion from element i against that from element j . This matrix, denoted by A ($=[a_{ij}]$) in our notation, is called the pair-wise comparison matrix[See below equation (2)].

$$A = \begin{pmatrix} w_1/w_1 & w_1/w_2 & \dots & w_1/w_n \\ w_2/w_1 & w_2/w_2 & \dots & w_2/w_n \\ \dots & \dots & \dots & \dots \\ w_n/w_1 & w_n/w_2 & \dots & w_n/w_n \end{pmatrix} \quad (2)$$

It is straightforward to show that when A is consistent, the weight vector W , which gives the relative priorities of the elements, is identical to any one of the columns of A within a normalization factor. And when multiply

importance vector $W(w_1, w_2, w_3, \dots, w_n)$ by matrix A [equation (2)], equation (3) is extracted.

$$AW = nW \quad (3)$$

Since the relative importance of the elements depends only on the relative amplitudes of the components of the vector W , we may normalize W by requiring as shown on equation (4)

$$\sum W_i = 1 \quad (4)$$

In fact, the fuzzy nature of the comparison process dictates that inconsistency cannot be completely eliminated. It has been argued that even when A is not consistent, the weight vector W is still determined by the dominant eigenvector of A . The equality is reached only when the matrix is consistent. To measure the consistency of the matrix A , we define the Consistency Index (C.I.) as follows:

$$C.I. = (\lambda_{\max} - n) / (n-1) \quad (5)$$

When the consistency is perfect, $C.I.=0$, which means $\lambda_{\max}=n$. And when the consistency is low, $\lambda_{\max} > n$, so consistency index becomes high. In practice, we consider A is very consistent if the consistency index ratio is less than 0.1, which is the average consistency index of a random reciprocal matrix of the same dimension. And the consistency of A is acceptable if the ratio of C.I. is about 10% or less, we accept the estimate of W . Otherwise, we attempt to improve consistency [7] [10].

4. Conclusions

4.1 Results

This study divided the forms of e-SCM implemented in the Internet environment into

two types, such as the company driven type and the market portal type, and suggested evaluation items and their weights of each e-SCM type through previous studies and AHP technique.

The performance evaluation items of e-SCM were composed of the relationship between suppliers and firms, the relationship between partners and firms, the relationship between customers and firms. The detailed evaluation items of each were drawn. The analytic hierarchy was presented in Figure 3(see Appendices).

Program 'Expert Choice 9.5' was used for analysis. Results of the performance evaluation items satisfied non-consistency level 0.1 as Satty recommended. Firm driven type is 0.05, and Market portal type is 0.08, so Satty's standard was satisfied. To assign the importance of each evaluation item extracted by prior studies and interviews with experts, the related data were collected from the experts who had participated in the interview.

For the company driven type, the order of importance was calculated that the relationship between customers and firms is the first, the relationship between suppliers and firms, the second, and the relationship between partners and firms, the last. Among the sub-items of the relationship between customers and firms, the weight of customer service is the highest (Table 1 & Table 2 : See Appendices).

On the other hand, for the market portal type, the order of importance was calculated that the relationship between suppliers and firms is the first, the relationship between customers and firms, the second, and the relationship between partners and firms, the last. Among the sub-

items of the relationship between suppliers and firms, the weight of purchasing and procurement is the highest. In the company driven type, the importance of customers was highlighted because it is comparatively easy to manage relationship with suppliers by managing limited suppliers (Table 1 & Table 2 : See Appendices). For the market portal type, the relationship with supplier was emphasized since managing suppliers is relatively hard and on-line purchase was important.

4.2 Implications

It is natural to implement SCM on the Internet and make a performance using this tool. Many firms are using e-SCM in the developed countries, and Korea also recognizes the necessity of it and is using or implementing e-SCM. This study developed the evaluation items of the performance of e-SCM and established the evaluation framework to draw the weights of the items and performance evaluation method (Table 3 : See Appendices). Therefore, this effort contributes to evaluate each firm performance by providing evaluation criteria. Furthermore, this study provides a foundation of the study about e-SCM performance evaluation.

However, this study didn't provide the evaluation items subdivided according to industry and didn't verify the drawn evaluation items. The evaluation items of the performance presented in this study can be adopted as a general criterion. But the weight of each item could be different, and some items could be added or deleted according to firms. Therefore, it should be considered for the future study.

Abstract

This work proposes an intelligent information management environment for mobile commerce. The environment contains four modules, namely, interface manager, information repository, information analyzer, and information collector. The interface manager provides an intelligent interface for generating and collecting business information from the mobile device. The information repository contains the user-specific information and the meta-information of information sources. The information analyzer performs the tasks of user behavior analysis, quality of information service measurement, information repository management, cost evaluation, anytime information supporting, and information filtering. Finally, the information collector dispatches different information agents for collecting business information from different information sources.

1. Introduction

Mobile commerce (MC) provides the user best mediation to complete business activity and to receive valued-aided services through the wireless communication network [1][6][11]. The user can use mobile devices, such as, mobile phone, pocket personal computer, or personal digit assistant for obtaining services or merchandises. The service provider of MC tries to provide numerous functions to satisfy different requirements. However, they have not met the service requests since they still have some problems need to be solved. First, the portable and small display screen of the mobile device is not easily to display the transaction information clearly. It is not suitable for the small screen by using the dense hyperlinks in transaction process. Moreover, the limited processing capability of the mobile devices also obstructs the business information display. Second, the service providers of MC did not provide sufficient supporting information for the user to complete the business process. For example, they did not consider the communication cost and service charge of the user transaction [3]. Third, the service provider of MC did not use the user profiles for helping the business process. For example, they did not consider the geographical location and business behavior of the users [11]. Fourth, the service providers of MC did not personalize the transaction information based on the user interest. The large number of business information may increase the overloading of the user as well as the

processing capability of the mobile devices. Finally, the specific specifications of the mobile devices, the different system interface of the operation environment, and the different transmission protocol of the communication networks may also limit the information usability of the user.

This work proposes an intelligent information management environment for mobile commerce. The environment contains four modules, namely, interface manager, information repository, information analyzer, and information collector. The interface manager provides an intelligent interface for generating and collecting business information from the mobile device. It uses the mobile commerce markup language (MCML) for displaying the business information. The MCML provides the meta description script to support the information manager to optimize the appearance of the business information in different mobile devices and operation platforms. Moreover, the interface manager collects the transaction behavior logs of the users in the business process. The information repository contains two models, that is, the user model and information source model. The user model manages the user-specific information, such as, user behavior, user interest, and transaction history. The information source model records the response time, information quality, and up-to-date data of the information source. The information analyzer is the main component of the system to analyze the user behavior from the transaction behavior logs, measure the quality of information service, manage the information repository, evaluate the communication cost, support anytime information, and filters information based on the irrelevant and valueless information based on the interest and geographical location of the user. Finally, the information collector dispatches different information agents for collecting business information from different information sources.

2. System Architecture

The environment contains four modules, namely, interface manager, information repository, information analyzer, and information collector (Fig. 1). The interface manager provides an intelligent interface for generating and collecting business information from the mobile device. It uses the MCML for displaying the business information. The MCML provides the meta description script to support the information manager to

optimize the appearance of the business information in different mobile devices and operation platforms. Moreover, the interface manager collects the transaction behavior logs of the users in the business process.

The information repository contains two models, that is, the user model and information source model. The user model manages the user-specific information, such as, user behavior, user interest, and transaction history. The information source model records the response time, information quality, and up-to-date data of the information source.

The information analyzer is the main component of the system to analyze the user behavior from the transaction behavior logs, measure the quality of information service, manage the information repository, evaluate the communication cost, support anytime information, and filter information based on the irrelevant and valueless information based on the interest and geographical location of the user.

Finally, the information collector dispatches different information agents for collecting business information from different information sources.

Fig. 1 System architecture

3. Interface Manager

The interface manager provides an intelligent interface for generating and collecting business information from the mobile device. Specifically, the interface manager uses a MCML for displaying the business information. The MCML is an information description language, which extends the Compact HTML (CHTML) [12] for mobile commerce. The MCML provides the meta description script to support the information manager to optimize the appearance of the business information in different mobile devices and operation platforms. Moreover, the MCML integrates the extensible markup language (XML) [13] and cascading style sheets (CSS) mobile profile [14] into the CHTML for enhancing the information display capability in small information appliance.

Furthermore, the interface manager collects the user transaction behaviors into transaction behavior logs. It collects the interaction message from the client and server-side. Each interaction message contains information regarding the interaction events and the message of interaction protocol. The interface manager uses the MCML and server logs to capture the user behaviors. The information analyzer then extracts the user information from the transaction information.

4. Information Repository

The information repository contains two models, that is, the user model and information source model. The user model manages the user-specific information, such as, user behavior, user interest, and transaction history. The user behavior records the transaction steps of the user for completing the business process. It uses the behavior network to represent the behaviors correlation of the user. Fig. 2 illustrates the topology of the behavior network. The square box is used to represent the business task, such as, browsing, searching, buying, and payment. The circular node is used to represent the name and frequency of the behavior with the interaction item. Moreover, the decorated link is used to represent the successive relations between behaviors and their frequency. The behavior network was updated after the user completed the business process. Notably, the behaviors use fuzzy relationship to represent the degree of relations. Fig. 3 and Table 1 exemplify the relations between transaction behaviors. The user interest records the favorite products and brand taste of the user. The transaction history records the user transaction information in mobile commerce. It uses cases to store the transaction history. Each case contains instances of the transaction time, geographical location, and product category.

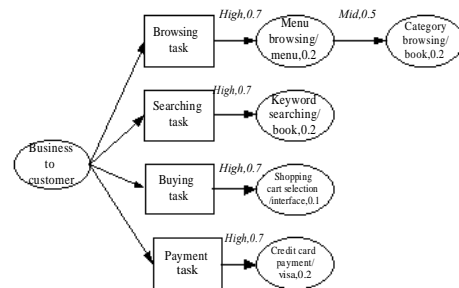

Fig. 2 Behavior network

Fig. 3 Fuzzy partition of behavior relationship

Table 1 Example behavior relationships

Relationship	Menu browsing	Product browsing	Product selection	Shopping cart selection
Menu browsing		High, 0.7	Mid, 0.5	Very low, 0.1
Product browsing			High, 0.7	Low, 0.3
Product selection				High, 0.7

The information source model contains the service characteristics and quality of service information of the information source. The information source model records the response time, information quality, and up-to-date data of the information source. This information can support the information analyzer for providing the anytime service.

5. Information Analyzer

The information analyzer performs six tasks, including user behavior analysis, quality of information service measurement, information repository management, cost evaluation, anytime information supporting, and information filtering. The user behavior analysis uses the induction-based technique for mining the behavior relationships. It uses support vector machine [4] and k-means [2] to classify the user transaction behavior logs into different classes. It then uses the induction method [10] to find the behavior relationship of each class. The information analyzer uses the fuzzy behavior proximity (FBP) to update the behavior network of the user model.

$$FBP_{ij}(k+1) = FBP_{ij}(k) + a(|A_{ij}(k+1)| - |A_{ij}(k)|) \quad (1)$$

where i and j is the i th and j th behavior and i is the precedence of j , k is the k th business task, a is the learning rate, and $|A_{ij}(k)|$ is the frequency of the behavior j follow the behavior i . Moreover, the user behavior analysis also analyzes the interests and brand taste of the user based on the transaction information [9]. The interests record the domain habits, that is, the visited or used terminology, of the user. The term frequency, T , is used to calculate the frequency of the terminology.

$$T = T_i / n \quad (2)$$

where T_i represents the occurrence of the terminology i and n is the terminology number. Additionally, brand taste records the brands that are frequently occurrence in the transaction behavior. The brand test, B , is used to compute the frequency of the operations.

$$B = B_i / n \quad (3)$$

where B_i represents the occurrence of the brand i and n is the brand number of the transaction behavior.

The quality of information service (QoIS) measurement computes the quality of service in the network and information services. The network service measures the response time, connectivity, and reliability of the information source. The information service evaluates the availability, timeless, accuracy, and consistency of the business data.

The information repository management records the user behavior relationship, user interest and taste, and quality of service information into the user model and information source model in the information repository correspondingly. The information repository management records the up-to-date information of each information source for providing the anytime service. Moreover, the information analyzer also update the information repository based on the analyzed user

behaviors. The information analyzer then manages the transaction history of the users by case-based reasoning [8]. Fig. 4 illustrates the architecture of the case-based reasoning. The architecture contains three main modules, namely, the case library, case selector, and case evaluator. Basically, the case library contains instances of the transaction time, geographical location, and product category. The case library organizes the cases in the flat structure. Each case represents the data in the feature-value pair. The case selector selects the similar cases from the case library according to the transaction information. Moreover, the case evaluator compares the difference between the similar cases and transaction information. The case evaluator also abstracts the similar cases into prototype. Finally, the case evaluator then updates the case library by replace the similar cases into the prototype case.

Fig. 4 Case-based reasoning

The cost evaluation predicts the transaction cost for the user by measuring the communication cost and service charge in the mobile commerce. It uses the information source model to predict the completion time of the business transaction from the service provider. It then computes the communication cost and service charge based on the QoIS measurement. This information may advise the user by considering cost and benefit before the transaction. The anytime information supporting also uses the QoIS measurement for providing the anytime information service for the user. The information source model may provide the anytime information when the QoIS was not good enough or the transaction data was time-invariant. The information filtering provides the personalized and location-based transaction information for the user. The information filtering filters out irrelevant and valueless information based on the interest and geographical location of the user. The information filtering then rearranges the information based on the user preference. These decorated transaction information were sent to the interface manager for displaying.

6. Information Analyzer

The information collector dispatches different information agents for collecting business information from different information sources, heterogeneous databank, or Internet-based information sources. The information agents were generated from the agent pattern

library that contains different agent components to do different tasks. The information collector instantiates and composites these patterns to construct different information agents. It retrieves, filters, synthesizes, and sends the most reliable data that the agent collected so far to the data analyzer. Fig. 5 shows the pattern of Connect_data_server in the pattern library.

```

Pattern name: Connect_data_server
Pattern task: Data server connection
Receiving: Data server location, database type
Production: Connection status
Context: N/A
Executor:
import java.rmi.*;
import java.sql.util.Vector;
public interface Connect_data_server extends Remote
{ void accept(Agent agent) throws RemoteException;
  Vector Connect() throws RemoteException,
    SQLException;
}
public interface Agent extends java.io.Serializable
{ void run();
}

```

Fig. 5 The Connect_data_server pattern

The information collector also dispatches the information agents to get the service information from the service brokers in web service environment [5][7]. The information agent collects the functionality and value-added service information of the information sources from the brokerages. Finally, the information collector collects and synthesizes the business information to the information analyzer.

7. Conclusions

This work proposes an intelligent information management environment for mobile commerce. The environment contains four modules, namely, interface manager, information repository, information analyzer, and information collector. The interface manager provides an intelligent interface for generating and collecting business information from the mobile device. It uses the MCML for displaying the business information. The MCML provides the meta description script to support the information manager to optimize the appearance of the business information in different mobile devices and operation platforms. Moreover, the interface manager collects the transaction behavior logs of the users in the business process. The information repository contains two models, that is, the user model and information source model. The user model manages the user-specific information, such as, user behavior, user interest, and transaction history. The information source model records the response time, information quality, and up-to-date data of the information source. The information analyzer is the main component of the system to analyze the user behavior from the transaction behavior

logs, measure the quality of information service, manage the information repository, evaluate the communication cost, support anytime information, and filters information based on the irrelevant and valueless information based on the interest and geographical location of the user.. Finally, the information collector dispatches different information agents for collecting business information from different information sources.

In summary, the proposed intelligent information management environment exhibits the following interesting features. First, the proposed system has an intelligent interface that supports different mobile devices to display the business information. Moreover, the MCML provides the XML-based meta description script with device-independent information for different mobile devices. Second, the information analyzer uses the user model to personalize the transaction information and to analyze the user behavior. Notably, the task of user behavior analysis and user model management was supported by the support vector machine and k-means. Third, the information analyzer uses the information source model for providing the cost evaluation and anytime supporting. The network and information service evaluation was supported by invoking the information quality measurement. The information analyzer manages the information source model by computing the QoS and recording the up-to-date data of the information source. Finally, the information agent was dispatched to collect the transaction data within business process. These agents were cooperated with each other to collect data from diverse databank and Internet-based information sources by using the agent communication languages (ACL). Moreover, the information agent can also be dispatched to collect information from the web-service-based environment.

Track Area: Electronic Commerce Management

The development of Internet has brought enormous business opportunities and given new connotation to traditional commercial activities. E-commerce emerged as the times require. The business-to-consumer (B2C) is the most visible business of e-commerce. The so-called B2C is a commercial mode that starts from companies and ends at consumers. We often call B2C online shopping. With the inflation of Internet population, online shopping has been favored by more and more consumers. The benefits of online shopping are well known. The most common incentives for consumers to shop online are convenience, competitive pricing, greater access to information, complementarity of traditional stores and broader selections. Online shopping has broken through the restriction of space-time, changed the form and the way of transaction, and changed consumer concept and behavior.

As an online consumer, he/she has a dual identity, on one hand he/she is a shopper, he/she is a user of computer and Internet on the other hand. So the factors influencing online consumer should include information system, marketing and psychology. Since more and more companies swarm forward, the competition is becoming fiercer. To carry on the effective competition with “brick-and-mortar” stores and other online stores, there is urgent need for online stores to understand the factors that influence online consumer behavior, which motivates this

study.

There are some classic models or theories introduced to the research of online consumer behavior [3, 7, 9, 10]. Those theories include Technology Acceptance Model (TAM) [5], the Theory of Planned Behavior (TPB) [1] and flow theory [4].

TAM is the most widely used theoretical model for explaining end-user behavior of a system. In this model, perceived usefulness (PU) and perceived ease of use (PEOU) are the primary determinants of system usage. TAM has been successfully applied in the acceptance of Internet related technologies, such as e-mail, WWW and e-commerce. Using it as the basis for studying consumer acceptance of online stores is proven a highly reliable and valid approach.

Another model is developed based on flow theory [4]. Not of its original meaning, flow is used to describe a state of mind sometimes experienced by people who are deeply involved in some activity [8]. Flow has also been studied in the context of computer-mediated environments. Due to its valid results, flow has been recommended as a valuable metric of the online consumer experience. Many studies found that shopping enjoyment is an important predictor of online shopping.

Koufaris [7] has applied TAM and flow theory to online consumer behavior. He came to a conclusion that shopping enjoyment (considered in flow theory) and perceived

usefulness are important factors influencing consumers' intention to return. But the study had some limitations, i.e., subjects and missing of an important variable (e.g. planned purchases).

Chen [3] also had some findings of online consumer behavior with an extended technology acceptance perspective, by using TAM as the basic model. He indicated that compatibility, PU, and PEOU are the primary determinants of consumer attitude towards using virtual stores.

In social psychology, TPB is a well-established general theory. TPB shows the relationships between specific salient beliefs, given behavioral perceptions and subsequent actual behavior. Three types of beliefs will impact three constructs: behavioral beliefs that influence attitudes, normative beliefs that affect subjective norm, and control beliefs that shape perceived behavioral control.

Palvou [9] has studied the drive of e-commerce by using TPB. One of his important contributions was considering perceived behavioral control, trust, and perceived risk as determinants of B2C e-commerce adoption, drawing from TPB.

As to perceived risk, it's increased by two types of uncertainty in e-commerce. One is behavioral uncertainty, which arises because web retailers may behave in an opportunistic manner. Another is environmental uncertainty that occurs because of the unpredictable nature of the Internet technology that is

beyond the control of the consumer. Given the uncertain environment of EC, it is expected that perceived risk would lower consumers' intentions to shop online.

Palvou [10] pointed out perceived risk is a direct negative antecedent of intention to transact online and privacy and security perceptions indirectly reduce perceived risk and influence intentions to transact online. That perceived usefulness and perceived ease of use influence online usage intentions was validated again.

In our study, we attempt to provide both theoretical and empirical analyses to explain consumers' behavior in online shopping by applying TAM, TPB, flow theory and other relevant theory in an integrated theoretical framework. Based on these well-established theories, we retain PU and PEOU of TAM, shopping enjoyment, subjective norms of TPB, and perceived risk in the proposed model. And we add some factors that we consider important to develop a more comprehensive model. We think price advantage, perceived convenience and product involvement are important antecedents of PU and shopping enjoyment. Privacy perceptions and security perceptions of the consumer and after-sales service of the online stores will influence perceived risk of online shopping importantly. So we keep them as the antecedents of perceived risk. Figure 1 shows the proposed model, which incorporates the factors we mentioned above. The relationships in figure 1 can be stated in 15 hypotheses.

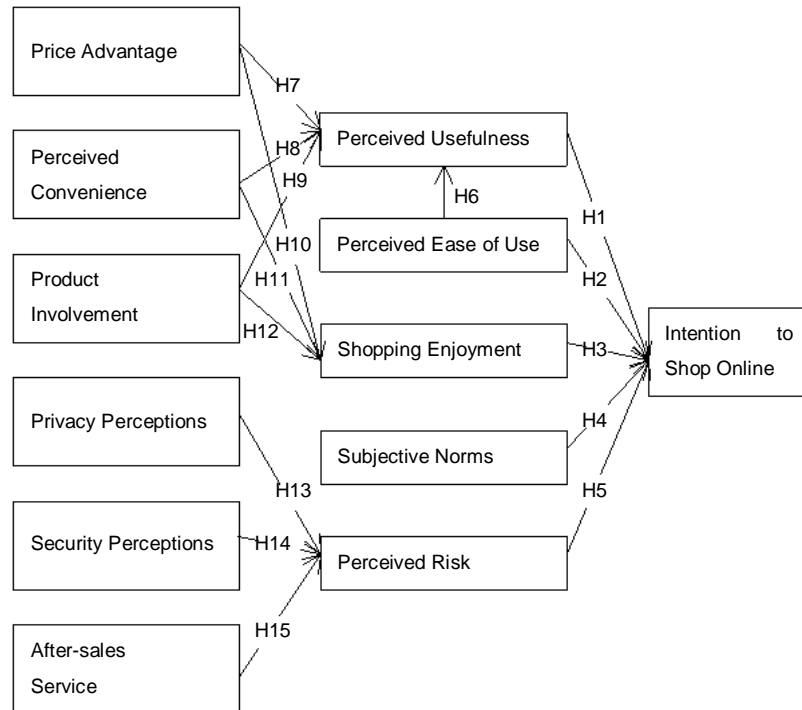

Figure 1 The Proposed Model

A questionnaire-based empirical study is used to test the proposed model. The questionnaire was completed by 183 subjects, including 125 university students and 58 office staffs. Their average age is 23.2 and 57.9% of them are males.

As shown in figure 1, there are 12 constructs in this model. To validate their internal consistency, we develop several items for each construct, which use 7-point scale. All constructs have acceptable internal consistency (Cronbach's alpha values, from 0.7579 to 0.9725).

The results of the regression analysis show that the model has an excellent fit and explains a large percentage of variance. To sum up, Hypothesis H1, H5, H6, H7, H8, H9, H12, H14 and H15 are supported by the survey.

From the results, some findings are drawn, which include:

1. The classic theories on IT and psychology are still valid in explaining online consumer behavior in the B2C e-commerce context.

2. Different from Koufaris's conclusion [7], shopping enjoyment cannot play an important role in our study.

3. Perceived usefulness and perceived risk are the primary determinants of intention to shop online. The former has positive impact and the latter negative.

4. The factors that influence perceived usefulness include perceived ease of use, price advantage, perceived convenience and product involvement.

5. Perceived risk is determined by security perceptions and after-sales service.

For managers of an online store, in order to entice consumers, it is useful to increase consumers' perceived usefulness of the store and reduce their perceived risk. To increase consumers' perceived usefulness, the store can put effort to the antecedents of it, such as offer more competitive price, make access and payment more convenient, and diversify products. To reduce perceived risk, the store can raise the level of security and after-sales service.

Abstract

Electronic Commerce (E-Commerce) is considered a new channel of distribution that consumers can reach websites at anytime and from anywhere. In reality, however, consumers are not yet confident in on-line transactions. Several Thai website owners who operate business to consumer (B2C) e-commerce stated nine major success factors: government support, security and privacy, customer service, administrative support, online promotion, product uniqueness, logistics, product variety, and image creation. It is necessary that website merchants study various success factors, having impact on achieving business value of e-commerce investment and building customer trust which would then bring long-term profits to the organization.

Keywords: Electronic commerce, Business-to-consumer websites, Thailand

1. Introduction

The Internet, particularly the World Wide Web (WWW), has taken a greater role on business activities in the age of digital economy. This gave birth to an innovation called, "Electronic Commerce (E-Commerce)", a new way of doing business that helps the companies or individuals achieve their competitiveness. Businesses who invest in developing their own websites are able to expand their domestic and international markets while consumers can visit their shops with no time and space limitations.

Yet, e-commerce also poses a threat to businesses. That is, an increasing number of firms, who develop websites, have entered an "electronic market", a market with low barriers to entry. Furthermore, one of the important obstacles for the growth of e-commerce is the fact that most websites owners still lack true knowledge of conducting electronic business. They fail to consider key factors for the e-commerce and to convince stakeholders of significance of effective on-line transactions which could help the business to survive and bring customer trust and satisfaction.

At the same time, some customers hesitate to buy goods or services via the Internet because of security concerns. It is believed that on-line businesses will not be able to realize their success unless their customers have more confidence in the e-commerce. Moreover, Electronic commerce needs many management challenges to the firms to implement it successfully. Prior research on electronic commerce has mainly focused on the perspectives of consumers, frequently addressing issues such as benefits and barriers. Relatively little research has studied the electronic commerce management success factors by assessing from online website owners. Online website owners can have wider perspectives to determine the major issues affecting business success. The major objective of the study was to provide an online organization or other related organizations to concern about these issues and improve their business management via the Internet channel more efficiently. This article aims to present findings from the study of major factors for successful business to consumer (B2C) e-commerce from website merchants' perspectives. In other words, this article seeks to answer the following research question:

- What factors do online-companies anticipate from their implementation of business-to-consumers electronic commerce successfully?

2. Success factors for E-commerce

Electronic Commerce is frequently seen as an alternative channel of doing business enabling the owners or firms to be more competitive than traditional ones with retail stores. It helps suppliers to expand their channels of distribution to use

the Internet network. Many corporations, known as "Dot Com Companies", even use this channel to set up their business with low costs of investment. Additionally, consumers can reach the information they need with no time and space barriers, less expenses but more options. They also enjoy surfing through a variety of websites to search for goods and services [9]. However, success is not automatic on the Internet, the section below briefly noted the most commonly cited success factors.

Information technology infrastructure

Prior studies indicate that information technology infrastructure is one of the most important factors for doing effective on-line business [1,19]. This consists of network, and speed of the network. More than that, the World Wide Web (WWW), which is a part of the Internet and a channel of operating e-commerce, provides enormous sources of information for the users. Quality of information on the websites is still questionable for some groups of people. Many Internet users also experience information overload [2,13]. Furthermore, web applications, relating to data processing for executives and service providing to customers, such as the ERP, the CRM and sales support system are also vital.

Security and privacy

The next factors affecting the e-commerce are security and privacy. These have hindered on-line businesses from their success since consumers still lack confidence on security and privacy policy of the firms [8,12,16]. They are concerned about their safety, the misuse of their private information as well as the authentication of parties involved in the business [6].

Product issues

There are various product issues involved on-line transactions, for example, variety, uniqueness, and quality of products and services [2, 10]. They are significant to the clients' buying decision.

Marketing management

E-commerce needs good marketing efforts such as sales promotion and advertisement to introduce their websites to consumers [7,15]. Additionally, after sales service is necessary to maintain customer satisfaction. When clients are satisfied with the quality of the services, they are more likely to be loyal to products or services of that particular website. Despite the fact that the sellers and buyers do not actually meet and there is no proof of authentication, effective after sales service helps businesses sustain customer trust and satisfaction. Besides, good targeting and expansion to new markets are indispensable for the growth of e-businesses [7].

Logistics

Doing business via the Internet frequently involves the transport of goods to customers at distant locations or in foreign countries. Consequently, the entrepreneurs will have to consider the importance of packaging and transporting their products. Research indicates that B2C e-commerce will be more successful if the company can deliver the products in perfect shape and in a timely manner [2,10].

Management

Other websites management includes human resource management and organizational restructuring. Website owners will not fully benefit from e-commerce unless they have an appropriate structure to deal with the changing way of doing business. It is also necessary that their employees learn management know-how and how to give the best service to their clients. E-commerce owners might want to have business alliance in order to reduce their management costs [5]. In addition to this, websites have to be developed and updated regularly. The owner of each website will have to register for the "domain name". To use the right domain name could be very beneficial to the business. The domain name should not only relate to the brand of the product but also be easy to remember. Good management for the domain name registration and use of a recognizable domain name will help the business improve their image and to spread their brand's name [3].

Government support policy

An external factor that can promote the long-term growth of e-commerce is the favorable policy of the government to support online business and consumers protection. Government supports are among the most crucial forces affecting adoption of electronic commerce by consumers [19]. The government can greatly contribute to e-commerce by the implementation of such facilitating measures and regulations as legal infrastructure, consumer protection, taxation and other laws concerning e-commerce [14,17,11].

3. Research methodology

Data for the study was collected by means of a questionnaire to capture perceptions about these success factors. The questionnaire content was divided into two sections. The first section is about the success factor items, measured by a Likert's scale ranging from 1 = strongly disagree to 5 = strongly agree. The initial list of items was discussed with a number of experts, including faculty member, electronic commerce specialists, and managers in the field of Internet commerce to verify that each item represented the concept it was supposed to measure well. Items with which the experts did not agree were changed or eliminated to clarify wording. Two additional items were added: "apply push technology or marketing", and "real-time communication between buyer and seller".

The sampling frame was constructed based on the e-commerce websites provided by Electronic Commerce Resource Center in Thailand [4]. The 180 Thai websites constitute most of the population who actually do transactions with payment on the Internet. The respondents are persons who are the managers of the websites or marketing persons etc. Data was gathered by personal interview.

4. Demographic profile

A total of 143 website merchants responded to the survey, yielding a response rate of 79 %. As Table I shows, the majority of the respondents conducted electronic commerce over the Internet less than one year (about 50%). These electronic commerce websites were fairly small in size. Out of 143 respondents, 59 percent have invested less than 100,000 Baht in electronic commerce. On average, they had annual sales via the Internet channel ranging from 50,000 Baht to more than 5 million Baht.

Table I: Business-to-consumer website merchants' demographic profile

Characteristics	N	Percent[*]
Duration of E-commerce business		
≤ 1 year	71	50.35
> 1-2 years	50	35.46
> 2-3 years	13	9.22
> 3-4 years	6	4.26
> 4-5 years	1	0.71
Investment (Baht)		
≤ 100,000	83	59.28
100,001-300,000	27	19.28
300,001-500,000	7	5.0
500,001-700,000	1	0.72
700,001-1,000,000	3	2.14
> 1,000,000	19	13.58
Annual Sales (Baht)		
≤ 50,000	47	35.61
50,001 – 100,000	20	15.15
100,001 – 300,000	24	18.18
300,001 – 500,000	10	7.58
500,001 – 1,000,000	7	5.30
1,000,001 – 2,000,000	8	6.06
2,000,001 – 5,000,000	5	3.79
> 5,000,000	11	8.33

5. Findings

Exploratory factor analysis was used to examine the dimensionality of electronic commerce success. A principle component factor analysis with Varimax rotation was undertaken, and a nine-factor solution was found, which explained about 60 per cent of variation in the items (Table II). The tests suggested that the subsequent overall nine factors solution adequately accounted for the underlying structure of the data (Barlett's Test of Sphericity p-value=0.000, KMO measure of sampling adequacy = .740). Dimensions with Eigenvalues of 1 or above were retained and nine factors emerged. Table II indicates some items with an asterisk. These items can be dropped because they did not load above 0.5 on any factor.

The result showed that there are nine success dimensions. Most of the factors are meaningful sets of items. The first factor, named government support, focused on government supports in electronic commerce and consumer protection law. The second factor, security and privacy, included network security, payment security, and privacy protection. The third factor called customer service included online after sales service, responsive communication, and clear targeted customers. The next factor, called administrative support, consisted of application support system for management, qualify personnel, and business process redesigned to conducted business via the Internet more efficiently. Another two factors are online promotion and uniqueness of product factors, which included only one item in each dimension. One factor, named secure logistic, focused on reliable product delivered, secure product packaging. Probably, the ninth factor, product variety, dealt with the variety of product and content of the website. The final factor, image creation, included domain name setting, quality of product and push strategy to management online business.

Table II: Factor analysis for Business-to-Consumer Success Dimensions

Items	Loading for Factors								
	F1	F2	F3	F4	F5	F6	F7	F8	F9
Factor 1: Government support									
E-commerce tax law support	.878								
E-commerce law support	.841								
Consumer law protection support	.747								
Factor 2: Security and Privacy									
Security protection		.748							
Secure payment system		.697							
Privacy protection		.502							
Internet speed of consumer computer system*		.431							
Speed of the website network system*		.430							
Factor 3: Customer service									
Online after sale service			.786						
Having clear target customers			.536						
Realtime communication between seller and buyers			.502						
Provide certification authority*			.444						
Factor 4: Administrative support									
Application support systems for management				.680					
Qualified personnel				.660					
Business process redesign				.629					
Business alliance*				.423					
Factor 5: Online promotion									
Online domain name advertising					.877				
Online sale promotion*					.421				
Online purchasing support system*					.414				
Factor 6: Uniqueness of product									
Differentiated product for online sale						.763			
Search for new markets and customers*						.428			
Factor 7: Secure logistics									
Reliable product delivery							.809		
Secure product packaging							.552		
Cheaper price*							.464		
Factor 8: Product variety									
Variety of product provided								.910	
Website content								.500	
Factor 9: Image creation									
Easy domain name setting									.604
Product quality									-.564
Apply push technology or push marketing									.536
Eigenvalues	2.810	2.322	2.211	2.148	1.946	1.864	1.785	1.530	1.422
% of Variance	9.366	7.742	7.37	7.16	6.485	6.213	5.951	5.101	4.741
Cumulative % of Variance	9.36	17.10	24.47	31.63	38.12	44.33	50.28	55.38	60.13
Bartlett's Test of Sphericity = 1165.709 df = 435 Sig. = .000									
Kaiser-Meyer-Olkin Measure of Sample Adequacy = 0.740									

Note: * Items omitted because loading did not exceed 0.5

6. Conclusion and Implications

It can be concluded that nine factors have an effect on the B2C e-commerce, and this corresponds to past studies and can be generalized. For instance, government support is the most important indicator. Legal infrastructure and consumer protection factors are also significant and are widely discussed domestically and internationally, such as in health care, food and pharmaceutical businesses.

Next, the security and privacy factor includes the safe process for payment and privacy policy. This still discourages consumer confidence about e-commerce. Further, to conduct the online business more successfully, other important factors are to adjust business process to perform more efficiently, to provide information system applications to support management, and to have adequate knowledgeable personnel.

More than that, Thai website owners feel that traditional marketing efforts can be applied to on-line businesses. Continued advertisement of domain name, promotion, after sales services are helpful to build customer satisfaction. E-commerce needs to clearly specify their target groups and keep expanding their markets. Variety of products, good packaging and safe transport of products must also be considered as this type of business involves both domestic and foreign markets.

Furthermore, in this information age where people can reach websites anytime from several parts of the world, content on the web has to be always updated as this will help consumers to better decide to buy goods and services via the Internet. Would-be on-line businesspersons, thus, need to take into consideration the accuracy, relevancy, completeness of their products or services information. Besides, their websites should be designed for the ease of use while web content development and maintenance is also important.

This study makes a contribution that website merchants are also concerned about the factors that affect customers such as security and privacy, service and support, secure product delivery. Thailand's electronic business via the Internet channel will not succeed with long-term profits unless consumers accept it. To sustain the success of Thailand's electronic commerce, it is necessary to build customer confidence in consumer protection. They will have to be protected by the laws when they experience unfairness from the businesses and involving parties such as logistics companies, banks. The future success strongly needs the support from government sector integrated with the reliable management of website merchants in order to make consumers trust of the online system.

Moreover, this study suggests that electronic commerce implementation should not mindless hurry to a new technology without some extent of seriously management planning. Current and prospective online businesses need to merge excellent information technology, marketing and management efforts, for their moves towards business competitiveness. Limitations for this research are the fact that there are only a small number of companies conducting e-commerce with on-line payment. When there are increased numbers of on-line businesses, it could be possible to focus the study on one particular industry-export, tourism, on-line department stores or financial services-as well as to extend the framework of analysis to the Business-to-Business (B2B) e-commerce. Future research might have to use other variables to find out the result of these success factors, for example sales growth, return on investment, consumer loyalty.

Abstract

Internet banking has become one of the new electronic service delivery channels that banks use in order to improve services they provide to their customers. Internet banking has allowed banks to offer information and services to customers at their convenience, and many Thai banks follow the worldwide trend to implement Internet banking. Information benefits are the major benefits for corporate customers, whereas transaction benefits seem to be less valuable because of concerns about security and reliability on the web. Banks do believe that Internet banking reduces operating costs and assists banks to interact with their customers more efficiently. Hence, when banks decide to use web technology to enhance customer interest and to develop customer relationships, they have to figure out how to create customer value and lower barriers of the web so that they can maintain long-term customer relationships and gain sustainable competitive advantage.

Keywords: Internet banking, web benefits, Thailand

1. Introduction

Today it is increasingly apparent that Internet innovation will become a critical service delivery channel in financial sectors. Internet banking, an example of technology and service innovation, is a web-based service innovation that allows bank customers to view their personal financial information and make online transactions via the World Wide Web. Banks are moving towards web-based service delivery – Internet banking – in order to provide better service to their customers [8,45,48]. From the banks' viewpoint, adoption of Internet banking will lead to cost reductions, improve customer service, and create long-term customer relationships.

Many banks have implemented Internet banking as a new electronic service channel, to offer their customers a variety of online services with more convenience for accessing information and making transactions [31,45]. Prior research indicates that web technology does provide information benefits to business [18,24,34,49]. Firms can provide information to communicate with their customers at several levels of information detail, and configure sites to allow them to drill down to the desired level. Information benefits can provide quality information, easier access to information, and information sharing [18,42]. Another benefit from web technology investment is a transaction benefit, which provides the firm ability to automate business functions via the web and provides service to customers with more responsiveness [18,35,39].

When banks decide to use Internet technology to enhance customer interests and to develop customer relationships, they have to follow up the results and evaluate whether this electronic channel actually creates business value and enhances long-term relationships with their customers, and finally provide competitive advantage to the banks [3,51]. Hence, the main purposes of this paper are to gather perceptions from Thai banks about using the web channel to offer services to their customers and how banks believe this channel provides benefits to their customers. In particular, this study is intended to illuminate how Thai banks achieve their goals to implement Internet banking service channels, which they expect to create competitive advantage, improving customer relationships and making long-term profit.

2. Literature review

In recent years, web technology has become an important tool for information search, and is considered to be a very useful information resource for customers and businesses [1]. Most companies use their web sites to publicize information about their companies. In addition, firms use web technology as a channel to provide information for commercial purposes. Firms can provide information about product specifications, price, and service delivery methods [18,42]. Further, firm websites can be used as the online promotional media for firm [31,40].

To obtain benefit from information provided via the web, firms must understand the nature of information, maintaining good quality to meet customer needs [6,11]. Prior research mentioned that one drawback of information provided via the web is the low quality of information; e.g., inaccuracy, irrelevance, out-of-date [11]. Information quality should focus on customer needs [4,10,32]. Once quality information is distributed to customers, they will perceive its quality, leading to trust in the information provided [16].

Quality information should be relevant, which means providing information related to customer needs and interests and which add value for customers [14]. Firms have to focus on relevant information which responds to customer needs and attract them to keep approaching the firm website as a quality information source [26]. The information benefit is more valuable to customers if websites owners provide accurate information [9,11,16]. Accuracy refers to “how well the information represents the phenomenon it purport to describe” [16, p. 216]. Finally, quality information has to be timely, which means that up-to-date or current of information must be provided [16, p. 216].

In addition, one of the major attractions in commercial use of the web is the ability to access information more responsively. If the firm website is easily accessible, customers can access information faster, encouraging them to continue connecting back to the firm website, so they can maintain access to firm information [9].

Moreover, information benefit should provide a selection of appropriate links or connections to other websites (site-to-site connectivity) that give more detailed information about related topics that are interesting for customers. The objective of the connectivity is to provide customers with all the information they want. Several recent studies on electronic commerce have noted that some features of websites related to these issues are critical to their business success. For instance, Lin and Arnett [37] suggested that a major factor for the success of a website is the design of information interfaces and navigation. Firms have to pay particular attention to creating flexible ways to disseminate information resources to their customers [34].

Online information sharing has been conceptualized in different ways. One of the popular issues mentioned by researchers is information sharing via a virtual community. Virtual communities can be used to attract customers and enhance their involvement with the firm [7,32,53]. Firms can now interact with customers on a global scale, in real-time, and using two-way interaction [24]. Information sharing among customers can help enhance customer service by increasing convenience, collecting service performance information for management decision support, and offering more customized products or extra services according to customer needs [22].

Business expands its traditional business processes by using the web as an electronic channel to link with its customers. Web technology adoption has influenced the transactional level in terms of convenience provided to customers. Well-implemented web technology consists of marketing tools designed to reach customers outside the firms and to support customers [36,51,52]. Prior research shows that businesses use the web to offer transactional benefits to customers through lower transaction costs, responsiveness of customer service, and service customization.

In doing business, both buyers and sellers try to minimize transaction costs. Customers perceive cost advantage if their service providers set price lower than others. Cost advantage leads to superior performance if service providers can provide an acceptable level of value with lower costs to their customers. One of the major contributions of the web is the reduction in transaction costs as buyers and sellers can contact each other directly. Service providers can gain operational benefits by reducing time, overhead costs in operation, and also eliminate service participants such as company service personnel [17].

In the financial services industry, the web is used as a means of payment or money transfer. This web-based payment process may be perceived as more convenient, and creates saving dimensions for customers. Prior empirical research about Internet banking reveals that time and cost are the key factors affecting Internet banking adoption of the bank. Many observers claim that Internet banking is a new channel that reduces time and cost to both customers and banks. In addition, Polatoglu and Ekin [45] found that cost and time saving dimensions are perceived as a larger benefit when customers use Internet banking services more often and for larger transactions.

To use web for commercial purposes also requires that the level of service provided to customers remain much the same as is provided from a sales force in traditional marketing [21,40]. The web is often used as a channel to communicate and provide support to customers in order to improve customer relations [15,31,40].

Firms have to communicate to their customers in order to provide them with more information on related products or services which they offer. Parasuraman et al. [43] found that information technology provides powerful tools to communicate with customers. In research on electronic services, Rust and Lemon [47] found that web technology provides situation-specific or personalized communication. For instance, customers can complain about a product or service in order to get their problem

solved or request for their specific needs and wants via multiple means (e.g. email, live chat, toll-free number or FAQ page), whereas the supplier or service provider can respond to customers more rapidly.

Customer service can improve by using web applications to identify and report problems more quickly, and allow more accurate diagnosis and faster responses to firm customers. Web applications such as customer relationship management (CRM) can gather data and analyze a customer database for specific customer needs and wants so that firms can have immediate feedback on services or products available as requested.

Kardaras and Papathanasslou [10] found that when banks provide service via the web for its corporate customers, customers demand many types of support from banks, such as after sales service support for customer training in using the Internet banking system.

Many companies have succeeded in using web-based business to implement innovative ideas by providing new services to their potential customers [34]. The new radical changes of services has led to superior offerings and provided significant economic benefits to their customers [55,40]. As mentioned before, the most commonly cited effective business use of the web is its value as an information source, offering accessibility, and sharing capabilities [18,31,32]. The power of the web in terms of information accessibility provides the firm an effective channel to respond to customer needs. This contribution allows service providers to gather customer information more quickly, conduct faster analysis, respond in shorter time, and customize services or products according to customer needs [18,31,34].

In addition, web technology empowers employee collaboration, information sharing, and knowledge integration which can create innovation faster. Rapid innovation offers even more opportunities to customize a specific service or product according to customer needs [23,25,28]. Service innovation is defined as “the process through which a firm undertakes changes in its philosophy, culture and operations and procedures to add value to the result of the service / product for the benefit of the customer” [29, p.54]. In the financial service sector, service innovation has become very important for service providers to keep ahead of the competition. Currently, corporate customer adoption of web-based service delivery showed that the web creates new opportunities for corporate customers and the bank to improve collaboration in product design and customization.

In recent years, an increasing number of businesses have recognized the benefits of establishing and maintaining relationships with their customers. Relationship building and management – relationship marketing – is frequently called a new marketing paradigm [19]. Relationship marketing has been conceptualized in different ways among academic researchers. For instance, Gronroos [19] defined relationship marketing as “marketing to establish, maintain, enhance and commercialize customer relationships so as the objectives of the parties are met. Gummeson [20] defined marketing relationship as relationships, network and interaction. He pointed out that the strength of the relationship can be enhanced through internal considerations or outside the organization. In other words, relationship marketing provides an approach that helps businesses to establish relationships with customers and other parties involved in the business process.

Berry and Parasuraman [2] proposed three levels of relationship in services marketing. At the initial level, service providers primarily use pricing incentives to encourage customers to use their services or products. For instance, a bank may offer lower loan interest rate to large corporation. Using price incentives essentially contributes little to building lasting relationships between customer and service provider.

Level two relationships go beyond pricing incentives. This level emphasizes personalized service delivery and the transformation of customers into clients that are served on an individual basis. Level two of the customer relationship is more according to customer needs and wants. It may include creation of long-term social relationships with customers, and it is more difficult for a new competitor to imitate than level one relationships. For instance, banking assigns account personnel to take care of specific customer accounts and visit the customer to build the business relationship and perhaps create social relationships with bank customers. Relationship building provides personalized service to customers, according to customer needs and wants [2,13].

Level three of customer relationships is to provide value-adding services to clients which may not be directly part of the specific service purchased in the transaction. Such services may not be available from elsewhere. Sometimes, the services are designed in the service system that helps clients to operate more efficiently, such as joint technical support assistance, or use of software provided by service provider which is not necessarily specific to the services bought from the service provider. Most higher relationships are about more value-adding services beyond the transaction involving what the customer buys from the bank. This level raises the clients’ costs to switch to other competitors and represents the greatest degree of competitive advantage and the most difficult for imitation. Such business value in relationships is difficult or expensive for customers to provide themselves and are not readily available elsewhere [2].

Corporate bank customers are mostly concerned about interaction, information exchange, and expect transaction-specific services from banks [50]. These two levels or natures of customer relationship are personalized service to clients, and business relationship value to clients. In other words, blending technology with customer needs is an important success factor in establishing and developing customer relationships [5,12,28,44,56].

In the financial services industry, Mulligan and Gordon [41] recently assert that web technology plays a major role in supporting relationships between customer and service provider by providing new standards of service delivery, allowing response more rapidly to customer needs and wants, and affording customers the opportunity to perform their business more efficiently. These things lead to improved customer relationships.

3. Research methodology

The qualitative research was conducted through a series of face-to-face interviews with Thai banks which offer Internet banking. Prior studies about information systems and electronic commerce have sometimes applied a qualitative approach in order to present better detail for exploring perspectives in the early stages of research, allowing the researcher to gain a better initial understanding of the problem, to identify facts, attitudes, and influence, and to provide knowledge [38,54]. The interviews were conducted with advance appointment. The list of guideline topics was developed from the literature, and occasionally supplemented by new issues that came up in the interviews.

In selecting appropriate respondents from the banks, the research used three criteria. First, Thai banks that are the leading Internet banking service providers were chosen as the target group. Secondly, banks where the researchers had sufficient connections to gain access were chosen. Those who have conducted research in Asia, where the tradition of business secrecy is very strong, will appreciate the necessity of such connections to obtain any useful information. Finally, the top level positions of bank managers who play the major roles in determining strategic direction of implementing Internet banking for corporate business groups were selected as interviewees. The interviews were conducted with a senior vice president of e-Commerce and e-Banking from the first two banks. For the third bank, the researcher has a good chance to interview three management positions. These three respondents are vice presidents of electronic channel management department, vice president of corporate business group, and division manager of corporate business marketing and products department. Therefore, total five top level executives from Thai banks were interviewed.

The in-depth interviews took about an hour for each respondent. All in-depth interviews were conducted in Thai language. A qualitative content analysis is used for paraphrasing the range of significant issues and categorized according to the concepts discussed above.

4. Results

Specific to Thai Internet banking service providers, all the respondents mentioned that Internet banking provides real-time financial information to their customers. Whenever customers want to view the statement, they can request it immediately via the Internet banking system, and do not have to wait until the end of each month to view the statement. The following statements illustrate this issue:

“It is very convenient to use Internet banking. It saves customers time and cost. Customers can check their account balance and request the statement at any time they want.”

“In the traditional system, customers have to wait until the end of each month to get financial statements. If customers want to request a statement during the month, they will get charged.”

“The only thing that customers will go to the bank for is to deposit cash or checks.”

Thai Internet banking service providers mentioned that Internet banking is the powerful channel for customers to access information. The following statements support this benefit:

“Customers are able to check their account balance and plan their cash management early in the morning.”

“Customers don’t have to wait until banks opened. They can check their account balance, fund transfer, and request for today and history statements during 9 am to 11 pm. Customers can have transaction services during closing hours of the bank or weekend.”

In addition, two Thai Internet banking service providers do provide links to other websites in order to motivate customers to visit the bank websites, e.g., they provide daily highlight news, and links to other financial information sources, such as the Stock Exchange of Thailand, and Bank of Thailand.

However, the accessibility through the network of Internet banking is sometimes quite slow because of the low speed of network infrastructure. Banks also realize that this is one of the usage barriers to customer adoption.

Unfortunately, the Thai Internet banking system hardly provides virtual space for their customers to share their experiences. One bank states that:

“To provide virtual space for customers needs additional investment on information technology. Currently, Internet banking systems require intensive investment of information technology, while customer adoption of Internet banking is not so high to cover the investment costs.”

However, two banks have realized that the value of interactions among customers, or even between the bank and customers, can create increased understanding of customers and adaptation of services offer to customer specific needs and wants. One respondent responds to this issue that:

“This is an interesting topic, we may consider providing the virtual space to our customers in the near future.”

Most of the respondents in our research also claimed that Internet banking becomes the cheaper service-delivery channel for financial transactions because it provides time and cost savings to customers. Two bank respondents' comments illustrate this point well:

“Internet banking provides customers with lower cost per transaction than traditional face-to-face or other service delivery channels.”

“I can say that Internet banking offers customers more convenience, customers save time and cost in making transactions via Internet banking system. I also believe that Internet banking is a win-win situation, both the bank and customers can reduce operating costs and increase profit in the long run.”

Thai Internet banking also provides online services, such as call centers and online help desks, that customers can use when they face problems. Thai banks provide training to their customers to try to add value for Internet banking customers in order to build trust. All the three banks provide service channel to their customers, as shown in the following statements:

“Internet banking provides a primary online help desk to customers or a call center for them to call the bank 24 hours. In case that customers want to talk to bank personnel they can contact the personnel in charge of the Internet banking system.”

“Our bank realizes that customer service and bank interaction with customers are important. Besides the current services for Internet customers, our bank plans to employ customer-oriented service by developing many applications such as customer relationship management (CRM) in the next year.”

Some Thai banks have developed applications according to the specific character of bank customers in order to handle the financial processes via the Internet banking system. Banks are willing to provide personalized service to corporate customers. For instance, Thai banks now implement a customized business-to-business (B2B) web based on invoice and payment processing – electronic bill presentation and payment (EBPP). This system is used to replace manual paper processes of the billing systems, which allows bank customers to interact with their customers via the bank website, e.g., bill presentation, invoice and payment handling. Bank corporate customers can download their accounts receivable system to the EBPP system of the bank and their customers can view the credit amount due via the bank website and make payment via the Internet banking system. This service allows customers to perform their traditional operations more effectively, and the capability to reduce operations costs. In addition, corporate customers and the bank also interact and exchange information with one another (e.g., using phone call or e-mail) in order to confirm whether the payments are paid.

Thai banks try to build long-term relationships with their existing and prospective customers in order to increase customer satisfaction. Banks get feedback from their customers that Internet banking provides new value to customers. Web technology provides tools or applications that can be used to interact with customers more efficiently. For instance, the call center is used as a response vehicle to communicate with customers or to provide customers with after-sales support, and to leverage sophisticated customer databases. Therefore, interactive communication and responsiveness of service and support via Internet banking are considered as important issues for building relationships to customers. Finally, customization of service according to customer needs and wants has potential to create customer relationships because it can reduce costs and generate revenue to customers.

In sum, in Thai Internet banking, many banks reveal that Internet banking is a powerful channel for banks to interact with customers faster. Internet banking enhances and improves bank and corporate customer relationships in terms of service responsiveness and service personalization. However, there are still few corporate customers adopting Internet banking because of many lack trust in web infrastructure. Many respondents point out that Thai customers still like to have personal interaction with the banks, they do not like to read but like someone to explain to them instead. They prefer face-to-face service and personal contact with the bank. These banks accept that major barriers to Internet banking adoption by corporate customers are trust in security of the web system and in the reliability of service delivered. Bank respondents mentioned that

banks have intensively invested in building security infrastructure to safeguard bank financial information systems via the Internet network systems. The following statement highlights concern about the security issue:

“Actually, many banks are concerned about the security systems. Banks never overlook security issues but take this issue as a major concern and invest a lot of money to protect the security system of the bank in order to enhance customers’ trust in banking service via the web channel.”

Moreover, banks also realize that many corporate customers are concerned about the reliability of making transactions via the Internet banking system, and also the documentation for transactions made via the web. However, banks have developed a system that allows customers to print out the transaction which is sent. The following statements illustrate how banks solve this point:

“Customers now can get the cyber receipt via the Internet banking.”

“If customers face a problem because of making a mistake via the Internet banking system, the bank can trace the record from log files. We keep customer history log files for five years.”

“From our past experience, when customers have problems, e.g., transferring money to the wrong account or any problem that needs the court to resolve the problem, we try to protect our guiltless customers and assist them to get their money back.”

5. Conclusion and limitation

Currently, banks perceive that web benefits do improve customer relationships with their corporate customers, but the web benefits do not seem to provide higher switching costs or higher customer loyalty through Internet banking channel. Thai banks realize that Internet banking provides information benefits to corporate customers. Customers are able to access their financial data in the more flexible way and on a real-time basis. In addition, Internet banking can reduce operating costs to both banks and corporate customers in the long run. Evaluating their corporate Internet banking customers, banks can judge that Internet banking assists them to develop and enhance customer relationships with their corporate customers in terms of providing service according to customer needs and wants with lower costs and service responsiveness. Furthermore, these banks are leaders in Thai Internet banking try to implement strategies that enable them to outperform other banks, such as developing web applications like CRM to gather and analyze customer information more efficiently.

Banks also believe that corporate accounts have greater potential for web applications because transaction amounts from corporate customers are bigger volume. Corporate customers are the main target group for Internet banking. They predict that the trend for corporate Internet banking customers will be continuous growth. The results show that implementing Internet banking helps to reduce operating costs, contributes to long-term relationships with their customers, and provides strategic benefit with higher profit to Thai Internet banking service providers.

On the other hand, while we have focused on the benefits in this discussion, Thai banks also face the barrier of customer trust in web-based service delivery via the web channel. Bank customers are concerned with the security and reliability of transactions via the web, which are the major barriers mentioned in many studies [33,46]. The results of in-depth interviews with bank respondents indicate that banks seem to understand their customers fairly well, at least realizing that security and reliability of web-based service are major customer concerns. They plan to invest in security infrastructure and web applications in order to build customer trust in Internet banking.

Finally, banks recognize that using web channels for commercial purposes will take some time for adaptation of management attitudes among corporate customers. Management has to be inclined toward a new technology adoption vision, and firms should have qualified staff to support management vision in order to enhance the growth of Internet banking. Thai Internet banking service providers believe that Internet banking will provide banks strategic benefits in terms of long-term profitability in the near future. Banks try to implement Internet banking by focusing on their specific groups of corporate customers in order to provide better service according to customer needs and wants.

The key limitation of this study was a small sample, because very few Thai banks offer Internet banking. Caution must be exercised regarding generalizability of the study. It does reflect the views banks currently offering Internet banking to corporate customers, but it may not necessarily reflect views of other banks as they begin to move online. More empirical work will be required to keep track of industry views about the issues developed in this paper, as later adopters may differ in their assessment from earlier adopters. In addition, clearly we need to get data from corporate customers themselves, especially those who have higher transaction volume with the banks. They are the main target market of Thai banks, and it will be important to determine how closely they share the banks’ vision. Future work may also need to investigate the impact of Internet banking on customer loyalty to the banks, i.e., look at the long-term customer response, not only immediate perceptions.

Abstract

The ability of Multinational Corporations (MNCs) using different entry mode choices to strategically influence their environments has become an important concern in international business research. We adopt the concept of institutional strategy to explain patterns of MNCs' action that are directed toward managing the various institutional pressures. The institutional strategies vary with different multinational entry mode choices used by MNCs.

This study proposes that the MNCs using different entry mode choice adopt different institutional strategies to respond two primary institutional pressures---internal (parent) and external (host country). In order to provide a constructive alternative explanation for multinationals' entry mode choice in institutional perspectives, further empirical research and literature review is required.

Key terms: Multinational Corporations (MNCs), institutional strategies, entry mode choice, institutional theory

1. Introduction

Early studies in international business field have identified many determinants that influence the choice of an entry mode for a selected target market. The explanations of determinants draw from transaction-cost theory(Anderson & Gatignon, 1986; Erramilli & Rao, 1993), eclectic theory (Agarwal & Ramaswamy, 1991; Kim, Hwang & Burger, 1989), resource-based view(Chang, 1995) and Dunning's integrating perspective(1977, 1980, 1988). For all of these entry mode choices involve different level of resource commitments, MNC's initial choices of a specific mode are difficult to change without substantial loss of time and money(Root, 1987)Entry mode selection is a very important strategic decision(Agarwal & Ramaswamy, 1991). However, after MNC's selecting the entry mode choice, MNC must face two sources of isomorphic pressures: (1) host country institutional environment and (2) internal institutional environment or the parent organization(Davis, Desai and Francis, 2000) This paper focus on how MNC with different entry mode choices cope with these institutional pressure.

The ability of Multinational Corporations (MNCs) using different entry mode choices to strategically influence their environments has become an important concern in international business research. We adopt the concept of institutional strategy to explain patterns of MNCs' action that are directed toward managing the various institutional pressures(Lawrence, 1999). In order to gain the legitimacy in organizational field, membership rules and standards of practice remain acceptable response to institutional pressure. Institutional structures are conceptualized as pragmatically rules of membership and standards of practices. Organizations depend on these institutionalized rules and standards as guides to legitimate action within their organizational field(Hinings & Greenwood, 1988). The institutional strategies vary with different multinational entry mode choices used by MNCs.

2. International Entry Mode Choice

Of theoretical interest, there are four distinct international entry modes of wholly owned subsidiaries ,licensing, joint venturing and exporting. We simplify the entry mode choices because much of the international business literature emphasizes on these three distinct modes and suggests that each of these entry modes is consistent with resource commitment (Vernon, 1983) and a different level of control (Caves, 1982; Davis, Desai & Francis, 2000).Control indicate authority over operational and strategic decision making; resource commitment emphasize dedicated assets that cannot be redistributed to alternative uses without loss of value. Kim & Hwang(1991) suggest that wholly owned subsidiaries can be described as relatively high level of resource commitment and control, the opposite should be exporting. With respect to licensing agreement and joint venture, although the levels of resource commitment and control vary with the nature of the ownership split, their extent can be said to lie between that of wholly owned subsidiaries and exporting.

Prior clarifications for entry mode choice most draw from eclectic theory(Kim & Hwang, 1992), resource-based view(Chang, 1995), and transaction-cost economics(Erramili & Rao, 1993). Because so many factors may influence entry decision, the existing

frameworks are vague or contradictory for the patterns of entry mode choice. Our purpose is not to contest previous models, but to explore whether institutional relationships and strategies provides a constructive alternative explanation for multinationals' entry mode choice.

3. Institutional Theory and Institutional Strategy

3.1 Institutional Theory

Different from the traditional task environment perspective that focus on the role of competition, resource and markets, institutional theory emphasizes on the state and professional associations in an organization's institutional environment and their insightful influence in shaping the legitimacy and performance of an organization (DiMaggio and Powell, 1983; Scott, 1995; Zucker, 1987). Institutional theorist presume that organizations search for social approval and legitimacy (DiMaggio, 1988); the building of institutional relations assists the organization to mobilize cultural support for its activities and goals and to reveal its social validity and conformity with regulations, institutional rules and norms (Myer and Rowan, 1977).

Earlier institutional theorists highlighted the attribute of beliefs, rules, and myths as shared social reality and processes (Oliver, 1991). Prevailing theorists suggest that various institutions exert pressures on organization and result in appropriate and fundamentally meaningful organizational behavior (Zucker, 1983). Institutional theory could explicate the influence these pressures exert on organizations (Myer, Scott & Starng, 1987) and strategic behavior (Oliver, 1991). However, particular institutional context could determine an organization's appropriate behavior or activity (Davis, Desai, & Francis, 2000).

Institutional theory provides a rich, complex view of organizations. It emphasizes those normative pressures, sometimes coming from external sources, other times coming from within the organization itself, influence organizations. Under some conditions, these pressures lead organization to be guided by legitimacy. Adoption of legitimacy, leading to isomorphism with the institutional environment, increases the survival chances (Zucker, 1987).

Traditionally, institution theory focuses on the external institutions in influencing organizational behavior. The institutions contain public opinion, interest group, professions, regulatory structures, agencies and law (Oliver, 1991). Now the meaning of institutions has been extended to other business units in an organizational network (Kostova & Zaheer, 1999). According to this perspective, the parent organization's network will exert institutional pressure to its business units. The isomorphism mechanism will force business subunits to conform to parent organization's norms. However, the external and internal sources of pressure influence significantly on the entry-mode choice of MNC.

Isomorphic pressure institutionalizes MNC's structure and behavior. MNC's subsidiaries face simultaneous pressures to resemble other sub-units of the parent MNC, and to adapt to the institutional demands of host countries (Rosenzweig & Singh, 1991).

3.2 Institutional Strategy

According to Lawrence's perspective (1999), institutional strategy developed from institutional theory means patterns of action that are concerned with managing the institutional structures within which firms compete for resources. It focuses on organizations' strategic responses to institutional pressures and the active role of organizations concerned with constructing new institutions, and transforming existing institution to inspect institutional structure.

The conceptualization of institutional structures depends on an understanding of reality as socially constructed and enacted in discussion (DiMaggio & Powell, 1991). However, the key attribute of institutions is their pragmatic orientation: social actors draw on institutionalized knowledge as a resource in their routine life. At organizational level, organizations are driven to fit in the practices and procedures defined by current rationalized concepts of institutionalized in society and organizational work (Meyer and Rowan, 1977).

The concept of organizational fields plays a role of domain of meaning— fields of activity within which social structure and common languages develop. It also consists of sets of subject positions bound together by standards and institutionalized rules (DiMaggio & Powell, 1983; Bourdieu, 1993). To maintain legitimacy in an organizational field, an actor must conform to these institutionalized rules. Lawrence (1999) suggested that these practical rules help actors to respond two question: "Where can I go,?" and, "What can I do?". The first question relates to institutionalized boundaries issues, which limit the organizations' form of life into rules of memberships. The boundaries include culture, race, gender, profession or relationships. The second question asks what the coping skill within an organizational field. Standard of practice give norms, guidelines and legal prescriptions relating to how practices are to be carried out in some institutional setting (Clegg, 1989).

The importance of membership rules and practice standards in an organizational field doesn't imply that organizational action is determined by the rule. Rather, the basic relationship between social rules and action implies the possibility of change, as well as reproduction. Continual reproduction in social action determines the legitimacy of rules and practice. It implies that institutional rules are not fixed, but rather transformed by motivated actors (Clegg, 1989; Lawrence, 1999).

Institutional strategies are patterns of organizational action concerned with the transformation and formation of institution, the rules and standards that control those structures. Although all organizational strategy occurs within an institutional context, institutional strategy is distinguished by its orientation to that context. These

strategies emphasize more on transforming institutional standards and rules rather than gaining competitive advantage. Institutional strategies focus on managing existing institutional structures to establish a strategically favorable set of conditions. We adopt three types of institutional strategy: (1) membership strategies and (2) standardization strategies (Lawrence, 1999). (3) Hybrid strategies of membership and standardization; in this paper.

In response to normative pressures, which stem from professionalization, membership strategies rest on the power implicit in membership. Membership strategies include the definition of rules of membership and their meaning for an institutional community. An organization's capability to influence the membership rules of an organizational field is positively related to its control of institutional information and the degree to which it is perceived as a leading organization in the field (Lawrence, 1999). However, we proposed highly control entry mode of MNC will pursuit membership strategy to response normative pressure.

In response to coercive or mimetic pressures (DiMaggio & Powell, 1983), standardization strategies force other actors to conform to institutional standards. Standardization strategies emphasize the establishment of legal, technical or informal standards to define normality of a product, service or practice through regulation (Selznick, 1957; Montagna, 1990). An organization's incapability to influence the standards of practice in an organizational field is negatively related to its technical, legal, political and marketing expertise and the degree to which it is perceived as a leading organization in the field (Lawrence, 1999). However, we proposed low control entry mode of MNC will pursuit standardization strategy to response coercive or mimetic pressure.

Figure 1 "Conceptual Framework" summarizes the relationships proposed here between MNCs' entry mode choices and institutional strategies.

4. Proposition

MNC's business units using wholly owned modes of entry would have higher MNC's parent isomorphism pressure (Davis, Desai & Francis, 2000). To response this pressure, we propose that MNCs need some membership strategies. These strategies involve the definition of rules of membership and their meaning for an institutional context.

An organization's ability to affect the membership rules of an organizational field is positively associated with its control of institutional information and the degree to which it is perceived as a leading organization in the field (Lawrence, 1999). The relationships between MNCs' entry mode choice, parent isomorphism pressure and membership strategies lead to proposition one:

Proposition 1: MNCs using high level of control entry mode (e.g. wholly owned modes of entry) will favor

membership strategies than MNCs using other modes of entry.

MNC's business units using exporting modes of entry would have higher MNC's local market adaptation pressure (Davis, Desai & Francis, 2000). To response this pressure, we propose that MNCs need some standardization strategies. These strategies are concerned with the establishment of legal, market or technical standards that define the normal process involved in the production of some good or service (Lawrence, 1999). The relationships between MNCs' entry mode choices, local adaptation pressure and standardization strategies lead to proposition two:

Proposition 2: MNCs using low level of control entry mode (e.g. exporting modes of entry) will favor standardization strategies than MNCs using other modes of entry.

MNC's business units using multiple modes of entry would have similar pressure of both parent isomorphism and local market adaptation level (Davis, Desai & Francis, 2000). To response these pressures, we propose that MNCs may achieve a balance to adopt both institutional strategies. That suggest proposition three:

Proposition 3: MNCs using median level of control entry mode (e.g. multiple modes of entry) will favor similar level of both membership strategies and standardization strategies.

5. Discussion

Prior research in international business field have proposed many factors that affect the choice of an entry mode for a selected target market. This paper provide a way to explain how MNC with different entry mode choices to deal with institutional pressures. This study proposes that the MNCs using different entry mode choice adopt different institutional strategies to respond two primary institutional pressures---internal (parent) and external (host country). The concept of institutional strategy is intended to move the discussion of institutional setting beyond notions of environmental determinism toward more examinations of the complex dynamics of institution and field. The proposition in this paper deduce how MNC with different entry mode choices cope with these institutional pressure.

For practice implication, we propose a way to manager of MNC as they attempt to understand the strategies that MNC with various entry modes should response to the institutional pressure. In order to provide a constructive alternative explanation for multinationals' entry mode choice in institutional perspectives, further empirical research and literature review is required.

Complexity and Commitment in Supply Chain Management Initiatives

Yu-Ni Ham, Robert Johnston, Kai Riemer

Department of Information Systems

Melbourne, Australia

y.ham@pgrad.unimelb.edu.au

Abstract

While the benefits of supply chain management have been widely reported within industry, adoption of supply chain management initiatives have been slow and below industry expectations. To better understand and effectively address this problem of adoption within industry, this paper takes a closer look at the individual supply chain management initiatives to achieve a new understanding on the barriers that hamper the adoption process. This paper presents a framework that categorises different SCM initiatives according to a complexity-commitment continuum. By analysing three initiatives from the grocery industry, we argue that the inherent complexity of SCM initiatives poses barriers to adoption due to the degree of organisation commitment required.

1. Introduction

Over the last two decades, organisations have progressively moved towards establishing closer relationships with business partners to collaboratively achieve competitive advantage [1]. Several studies suggest that the scale of competition is shifting from between firms to between groups of firms such as supply chains [2] [3]. The concept of supply chain management emerged aiming at leveraging the benefits of inter-organisational partnerships through systemic thinking and integrating business processes to ensure certainty and efficiency in the flow of information and materials from upstream to downstream [4]. Although the benefits have been widely reported within academia and industry [5][6], the extent of adoption of supply chain management initiatives still falls short of industry expectations [7][8]. While many organisations have piloted initiatives such as Efficient Consumer Response and Collaborative Planning, Forecasting and Replenishment with selected business partners, there are considerably fewer examples where these initiatives have been adopted on a supply chain level involving multiple trading partners [5].

To better understand and effectively address this lack of adoption, we have to identify and understand the barriers that hamper the adoption process. Existing research tend to focus on inter-organisational barriers [9] [10] that involve trust issues, the willingness to participate, mutuality of benefits, risks and costs, as well as asymmetries in technical, organisational and cultural

systems. Furthermore, barriers in the process of implementing these initiatives can be attributed to difficulties in establishing partner selection criteria [11], complexities of project management across multiple organisations and so forth. We argue that inherent complexities within specific supply chain initiatives pose an important barrier to adoption that has not been adequately addressed so far. Generally, we can distinguish between three levels of barriers that affect each other. Firstly, inherent complexities pose significant challenges for individual organisations to adopt SCM initiatives; secondly, on an inter-organisational level, existing asymmetries between organisations further challenge the adoption process. Finally, the process of implementation itself poses further challenges as it involves multi-party development projects. As the first group of barriers remains largely unaddressed so far, we believe that a better understanding of these barriers inherent to the SCM initiatives is essential for the discussion of SCM adoption.

In this paper, we argue that the inherent complexity of SCM initiatives poses barriers to adoption due to the organisational commitment that is required to address these complexities. In doing so, we will present a framework that categorises different SCM initiatives according to a complexity-commitment continuum. Using three specific SCM examples from the grocery industry, we show that newer SCM initiatives have become increasingly complex, impacting on individual organisations in terms of the required managerial commitments for the initiatives to be adopted. The next section will introduce supply chain management and our framework, followed by a section on our deductive analysis using the industry examples, and then a final discussion on the implications for further research.

2. Supply Chain Management Initiatives: A Continuum of Complexity and Commitment

2.1 Supply Chain Management: A Vision of Intra-firm and Inter-firm Synchronisation

Mentzer et al (2001) suggests that supply chain management (SCM) can be defined as:

‘The systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across

businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole' [4, p.18]

Basically, SCM envisions managing and coordinating the flow of information, products, services and financial resources from upstream suppliers to downstream customers along the supply chain in order to improve customer service and ultimately supply chain profitability. To embrace the overall concept of supply chain management (SCM), individual organisations have to, firstly, adopt a systems perspective of their business, that is, an understanding of the interdependencies between individual actions and the implications of managing upstream and downstream flows of products, services, finances, and information across trading partners. Secondly, and more importantly, supply chain management requires organisations to implement this supply chain orientation involving suppliers and customers. [4, p.11]

From a strategic perspective, SCM envisions the synchronisation of supply chain activities, or processes, to compete against other supply chains [2] on a network level. In order to achieve the envisioned level of information and process synchronisation within and across organisations, organisations in various industries aim at adopting and implementing specific industry-based supply chain management initiatives.

2.2 Supply Chain Management Initiatives: Adopting and Implementing the SCM Vision

Supply chain management initiatives provide concepts to enable organisations and their trading partners to implement industry best practice to achieve the benefits of SCM. In various industries, a range of supply chain management initiatives exist that aim at orientating organisations towards achieving the ultimate SCM vision that involves the integration of all intra-firm and inter-firm policies and processes. To support our argument that new and increasingly sophisticated SCM initiatives pose inherent challenges to adoption, we will show that these initiatives cumulatively build on each other and that they vary in complexity according to the extent of intra-firm and inter-firm integration they require. Generally, SCM initiatives move beyond the traditional arms-length interaction, where organisations operate in a laissez faire environment and interaction is limited to transactional exchanges. As new information technology and process optimisation strategies become available and more developed within industries, new SCM initiatives propose closer, more collaborative, trading partner relationships. The following section introduces a framework to organise the different types of SCM initiatives according to their level of inherent complexity and extent of organisational commitment required.

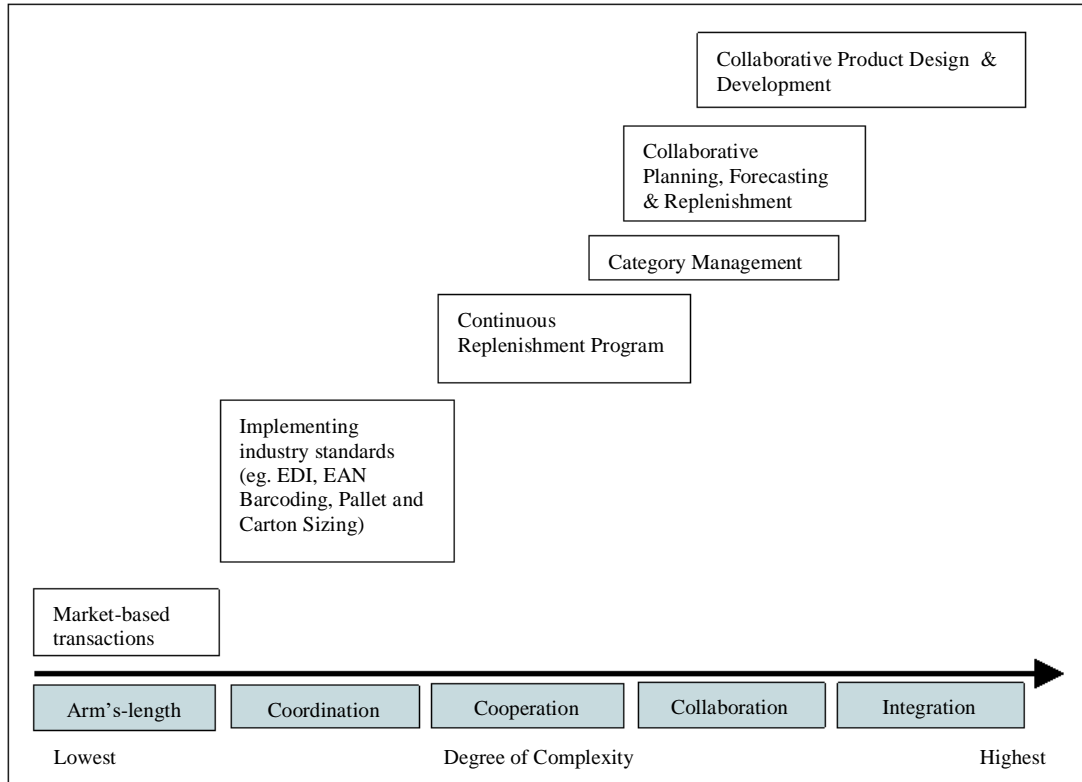

Figure 1. A continuum of SCM initiatives

2.3 The Complexity-Commitment Continuum

In his study of relational change strategies, Himmelman (1996) suggested a set of strategies that build upon each other along a continuum of commitment and complexity [12]. We have adopted this model as the basis for developing a framework in order to organise the different types of SCM initiatives according to their level of complexity and commitment accordingly. We suggest that there is an increasing complexity inherent in different types of SCM initiatives that require cumulative levels of organisational commitment as we approach a level of strategic integration among organisations. Figure 1 shows different types of SCM initiatives along this continuum of increasing complexity.

2.3.1 Different types of SCM Initiatives

Coordination Initiatives

Coordination initiatives envision organisations altering the way information is exchanged and managed and involve implementing industry data standards so that organisations can more efficiently manage the flow of information and flow of materials between organisations. However, coordination initiatives do not expect organisations to alter existing business processes. Some examples of coordination initiatives include adopting standardised messaging infrastructures such as electronic data interchange (EDI) based on EDIFACT or similar standards that might use Extensible Markup Language (XML). Apart from informational exchange capabilities, initiatives to improve the materials handling infrastructure between trading partners include product identifying standards, such as Universal Product Code (UPC) and European Article Numbering (EAN) barcoding standards, containerisation and pallet sizing.

Cooperation Initiatives

Cooperative initiatives see organisations exchanging information, altering operational activities and sharing supply chain resources. Cooperation initiatives present a series of industry process standards focused on optimising the flow of information and materials along the supply chain. The initiatives require basic coordination capabilities, as described above. More importantly, these initiatives also require organisations and their trading partners to adopt new processes for performing daily operations. Some examples include Just-in-time (JIT) delivery, Continuous Replenishment Program (CRP) and Quick Response (QR) in the electronics, grocery and textile industries respectively.

Collaboration Initiatives

Collaboration initiatives require organisations to exchange information, to alter operational and tactical activities and share resources in an extensive way.

Moving beyond cooperation initiatives, they add another level of complexity by requiring organisations to align processes at the tactical level, including planning, forecasting, sales and marketing and purchasing. These initiatives also assume the existence of infrastructural and process capabilities from coordination and cooperation initiatives to effectively carry out collaboration initiatives. Some examples of initiatives include Category Management and Collaborative Planning, Forecasting and Replenishment.

Integration Initiatives

Integration initiatives suggest the next step up from collaboration initiatives and involve process standardisation at the strategic level of the organisation. Joint product development for example, requires not only alignment of strategic objectives and involvement of strategic processes such as research and development to design and develop the product concept, but also the need to be able to agree on a way to market, manufacture and distribute the product to the consumer. This requires operational cooperation, collaborative tactics and a sophisticated underlying communication infrastructure as a prerequisite to enable the exchange of strategic information, such as product designs, and joint planning and logistics processes. This implies that for integration to be achieved, all the previous types of initiatives have to be in place.

2.4 Increasing requirements for organisational commitment

Having argued that SCM initiatives become increasingly complex, we can state that this inherent complexity requires increasing organisational commitment likewise. For the purpose of our framework we distinguish four major levels of management in organisations – the infrastructure level, operations level, tactical level and strategic level. As complexity increases for each of the above initiatives, the level of commitment required by organisations in terms of time, resources and managerial attention to achieve the visions increases as we approach integration type initiatives (see figure 2). With coordination initiatives, commitment is predominantly at the infrastructure level of management. With cooperation initiatives, commitment on the infrastructure and the operations level is essential, and so forth. Finally, with integration initiatives, all management levels of the organisation are impacted and therefore commitment has to be lead by strategic management but will involve resource and managerial commitment from the infrastructure, operations and tactical level as well.

To show the validity of our framework and to ultimately support our argument that the inherent complexity of SCM initiatives poses barriers to adoption due to the organisation commitment required, we will analyse three

exemplary initiatives from the grocery industry in the following section. We will examine the level of standardisation that each initiative requires and show their cumulative nature (one initiative based on the achievements of the other).

This will allow us to deduce the organisational impact of the initiatives in terms of the required managerial commitments according to the above illustrated management levels.

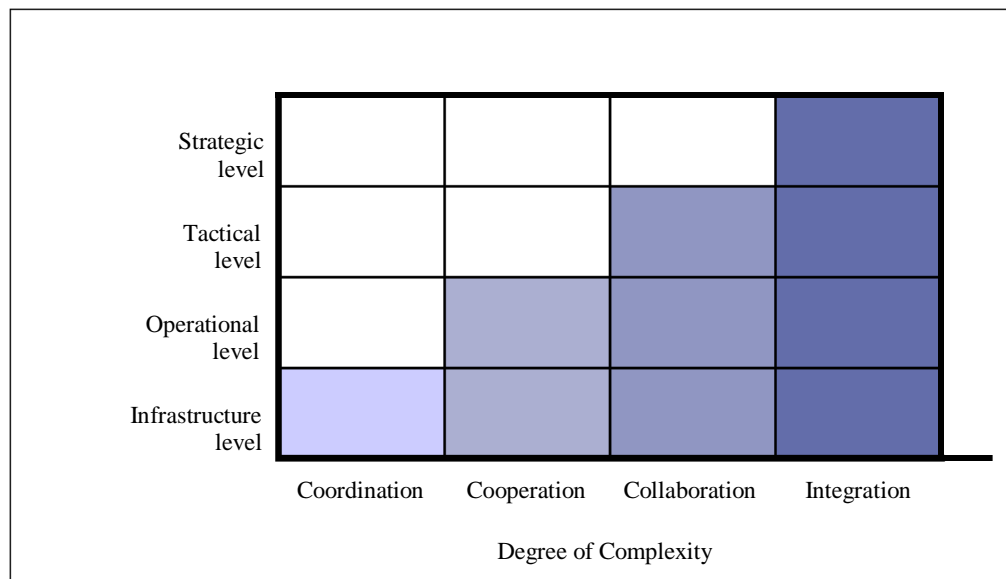

Figure 2. The Complexity-Commitment Continuum

3.0 Exploring Grocery Industry Initiatives: An illustration of the framework

3.1 Methodology

For the purpose of our analysis, we have chosen to explore three initiatives that are well known within the grocery industry – Electronic Data Interchange, Continuous Replenishment Program and Collaborative Planning, Forecasting and Replenishment. These initiatives have been chosen to illustrate the extent of organisational commitment required to achieve the envisioned level of coordination, cooperation, and collaboration respectively. For the purpose of making a clear comparison between these initiatives, we will focus our analysis on the replenishment aspect of each initiative. For each initiative, analysis will be organised in three sections: (1) review of the vision and aim, (2) description of the extent of standardisation required, and (3) description of the extent of organisational commitment required to achieve the envisioned level of standardisation.

3.2 Electronic Data Interchange (EDI)

3.2.1 Vision and Aim

Electronic Data Interchange (EDI) envisions a seamless exchange of information between two or more organisations to carry out daily replenishment operations. Taken as an initiative, EDI aims to set up an inter-

organisational communications infrastructure that allows two or more businesses to electronically transmit standard transaction documents in a structured format from one company's business process application to another's business process application [13][14]. EDI's vision impacts on the replenishment process in one major way. By adopting EDI message standards, transaction documents can be recognized and understood swiftly and without unnecessary delays and errors from inaccurate interpretation and manual data entry. For example, EDI messages can be used to invoice buyers, send purchase orders, and authorise items for delivery and transfer. Shipping schedules can be transmitted directly to a shipper's computer and responded to with an electronic shipping notice more quickly than if manually processed. Because all these processes can be performed more efficiently and frequently, with fewer errors, lead times and inventory holding costs are significantly reduced [15].

3.2.2 Extent of Standardisation

Infrastructure Standardisation

EDI requires organisations to standardise the message format that is exchanged such that business applications at both ends of a transaction can transmit and receive the messages electronically. Standardisation at the data level enables organisations to transact electronically without having to implement a new system or to make major changes to existing systems. EDI standards are made up

of four major components. These include (1) transactions sets, (2) segments, (3) data elements and (4) transmission control standards [14]. Basically, an EDI transaction set identifies a standard business document (eg. Invoice document), and segments are groups of data elements identifying the details within each document (eg. Address information, supplier name, items ordered, total amount, etc). Finally, transmission controls standards apply to the secure way EDI messages are packaged for transmission. These standards ensure that EDI messages reach the intended party in the intended form.

Operations and Tactics Standardisation

There are no formal requirements within the traditional EDI vision to adopt a standardised operations process, nor standard processes at the tactical level.. This means that businesses can organise their operations functions in whichever way they deem fit as long as they can transmit and receive the necessary transactional documents in EDI format to and from another party.

3.2.3 Extent of Organisational Commitment

Primarily an infrastructure level project, resources and services of the IT function is required to implement the EDI message standards and update existing business applications to allow the output and input of messages in conformity with the chosen standard. Once the infrastructure is in place to conduct transactions via EDI, the commitment on each participating organisation is to maintain this standardised communications link, or interface. In terms of impact on organisational tasks, processes and people, EDI does not require changes to be made to existing business processes.

3.3 Continuous Replenishment Program (CRP)

3.3.1 Vision and Aim

Continuous Replenishment Program (CRP) is a major strategy under the Efficient Replenishment pillar of the Efficient Consumer Response (ECR) movement. CRP envisions suppliers, distributors and retailers cooperating towards achieving a smooth and continuous flow of product along the distribution channel, thereby, reducing channel uncertainty, inventory levels and transportation costs [16][17]. CRP encompasses three alternative replenishment arrangements – direct-store-delivery, cross-docking and flow-through [9]. The major achievement of CRP is that the stock level and order requirements at the retailers' stores are revealed and shared with the manufacturers, and manufacturers use this information to fulfill store level orders more frequently and in smaller batches. With direct-store-delivery, orders are delivered directly from suppliers to individual stores, bypassing the distributor. With cross-docking, suppliers deliver consolidated store orders to a distribution center, where they are unpacked, sorted into

their store destinations and dispatched. Finally, with flow through, specific store orders are packed at the suppliers and delivered to the distribution center, checked and immediately dispatched without any sorting required. This improved flow of goods aims at eliminating buffer stock at the distribution center, reducing errors in deliveries and improving order response time, thereby, reducing out-of-stocks in stores. To achieve the maximum potential of the CRP vision, trading partners need to be able to facilitate high information coordination and be willing to align replenishment policies and operations with their trading partners' [17].

3.3.2 Extent of Standardisation

Infrastructure Standardisation

To facilitate the fast and accurate flow of replenishment information between retailer, distributor and supplier information systems, EDI is an essential enabling technology in CRP [18][19]. CRP requires stores to be able to electronically transmit information on stock levels and order requirements to a central buying office, where individual store orders are consolidated into an EDI purchase order message and transmitted to individual suppliers on a pre-agreed time schedule. Suppliers need to be able to then respond by transmitting an Advanced Shipping Notice (ASN) in EDI format either directly to the store or distribution centre to notify them of impending deliveries. Essential for enabling efficient handling of shipments and production of ASNs, suppliers need to be able to produce a bar coded serial shipping container code (SSCC) to identify shipments. Application of product identification standards, such as the European Article Numbering (EAN) system, in the form of bar codes on pallets and cartons are also essential for identifying and sorting at distribution centres. Bar codes on cartons and pallets are scanned and the data directly updated on the inventory management systems. This eliminates time consuming and error-prone manual data entry, thus, increasing the efficiency of the receiving, sorting and dispatching tasks.

Operations Standardisation

The CRP vision presents a change in the way orders are traditionally sent, received and fulfilled. Traditionally, individual store orders are aggregated at the retailer's DC and a purchase order sent to the suppliers, which then deliver a large shipment of goods to the DC. Orders are, generally, large and are sent infrequently and provide essentially no visibility of consumer or retailer ordering patterns for the manufacturers. However, in CRP, suppliers have visibility of store level requirements in their EDI orders and are expected to respond to this requirement almost immediately. This means that, firstly, suppliers must have the capability to respond to complex purchase orders that consist of many items in small

quantities and for multiple stores. Secondly, suppliers must be able to deliver these small batches of orders more frequently with a shorter lead-time (around 1 day typically).

Tactics Standardisation

In terms of replenishment processes, CRP only attempts to improve logistics and distribution operations and, therefore does not involve any processes at the tactical level of the organisation.

3.3.3 Extent of Organisational Commitment

The adoption of the CRP standard replenishment process impacts participating organisations at two levels of the organisation – the infrastructure and operations levels. At the infrastructure level, all participating firms are required to commit resources to implement a standard way of communicating messages to each other, and recognising shipments, cartons and items. In the grocery industry this is done using EDI and EAN product numbering and barcoding standards, thus, EDI and barcode compliance are a prerequisite for CRP. At the operations levels, participating retailers and manufacturers must alter the way they traditionally send, receive orders and dispatch orders. Retailers must have capabilities to send out purchase orders with individual store requirements and sort individual store order deliveries from different suppliers at their distribution centres. Suppliers, on the other hand, are required to have complex order processing capabilities to handle complex orders from retailers. Suppliers must also alter the way they traditionally dispatch orders to retailers, from large, infrequent deliveries to small, frequent deliveries. Therefore, CRP impacts mainly on the logistics and distribution functions of both supplier and retailers.

3.4 Collaborative Planning, Forecasting and Replenishment (CPFR)

3.4.1 Vision and Aim

Established in 1997, CPFR was developed to address the gaps that were present in previous initiatives, such as continuous replenishment. As such, CPFR is seen as an evolution from ECR, and more specifically, from CRP [10]. CPFR envisions two or more organisations exchanging market information to jointly develop a market-specific business plan that describes the product to be sold, the way it will be merchandised and promoted in the marketplace, and the time frame in which this happens [20]. Developed as a nine-step guideline for retailers and their manufacturers, the roadmap instructs CPFR partners to jointly develop a front-end agreement on terms of collaboration, targets and performance metrics, create a joint business plan, jointly create a sales forecast, identify any exceptions, jointly address and

resolve the exceptions, generate an order forecast, and execute the order. By sharing promotion schedules, point-of-sales data and inventory data, a single shared forecast of consumer demand, at the detail of a product, is developed. The retailer and manufacturer can then base all internal planning activities relating to that particular product on the shared demand forecast, representing a major step towards value-chain integration. CPFR aims to increase visibility of demand information along the supply chain and leverage a collaboration-oriented relationship between retailer and manufacturer, to increase the flexibility of the supply chain in planning for and responding to volatile demand. This implies the need for an infrastructure that can facilitate high levels of information exchange, a sophisticated planning and forecasting system that is integrated with the production and logistics systems, and a willingness of trading partners to align planning objectives, promotional tactics, and replenishment policies and operations. The following section discusses the extent of standardisation embedded in the CPFR vision.

3.4.2 Extent of Standardisation

Infrastructure Standardisation

In terms of data and communications interfaces, EDI and product identification standards are prerequisites to achieve the level of collaboration envisioned in CPFR. The high frequency of iterative interaction between organisations while sharing sensitive information to collaboratively develop forecasts makes it even more critical for organisations to adopt data standards. Using the EDI infrastructure, organisations can transmit and receive critical data swiftly and securely while ensuring a high data integrity. Moreover, EDI can facilitate information exchange between different functional units, which under CPFR, are envisioned to collaborate closely with each other. In terms of efficient handling of goods, the requirements are very similar to CRP, thus, organisations are required to adopt the bar coding standards infrastructure for CPFR as well. This is important in CPFR because point-of-sales data is extremely valuable in CPFR for capturing consumer demand necessary to generate sales and order forecasts.

Operations Standardisation

To effectively conduct CPFR, organisations must have the capabilities to perform replenishment operations very much in same efficient way as in CRP. Therefore, the operations process standards, in terms of order receiving, sorting and dispatching, are necessary also to achieve efficient delivery execution in CPFR. However, unlike previous initiatives, inventory management is now integrated with the planning and forecasting processes [5].

CPFR represents a radical transformation in the way businesses plan for promotions and develop forecasts to improve their replenishment operations in response to consumer demand. Evolving from having established a shared understanding on how orders are fulfilled, as envisioned in CRP, CPFR takes process standardisation to the next level, requiring a retailer and a manufacturer to adopt a standardised way of business planning. Retailers and their manufacturers are required to share information about their business development activities for a particular product within a period of time. Based on this planning information and unprecedented access to inventory level information from Distribution Centers to stores, trading partners jointly develop and manage a forecast over this period of time. With even greater demand visibility, forecast accuracy increases and manufacturers can match production to demand and fulfil orders more effectively, reducing inventory levels along the pipeline and out-of-stocks in retailers' stores.

3.4.3 Extent of Organisational Commitment Required

CPFR requires participating organisations to adopt standard business information formats, standard replenishment policies and operations, as well as standard processes in business planning and forecasting. The extent of data and process standardisation embedded in the CPFR vision requires commitment at the infrastructure, operations as well as tactical levels within each participating organisation. At the infrastructure level, CPFR requires organisations to commit IT resources to adopt message and product numbering standards to facilitate communication of basic EDI messages and numbering and barcodes as before. Additionally, due to the iterative nature of the collaborative forecasting process, more sophisticated information technologies, such as collaborative hubs, might have to be implemented to enable real-time collaboration. At the operations level, the impact here is similar to CRP, each participating organisation must standardise the way they receive and dispatch orders, thus, impacting on the logistics and distribution functions. However, there is a new and more demanding need to standardise ways of planning, forecasting and managing product life cycles which extends the demands on companies to tactical management and longer timescales. This new level of standardisation will impact on the merchandising function (for retailers), sales and marketing function (for suppliers), and planning functions (for retailers and suppliers). More importantly, whereas previous initiatives like CRP focused on optimising individual units and not the whole process or company [5], CPFR envisions several functional units within organisations, and to some extent across organisations, to collaborate to improve the performance of the replenishment cycle.

4.0 Discussion

Through exploring the extent of standardisation required by each of the three grocery industry replenishment initiatives, we find that the level of standardisation increases cumulatively as we move from EDI to CPFR. Each initiative was observed to require the capabilities of the earlier initiatives, and at the same time, requiring new capabilities with more complex and demanding effects. As described above, EDI requires organisations to adopt a set of industry message standards. CRP requires organisations to standardise their messages as well as standardise the way orders are received, sorted and dispatched. CPFR finally requires organisations to standardise messages, standardise the way orders are received and fulfilled, and besides this, standardise the way promotions are planned, forecasts are created, and performance is measured.

Table 1: Summary of analysis

Initiative	Level of Standardisation	Impacted organisational parts
EDI	Infrastructure: data, communication interface	Technical functions: IT
CRP	Infrastructure: data, communication interface, product identification (barcodes) Operational: Order receiving, sorting and despatching processes	Technical functions: IT Operational functions: logistics and distribution
CPFR	Infrastructure: data, communication interface, product identification (barcodes) Operational: Order receiving, sorting and despatching processes Tactical: Business planning processes	Technical functions: IT Operational functions: logistics and distribution Tactical functions: sales, marketing, purchasing, planning

Hence, as the extent of standardisation becomes greater, organisations face the need to commit an increasing amount of resources and managerial attention to achieve those targets. In EDI, the focus is at the infrastructure level. Major commitments of resources have to come from the IT function only. There is little commitment necessary from the rest of the organisation. In CRP, the focus extends beyond the infrastructure level to incorporate resources and managerial attention at the operations level. This affects not only the IT function, but also the logistics and distribution functions, where orders are received, sorted and dispatched. In CPFR, the focus is extended further. Organisations must now commit managerial attention and resources at the infrastructure and operations levels of the organisation, and also at the tactical level, involving sales, purchasing, or merchandising (at retailers), and planning functions

within the organisation. Moreover, CPFR requires close collaboration between the functions at the operations and tactical level to enable a responsive replenishment cycle.

By analysing the requirements of the various initiatives, we see the level of commitment compounding as complexity increases from coordination to collaboration along the supply chain. The number of functional parts involved in operationalising the initiatives increases, implying that greater levels of commitment in terms of time and resources, and involvement of more senior management, are required by each participating organisation to manage the interdependencies of the different parts in achieving the vision.

5.0 Conclusion

This analysis supports our argument that collaborative supply chain initiatives create their own barriers to adoption because the level of complexity inherent in its vision becomes increasingly complex and expensive to implement within each organisation, and more critically, with multiple trading partners.

As supply chain initiatives become more complex due to an increasing need for standardisation, the adoption within the individual organisations is challenged by the degree of organisational commitment that is required. With more people, more organisational units and technical systems involved, the adoption respectively becomes more complex and expensive.

These barriers to adoption at the individual organisational level have to be taken into account when extending the analysis to an inter-organisational level involving multiple business partners. With these inherent complexities complementing those barriers stemming from organisational asymmetries and project management across organisations, we can begin to understand SCM adoption in a more holistic way. Just as the single initiatives have a cumulative nature of complexity and commitment it might be worth researching whether this is mirrored in the project management to implement these initiatives. Further research into the nature of projects for the implementation of SCM initiatives should aim at exploring the project management challenges that come with implementing increasingly complex initiatives with multiple trading partners.

Abstract

Previous research on e-Learning in the business firms has remained a learner's characteristic perspective and even if the causes for learning performance have been clarified to some degree, these have not been practical research. However, the present study focuses in verification for the influential factors from an organizational context point of view on the individual learning performance.

The results of this study are as following,

- 1)e-Learning operation strategies related with management strategies have significant positive relations with the individual learning performance.
- 2)Organizational atmosphere is significant partially. - Learning motivation of organization has significant positive relations with the individual learning performance. But Innovative disposition of organization is not significant.
- 3)Reward / evaluation system has significant positive relations with the individual learning performance.

The academic significant of the present study lies in that, while previous research on e-Learning has remained conceptual or perspective on individual(learner's)

characteristic about training effect, the present study tried to approach from the organizational context standpoint.

Practical issues that the present study presents are that e-Learning managers should realize the importance of, and try to find ways to promote organizational learning motivation to adopt use of e-Learning system. Besides e-Learning operation strategies and a more practical reward / evaluation system should be implemented.

I. Introduction

Despite the changes in the world, the notion that companies exist for the pursuit of profit is the same. Corresponding to the fast paced environment, with a view to occupy a competitive advantage, we have raised our voices that we should accumulate and administrate intellectual capital into financial and material capital. The companies pursuing knowledge management, as a method of the knowledge management for the creation and transition of knowledge, seek learning in order to enhance the performance of their employees, departments, and their own companies. In other words, they aim at influencing the performance of their companies by attempting the creation of competitive advantages, future

intention, and business improvement through learning. This way, the best alternative to accumulate quality capital within an organization is considered e-Learning.[31]

However, the studies on e-learning so far have been mostly educational approaches, while their content were confined to the build-up, use, and operation of e-learning itself and very few studies have demonstrated and analyzed any factors which influence the practice of e-learning from an enterprise point of view.

Under these backgrounds, this study has its objective in inducing the influential factors of e-learning which many companies have recently been adopting with a greater recognition of its significance.

II. Literature Review

2.1 The Definitions of e-Learning

e-learning is identified to design, deliver, select, expand, and coach learning by utilizing technologies for all kinds of learning. This is not simple learning but utilizes Internet technology which delivers a variety of solutions for the enhancement of knowledge and performance. This is identified to include knowledge management or electronic performance supports beyond a simple on-line CBT (Computer Based Technology).[23]

‘e’ of e-learning means ‘Effective, Global, Entertaining, Evolving, Educationally Sound, Exciting, Affordable, Expensive, User centric, Need to know, Enhancement, Collaborative, Extended, Accessible, Reliable e-Learning’. The definition of e-Learning is, in a different point of view, classified diversely by base technology, delivery method, use scope, etc but it is generally used having almost the same meaning as on-line education and cyber education.

Figure 1. Subsets of Distance Learning [36]

III. Research Methodology

3.1 Method

As there are very few studies on the success factors in the enterprise of e-learning, we have decided to induce the influential factors of e-Learning by inquiring on the main factors of success and influence of many different fields covering e-learning, knowledge management, information systems, organization innovation, etc. This is because e-Learning is a sector belonging to knowledge management, while utilizing information systems and the innovation of organizations have recently developed in association with the issue of organizations creating knowledge and pursuing learning. Reflecting the definition of an organization's administration and innovation by Venkatraman, Loh & Koh(1994), it includes meanings covering an organizations' adopted change, the elements which bring changes to organizations, administration routine, and procedures, and an extensive view considering the association between organization and the external environment, etc.[15] Therefore, in the event that e-Learning is adopted, developed, and practiced within an organization, it should be interpreted in the same context.

Consequently, the consideration of influential factors in an organizations' innovation is required as a previous study of e-learning..

3.2 Participant

This study has been carried out with a purpose to discover the factors which influence the learning performance of learners when the members of an organization learn through e-Learning. Therefore the unit of analysis is individual.

For this study, we made questionnaires for the companies chosen at random in order to test the reliability and validity of the measuring tools. Besides this, considering that e-Learning can be carried out in the computerized sector, we did not confine ourselves in targeting a specific industry. As a result of doing e-mail surveys of 300 people totally who have ever experienced or currently experience e-learning, 277 of the responses were returned in 2 weeks. Among them 257 responses were used for the material analysis except for 20 untruthful responses. The questionnaires were composed of 74 questions and every category used a single balanced 5 point Likert scale for the simplification of answering. Also the responders were anonymous. The collected data was worked on at SPSS 11.0 program.

3.3 Independent variables

3.2.1 The Association of Operational Strategies of e-learning and Management Strategies

As a result of the previous study, a great deal of references emphasize on the importance of strategy. [21]

Chandler identifies that strategy is a basic long-term goal, purpose, and the crystallization of both allocation of resources and behavior patterns in order to achieve them while Ansoff defines it as the decisions, rules and guidelines of deciding the scope of an organization and its growth direction.[2] In addition, Porter (1985) expands on this meaning by stating that it includes the steps organizations take for competitive gains.

Company education is eventually designed to achieve the high performance level a company aims at by fostering its employees' individual capacity and the company in the long run can specify the strategy of the company. Therefore, the meaning of strategy in this study is dealt with as a guideline which encourages the members of an organization to perform targets for organization's goals in order to gain a competitive advantage in the transition environment. Accordingly, the association of e-Learning strategy with other management strategies in an organization has been highly regarded. We have decided that not a temporary measure but a long-term operational strategy is required to gain the source of competitiveness.

For the association of strategy between e-Learning and management, we have measured the existence of a direction which can measure whether the practice of e-learning is helpful for the organization's goals and the existence of a complementary integration between off-line classroom education and on-line e-learning.

3.2.2 Organizational Atmosphere

The distinction of culture and the atmosphere of an organization has not been clarified. Yet, according to Ashforth the organization culture is conceptually identified as a value proposition shared with the members of an organization whereas organizational atmosphere as a concept shared with the members of an organization. [3] In other words, organizational culture emphasizes basic values, propositions, artificial creation etc which influence each member of the organization and its collective behavior whereas an organizational atmosphere emphasizes the image of the organization of which the members sense.[21] This study has induced two divided factors; one is learning motivation in which the members of an organization recognize their organizational atmosphere[10][19] and the other one is its innovative

tendency.[33]

Learning motivation means in what degree people recognize the necessity of information obtaining and sharing, and to what degree people comprehend the purpose of an organization's carrying out e-learning. Furthermore, they are measured by the degree of recognition that knowledge is competitive, the degree of comprehension shown in an organization that knowledge sharing is mutually profitable, the degree of knowledge obtaining desire, the degree of comprehending an organization's learning purpose, etc.

Rogers identifies innovation saying, "adopted and utilized ideas or practical policy or objects that individual or organization recognize as new" Havelock(1969) expands its scope of meaning saying "Utilization and diffusion of knowledge". Therefore, in this study the innovative tendency is identified as an inclination of utilizing and diffusing knowledge through the adoption of new systems. The innovative tendency is measured by the degree of positive and favorable feedback about the adoption of new systems, and the degree of creation and venture intention, etc.

3.2.3 Reward/ Assessment System

As a result of the previous study, both a reward or assessment system[31] has been proved as influential factors of knowledge management and information systems.

Therefore, we regard these as one factor. In this study, the reward or assessment system means the formalized, objective material and non-material reward provided internally by the organization which are directly involved with learners or organizations for the accomplishment of e-Learning as well as the systemization of assessment rules related to the degree of use.

Looking at the past case study on information systems, the indexes of the actual and intended use of system and

users' attitude, etc were used for the measurement of success. Other perspectives focused on the measurement of cost or profits. Yet, as the accurate measurement of cost or profit is impossible, alternatively, the existence of a developed material reward system such as pay rises, incentives, etc, and the existence of a developed non-material reward system such as promotion, encouragement, recognition, etc have been measured. In addition to this, whether or not there are developed assessment systems of use frequency, of managing the type of used information, of voluntary use, of information satisfaction about the difference between seeking information and received information, and of information comprehension is important.

3.3 Dependent variables

As there are few case studies that clarify the direct or indirect influence of e-Learning to the performance of an organization, it seems to be hard to consider organization performance such as ROI or average profit growth rate, etc as dependent variables. Therefore, this study has been accomplished to discover the influential factors of the performance of individual e-Learning. Also dependent variables of each factor are defined as individual performance which includes user satisfaction [8][9] and the improvement of work performance.[8] The user satisfaction seems to be the more proper indication of the assessment of performance than the degree of utilization when the use of information systems is systematically and traditionally compulsory.

3.4 Hypothesis

H1: The association of strategies between e-Learning operation and company's management enhances the performance of individual learning.

H2-1: The organizational learning motivation enhances

the performance of individual learning through e-learning.
H2-2: The stronger the innovative tendency within an organization, the higher the performance of individual learning through e-learning.

H3: The well developed reward or assessment system of e-Learning enhances the performance of individual learning.

IV. Analysis

4.1 Analysis of Validity and Reliability

This study has been carried out on the factor analysis about concept validity in order to discover whether the abstract concepts that surveyors desired to measure were actually measured by proper measuring tools. In other words, we have carried out a factor analysis of concept validity in order to discover whether the manipulative definition of concepts was proper.

There are no absolute standards defining what degree of factor loading quantity can be meaningful to adopt as variables. Yet, 0.4 and above can be regarded as an average meaningful variable and above 0.5 is considered a very decisive factor.[30] Accordingly, we have arranged 0.4 of factor loading quantity for the distinction validity while excluding a variable of 0.344 which is clustered as a factor but reaching below the standard of factor loading quantity. Also, the result of measuring Kaiser-Meyer-Olkin(KMO) and Bartlett's Test for the validity proof of factor analysis showed Bartlett's test of Sphericity of 10394.926 and its significance level of .000, thus proving the factor analysis was proper. In addition, the measurement of KMO MSA(measure of sampling adequacy) of .921 ($> \alpha=0.5$) appeared suitable to be selected as a variable for analysis.

Generally speaking, Cronbach's alpha coefficient showing 0.6 and above indicates relatively high reliability while allowing the analysis by integrating the entire

variable as one measure.[30] In this study, all the questions showed relatively high reliability of 0.7 and above as a result of the reliability analysis.

V. Results

The results of this study are as follows.

Firstly, the association of strategy between e-Learning and company management which is a strategic factor of e-Learning appear to enhance learning performance. This indicates that when an organization has clarified its purpose of e-Learning and established a guideline of how to efficiently fit each member's ability into the organization individually it shows a high performance of learning.

Secondly, the result of the organizational atmosphere shows the most remarkable feature. The innovative tendency of an organization, covering knowledge management, information systems, organization innovation, etc which were presented in the existing references commonly as very important influential factors, have been declined. Instead, organizational learning motivation has been adopted. It is understandable that the recognition of the necessity of knowledge obtaining and sharing and having positive and active attitudes toward learning give relative significance to the performance of individual learning. However, regarding the fact that the organization's innovative tendency has been adopted as an influential factor can be interpreted in many different ways.

In other words, there are two possibilities estimated of two types companies both adopting e-Learning each with different innovative tendencies, or companies which adopt e-Learning in order to revive a new atmosphere because they have a weak innovative tendency. Therefore, a further study is required regarding this matter.

Thirdly, the reward or assessment system has been discovered as a meaningful factor of enhancing the

performance of individual learning. The original purpose of e-Learning was enabling learners to voluntarily learn without the restriction of time and space. Actually, reflecting that the reward or assessment system affects the performance of individuals, this shows that a certain degree of compulsory learning is required.

VI. Conclusion and Discussion

The significance of this study can be considered from both a theoretical and practical perspective. Firstly, regarding the theoretical perspective, the studies so far have been concentrating on the effect of education by the characteristics of learners whereas this study has tried an approach on an organizational perspective so that we could induce the factors targeting the field of organization management which is related to e-Learning. As a result of demonstration, in particular, the fact that organizational atmosphere appears to be a more significant factor for the development of strategies and systems indicates that Korean characteristics are reflected by the study sample.

Through the examination of three meaningful factors found in the companies which are practically carrying out e-Learning but the measurement of learning performance is impossible, we are able to present an indirect standard of assessing the success of e-Learning. Also, we have discovered an essential requirement enabling prospective companies which will accomplish e-learning to reduce any possible failure. Of course, these factors could not be sufficient. However, this could be utilized as a guideline for the organizations which fall behind but would like to save even a step.

The limitations of this study can be pointed out as follows. The assessment is desirable when carried out objectively but considering the features of e-Learning there are some difficulties of objective assessment, in which it is very hard to measure cost or profit in currency due to their intangibility and it takes time for learners to acquire knowledge rather than showing an instant learning

performance, etc. Besides this, under the circumstance where there is no established method to measure the standardized performance by e-Learning, it is tough to eliminate many other extraneous variables when measured in ROI which is presented as a representative measuring standard. This is the reason this study has selected not organizations but individuals for its analysis unit. As we have considered learners' satisfaction and performance improvement as dependent variables, we believe that a further study which will discover any functional relation between an individual's learning performance and the performance of an organization is required. In addition, I hope more specified studies based on the result of this study will be accomplished in order to discover an association between organizational culture and learning.

Abstract

For the effective teaching, the teacher must monitor the effectiveness and performance of the teaching methodology and techniques. For this purpose teacher can use various tools. The effective teaching can be achieved by using different elements of teaching. This paper proposes a system tools called OCAT-PA – Online Course Administration tool for Performance Analysis. This tool can be implemented as standalone system, client-server system or web enabled system. This paper focuses on the web-enabled implementation of the tool. It also focuses on the involvement of the Application Service Providers. This paper discusses the role of application service providers in the proposed system with benefits.

1. Introduction

In a typical teaching activity, the teacher prepares a schedule of the course and the course material by studying the subject contents, scope, depth required, and the level of the students. He also uses his past experience in this planning. It is a challenging task to manage the work planning as per the schedule. The other essential activities may disturb this planning. The other regular activities apart from only teaching include conducting tests, regular assessment and recording feedback from the students. As such, there is need of some comprehensive tool to manage all these activities in an integrated manner. The development and use of such tool require substantial amount of investment. This paper describes the basic structure of a course for effective teaching, the architecture of the course administration tool, its implementation and role of Application Service Providers in its implementation.

2. Elements of a Course

A course is not just teaching the prescribed syllabus, but it also includes many essential elements, which forms a basic comprehensive foundation for the teacher [1]. The essential components include – syllabus, the topic list from the syllabus, teaching plan, question bank, frequently asked questions, acronyms, notes, slides, handouts, books, resources for reference, research papers, student list, attendance record, performance record, test mark record, etc.

2.1 Syllabus

The university and/or the specific authority prescribes a detailed syllabus. It includes many units with summary of each unit in short. The summary may not specify each and every topic. As such, the teacher is responsible for reorganizing the subject syllabus in accordance with the scope and level of the students. He may include more essential topics, which may not be specified in the syllabus.

2.2 Topic List

The reorganization of the syllabus as per the need results in the comprehensive topic list. The teacher prepares the topic list with the details. The details include book references, research papers, and web reference for each topic.

2.3 Teaching Plan

In teaching plan the topic list is arranged as per the weekly schedule and lectures. A list of the available weeks and topics to be covered is prepared as a teaching plan.

2.4 Question Bank

The teacher prepares a comprehensive list of questions for each topic. The questions are very necessary to assess the depth of understanding of the topics. The questions may include objective type questions, broad questions, short questions, etc. The question bank also consists of the desired answer plan of the question. This question bank is prepared per topic to make it accessible after teaching a topic.

2.5 Frequently Asked Questions

The students normally ask many questions not directly related with the subject. These questions are prepared with actual answers forming a typical FAQ. This FAQ is prepared for the whole subject, not per topic, since it is typically a smaller list as that of the list of subject questions.

2.6 Acronyms

Teacher prepares a list of all the acronyms with meaning and details, related with the subject.

2.7 Lecture Notes, Slides and Handouts

The teacher prepares notes, slides and handouts for each topic. The notes are the well-formatted documents with text, diagrams, formulae and other needed things. The slides are used during teaching for explaining the topic contents. The handouts can be distributed to the students for reference and for taking some notes during the classroom teaching.

2.8 Books, Resources for Reference and Research Papers

The teacher prepares a list of books required during the learning of the subject. He can mark the textbooks and reference books separately. He prepares a list of research papers per topic for reading. He also prepares a list of web references, online articles, web sites and other available resources as a resource list. This list may be prepared per topic or as a whole for the subject.

2.9 Student List and Performance Records

The teacher is responsible for monitoring and evaluating the performance of each student. He prepares list of students with test marks and grading for this purpose.

2.10 Lecture Record

The teacher records the actual coverage of the proposed teaching plan by preparing a lecture record while teaching during a semester.

3. Monitoring the Progress of the Course

The progress of a course can be monitored using the teaching plan and actual lecture record. The progress can be evaluated in terms of the syllabus covered. The teacher supervisor is responsible for regular assessment of this record for each course and accordingly directing the teachers to improve the performance of teaching and planning.

The teacher is responsible for regularly testing the students by organizing the quiz and tests. This will result in continuous assessment of the students by the teacher. From this record the teacher can direct the student to improve their performance and understanding of the course.

4. Structure of the Tool

The previous section describes the essential factor for effective teaching and performance monitoring. Here we propose a system for managing the course called “Online Course Administration Tool with Performance Analysis”

(OCAT-PA). The Figure (1) describes the architecture of the system.

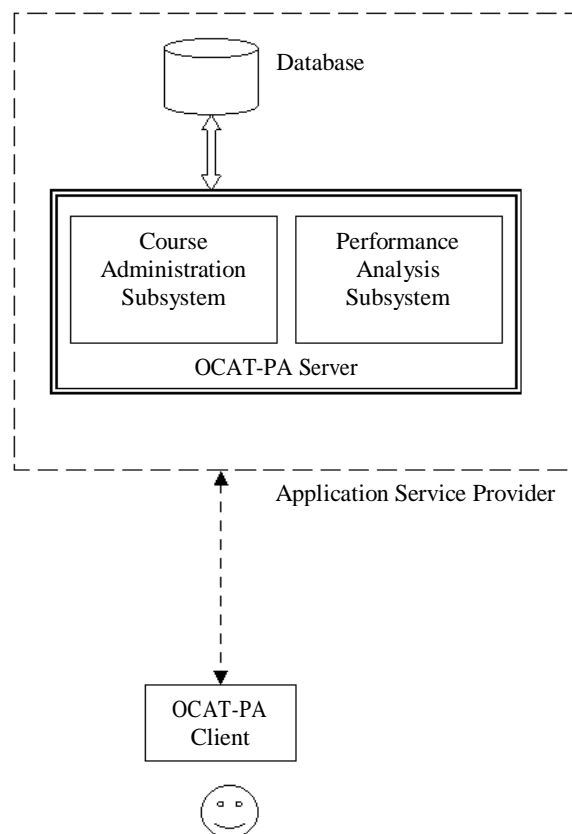

Figure 1 – Architecture of OCAT - PA

The OCAT-PA system consists of the OCAT-PA server and client as it is web based. It also shows central database.

The OCAT-PA server architecture can be assumed in basically two subsystems – Subsystem for Course Administration and Subsystem for Performance Analysis. The figure (2) and (3) describe the architecture of these subsystems.

4.1 Course Administration Subsystem

The Course Administration Subsystem is an important subsystem of the proposed tool. It includes the modules for building and managing elements and aspects of the general course and course administration. Figure (2) describes the detailed architecture of the Course Administration Subsystem.

The elements of a course include the syllabus, topic list, course calendar, teaching plan, question bank, quiz questions, frequently asked questions, acronyms, online notices, notes, slides and handouts, and reading list. The reading list contains the books, references, research papers, etc.

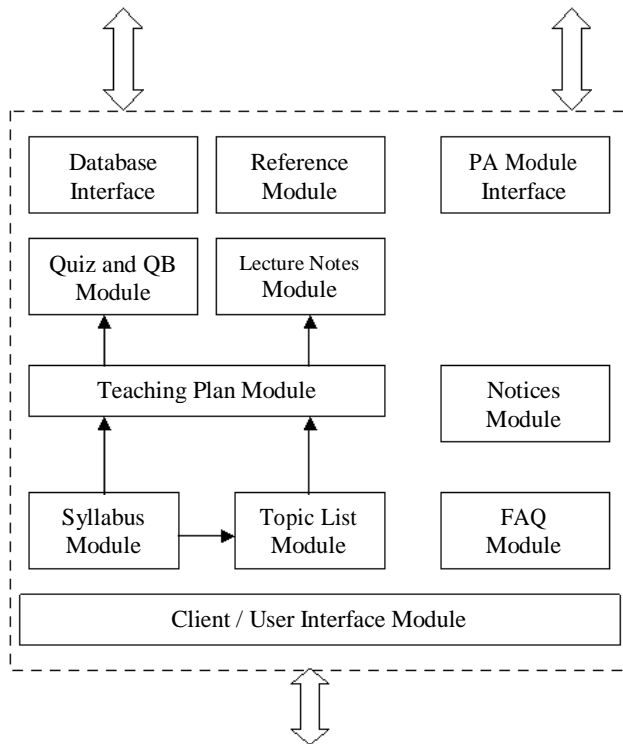

Figure 2 : Architecture of Course Administration Subsystem

The architecture shows many modules, each for handling an aspect or element of the course. It also includes the database interface module needed to communicate and interface the tool with the database. The architecture also shows an interface for the Performance Analysis subsystem.

The client/user interface module is needed to have an interface between the Course Administrative Subsystem and OCAT-PA client.

4.2 Performance Analysis Subsystem

The Performance Analysis Subsystem is a subsystem for monitoring the performance of the various aspects of the system. It includes the modules for managing the lecture record, attendance, quiz and test records.

This module can generate the progress report and various other reports to analyze the performance of students and other elements of the system.

Figure (3) shows the details of the performance analysis subsystem of the proposed tool.

It includes the modules for monitoring the lecture record, students list, students assessment and test records, quiz results, etc.

The architecture shows many modules, each for handling an aspect or element of the performance analysis.

It also includes the database interface module needed to communicate and interface the tool with the database. The architecture shows an interface for the Performance Analysis subsystem.

The client/user interface module is needed to have an interface between the Performance Analysis Subsystem and OCAT-PA client.

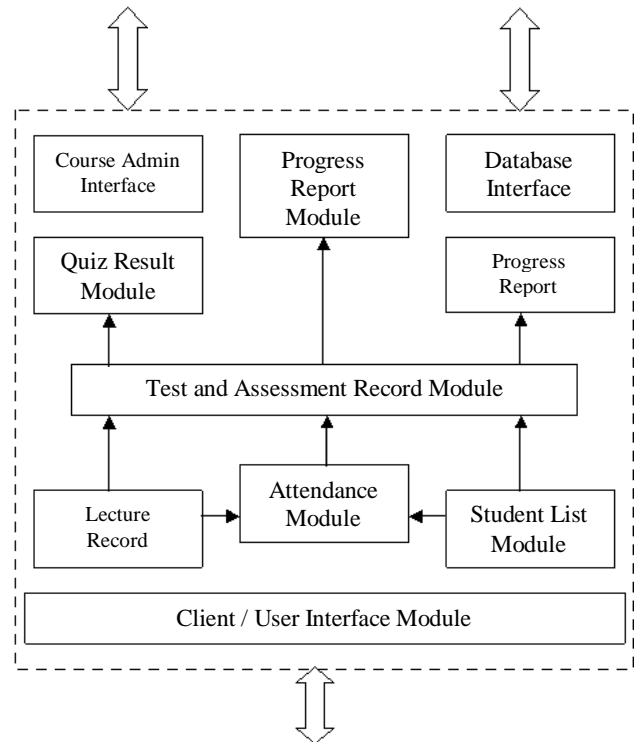

Figure 3 – Architecture of Performance Analysis Subsystem

5. Need and Role of Application Service Providers (ASP)

The teacher can use proposed tool to improve the course administration as well as management of the teaching activity. It will make the activities of a teacher well manageable. But developing and maintaining the system is expensive. It will need huge financial investment as well as manpower in developing the system. The task of maintaining the system is again challenging for the teacher.

The problem can be solved by introducing the Application Service Provider in the OCAT-PA system. The ASP will be responsible for whole development and maintenance of the system [2]. The database in the system will be larger in size and hence needs more effort to maintain and use it efficiently. Due to the ASP, it will be easy to continuously work on the system and make it more effective and better by studying the current constraints and limitations of the system.

The ASP type of business model is necessary where there is need of a common type of software which can be

development and used across many organizations. The software is not needed to be purchased by the organizations but is used through the Internet. The Application Service Provider charges the organization based on the uses of the system.

Due to ASP, the teacher and institute are free from the development and maintenance overhead. The ASP can assist them in various tasks like some data entry and report printing. Due to ASP, it becomes possible to use the system more efficiently.

The online course administration Tool with Performance Analysis system allows the teacher to improve the quality of teaching by providing a better uniform framework for course administration and management. By introducing the Application Service Providers, the system becomes more feature rich still inexpensive.

ASP can design various courses and develop standard study material; which can be useful to the teacher. This will increase the earning potential of the ASP and this way system can indirectly improve the teaching and learning process.

6. Benefits of the Tool with ASP

The OCAT-PA system is itself very useful and effective. By introducing the Application Service Providers the system performance and usability can be improved.

Apart from this obvious benefit, there are several advantages of using the ASP based OCAT-PA system, which are listed below.

- The educational institutes are free from the development and maintenance overhead.
- Due to web based implementation, it becomes accessible from anywhere, anytime.
- The system is inexpensive as there is no need to purchase the software.
- The system can be constantly improved.
- The system provides a standard framework of course elements for a teacher, which can improve overall performance of the teaching process.
- The ASP can provide value added services like pre-designed courseware, expert assistance in managing the teaching plan, etc.
- It provides a feature rich but inexpensive system
- It can improve the inter-institutional relations.

7. Conclusion

The online course administration Tool with Performance Analysis system allows the teacher to

improve the quality of teaching by providing a better uniform framework for course administration and management. By introducing the Application Service Providers, the system becomes more feature rich still inexpensive.

Abstract

Teaching and learning programming language is a challenging task at the undergraduate level. This paper focuses on the basic elements required in learning the programming languages at undergraduate level. In this paper authors share their experience of the development of course material using the multimedia tools. They found that it is difficult to maintain the system, as it requires constant development. They propose a component model in the continuing development of such multimedia courseware incorporating the industry with a business model to support this development.

1. Introduction

In teaching a course the most important aspect is the courseware of the subject. The structure of the courseware depends upon the kind of the subject also. The quality and depth of teaching can be well defined and managed using the quality of the corresponding courseware. Due to advancement in the technology, the newer techniques and tools can be incorporated in developing better courseware for enhancement of teaching.

This paper explores the structure and elements of a courseware in general and explains how they are different for the programming language subjects. It also focuses on the use of newer multimedia and presentation tools in preparation of the better courseware. The paper discusses these aspects in the context of an effort to develop the courseware for teaching and learning the C Language Programming. It also discusses the difficulties and obstacles in such effort of developing courseware. The paper then introduces a new concept of development of better courseware with the help of software development industry based on a business model. This business model is beneficial to both industry and academic institutes.

2. Structure of Courseware

A course configuration includes many essential elements, which forms a basic comprehensive foundation for the teacher [1]. The essential elements include – syllabus, the topic list prepared from the syllabus, teaching plan for the semester, question bank, frequently asked questions, acronyms, class notes, slides, handouts,

reference and text books, resources for reference, research papers for each topic, list of enrolled students, attendance record of the students, students performance record, and test mark record. The figure-1 shows the most common configuration of a courseware.

The syllabus is prescribed by the governing authority like a University. It consists of a broad list of topics and summaries of subject which is expected to be covered in the course.

The topic list is the detail list of topics which are implied by the syllabus. Some topic may not be explicitly specified in the syllabus, but may be needed for deep and detail understanding of the subject.

The teacher then prepares a teaching plan dividing the topic list in the number of weeks and topics to be covered per week. This teaching plan guides the teacher in teaching and managing the teaching during the entire course. It keeps track of the teaching and teaching related activities in the entire duration.

The other essential elements of the courseware include the question bank, frequently asked questions, acronyms, lecture notes, slides and handouts. It also includes the text and reference books, web addresses of the web resources, and research papers.

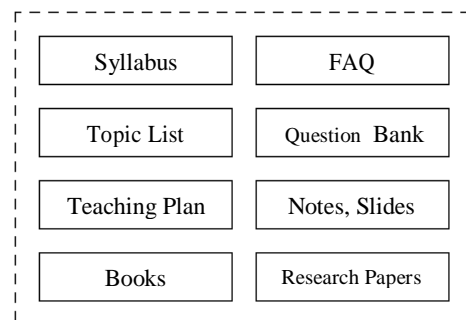

Figure 1– Courseware Configuration

3. Courseware for Programming Courses

The courseware elements discussed in previous section may not be appropriate in the course on programming languages. The programming language learning and

teaching is mostly related to the actual programming. It is mostly non theoretical. Due to this major difference the courseware for the programming language course is mostly different.

The elements of the courseware for the programming language teaching and learning as shown in figure-2, involves the syllabus, topic list, teaching plan, objective questions on programming, questions involving analysis and design of the programs for the given problem, results and variations of the various programs, different version of the program.

The programs involve execution. The courseware should be able to express step-by-step execution with animations and explanations. The traditional approach of courseware development does not have this capability. These obstacles affect the quality of courseware for programming language subjects.

As such the courseware for such subjects should be developed with the help of modern technologies. These modern tools provides facilities to express the dynamic aspects of the courseware. These facilities may be animation, sounds, videos, texts, simulation, etc.

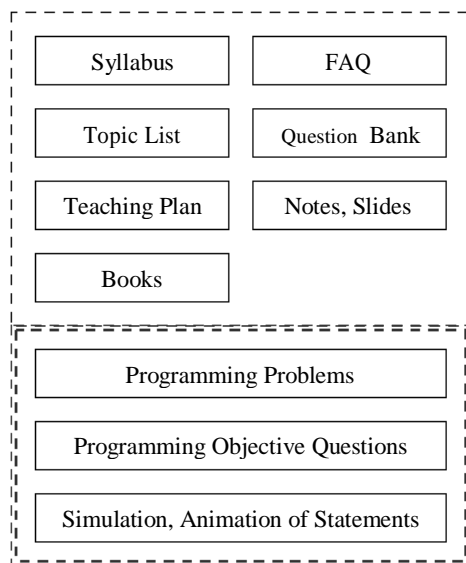

Figure 2 - Courseware Configuration for Programming Language Subject

4. Case Study

This section focuses on a case study of multimedia courseware development for the “C Programming” course [2]. The syllabus specifies, programming in C with basic programming constructs, functions, files, pointers, and advanced programming concepts should be covered.

The syllabus can be divided into the topic list as shown below. It shows about 29 topics. Each topic may be of one or two lectures duration.

The topic list for C Programming is –

- 1) Introduction to programming
- 2) Introduction to C
- 3) C programming basics
- 4) Writing first C program
- 5) Basic data types
- 6) Input and output statements
- 7) Operators in C
- 8) The for loop in C
- 9) The while loop in C
- 10) The do while loop in C
- 11) Conditional statement – if else
- 12) Conditional statement – switch, break
- 13) The goto statement
- 14) Nested loops
- 15) Introduction to functions
- 16) Functions with parameters
- 17) Local and global variables
- 18) Advanced data types
- 19) Arrays
- 20) Pointers
- 21) Strings
- 22) Structure and union
- 23) Basic file handling
- 24) Advanced file handling
- 25) C preprocessor
- 26) Command line parameters
- 27) Unsolved programming problems
- 28) Mini project
- 29) Review

Each topic from this topic list is again divided into some subtopics. For example the topic “Basic data types” can be subdivided as –

- 5.1) Need of data types
- 5.2) List and example of data types
- 5.3) Integer data type
- 5.4) Float data type
- 5.5) Char data type
- 5.6) Double data type

Each subtopic here needs basic explanation, syntax, programming examples, and unsolved problems. For each point many slides with animation are required. These slides or presentations should again be under constant development in order to include more and more new examples and novelty.

The number of such subtopics can be then calculated as 29 main topics x 5 subtopics per main topic. It comes out to be 145 subtopics in total. In practice each topic takes about 5 animation slides. In all it comes out to be about 725 slides for a subject.

Every slide needs to be developed with novelty and with the technical contents. As we want to include more and more examples always, most of the slides will be under constant updating and development.

Each slide needs the development time in the range of hours. For this project in all the total development time is much more.

5. Difficulties

As described by the previous sections, the nature of courseware for traditional is static; where only text and simple documents are sufficient to express the contents. It does not have any need of animation, simulation facilities to express the topics.

But, the programming language subjects are of dynamic nature. Most of the topics in these subjects need the explanation using some sample execution of the program or programming statements. Due to this difference the programming language subjects courseware should be developed in some different manner. In the teaching and learning of computer programming we may develop the courseware which can itself deliver knowledge to the learner even in the absence of any trainer or teacher.

As our case study describes the courseware can be developed in the form of many animated slides. The slides can be developed with many software tools like Power Point or Flash available in the market. Many new tools always emerge in the industry. It is a challenging task for the teacher to learn to use these tools proficiently and apply them in the development of the courseware.

It will be a difficult task for a teacher to self develop and use these slides constantly. As seen in the case study, it will take much time to develop the courseware as there are large number of dynamic subtopics. We can define the dynamic subtopic as a subtopic which needs constant updating. In the programming languages, we need to update the programming example, style of teaching the topics always.

The most significant reason of these difficulties is in the fact that, the multimedia courseware development and teaching with this multimedia courseware are two different aspects and we are forcing the teacher to become multimedia courseware developer.

In order to develop the multimedia courseware for e-learning as well as self paced learning, we need to develop the courseware professionally with the help of industry and utilize it in the actual teaching and learning process.

6. Developing Courseware with Industry

The problems in the development of multimedia courseware of programming languages can be solved by introducing the industry-academic partnership in the development of these courseware. This partnership will enable us to get best of both the worlds.

The development of the courseware can be performed by the industry experts while, the contents of the courseware will be described by the expert persons from academic institutions.

The courseware is one type of software. It is not needed as a whole at a time. It can be delivered in parts also. These parts may be developed independently based upon the topic list of the subject. This will also enable the developer to upgrade a part of the courseware system at a time as well as whole team can work in parallel on the whole project.

The developers have expertise in using the latest software development tools. As such less time is needed to develop the courseware as compared to that of the time taken by the teacher to develop the courseware.

The structure of the courseware, contents, illustrations, examples can be depicted by the teacher. Developer can utilize this information and the teacher's experience in the development of the more effective courseware.

The partnership can be based on a business model. The business model may involve the production and marketing of standard quality courseware. The academic institutes will get their share in the financial aspects.

7. Benefits

Student is the focal point of all the teaching learning processes. The multimedia courseware development for e-learning and self paced learning of the programming languages and its direct use by the teacher while teaching the subject will result in the better understanding and more exposure to the students.

Apart from this direct benefit many other possible benefits are –

- Better and production quality in multimedia courseware as it is developed by industry experts

- Better quality of educational contents as the content is developed by the experts from academic institutes

- It will improve the collaboration between industries and academic institution

- Increased number of programming examples can be possible since a team is working on the development, not only a teacher

- Industry can make collaborations with many academic institutes which will result in more

detail and better quality of technical and educational contents in the courseware.

The industry can constantly work on the development of the courseware; producing more effective and high quality courseware.

The development time needed for the courseware development will be much less than that of the time taken by the development within academic institutes.

A faculty can be involved in the development of more than one courseware; which was difficult with the development within the academic institutes.

As the courseware is in the form of a multimedia presentation product for e-learning, it can be marketed. This will result in revenue generation for the academic institutes.

The multimedia courseware will also be available for the other people outside the academics.

The other people which will use the multimedia courseware for self learning and not involved in academics, can avail the excellent faculty indirectly.

This system will produce the courseware which will be suitable for the distance as well as continuing education

This approach is so beneficial that its application in other areas will also result in better quality learning material.

- [2] Brian W. Kernighan, Dennis M. Ritchie The C Programming Language (2nd Edition), Prentice Hall 1988

8. Conclusion

Multimedia courseware is the most important aspect of teaching programming subjects. This courseware can be developed by the teacher himself, but this will not produce production quality courseware. The academic collaboration with the industries in the courseware development will result in production quality, better courseware. This courseware will be in the form of self learning package. It will be beneficial for the people who want to avail good faculties and learning facilities.

This collaboration of industry and academic institutes will improve the penetration of distance and continuing education of computer programming languages.

This approach will be beneficial not only in programming subjects but all other courses also.

Abstract

The paper suggests a framework advocating an integrated approach to software development stipulating the interconnection between Design, Organization and Business value networks (DOB). These three focus areas span collaborative development processes applying a range of facilitating tools, including distributed knowledge management product state models. The paper draws upon a series of discussion with Scandinavian IT Group (SIG). With an interest in how performance in their new organization develops SIG invited the research group to study measures of organizational performance and the use and effect of knowledge management tools in software development. The paper does not represent the viewpoint of SIG but outline our framework and major research questions. The paper is a research in progress contribution.

1. Introduction

Upon explorations within an action research framework in a software developing company the objective of this project emerged as a contribution to knowledge management enhanced vigilance and flexibility in software development upon further “Studies in Requisite Information Collaboration and Knowledge Management” (SIRICUM). Action research stipulates that researcher and practitioner have a common interest in addressing a select set of problems expecting to find how the company may better take advantage of resources, tools for project management and for distributed collaboration, developing fitting and efficient knowledge management practices. Knowledge management methods, mechanisms, and practices are captured in a framework, DOB (table 1) for analyses of integrated development processes.

1.1 Case Company: Scandinavian IT Group

Scandinavian IT Group (SIG) with 45 years of experience in building complex and business critical systems specializes in the development, maintenance, integration and operation of IT-solutions for the international airline industry, as well as for other service-oriented businesses, committed to continuously seek new ways for these industries to improve their overall performance.

SIG (www.scandinavianit.com) employs more than 1300 people and has a turnover exceeding USD\$ 200

Million. SIG has developed more than 600 business solutions for the airline industry covering all core processes of an airline, ranging from management and planning activities to ticketing, check-in and aircraft handling, and delivering cost savings as well as expanded airline customer services. In particular, SIG delivers airport and enterprise solutions. Airport solutions vary from mobile self-service applications to security and airport administration solutions. The enterprise solutions seek to support basic enterprise functions fitting the client organisations' needs technologically and financially. Within infrastructure management SIG delivers world record-breaking service levels for mission critical non-stop operations on all major platforms and advanced desktop, messaging, helpdesk and support services.

2. Positioning the Research

Inspiration derives from a decade long research at Carnegie Mellon University where the “n-dim” group pursued in particular, information flows in product development in engineering manufacturing and recently has taken up their ideas in the context of workflow management systems and computer support for cooperative work applying the concept of information spaces for new product design teams (see: <http://www.ndim.edrc.cmu.edu/paperstop.htm>). This group has stressed the importance of participant action research as a necessary approach to develop models of information and knowledge management in relation to design and development. Their studies in product manufacturing engineering may not carry over to software design but may offer relevant lessons on design teams in product development and their collaboration with other units in the company (e.g. engineering services support, development and research support). We suggest an extended model to the n-dim incorporating distributed knowledge management within the business value network. Further, we also study the information flow (as one type of workflows) and how to conceive of knowledge workflows and (other) collaborative workflows (Majchrzak et al 2000).

Another inspiration we draw from studies at Trento University where a group of researchers supported by European funds is studying the implication for architecture and technologies if adopting a social and subjective rather than an objectivistic epistemology of knowledge (Bonifacio et al 2002). They explore the

enterprise portal as a distributed knowledge vehicle contingent upon a context description language with partial mappings between the local community (the team) and the organization wide context using links to semi-automatically map the one on the other. To overcome problems and limitations of simple matching this group suggest communication protocols to implement meaning negotiation between autonomous software agents. To bridge organizational units a broker is suggested to enhance the ability of a team to exchange knowledge across semantic boundaries. Like the n-dim group the suggestions of vehicles to cope with complex social interaction are confined relatively to the work group (design team) whereas the wider organizational universe is treated as a homogenous (outside) group.

In Denmark, our long running tradition on socio-technical studies has been complemented with studies in software process improvement using the standard capability maturity model (CMM) (e.g. Mathiassen and Sørensen, 1996, Kautz et al. 2001). Another line of research is knowledge mapping where identification of who-has-what-knowledge takes precedence over information and knowledge workflows (e.g. Eppler 2001, Nielsen and Pries-Heje 2001/2002).

3. Research Method

In our framework we expect to move beyond the technology-for-all issues of knowledge management in enhancing efficiency and effectiveness in software development where collaboration takes the form of participation, cooperation and partnerships. We employ a principle of inter-disciplinary teams of researchers each with a focus on the process-structure dualisms related to our framework.

Research will apply tools to capture and measure the organizational developments to discover ways of working and collaborating within SIG in using the RUP methodology and other support tools learning how the organization explore business opportunities and fulfil customer requirements.

From observations and data on workflows, ways and means of collaboration, and information flows within “groupings” (i.e. teams, organizational units, projects and subprojects) at SIG we develop four studies described below. To increase the value of each study we coordinate our research within the DOB framework and develop suggestions how to explore and exploit knowledge management issues and opportunities to enhance organizational learning, flexibility and adaptability.

The DOB Framework	Conditions	Process	Performance Objectives
Design	Resources Structural and process conditions	Project management Participation Goal achievement	Operational effectiveness
Organisation	Entrepreneurship Commitment Ownership	New services Decision support Coordination	Process effectiveness
Business Value	Purpose Finance Business Partners	Assets management Form of competition Partnerships	Business effectiveness (profitability)

Table 1: The DOB Framework.

The table reflects processes of application development present in all software engineering though not always highly integrated. We do not consider design, organization and business value network as stages in development but as relationships decisive to improve the business value of software engineering processes by collaboration based alignment of units responsible for the software development where software is both product and process to the designers, to the implementers as well as the end-users.

The research group collaborates with SIG management in developing appropriate interventions and experiments in using tools and in applying principles derived from our studies. On workshops and seminars with SIG we will discuss findings on organizational performance and develop suggestions of new knowledge management tools, guidelines and organization as part of the overall action orientation. Finally, we will develop our framework as a research synthesis along with other research findings.

4. Research Contribution

Competitive advantage from innovative application development requires an integrated framework for software engineering.

Our research questions are the following:

- A: How to apply workflow models for distributed design activities using collaborative tools in a virtual organization?
- B: How can pre-requirement specifications be enhanced by business value network methodologies?
- C: How does the methodology of workflows and knowledge flows reaching into the business value proposition contribute to software design processes?
- D: How do distributed knowledge management models add new insights and understanding to our methodologies and models of development of software?

The relations and interactions between the three focal objectives condition collaboration processes and tools.

Beneath, we outline our research questions.

4.1 Question A: The Design Process

We will look at the *design* process as a *participatory* process with distributed knowledge and information workflows reflecting development activities in a virtual organization.

Workflows with distributed activities have been used for many years as buying, production, selling, logistic, and management often are distributed activities usually manually supported by computers' information processing. Today distributed activities forming inter-organizational systems require integrated applications in business value networks. Many different transaction models have been proposed as a tool to manage requisite information workflows trying to relax the ACID (Atomicity, Consistency, Isolation and Durability) properties in order to get better performance, parallelism, and availability (Frank 1999, Frank & Zahle 1998).

In coping with ACID properties in design, we will explore how CSCW systems and workflows support distributed software engineering and knowledge management. How are relaxed ACID properties used in innovative solutions to requisite information interchange within collaborative design processes (Majchrzak et al 2000)?

The design process is collaborative taking advantage of tools (e.g. e-mail, conference systems, web-sites, document sharing, subject catalogues, keywords) vital to the progress and coordination between groups of developers and users. Successfully to choose and implement appropriate groupware in distributed collaborative settings implies getting distributed groups to collaborate on select, relevant issues in their work, which we position also as a knowledge management issue focusing on distributed development organizations.

4.2 Question B: The Organization Process

The relation between *design* and *business value network* emerges from the perspective of strategic alignment, which, in its current form is constrained by the fact that IT-designers - and in particular IT-design projects - rarely have the mandate to develop or to critically examine and evaluate business related IT-strategies.

The challenge, how to get designers into business process modelling and how to get business consultants into design, has rarely been realized though often been advocated. In a deductive and linear system development approach business objectives have been transformed into requirement specifications with little reference to business value opportunities. Adoption of a pre-assessment approach (e.g. MUST, see Bødker et al 2000) with enhancements of performance-based procurement measures transform the relationship between design and business value networks, if properly supported, into a multi-dimensional framing of efficiency and effectiveness of software development processes.

The research questions addressing these issues include

which characteristics of value may be defined, and to what extent and how are these characteristics of value supported in the development process?

4.3 Question C: The Business Value Network

A study of relationship between *organization* and *business value networks*.

Development of business value networks requires value measures and to link these to the design of software using models and methodologies. Within a distributed knowledge framework these values would reflect various patterns of knowledge representing emergent and maintenance spaces and types of knowledge, cf. figure 1 (Davis et al 2001).

In previous research a product model methodology has been suggested as a mechanism to interrelate business value, application development and *design*, addressing exchange of emergent as well as maintenance knowledge and exploring how product model development processes may strengthen both value networks and organization of information systems development (Pedersen and Larsen 2001, Pedersen 2002).

Models Supporting Knowledge Exchanges of Emergent and Maintenance Knowledge

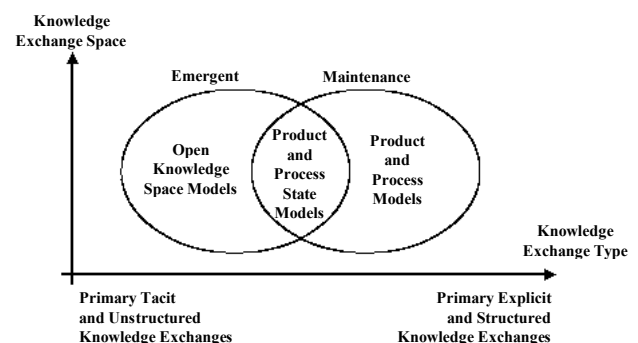

Figure 1: Models Supporting knowledge Exchanges of Emergent and Maintenance Knowledge.

In relating product models to workflows (cf. Larsen 2003), a synthesis of process and product models may be explored proposing a knowledge management tool for quality assurance in SW development and fulfilment processes.

In the DOB framework development processes are distributed, so we need to research if a product model approach is valid across several contributing business lines and business partners. How to integrate the stakeholders in a product model at the level of both transactions and knowledge exchange represents both a practical and a theoretical challenge extending the question how knowledge management systems support communication and analysis in design teams (Gray 2001).

4.4 Question D: The Integrated Software Development Framework

This research question focuses on our very framework. It is the ambition of the researchers to learn from practices in SIG, eventually to suggest a range of approaches and tools in an effort to enhance software engineering quality, systems development and collaboration between participants while attending to business value networks. The framework ignites a range of activities broader in scope than most design projects, yet required in application development for business networks. We will explore iterative and recurrent activities across design, organization and business value networks (Simonsen 1999).

Moreover, we will epistemologically test the framework parameters to evaluate the robustness of the framework. In our action research issues found in practice will inform our synthesis with the ambition to generate positive performance effects in practice.

5. Perspectives

The four issues have been described in terms that reflect both questions of design, organization and business since we perceive these as highly interrelated and therefore to be studied in close connection.

Though guided by the DOB-framework the research activities will reflect back upon this framework inspiring revisions and suggestions. From the project activities studied at SIG we will add new mechanisms to help specifying the framework making it more useful and powerful to both practice and research. How far does the framework take us towards an integrated methodology? By which mechanisms and tools does the framework come alive to customers, managers, users, developers and designers? And how do we as researchers ourselves take advantage of the framework in designing and implementing our research?

Abstract

Customer Relationship Management (CRM) is increasingly important since the emerging of electronic commerce in the past years. However, most of the current researches that deal with the decision-making problems of CRM system investments are from the perspective of the information technology adoption and organizational innovation. It is still very difficult for enterprises to measure the value of CRM systems and the subsequent decision-making on adoption priority of various CRM functions. Based on the Value-focused thinking and Quality Function Deployment (QFD) process, this paper developed a multi-layered transformation matrix, and proposed a measurement process that can be driven to a quantified value model. In order to verify the effectiveness and feasibility of the model, twelve CRM experts were interviewed including senior managers in leading management consulting companies, CRM system providers, and market researchers. Following the on-site interview, a questionnaire survey was conducted with 1000 firms in the list of the Common Wealth top 2000 firms of Taiwan. The analysis result based on 188 valid replies indicates that the outcome of the proposed value measure model has significant correlation with the investment intention of CRM systems.

1. Introduction

The widespread internet technologies and e-commerce applications create a great opportunity for business organizations to communicate with their individual customers at a much lower cost than the past. Companies recognize that Customer Relationship Management (CRM) is essential to business today. According to the CIO research reports of CIO.com in 2002 [6], approximately half of the 224 survey respondents have already implemented or are in the process of implementing CRM. "CRM is the future," said one CIO surveyed. "It is necessary to stay competitive."

The CRM technology market is rapidly evolving, and new technology advancements in e-mail response, data management, business intelligence, personalization, and profiling are happening all the time. The Internet challenges firms to create compelling customer experiences and tap new efficiencies. More and more

companies try to use customer service as a competitive weapon and put heavy investment in CRM systems. Unfortunately, Nucleus Research [21] has found that one in eight CRM deployments fails to achieve a positive ROI, and the biggest barriers to a positive ROI are launching a project without attainable business objectives and investing too much time or money in a solution.

Just like most of the IT investment, most of the current researches focus on technical-economic view of CRM adoption in reducing transaction costs, streamlining process efficiency, and getting competition advantages. Unfortunately, many CRM applications are priced based on vendors' internal revenue targets – and not on the value the solution provides. [21]

How companies evaluate their CRM needs and the value of CRM systems? "Conventional approaches to decision-making focus on alternatives." Keeney [11] argued in his book: "Values are more fundamental to a decision problem than are alternatives. Alternatives are the means to achieve the more fundamental values." Keeney illustrates the concepts and procedures of "Value-focused thinking" and various selected applications that including the choice of NASA space missions, transporting nuclear waste, research on climate change, air pollution in Los Angeles and design of integrated circuit testers. This methodology is also applied to the complex strategy decisions of British Columbia Hydro, Power Authority [12] and the internet commerce [13].

Keeney measured the value of e-commerce to the customer through "Customer Values." He interviewed over one-hundred individuals about all the pros and cons of using e-commerce that they experienced or envisioned. The results were organized into 25 categories of objectives. These categories were separated into 16 means objectives and 9 fundamental objectives used to describe the bottom line consequences of concern to customers [13].

The present study extends Keeney's methodology and creates the value model for CRM system that including two dimensions—customer values and business values. Through value-focus thinking and QFD, This paper also develops an actionable process to measure the CRM systems value.

2. Develop the value Model of CRM system

Customer value analysis is the start point of marketing research [10]. Businesses frequently use the concept of a value proposition to characterize the combination of end-result benefits and price to a prospective customer from purchasing a particular product or service [13]. It is also important to one to one marketing and business management [1][16].

Keeney's approach shows the way to measure the customer value of a product or service. For CRM systems, we need to consider not only just the end customers but also the organizations adopt the CRM systems. The business firms or organizations are the final decision maker of CRM system investment, not end customers.

"Who will benefit from CRM system?" Almost all of the people interviewed by the authors would agree that both the customers and the businesses that invested CRM system should be benefited. The values of CRM system to business is named as "business values" of CRM system in this paper. For the business value, we define it as the value proposition to characterize the combination of end-result benefits and price to a prospective business organization from purchasing a particular CRM system.

A common value model is the additive value function. We define the customer value of CRM is the sum of the value to end customers and the value to businesses.

$$V_{CRM} = V_{Customer} + V_{Business} \quad (1)$$

The equation (1) is very simple and straight forward. But the question is how to measure customer values and business value of CRM systems. Since the CRM system functions should meet customer needs, and create benefits to business through CRM processes and system functions for lower operation cost, streamlining process efficiency and increased sales or profits. Quality Function Deployment—QFD will be the idea methodology to convert the fundamental customer values to the necessary CRM processes and CRM system functions, and finally the benefits to businesses.

Since 1966, Quality Function Deployment (QFD) has been used world wide in every industry and sector to: prioritize spoken and unspoken customer needs; translate these needs into technical characteristics and specifications; build and deliver a quality product or service. Hauser and Clausing illustrates the QFD process is a chain of "What" and "How" conversions and translations. It will end up to a completed "House of Quality" [9]. In order to build the "House of Quality" and get the fundamental business values of CRM system, we need to link the customer needs to CRM processes and then convert the processes to required CRM functions. Figure 1 illustrates the process of these conversions. There are three steps (or three levels in the "house of quality"):

1. Link the customer needs (the customer values or fundamental objectives) to the means that businesses used to satisfy customers (the means objectives).
2. Convert the means objectives to related CRM processes.

3. Convert the CRM processes to related functions of CRM system.

Before we start to implement these steps, we need to understand the various deployment factors in above QFD process.

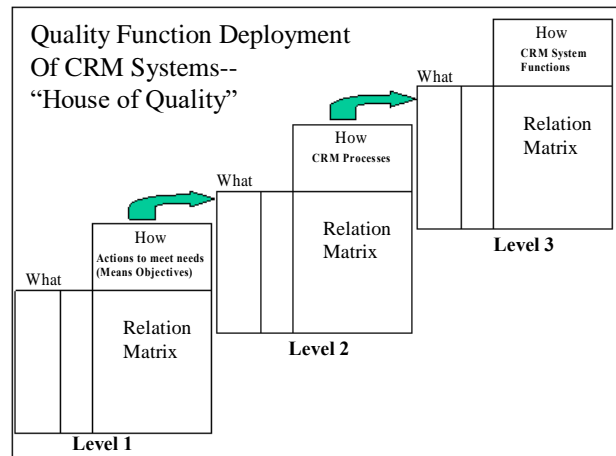

Figure 1 QFD process for CRM system

2.1 Customer values

"The best way to find out the customers value is to ask them." Keeney uses concepts of value-focus thinking in three steps [13]:

1. Develop a list of customer values,
2. Express each value in a common form,
3. Organize the values to indicate their relationships.

The results are a set of means objectives and a set of fundamental objectives. The fundamental objectives also provide the foundation for developing a quantitative model of customer values.

Base on the research result of Keeney, the authors collect other 8 papers regarding the customer values of product or service, and summarize the customer values into 8 fundamental value categories (fundamental objectives) in Table 1 [4][5][7][8][10][13][14][18].

Table 1 Fundamental customer values

Reference	13	7	8	14	18	5	10	4
Customer values								
Offer multiple services		√			√		√	√
Assure reliable service		√	√			√		
Minimize cost	√		√		√			√
Minimize time spend	√	√	√	√	√	√	√	√
Maximize service hours		√			√			√
Maximize convenience	√	√					√	
Maximize safety	√	√		√				
Maximize personal service			√			√		√

According to the approach of Keeney's value-focus thinking, these 8 fundamental objectives is defined as the customer value of CRM system and will be used in the first level of QFD (see appendix 1). The 16 means objectives developed by Keeney are reviewed and are used for presenting the action of businesses to meet

customer needs.

2.2 CRM processes

Peppers et al. [16] explain the four steps in the implementation of one to one marketing, which including Identify, Differentiate, Interact and Customize. The first two steps are the process of internal analysis of businesses. The other two processes are the implementation processes. For step one, enterprises need to define the target customers and record the custom, preference and shopping behavior. Step two is using 20/80 rule to find out the most profitable group of customers. It is very important to treat them differently so that the company can keep the customers and make more profits. Step three is to establish the interactive and automatic communication channel with customers. Enterprises can deliver timely information to customers and communicate with customer efficiently. Finally, enterprises should customize their products, services or even company procedures according to the differentiation of customers.

Srivastava et al. [19] define three core business processes in marketing: Product Development Management, Supply Chain Management and Customer Relationship Management. They further explain the detail processes of CRM including the eleven tasks. The other five articles regarding the CRM processes are reviewed [2][3][16][17][19] [20]. The summarized result is shown in Table 2.

Table 2 CRM Processes

Reference	19	17	16	3	2	20
CRM Processes						
Identifying potential new customers	√	√	√	√	√	√
Determining the needs of existing and potential new customers	√	√	√	√	√	√
Learning about product usage and application	√			√	√	
Developing/executing advertising programs	√				√	√
Developing/executing promotion programs	√				√	√
Developing/executing service programs	√				√	√
Developing/executing sale programs	√				√	√
Acquiring/leveraging information technology/system for customer contact	√	√	√	√	√	√
Managing customer site visit teams	√				√	
Enhancing trust and customer loyalty	√	√	√	√	√	√
Cross-sell and up-sell of product service offerings	√					√

In the step 2 of QFD process, the means objectives are converted and linked to the CRM processes (see

appendix 2).

2.3 CRM functions

There are many CRM system providers in the market. The functions of those CRM applications are different. Since there is no unique definition of CRM system, it is very difficult to get a complete list of CRM functions. According to the research report published by Marketing Intelligence Center (MIC, the leading market research institution at Taiwan for high-tech industries), CRM system can be classified to customer interaction system and customer relationship planning system. Customer interaction system can help enterprises to collect customer intelligences through different contact channels (face to face, telephone, web and call center). The customer relationship planning can analysis customer data (data mining) and optimize the customer relationship to increase sales/profit and enhance campaign management. Data mining, Online Analytical Processing (OLAP), interactive web page, Computer Telephony Integration(CTI), Automatic Speech Recognition(ASR), Interactive Voice Response (IVR), Automatic Call Distributor(ACD), Private Automatic Branch Exchange (PABX/PBX), Voice Over IP (VOIP) are various technologies and functions in CRM applications (see Figure 2 and Figure 3).

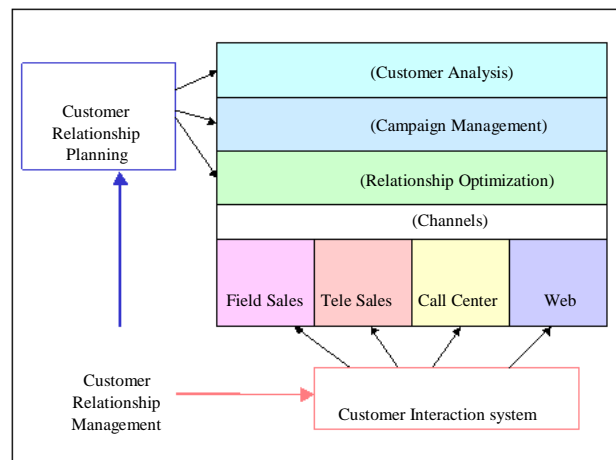

Figure 2 QFD process for CRM system

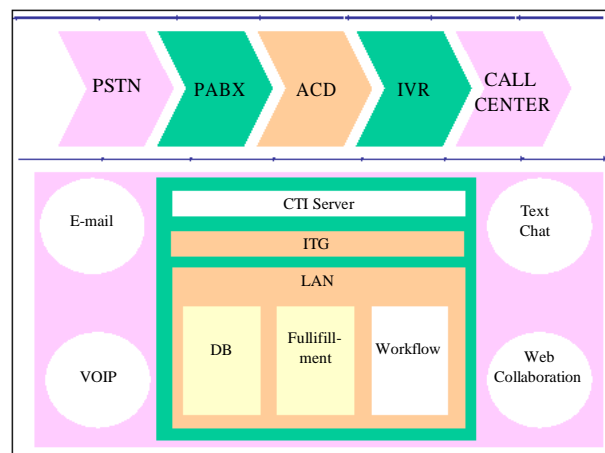

Figure 3 Technologies and functions in call center

Some of the CRM system providers divided their system functions into three areas: sales force automation, marketing automation, Customer-service automation. This definition encourage more software companies convert their conventional business software to the CRM applications. The increased CRM market competition makes the survey of CRM functions more difficult.

With the help from 3 CRM market researchers, this paper survey the product features of 11 CRM system providers including Oracle, eGain, ServiceSoft, ServiceWare, Primus, Quintus, AskJeeves, Kana, BrightWare, PeopleSoft and AKuP. 21 CRM system function categories are summarized in Table 3. In the step 3 of QFD process, the CRM processes will be converted and linked to the CRM functions (see appendix 3).

Table 3 CRM Functions

Web based Service	Help Desk for Service Agents	Sales/Marketing Support
Member Registration/ Identification	Sales Order Management	Market Research Support
VOIP	Customer Profile Management	Support New Product Development
On-line Chat	Data Analysis (Data Mining)	Promotion/Campaign management
Email reply management	Workflow for service agents support	Support Tel-sales Management
Email Auto Reply system	General database information search	Support Direct Sales Management
Web self-service	Customer service Knowledge database	
On-line help (search engine)	Service Agents Performance management	
Sales Automation (Web sales)	MRO service, scheduling and control	

3. Building the value model

The three QFD steps are conducted by authors through the interviews with 12 people with different CRM expertise (see Table 4). The purposes of the interview are:

1. Review the whole process to make sure it is effective and feasible.
2. Verify the completion of the list in customer values, means objectives, CRM processes and CRM functions.
3. Implement the QFD process with the help from independent CRM experts to build a generic value model for empirical study.
4. Follow up Keeney's value focus thinking methodology to covert the 21 CRM functions to fundamental objectives of business value.

The value model and processes are fine tuned according to the comments from those CRM experts. All the forms used in QFD and value-focus thinking are

reviewed and verified. No major defects are found.

Table 4 interviewed CRM experts

Classification	Area of expertise	No of people
Senior managers in leading consulting firms	CRM consulting	2
Senior managers in Market Research org.	market and technology trend research of CRM	2
Senior business managers in finance and telecommunication	CRM system users	4
Senior managers of technology provider	CRM technology provider	2
Senior managers of application provider	CRM application provider and integrator	2

Figure 4 explain the process to evaluate the CRM system through the value model. Enterprises can use the forms in Appendices to measure the CRM customer values and convert the customer needs to CRM business values through Value-Focus Thinking (VFT) and QFD methodology. Different companies might have different relationship matrix and weighting in three levels of QFD. This will enable the firms to build their own value model for their own and meet the needs of different industries.

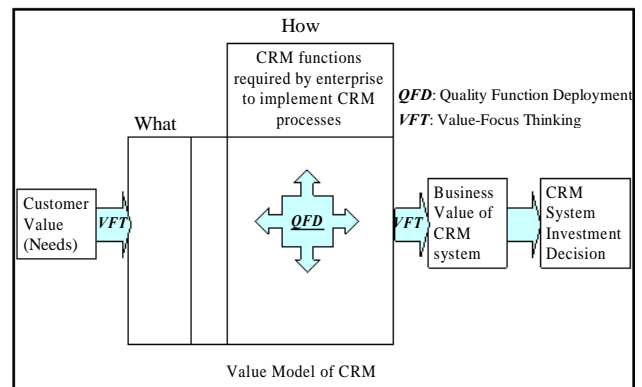

Figure 4 Implementation of VRM Value Model

The value model can provide the foundation for developing a quantitative model of CRM system values. Keeney develop an equation to quantify the customer value in his paper published in management science. Let O_1, \dots, O_n be the set of n fundamental objectives of a specific product or service. For each objective O_i let X_i be a measure that describes the product or service with respect to O_i and let x_i be a specific description. The vector $x = v(x_1, x_2, \dots, x_n)$ provides a description of the product or service and the process to obtaining it. The customer value can be quantified as:

$$v(x_1, x_2, \dots, x_n) = \sum_{i=1}^n k_i v_i(x_i) \quad (2)$$

Where k_i is the weight that indicates the relative priority of objective O_i and v_i is a scaling of the relative desirability (i.e., value) of different values of O_i . During the process of QFD, the importance is the weight that

indicates the relative priority of deployment factors. The weight accumulation and conversion in QFD process could be very helpful to decide k_i for each value factor. The equation of business value is similar to the equation of customer value, but the fundamental objectives (value factors) are different. The business value can be quantified as:

$$v(y_1, y_2, \dots, y_n) = \sum_{j=1}^m k_j v_j(y_j) \quad (3)$$

The value model we defined in equation (1) can be further developed to the following equations:

$$V_{CRM} = \gamma V_{Customer} + (1-\gamma) V_{Business} \quad (4)$$

$$V_{Customer} = v(x_1, x_2, \dots, x_n) = \sum_{i=1}^n k_i v_i(x_i) \quad (5)$$

$$V_{Business} = v(y_1, y_2, \dots, y_n) = \sum_{j=1}^m k_j v_j(y_j) \quad (6)$$

Where γ is the relative weight of $V_{Customer}$. Since there are only two components in V_{CRM} , the relative weight of $V_{Business}$ is $(1-\gamma)$.

4. Design of research framework for empirical study

The main objective of this study is to create an actionable process to measure the CRM system values and help enterprises to make decisions regarding CRM system investment. The above building processes and value model should be able to apply to different companies in different industries. In order to verify the validity of this value model, following the on-site interviews with the CRM system experts and users, an empirical study was designed and conducted.

The hypotheses of the empirical study are illustrated in Figure 5. The independent variables X1 and X2 are the two dimensions ($V_{Customer}$ and $V_{Business}$) of CRM value model developed by this study. There are 8 factors of customer values which are shown in Table 1. These 8 factors are measured by requesting the respondents to answer their perceived importance of each fundamental objective on a 5-point Likert scales. Both CRM experts and the pre-test result of survey suggest that CRM functions will be easier for people to compare the relative importance for business values measurement. $V_{Business}$ is measured through 21 CRM system functions (see Table 3) instead of 10 fundamental objectives of business values. These 21 factors are measured by requesting the respondents to answer their perceived importance to their business for each CRM function on a 5-point Likert scales.

The dependant variable Y is the evaluation result of

CRM system. It is measured by the intension of investment on CRM system (i.e. the possibility of investment). Z is the possible moderator that might affect the validity of CRM value model developed in this study. We define Z as the industry of the respondents' enterprises. The classification of the industry is based on the industry code defined by Common Wealth in the annual survey of top 2000 companies at Taiwan.

The validity of the value model will be verified through the test of three hypotheses:

- H1: The investment possibility of CRM system is highly correlated with customer values.
- H2: The investment possibility of CRM system is highly correlated with business values.
- H3: The positive effect of customer values and business values on the investment possibility of CRM system is consistent for different industries.

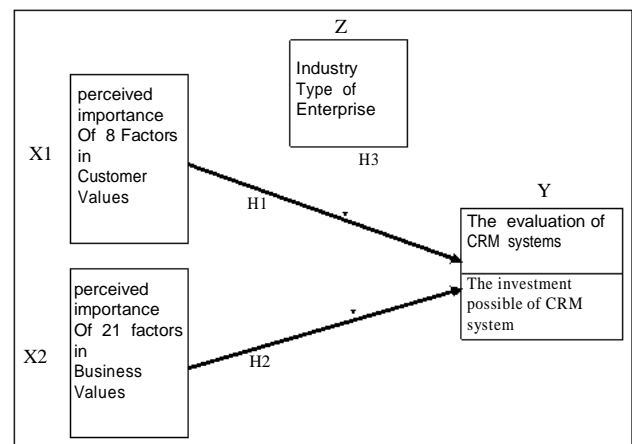

Figure 5 Hypotheses and model of empirical test

5. Results of empirical study

The survey instrument was developed to fit the study based on the literature search, previous interviews with 12 CRM experts and a pilot test. The sampling frame includes a wide range of industries such as computers, electronics, mechanical, automobiles, chemicals, pharmaceuticals, etc. A stratified random sample of 1000 firms was chosen from the database of Common Wealth top 2000 firms of Taiwan. The questionnaires are sent to the managers who are responsible for, or highly involved in evaluating CRM system investment decisions. Two hundred and fifty three questionnaires were completed and returned (25.3% overall responses rate). One hundred and eighty eight questionnaires are usable (18.8%) after eliminated the invalid questionnaires due to missing data.

The Cronbach's alphas of construct X1 and construct X2 are 0.8963 and 0.8013. They are all above 0.70 and demonstrate adequate internal consistency [15]. A series of exploratory factor analysis were employed for the multi-items to further purify the measurement indicators. The method of principle components in conjunction with the latent root criterion, which demands factors with eigen values greater than 1 to be considered significant, was the technique for extracting factors. A cutoff value of 0.5 was

adopted as criterion for screening significant factor loadings. The results were listed in Table 5 and the construct validity is verified.

Table 5 EFA (Principal Component Analysis)

Comp.	Eigen Value	Factor Items	Factor Loading
1.786		Offer multiple services	.644
		Assure reliable service	.637
		Minimize cost	.764
		Minimize time spend	.733
		Maximize service hours	.753
		Maximize convenience	.736
		Maximize safety	.786
		Maximize personal service	.639
1.637		Member Registration/ Ident.	.646

		Support Tel-sales Mgmt.	.767
		Support Direct Sales Mgmt.	.791
		Support New Product Develop.	.762

When $\alpha=0.01$, the correlations among independent variables and dependent variables are highly positive (see Table 6). The positive correlations are consistent across industries. The 188 valid questionnaires covered 16 industries. Since the distribution of the samples in different industries is not the same, the number of samples in several industries is less than 5. A Median Test is conducted to verify the hypotheses H3. The median test result shows $p=0.25$ is higher than $\alpha=0.01$ (see Table 6). This test result confirmed that different industries had same distribution possibility on the CRM investment possibility. The numbers of samples in different industries did not affect the validity of correlation analysis.

Table 5 Correlation Analysis

Independent Variables	CRM investment possibility	
	Pearson Correlation	Sig. (2-tailed)
Customer Value	0.67	0.00
Business Value	0.73	0.00

Table 6 Median Test

The possibility of CRM system investment	
N	188
Median	1.00
Chi-Square	18.32
df	15.00
Asymp. Sig.	0.25

6. Conclusions

The main contribution of this paper is the actionable process to measure the CRM systems value. Different companies can follow the above building processes and create their own value model. Through the value-focus thinking and QFD methodologies, enterprises can understand their customer better and find out the customer values of their product or services. There are several important potential applications of the proposed model: it can help the firms to evaluate the CRM system investment, and it can be used as a decision making tool for adopting priority of various CRM functions as well as for improving the customer management processes.

For academic research, it is still a long way to create a complete value model and to prove the effectiveness of the value model. The equations (4),(5) and (6) could be further developed to compute based value evaluation system. There is not solid theory development and test for the value model and the building process. This study is just a start point. More empirical researches or case studies might be helpful to further develop the research framework.

Prototyping for an E-Learning System of Organizational Procurement

Hsueh-Foo Lin Yong-Xiang Chen Rui-Tai Chen

Department of Information Management
National Pingtung Institute of Commerce
Taiwan, R. O. C.

sherry@npic.edu.tw

Abstract

This paper attempts to integrate concepts of framing, uncertainty expression, and negotiations to build a framework for influencing factors of pricing for organizational procurement and empirically explore it. System requirements based on the framework is analyzed by UML in building an E-Learning simulated system for novices of purchasing via hints from knowledge collected from veterans of procurement. Framework for negotiation of organizational market is built based on literature review of organizational negotiation and in-depth interviews with several top procurement representatives of Taiwanese high technology companies. Popular verbal terms using in purchasing area for possibility frequency and quantity are collected and analyzed, hypotheses for subjective estimation vs. verbal expressions under different types of market conditions, distributive bargaining vs. integrative negotiation, and risk choice framing are tested. The quantitative and qualitative data are collected to construct a verbal model for managerial decision-making on the organizational market. Findings on patterns of verbal expression among purchasing personnel with different backgrounds and risk attitudes might be useful for building a data bank in e-negotiation between buyer and seller. Also the relationship between framing, personal risk attitudes and efficiency and preference of pricing decision for an organizational procurement are proposed to assist the trades between industries.

1. Introduction

In the past years, many organizations have tried to expand or broaden their supply chains in e-marketplaces. Transitioning from traditional organizational markets approaches to an e-business model and adopting new technology present many organizational challenges. Building an Internet infrastructure and attracting more participants initially may not ensure the longevity of an e-marketplace. Risk attitude of purchasing personnel in a company, verbal expression and framing used for communication between buyer and seller are concerned as influencing factors during an organizational procurement.

Subjective verbal expression usually used to substitute digital variables during trade negotiation. Study of subjective verbal expression and framing become very important issues as the traditional organizational market move to electronic commerce via internet. Therefore, this research tries to cover the findings of studies on organizational procurement, personal risk attitude,

personal verbal expressions, framing and decision theory. The research methodology is comprised of three approaches:

- (1) Literature review for building a research framework in organizational procurement.
- (2) Interviews with top-level executives in some leading Taiwanese companies engaged into organizational procurement to validate and justify the Research Models.
- (3) System requirements based on the framework is analyzed by the Unified Modeling Language (UML) in building an E-Learning simulated system for novices of purchasing via hints from knowledge collected from veterans of procurement

2. Literature Review

Nicosia model, Howard-Sheth model, Engel-Blackwell model, Bettman information-processing model, and Andreasen model are descriptive theories and models that attempt to capture buying behavior. These models all share a similar list of six fundamental stages of the buying process. The stages are: (1) need identification, (2) product brokering, (3) merchant brokering, (4) negotiation, (5) purchase and delivery, and (6) product service and evaluation [11]. The merchant brokering stage combines the "consideration set" from the previous stage with merchant-specific information to help determine who to buy from. This includes the evaluation of merchant alternatives based on buyer-provided criteria (e.g., price, warranty, availability, delivery time, reputation, etc.). The major task of negotiation stage is how to settle on the terms of the transaction. Negotiation varies in duration and complexity depending on the market. In traditional retail markets, prices and other aspects of the transaction are often fixed leaving no room for negotiation. In other markets (e.g., stocks, automobile, fine art, local markets, etc.), the negotiation of price or other aspects of the deal are integral to the buying process.

Conflict can occur when the two parties are working toward the same goal and generally want the same outcome, or when both parties want a very different settlement. Multi-issue negotiation may produce mutual beneficial results to both negotiators while single-issue negotiation can not. However, there are difficulties in automating a multi-issue negotiation, since the search space grows dramatically as the number of issues increases. Although many concession strategy learning mechanisms have been proposed to deal with the problem, recent research uncovered that the fixed strategy of

concession and the fixed-pie bias are two major interferences in the automation of multi-issue negotiation [10]. In a single-issue negotiation, the term negotiated is limited to price. Most companies on the Internet are generally against it since it brings out price wars that not only causes chaos in markets but also ignores the importance of other issues such as warranty period and delivery time. Multi-issue negotiation is more beneficial comparing to single-issue negotiation [13].

Considerable research has examined the effects that alternative descriptions or “frames” can have on decision making- particularly how framing influences people’s preferences and choice for reviews [6, 7,16]. Frame that a decision-maker adopts is controlled partly by the formulation of the problem and partly by the norms, habits, and personal characteristics of the decision-maker [17]. According to prospect theory[4], outcomes are experienced as either gains or losses relative to a subjective reference point. Subjective value is predicted to be a concave function of utility in the domain of gains and a steeper convex function in the domain of losses. This S-shaped function implies risk aversion in the gains domain and risk seeking in the losses domain. In other words, prospect theory predicts that people would adopt the *final state* of affairs if nothing were done as their subjective reference point in response to prospects formulated as gains and they would adopt the status quo as their subjective reference point in response to prospects formulated as losses [8].

The traditional models of bargaining [15, 20] relied on the assumptions that the preferences and choices of bargainers’ could be explained by expected utility theory. The general results from these studies are that positively framed bargainers are more cooperative, more likely to settle, and receive greater profits and benefits than their negatively framed counterparts. In keeping with the prospect theory, framing has only an indirect impact on negotiator behavior through its affect on risk attitude. Murningham [12] noted that risk aversion is consistently advantageous only in situations of which settling involves a greater risk than not settling. The study of Schuur [17] confirmed that prediction. Other framing studies showed that positive framing was generally more advantageous.

The study of Bottom and Stud [2] integrate the findings into a more general explanation of the role of framing in bargaining. Framing determines risk attitude. The structure of the negotiation and the alternatives to settlement determine the effect of risk attitude on bargaining behavior and outcomes. Because of the conflict between distributive and integrative aspects of bargaining, negotiators come to a dilemma. Framing and risk attitude affect the approach negotiators take in dealing with the dilemma.

Verbal expression allows that replace digital expression with verbal vocabulary. To get the comparison between different expressions, the method employed was that of ratio scaling. The distinguishing characteristic of a ratio scale is that a true or absolute zero point can be defined; meaningful ratios can therefore be derived. Ratio

scaling uses magnitude estimation in which any value is assigned to a referent concept, and then all other stimuli are judged in relation to the referent concept. Magnitude estimation was employed to find the numerical equivalents of 39 expressions of frequency ranging from never to always, and 44 expressions of amount ranging from none to all [1].

On the attached form of Bass’s study [1], subjects are asked to assign a number to what he/she conceives “sometimes” to mean. Then, using the number which have assigned to “sometimes” as a standard, assign a number to each of the other words on the form indicating each word’ value relative to sometimes. Instructions used the referent “some” instead of “sometimes” when judgments of amount were to be made instead of judgments of frequency. The referent concepts “sometimes” (frequency) and “some” (amount) remained constantly throughout the experiment.

E-Learning is based on three fundamental criteria [14]:

- (1) Networkability: E-Learning is networked.
- (2) Web-based platform: it is delivered to the end-user via a computer using standard internet technology.
- (3) Integrated into a broader architecture of solutions: it focuses on the broadest view of learning-learning solutions that go beyond the traditional paradigms of training.

An E-Learning system will be a strategic business tool to increase business speed, flexibility, retention, and employee satisfaction. The E-Learning system provides a real-time and supporting learning environment for e-Business [3]. Because of traditional trainings can no longer cover all corporate trainings. Instead, E-Learning system will help to provide a more efficient way of delivering information and knowledge needed. Especially now many corporations adjust their paces to become learning organizations, what will most benefit them are knowledge and information.

In Ikujiro Nonaka’s study, the knowledge creation process is the conversion process between tacit knowledge and explicit knowledge [5]. By his definition, explicit knowledge can be expressed in words and numbers and easily shared. Tacit knowledge, such as subjective insights or emotions, is non-articulated, and embedded in contexts and actions. It is personal and hard to verbalize or communicate. Tacit knowledge, such as bodily skills or mental models, is rooted in an individual’s action and experience as well as in the ideals or values he or she embraces. In his SECI model, the knowledge creation process within an organization takes a spiral evolution form, which consists of four types of conversions.

Lin’s Study [9] developed the concept Internal Knowledge Evolution Network to describe the knowledge evolution framework. The study extracts four types of knowledge:

- (1) Comments or remarks on published works.
- (2) Guess or supposition to the solutions for project

problems Supposition.

- (3) Proof or confirmation on the guess or supposition.
- (4) Positive or negative comments or remarks on knowledge 1-3.

These four types of knowledge increase in the process and are dependence on each other. When linking with their context relationships, the knowledge fragments created inside team construct a directed network map. And along the direction of the arrows, pieces of tacit knowledge are continuously created based on previous knowledge, and converse to explicit knowledge.

3. Research Model

A research model for studying efficiency and preference of pricing decision for an organizational procurement is illustrated in Figure 1 based on the above literature reviews. Depth interviews with experts in the industry were employed to validate the research model. The personal variables for a purchasing agent include his/her risk attitude, purchasing ability, gender, age, education, working position in his/her company, and what kind of organization he/she is working on. There four operating variables are constructed in this research. (1) uncertainty expression is represented as verbal expression or digital probability to explore the possible relationship between them. (2) relationship between buyer and seller is divided as bargaining and cooperative. In distributive bargaining, the goals of the parties are initially at odds-or at least appear that way to some or all of the parties. In contrast, in integrative negotiation the goal of the parties are not mutually exclusive. (3) market status is classified as buyer dominated and seller dominated. While there are more firms to provide the same product in the trade, the market status is treated as buyer dominated. (4) framing is

classified as positive and negative. According to prospect theory introduced by Tversky and Kahneman [18], outcomes are experienced as either gains or losses relative to a subjective reference point. In this study, positive framing is designed as the selling price exceeds the average price in the market and negative framing is designed as the selling price is less than the average price in the market.

Purchasing agent's basic variables in this model are designed as follows:

- (1) Risk attitude is classified as risk seeking, risk neural or risk averse.
- (2) Ability of purchasing is classified as high or low.
- (3) Subject's Characters include gender, age which divided as 10 classes from 25 to 65; education is classified as high school, bachelor, master or Ph. D.
- (4) Working position is classified as manager or subordinate.
- (5) Organization is the company that a subject is working for.

A questionnaire built by Wallach & Kogan [19] is used to measure the general attitude of subjects face a choice with risk. The questionnaire contains twelve decision questions which are follow up twelve scenarios. The leading role in the scenario face of two or three probable for choose. One of the choices is attracting with lower probability to success and the other choice(s) reversed. Five methods of purchasing decision problems were adopted and shown as the form on Table 1, which were based on the reference point 35,000 and were coded to evaluate preference and performance of purchasing decision alternatives for each subject.

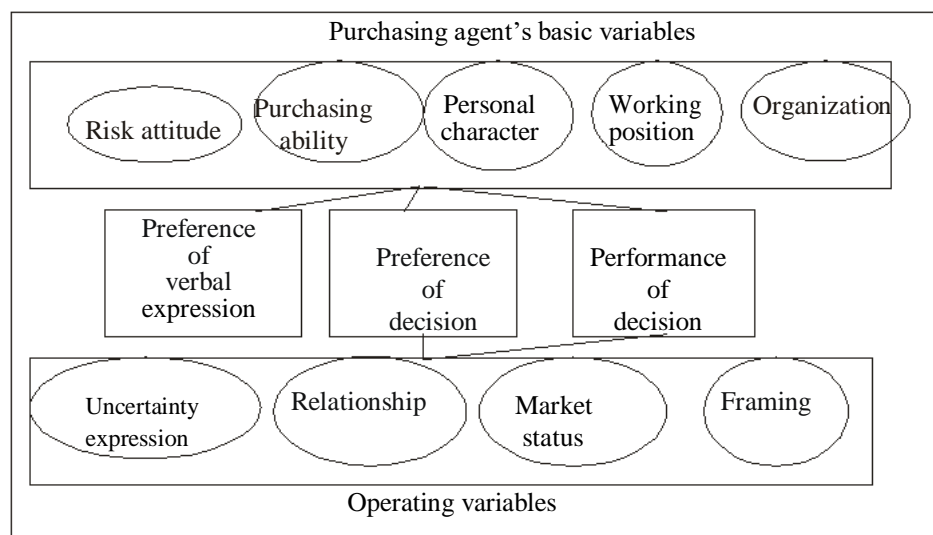

Figure 1. Research model

Table 1. Problem sets of purchasing decision alternatives

Method	Choice Problem	Explanation
I	A (39,000,80) B (38,000)	Scheme A has a higher expected value
II	A (39,000,20) B (38,000,25)	Scheme A has a higher expected value
III	A (41,000,45) B (38,000,90)	Probabilities of winning are substantial. Scheme B is the prospect where winning is more probable.
IV	A (41,000,001) B (38,000,002)	Probabilities of winning are minuscule in both prospects. Scheme A is the prospect that offers the larger gain.
V	A (41,000,25) B (39,000,25; 37,000,25)	Preference of Scheme B is in according with a value function that is concave for gains and convex for losses.

	Frequency	177	270	447
	Percentage	39.6%	60.4%	100%

4. Experimental Results and System Requirements

16 different cases are constructed based on the four operating variables in the model. Pair of choice problems in Table 1 is a variation of Allais' example, which differs

from the original in that refers to real-life rather than to extremely large gains. To appreciate the significance of the amounts involved and the market information, note that the average price for a personal computer is about 35,000 NT dollars. Each method that this study selected has been designed with different outcomes and probabilities.

Five Taiwanese technology companies are selected to survey for validating the Research Model. The companies selected are International Semiconductor Technology Ltd., Koninklijke Philips Electronics N.V., Walsin Technology Corporation, Yageo Corporation, and WUS printed circuit CO., Ltd... Fifty questionnaires were distributed to participants in these companies. 50 participants of the study are agents who are more familiar with organizational procurement in the procurement department of the above five companies. 27 valid questionnaires were collected in this study. Two Hypotheses are proposed as:

H₁: Efficiency of pricing decision is significantly different from Positive to negative framing.

H₂: Preference of pricing decision is significantly different from verbal expression and to probability.

Since the Research Model is justified and validated, the questionnaire survey is deployed next. Items appearing in the question are collect by choices of alternative. Data are collected through a survey of organizations that are actively involved in the planning or operation of e-marketplaces. The respondents were asked to pretend that they were actually making with the choice described as the problem sets, and to make the decision they would have made in such a situation.

In the comparison of personal characteristics of a purchasing agent, effect in habitually practice of Chinese verbal expression on possibility is significant. Hypothesis H₁ is tested by Chi-square analysis shown as Table 2. Result denotes purchasing agents perform a better performance in the positive frame situation. Hypothesis H₂ is also significant with $\chi^2_{(1)}=12.532$, $p<0.001<0.05$. Analysis result reveals expression types do significantly affect preference of purchasing agent's decision. A result also shows a purchasing agent with risk seeking attitude always makes a choice with higher performance than other with other types of risk attitude.

5. Prototyping of E-Learning System

The main advantage of object technology in Information System environments is for facilitating software maintenance and scalability. UML is recently used as a standard to capture modeling artifacts. The object approach to system development follows an iterative and incremental process. According to the proposed research model and findings of this experimental study, a prototype is constructed for training novices of organizational procurement negotiation in this study.

Table 5. Performance of decision

Performance of decision		Risk attitude		
		seeking	neutral	averse
Low	Frequency	23	294	97

There has two main scenario parts within this E-Learning System of pricing negotiation, Scenario Architecture and Scenario Content. This study mainly confer on experimental simulation about pricing negotiation, the scenario architecture designed is as Figure 2. The scenario architecture includes Merchandise, Bargaining mix, Frame, Market status, Relation between the two parties, Uncertainly expression, Negotiation style, and Scenario display of a purchasing negotiation. The challenges and demands come from inside user of organization and learner greatly changed. Negotiation style are classified as peer room when the buyer deals with only one seller and group room when the buyer deals with several sellers simultaneously. Scenario display of a purchasing negotiation is classified as text mode and media mode (text, image with sound). In the text mode, semantic analysis and verbal behavior will be applied to analyze the dialogues the content of negotiation to cumulate knowledge from experienced agents. In the media with audio mode, pattern recognition for sounds of conversations will be added on to analyzes the meaning of dialogues.

System behavior is what a system does when responding to external events. In UML, the outwardly visible and testable system behaviour is captured in use cases. The use case diagram of this study is shown as Figure 3. The class modeling elements include classes themselves, attributes and operations of classes, associations, aggregation and composition, and generalization. Class diagram is constructed from scenario architecture and Use case diagram. The composition of class diagram is described as follow:

- (1) Procurement decision class is composed of Procurement scenario class and Member class. Methods are Decision store and Knowledge collection.
- (2) Attributes of Merchandise are Name and Description; methods are Query Merchandise and Content Link.
- (3) Attributes of Procurement scenario are Frame, Market status, Relationship, Uncertainty expression, and Negotiation style included, methods are Content link, Framing add, Market status added, Relationship added, and Procurement scenario store.
- (4) Attributes Member class are Player type, Name, Age, Occupation, Seniority, Risk attitude, Personality characteristic, Purchasing ability, Position, and Company included. Method of the class is Query member.

The negotiation styles are all designed as Real-time Interaction to mimic the real world of negotiation. Class "Scenario display mode" is a generic abstract class for two concrete subclasses Text and multimedia (text, image with audio). Procurement scenario is linked to Scenario display mode and Scenario display mode. Class "Measurement" is for three concrete subclasses Characteristic, Attitude, and Ability. Statechart model for the class "Procurement

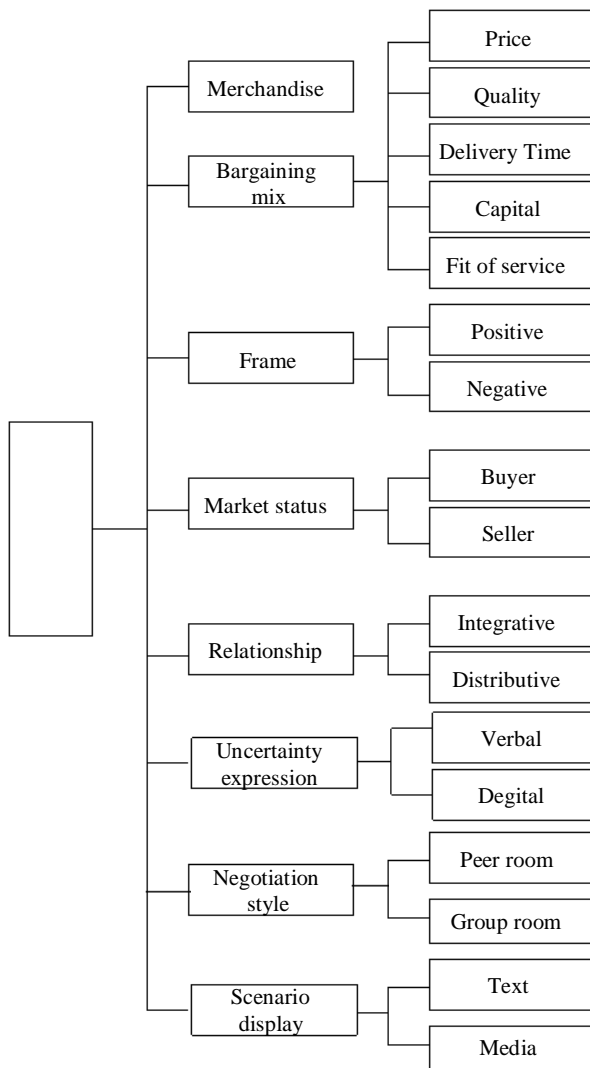

Figure 2. Scenario architecture of E-Learning system

Table 9. Use case description of E-Learning system	
Use case	E-Learning of organizational Procurement
Brief description	This use case allows a member to log in an E-Learning system to making decision for learning with various procurement scenarios. Members include learners and experts as mentor.
Actors	Host, Expert, Learner
Preconditions	Members had invited to the learning and the procurement scenario had been set up by host.
Main flow	The use case begins when the host set up the procurement scenario and invite members to take in by choosing the continue function. The system requests that the member enter the personal attributes. The member making decision and decide it by choosing submits to send it out. The system identifies the member as a learner or an expert, and process the submitted data by different ways. The system transfer experience of experts to knowledge and provide hints for learners from knowledge store.
Alternative flows	The member activates the submit function to making decision. The member chooses the abort to cancel the decision
Post conditions	If the use case was successful, the learning is recorded in the system's database. Otherwise, the system's state is unchanged.

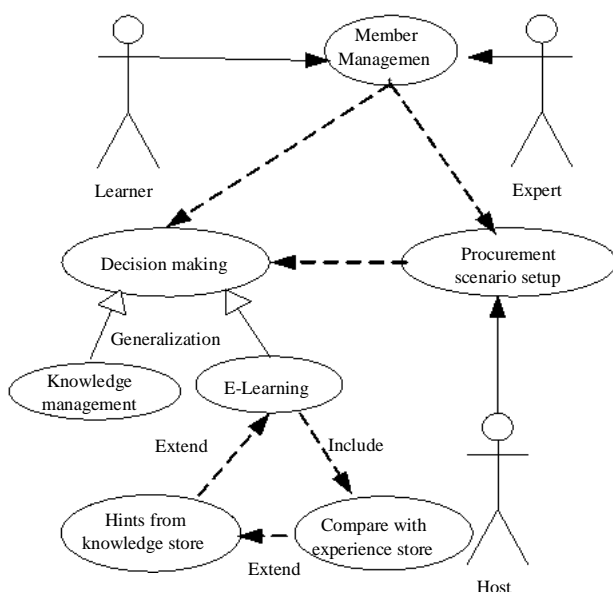

Figure 3. Use case diagram of E-Learning system

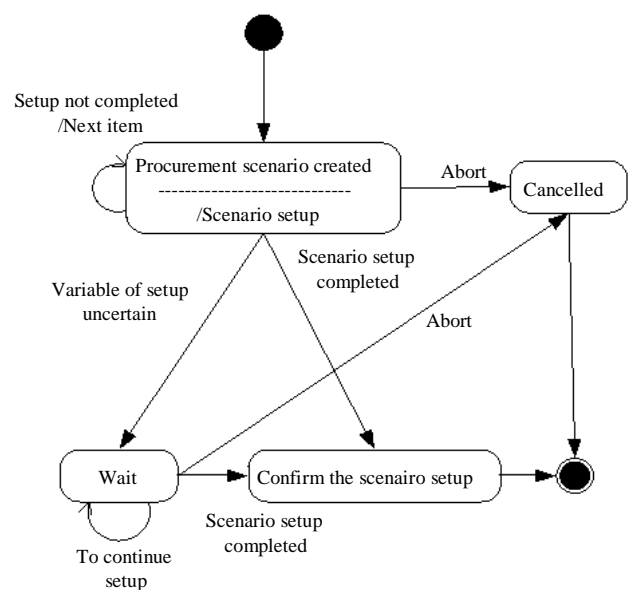

Figure 5. Statechart diagram of procurement scenario

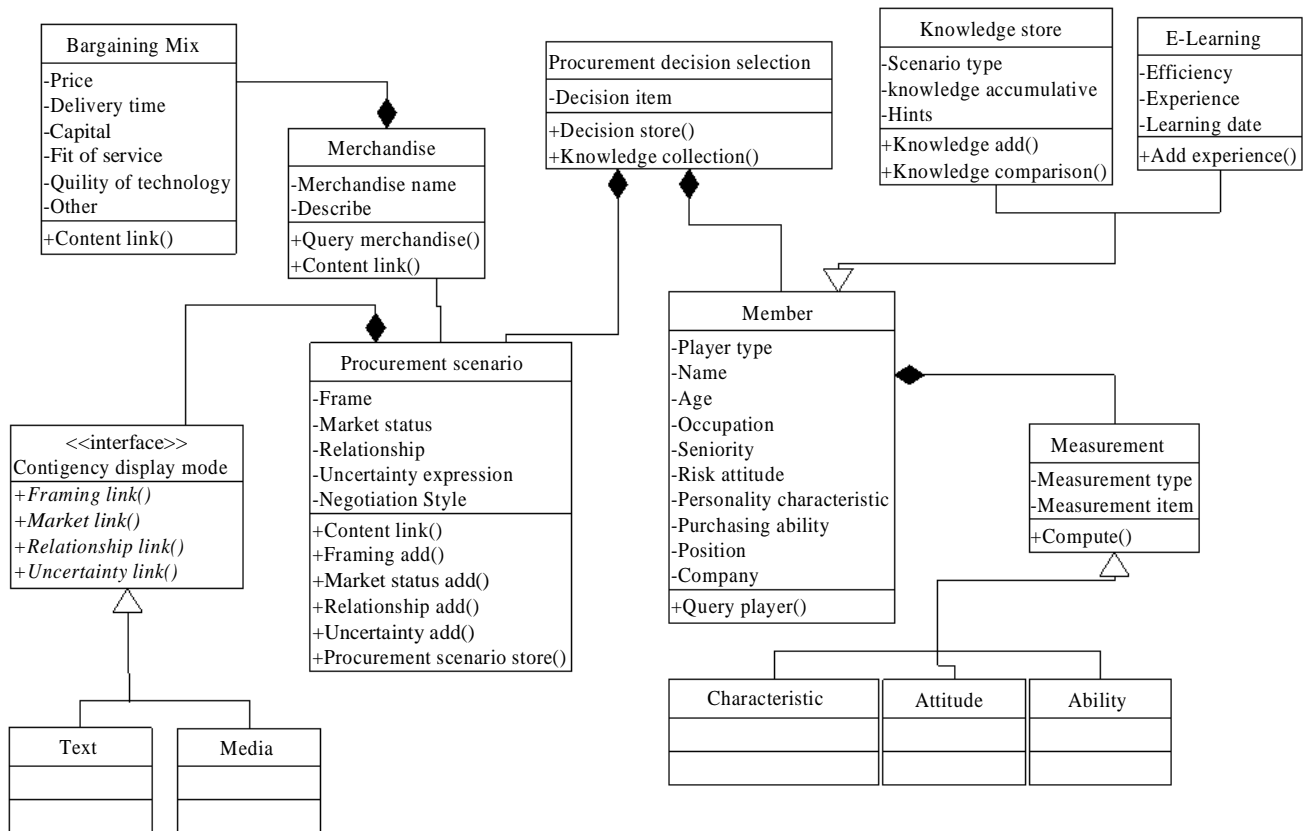

Figure 4. Class diagram of E-Learning system

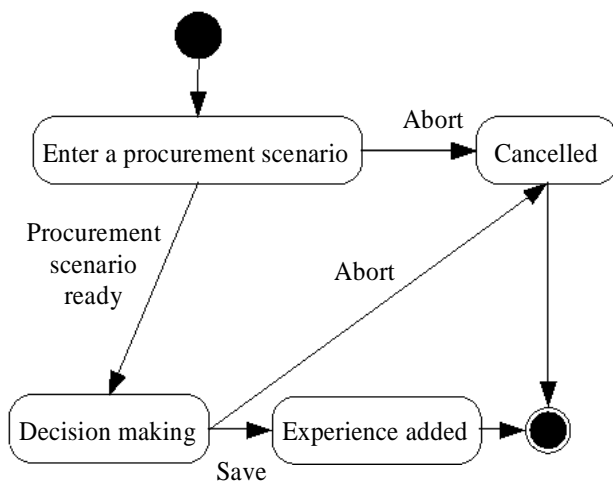

Figure 6. Statechart diagram of Knowledge store

scenario” is shown as Figure 5. The initial state of Procurement scenario is Procurement Scenario Create. There are three possible transitions out of the Procurement scenario create. On the Abort event, the Procurement scenario object goes into the Cancelled state. On the Variable of setup uncertain event, the Procurement scenario object goes into the Wait state. The Scenario setup completed event, when in the Scenario setup or Wait state, fires a transition to confirm the scenario setup.

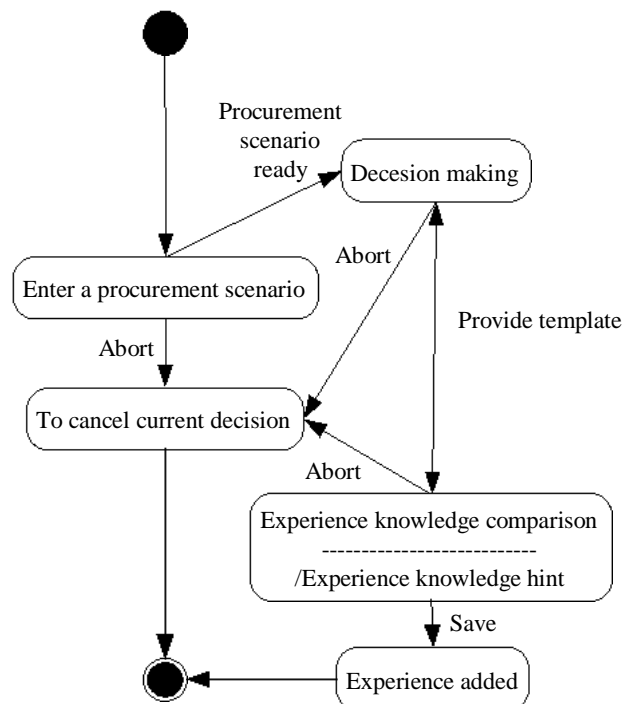

Figure 7. Statechart diagram of E-Learning

Statechart model for Class “Knowledge store” is shown as Figure 6. The initial state of Knowledge store is “Enter a procurement scenario”. There are two possible transitions out of “Enter a procurement scenario”. On “Procurement scenario ready”, “Enter a procurement scenario object” goes into the “Decision making” state. Event of Abort during “Enter a procurement” scenario or “Decision making” state, fires a transition to Cancelled. Meeting event of Save, “Decision making” object goes into “Experience added” state. Statechart model for E-Learning Class is shown as Figure 7. The initial state of E-Learning is “Enter a procurement scenario”. There are two possible transitions out of “Enter a procurement scenario”. “Procurement scenario ready” and “Enter a procurement scenario” objects go into “Decision making” state. Meeting event of “Provide template”, “Decision making” object goes into “Experience knowledge comparison” state and get into a loop until “Learning completed”. During event of “Save”, “Decision making” object goes into the “Experience added” state. Meeting event of Abort, “Enter procurement” scenario, “Decision making” state or “Experience knowledge comparison” fires a transition to Cancelled.

6. Conclusion

Goal of this research is hence to present a research model for influencing factors of pricing decision for an organizational procurement. These factors may create valuable information for e-marketplace administrators to build appropriate strategies for their businesses. The findings on patterns of verbal expression among purchasing personnel with different backgrounds and risk attitudes might be useful for building a data bank for e-negotiation between buyer and seller. Also the relationship between framing, personal risk attitudes and the efficiency and preference of pricing decision for an organizational procurement are proposed to assist the trades between industries. Verbal expressions are mostly used among purchasing agents to express their perception in the traditional market.

A model for the evolution of organizational market is built based on literature review of inter-organizational negotiation and interviews in-depth with domestic industry. Popular verbal terms using in purchasing area for possibility are collected and analyzed, and due to the purpose of the research, a questionnaire sampling is used to collect data from five high technology companies. Basic Statistical Analysis and Chi-Square Analysis are applied to analyze the purposively collected data. The results reveal framing does most significantly influence the trades, and preference of decision among purchasing persons are not significant, that might due to their experiences and professional knowledge on procurement. System requirements based on the framework is analyzed by UML for building an E-Learning simulated system for novices of purchasing via hints from knowledge collected from veterans of procurement.

Abstract

In Taiwan stock market, it has been accumulated large amounts of time series stock data and successful investment strategies. The stock price, which is impacted by various factors, is the result of buyer-seller investment strategies. Since the stock price reflects numerous factors, its pattern can be described as the strategies of investors.

In this paper, pattern recognition concept is adapted to match the current stock price trend with the repeatedly appearing past price data. Accordingly, a new method is introduced in this research that extracting features quickly from stock time series chart to find out the most critical feature points. The matching can be processed via the corresponding information of the feature points. In other words, the goal is to seek for the historical repeatedly appearing patterns, namely the similar trend, offering the investors to make investment strategies.

Keywords: Pattern Recognition, Taiwan Stock Market, Time Series, Feature Extraction

1. Introduction

Stock exchange is influenced by many factors, including politics, economics, international statuses, significant news, and so forth. The composite result will be displayed on the market, and thus the stock price volatility is reflected. Since the stock price is the final consequence of various components, it is more meaningful to present the variation of stock price with the chart than with numerical data. Hence, stock trend chart is one of the most useful tools for stock analysis [2][7][9][10].

In recent years, Behavioral Finance has been getting more and more attention. When one is making strategies, he, who is affected by mental elements, is not always rational. Certainly, daily stock price corresponds to the current circumstances. Thereafter, stock data mining [6], which obtains knowledge through relevant analysis, reveals that investors make investment strategies according to each factor.

Consequently, using the objective approach in this paper discovers investment behavior patterns — the curves of stock price trend. First, applying feature extraction to stock time series to extract the most critical feature points. Then, do the matching of the relevant information among the feature points. The proposed new pattern recognition method can substantially improve the

efficiency of pattern matching about time series data. Thus, it is useful for investors to make decisions.

2. Literature Review

2.1 Stock Market Volatility Factors

Stock price is affected by some factors [5], including stock market, industry, and corporation factors. Stock market factors involve macroeconomics, international statuses, and domestic politics. Industry factors consist of industry conditions, business life cycle, and law measures. Corporation factors concern with dividends, operating performance, firm structure and restructuring. To sum up, stock price is influenced by all factors; either corresponding to long-term or short-term trend.

Based on the self-similarity of fractal theory [9], the shape will not be changed even if a segment of long-term trend is either magnified or minified. In another word, the shape of long-term stock price trend is similar with short-term. The fluctuation of short-term trend will not be taken into consideration while observing long-term trend. In the same way, the volatility of ultra-short term trend will be neglected while focusing on short-term trend. For example, the minute stock price volatility will not be taken into account when considering daily stock price data. Therefore, it is necessary to find out quickly the critical feature points to represent the original curves.

Since the volatility factors are subjectively defined and explained by investors, investment will correspond to individual character and mental factors; that is, there is no objective standard. Thereupon, in this paper, an objective approach is applied to pattern discovery of repeated behaviors by the historical curves.

2.2 Time Series Feature Extraction

The reason for applying feature extraction to stock time series is because the preceding matching approaches are time-consuming. The most typical models are Hidden Markov Model (HMM) [1] and Dynamic Time-Warping (DTW) [4]. The parameters of HMM require being trained; the training process takes a lot of time. Though the parameters of DTW do not need to be trained, the matching process is rather time-consuming.

The proposed Perpetually Important Point (PIP) approach [3], which is suitable for time series feature extraction, indicates that major or minor volatility may be included in the stock time series. Discovering the critical

feature points ensures to filter the insignificant minor volatility. Thus, the complete time sequence can be expressed in terms of a small number of feature points. Let P denote a time series, where the length is N . The purpose is to find out m PIPs, which works as follows:

- Step1: The adjacent two PIPs are defined on the two ends of time series; in other words, the start point p_1 and end point p_2 .
- Step2: The third PIP p_3 is the point in P with maximum distance to the first two PIPs. The maximum distance denotes the vertical distance between a point p_3 and a line connecting the two adjacent PIPs (See Fig. 1), that is, $d = y_3 - y_c$.
- Step3: The process continues searching for the next PIP in P with maximum distance to its two adjacent PIPs until sufficient m PIPs are detected, and m is predefined.

The pseudo code of the PIP approach process is described in Figure 2.

Figure 1. Time series feature extraction.

The Perceptually Important Point (PIP) approach is adapted to find out important features for human visual identification, and two approaches in extracting PIPs are provided. The first one is to find out the most significant feature points on the complete time series. The characteristics of second one is that the time interval is approximatively equal after extracting PIPs. See Figure 3 (1st PIP approach), and Figure 4 (2nd PIP approach), respectively.

The second approach is developed to find out two adjacent PIPs with maximum time interval. After the step, it is found that the each interval between two adjacent PIPs is the approximative distance. The two feature extraction approaches will lead to different results, even with the same data.

```

Function PIP( $P, m$ )
  Input: sequence  $p[1...N]$ 
  Output: pattern  $pip[1...m]$ 
  Begin
    Set  $pip[1]=p[1], pip[N] = p[N]$ 
    Repeat until  $pip[1...m]$  all filled
      Select point  $p[j]$  with maximum distance to the adjacent point
      in  $pip$ 
      Add  $p[j]$  to  $pip$ 
  End

```

Figure 2. Pseudo code of PIP[3].

Figure 3. PIP Method 1. The feature points are represented by square points, the daily closing price are represented by solid lines, and the feature points are connected by dotted lines.

Figure 4. PIP Method 2. The feature points are represented by square points, the daily closing price are represented by solid lines, and the feature points are connected by dotted lines.

The two methods are chosen according to the problem domain. Here, the first method is preferred being applied to stock market data. The number of needed feature points can be given in advance. Since matching the original data is time-consuming; therefore, detecting the meaningful points by filtering detailed information can improve the matching work.

Let n denote the points on time series. The whole data has to be scanned once as long as seeking for one feature point. Hence, n^2 times of calculations are computed when detecting n PIPs. In real life, one usually keeps his eye only on several critical points, such as starting point, termination point, peak, valley, turning point, etc.

Therefore, only n ($n < N$) critical features are required. For this reason, n times of PIP approach calculations are computed when detecting time series, such that the time complexity will be $O(n \times N) = O(N)$. The other non-feature points can be neglected for being viewed as slight volatility.

3. Architecture

In this research, the data resource is derived from Securities & Futures Institute, where daily closing price is used to do the feature extraction by means of PIP approach firstly. Then, the angle and relative length are computed for matching similar patterns, namely resembling stock price trend (See Fig.5). Finally, the investment suggestion is given by the analysis.

3.1 Data Collection

Taiwan stock market is taken for example in this paper. The data originates from Securities & Futures Institute, where daily closing price is collected from 1994/1/5 to 2003/7/16.

3.2 Time Series Feature Extraction

The PIP approach is used to apply feature extraction to stock data because one will notice only a few significant feature points within a time period.

3.3 The Relation of Features

Calculate the slope of two adjacent feature points. Slope matching is complicated because slope lies within the range $[-\infty, \infty]$. Therefore, conversing the slope to the angle, and then using the angle to do the matching. There are some advantages of angle matching:

1. The different stock price (Y axis) can be matched with varied stocks. Hence, the stock price data needs to be normalized. For example, stock A falls within 10 to 30 dollars whose spread is 20 dollars. Stock B falls within 50 to 80 dollars whose spread is 30 dollars. The scale of stock B requires being reduced two-thirds, while stock A being magnified one and one-second can the angle matching be done.
2. Time axis (X axis) does not require being normalized. This is because there is no impact on two angles regardless of the length of time. As long as the number of the chosen feature points is equal, the data of M-day can be matched with that of N-day. For instance, 50 days of data can be matched with that of 60 days.

An error range ϵ is determined when matching, and the angles lie within the range $[-90^\circ, 90^\circ]$. Let α denotes the angle of a feature point such that $\alpha \pm \epsilon$ are regarded as the identical angles (See Fig. 6). The smaller of the error range, the more precise of the matching result; otherwise, the more similar patterns can be matched.

The time interval of two feature points may differ in various patterns, which contribute to divergent implications applied to stock market data. Therefore, the distance between feature points should be considered when matching. In comparison of different lengths of time series flexibly, let the relative time length be the measure through dividing the time interval of two adjacent feature points by the total length of time series (See Fig. 7). In Figure 7, the relative length between point 1 and point 2 is

a/N . The error of relative length is set not to be more than β when matching stock price time series.

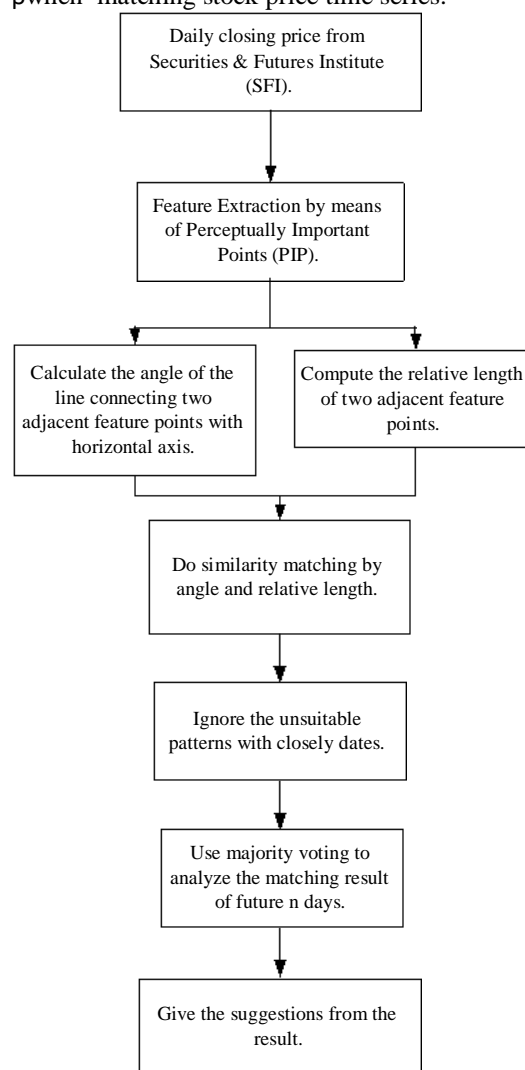

Figure 5. Research structure.

Figure 6. The matching angle is α , and the range of tolerance is ϵ .

3.4 Similarity Matching

The process of matching begins with finding out the most critical features by way of feature extraction; furthermore, compute the angle of feature point connecting to horizontal axis and relative length, described in section 3.3, for matching. First of all, angle

matching is employed with adjacent feature points. After matching the identical angles, the relative length is further matched. The matching patterns may be dissimilar even with the identical angle; that is why the relative length proceeds to be matched. The error of angle and relative length require being within the range of tolerance such that the matching of time series is regarded as identical. The stricter the making rules of similarity, the better resulting matching; nevertheless, the fewer times of matching the identical patterns. On the contrary, the looser the threshold, the matching result will be worse; yet, the more times of matching the identical patterns.

It is found in the experiment that the stocks of the same industry within the similar time period will usually result in identical trend. Therefore, finding out the same trend with different time period will be more meaningful.

Figure 7. The relative length is a/N .

3.5 Matching Analysis

After matching similar curves, the trend in the following n days is analyzed. The future trends of the following n days will be concluded by the majority voting method. Ultimately, the resulting pattern is determined if it is significantly meaningful by setting the voting threshold. In Section 4, all samples will be presented as examples.

4. Simulation

Data Resource: Daily stock closing price from Securities & Futures Institute between 1994/1/5 and 2003/7/16.

Experiment 1: Identical industry with the same time interval.

From an industry in Taiwan, Experiment 1 takes Taiwan Semiconductor Manufacturing Company (TSMC) and United Microelectronics Corporation (UMC) as the subjects. The six feature points are extracted for matching within 50 days. The angle error ϵ is set to be within $[-8^\circ, 8^\circ]$, and the relative length β is equal to 0.1. The result is shown in Figure 8.

Experiment 2: Different industries with the same time interval.

From different industries in Taiwan Experiment 2 takes Taiwan Semiconductor Manufacturing Company (TSMC) and Formosa Plastics Corporation (FPC) as subjects. The six feature points are extracted for matching within 50 days. The angle error ϵ is set to be within $[-8^\circ, 8^\circ]$, and the relative length β is equal to 0.1. The result is

shown in Figure 9.

Experiment 3: Identical industry with different time intervals.

From an industry in Taiwan, Experiment 3 takes Semiconductor Manufacturing Company (TSMC) and United Microelectronics Corporation (UMC) as subjects within different time intervals. The six feature points are extracted for matching within 60 days and 50 days, respectively. The angle error ϵ is set to be within $[-8^\circ, 8^\circ]$, and the relative length β is equal to 0.1. The result is shown in Figure 10.

Experiment 4: Different industries with different time intervals.

In different industries in Taiwan, Experiment 4 takes Semiconductor Manufacturing Company (TSMC) and Formosa Plastics Corporation (FPC) as subjects within different time intervals. The six feature points are extracted for matching within 60 days and 50 days, respectively. The angle error ϵ is set to be within $[-8^\circ, 8^\circ]$, and the relative length β is equal to 0.1. The result is shown in Figure 11.

Experiment 5: Self-matching on the same stock.

Do the self-matching on the same stock to search for the repeatedly appearing trend. Experiment 5 takes United Microelectronics Corporation (UMC) and Taiwan Semiconductor Manufacturing Company (TSMC) as subjects. The six feature points are extracted for self-matching within 50 days. The angle error ϵ is set to be within $[-8^\circ, 8^\circ]$, and the relative length β is equal to 0.1. The result is shown in Figure 12 and 13.

4.1 Simulation Result

In Experiment 1 and 2, it is concluded that the proposed approach in this paper can be applied to either the identical or different industries. In other words, the investment behavior may be the same even between low-correlated industries.

In Experiment 1, TSMC and UMC, both belonging to the electronics industry, have similar curves within [2001/2/21, 2001/5/4] and [2000/11/17, 2001/1/31], as shown in Figure 8 (a1) (b1). It indicates that the strategies of investors are similar because time-space background and influential effects are very close. It is found that the trends of the two stocks are similar in the following 10 days. For example, the trends of the two stocks go downward in the following 10 days, which are shown in Figure 8.

In Experiment 2, TSMC belongs to electronics industry, while FPC belongs to plastics industry. There is low correlation between the two stocks; however, the similar curves appeared in different time interval, as shown in Figure 9. It indicates that the investment strategy may be the same even in different industries.

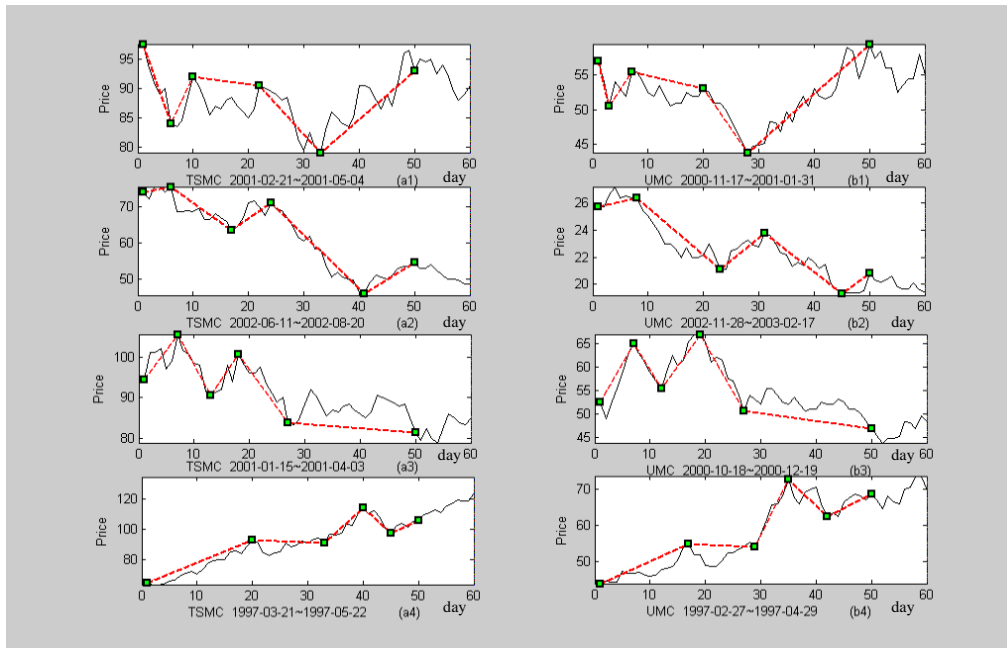

Figure 8. Experiment 1: The figures on the left (TSMC) respectively correspond to the right ones (UMC). (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 50 days are for matching, while curves of the last 10 days are the following trend.

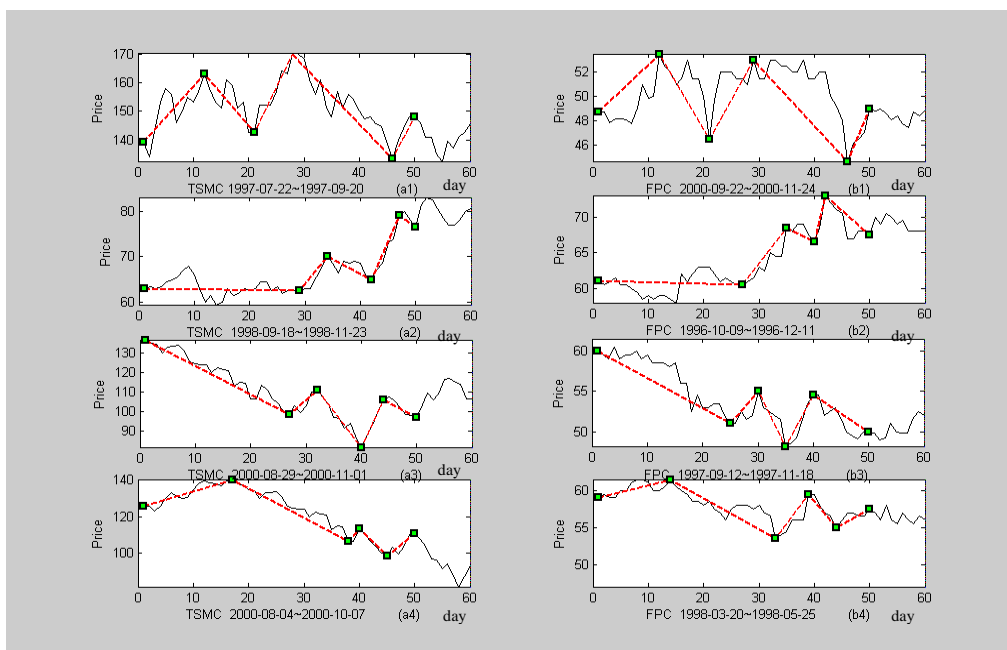

Figure 9. Experiment 2: The figures on the left (TSMC) respectively correspond to the right ones (FPC). (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 50 days are for matching, while curves of the last 10 days are the following trend.

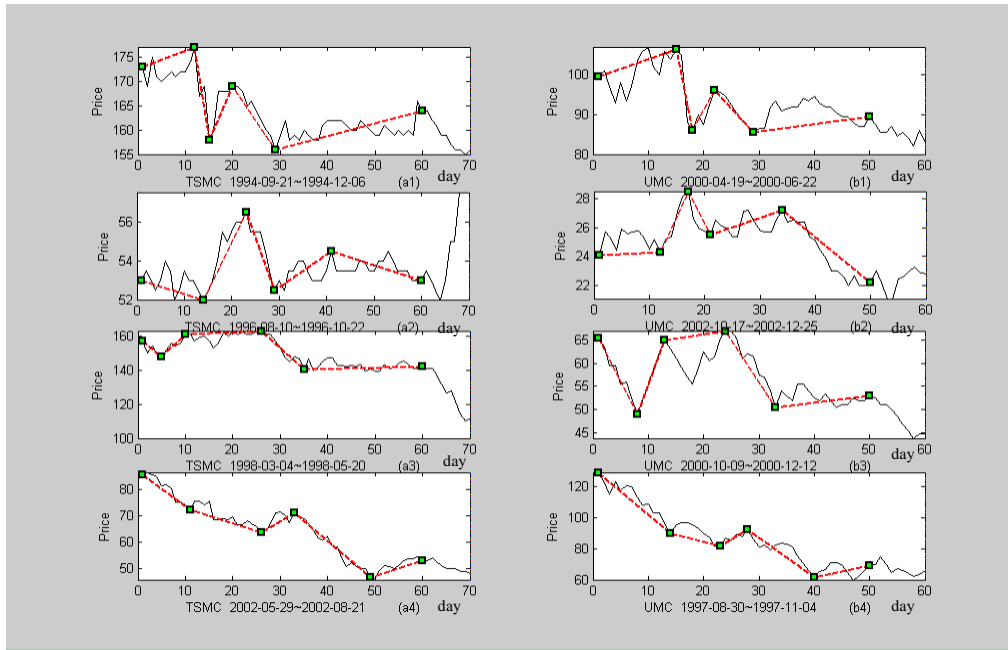

Figure 10. Experiment 3: The figures on the left (TSMC) respectively correspond to the right ones (UMC). (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 60 days for the left figures and 50 days of the right ones are for matching, while the curves of the last 10 days are the following trend.

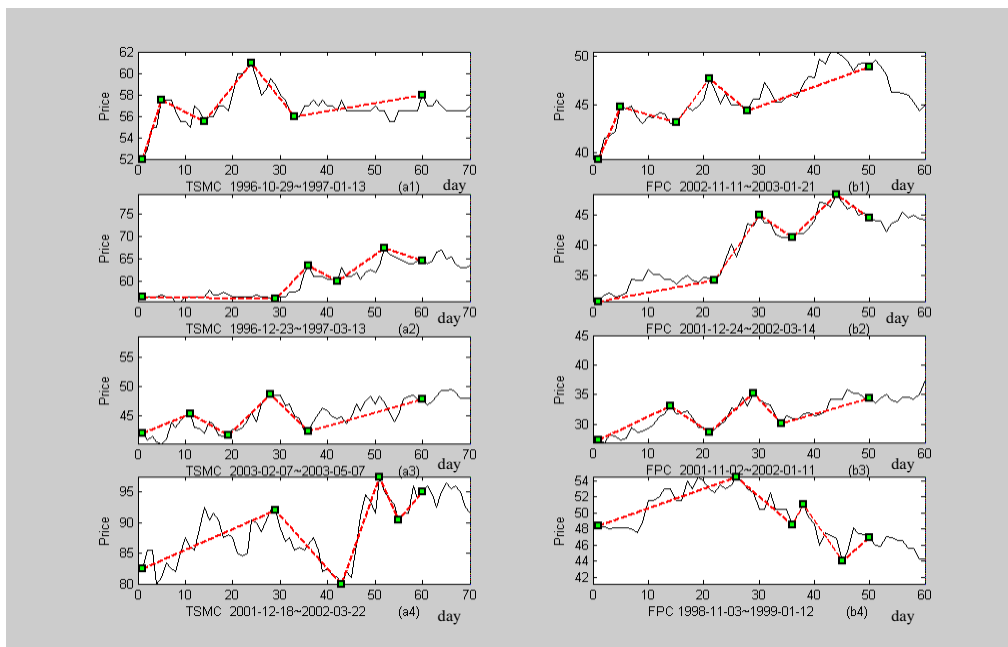

Figure 11. Experiment 4: The figures on the left (TSMC) respectively correspond to the right ones (FPC). (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 60 days for the left figures and 50 days of the right ones are for matching, while the curves of the last 10 days are the following trend.

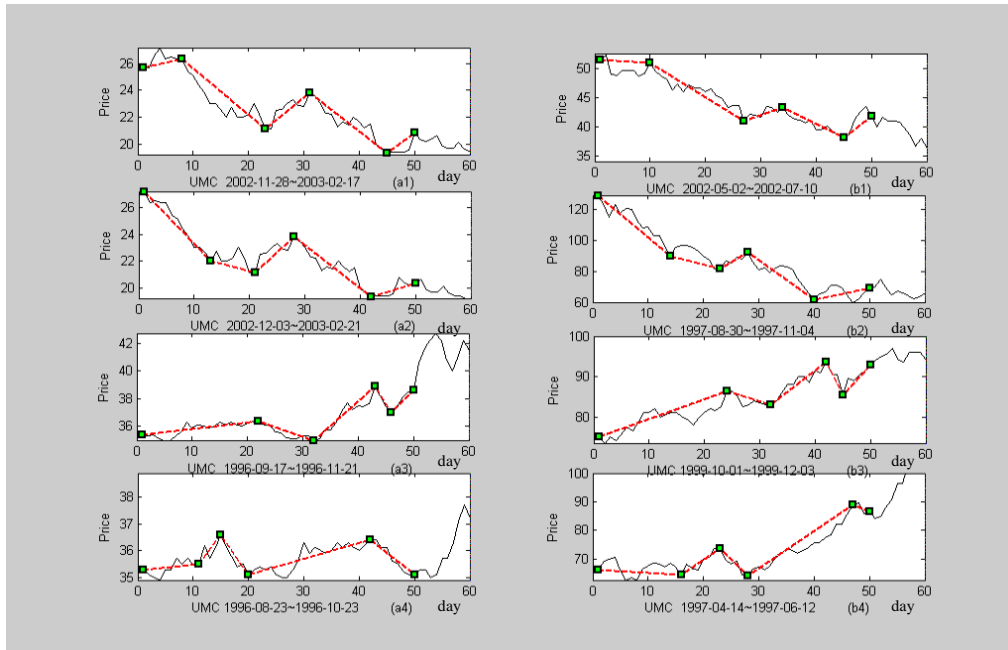

Figure 12. Experiment 5: The figures on the left (UMC) respectively correspond to the right ones (UMC) for self-matching. (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 50 days are for matching, while curves of the last 10 days are the following trend.

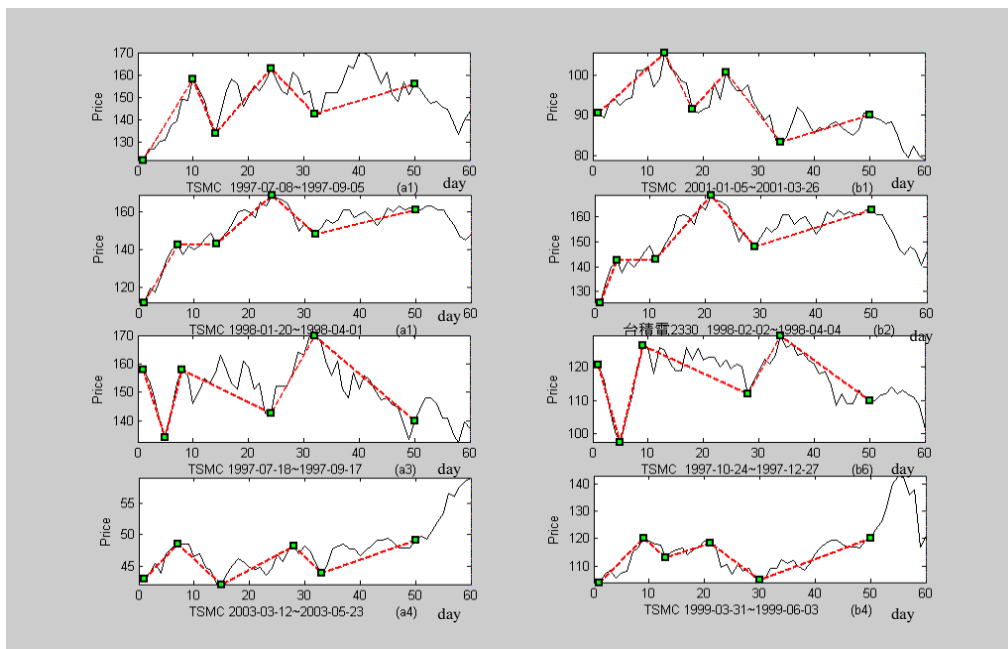

Figure 13. Experiment 5: The figures on the left (TSMC) respectively correspond to the right ones (TSMC) for self-matching. (i.e. (a1) is similar with (b1)). The original data is represented by solid curves, the future trend is represented by dotted lines, and the square points stand for feature points. The previous 50 days are for matching, while curves of the last 10 days are the following trend.

This is because the influential factors may be dissimilar during the same time interval. Nevertheless, the trend in the following 10 days is varied in accordance with different industries.

In Experiment 3 and 4, it is concluded that the proposed approach in this paper can be applied to different time intervals. Because the influential factors will differ according to the stock, the similar curves may appear in different time intervals.

In Experiment 3, different time intervals applied to the same industry can be matched with similar curves. It indicates that the similar trends will still appear in the following 10 days, which is shown in Figure 10 (a3) (b3), and (a4) (b4).

In Experiment 4, different industries with different time intervals can result in the similar curves. The reasons will be (1) all factors that affect the stock price will constitute the identical background even in different industries during different time intervals. (2) The long-term or short-term investment strategies will result in the similar curves. In other words, magnifying a segment of long-term curves is similar with the original long-term curves. However, it is found that in the following 10 days, the trends are not so significantly similar. Perhaps the investors have different judgment standard on different industries.

In Experiment 5, it is found that self-matching on the same stock, as shown in Figure 12 (UMC) and 13 (TSMC) respectively, will match the similar curves. Moreover, the trends in the following 10 days are still similar. In Figure 12 (a4) (b4) and Figure 13 (a2) (b2), the upward trend and downward trend are significantly appeared in the following 10 days respectively.

5 Conclusion

This paper applies feature extraction to stock time series data on critical feature points for similarity matching. The proposed approach is adapted to match either various industries or low-correlated stocks regardless of its data characteristics. The resulting Experiment indicates that stock price volatility will repeatedly appear along with investment strategies. Hence, investors can make current strategies according to the historical repeatedly appearing patterns.

The quantity of feature points is dynamically determined according to stock price data. It is important to describe the original data more appropriate, hasten the searching speed, and improve the accuracy. In addition, the stock volume can also be considered such that the effects will be improved greatly.

Abstract

This paper addresses the issue of using product models to support product lifecycle activities with particular focus on the production phase. The motivation of the research is that products are produced more costly and with longer lead-time than necessary.

The paper provides a review of product modelling technologies and approaches, and the overall architecture for the Product State Model (PSM) Environment as a basis for quality monitoring. Especially, the paper focuses on the circumstances prevailing in a one-of-a-kind manufacturing environment like the shipbuilding industry, where product modelling technologies already have proved their worth in the design and engineering phases of shipbuilding and in the operation phase. However, the handling of product information on the shop floor is not yet equally developed.

The paper reports from the Brite-Euram project (No. BE97-4510) QualiGlobe focusing on the development activities of the PSM architecture. An example discusses how to handle product related information on the shop floor in a manufacturing company and focuses on how dynamically updated product data can improve control of production activities. This prototype example of welding a joint between two steel plates serves as proof of concept for the PSM architecture.

1. Introduction

Enhancing the manufacturability of products demands an increasing exchangeability of information (Alting 1994, Pedersen & Larsen 2001). This paper addresses the issue of using product models to support product lifecycle activities with particular focus on the production phase.

In a manufacturing company, production operations involve information about the product. This information normally has a relatively static nature because it is a specification of how the product is intended to be. Production operations also involve manipulation, generation and use of product information which has a dynamic nature and involve information which describes the current condition or state of the product.

The product state is changing as a result of physical processing (cutting, welding, handling etc.). The state of a product at a given time, is therefore the accumulated result of the processes applied to the product that given time, cf. Larsen et al. (2001).

The product state information includes logistic information as well as the physical properties of the product. Both types of information typically describe conditions, which in some way will influence the subsequent production steps for the product. It is important to notice that this product information describes the actual conditions or circumstances of the product, not the planned. In response to this, the Product State Model (PSM) is defined as opposed to the Product Model, cf. Lynggaard (1996) and Sphitalni et al. (1998), which in this paper is considered as the model of the planned product.

2. Research Method

This research reports from the Brite-Euram project QualiGlobe (Product Quality State Based Fabrication in Global Production Environment), which started in 1997 and is finishing in 2001. The purpose of the project has been to define a so-called Product State Model and related applications.

The project partners were: Odense Steel Shipyard Ltd. from Denmark, Fundacion Robotiker from Spain, Institut für Schweisstechnische Fertigungsverfahren der Rheinisch-Westfälischen Technischen Hochschule from Aachen, Germany, Det Norske Veritas Ltd. from Norway, Svejsemaskinfabrikken Migatronics Ltd. from Denmark, and Fincantieri Cantieri Navali Italiani Spa. from Italy.

During the course of the project all partners have been involved in the development and testing of the prototypes. This paper will present some of the results from this work.

The research questions (RQ) pursued in this article are:

- RQ1: Why is a PSM needed in a manufacturing process?
- RQ2: What are modules in a PSM Environment that are necessary for the manufacturing process to execute efficiently?
- RQ3: How are the modules related?

The data founding this article was gathered through internal documentation and supplementary interviews. Extensive internal documentation were available, e.g. functional analysis (IDEF0) of the material flow of the production process and of the control of the production process, results and documentation of several Ph.D. and master theses, and other research project documentation

from the QualiGlobe project at Odense Steel Shipyard (OSS). This material provided substantial empirical insight into shipbuilding at OSS. Furthermore, various applications of information technology in the production preparation and production were analysed, i.e. robot controllers, product models, and intranet applications.

One of the objectives of the QualiGlobe project is to specify the product and process quality state model. The model is the basis for the monitoring and pre-adjustment activities, and the calculation of the part quality after processing. The quality model considers both the product and the process aspects, and the relation between them.

2.1 The Case Company Odense Steel Shipyard

Odense Steel Shipyard (OSS) had in 2002 a turnover of over 8,5 billion DKK and more than 8000 employees incl. 3000 in Denmark. In 1997 and 1998 OSS acquired three shipyards near the Baltic Sea, i.e. Volkswerft Stralsund GmbH in Germany (www.volkswerft.de), Baltija Shipbuilding Yard JSC in Lithuania (www.baltijos.lt), and Loksa Shipyard Ltd. in Estonia (www.ls.ee). OSS is a subsidiary of the A.P. Moller-Maersk Group.

OSS (www.oss.dk) builds double hulled VLCC's (very large crude carriers), crude oil carriers, and container vessels e.g. the worlds largest container carrier and reefer vessels (length: 347, breadth: 43 m, depth: 24 m, draught: 14,5 m, and 6600 TEU, 20 foot containers including 700 Reefers, operated by only 17 persons). In addition to the subsidiary yards in Estonia, Lithuania and Germany, the OSS Group has acquired a subsidiary repair yard in Egypt. Over the years, the primary customer is the owner of the shipyard, i.e. the A.P. Møller Group. In addition, the shipyard also charter ships to the A.P. Møller shipping company.

3. The need for a Product State Model

Today information applied for controlling processes in production is mainly provided by process planning systems and process specification documents. In addition, static product data (CAD drawings, bill-of-material, etc.) serves to support the manufacturing process. Production staff on the shop floor further adds (or modifies the) process data based on experience and knowledge. Finally, to some degree, they take into consideration specific facts about the current and actual conditions of a particular part. Automated processes are also able to adapt to real conditions by use of sensors, and thus compensate for the difference in the planned and actual circumstances. However, this is only true within limitation and depends on the magnitude of the variations. So far humans are better to adapt the process to the real product conditions than the automated equipment.

Following the above, we realise that we accept that the actual conditions differ from the specifications and consequently allocate human effort and skills, and make investment in technology and new operating procedures, in order to compensate for variation. Additionally, we

establish buffers in production plans in order to compensate for the temporal aspect, i.e. possible delays in production due to prolonged processing time or extra time required for repairing.

Hence, it is a fact that in order to achieve the desired quality, the cost is higher than necessary and the lead-time is longer than necessary.

The alternative of gaining more accuracy in the production process is extremely expensive in the manufacture of large, complex, one-of-a-kind products like a ship. Therefore an approach is needed, which allows us to handle the variations as natural phenomena and not as disturbances with damaging effects on logistics, cost, time and accumulated quality.

4. Product Modelling

This section reviews the product modelling literature in order to give insight to the development and elaboration of the Product State Model. Product modelling is an approach to structure knowledge and information related to a product. The traditional purpose of product models is to facilitate the specification activities of the manufacturing company. In the following some of the dominating schools within the Product Modelling community are presented.

University of Erlangen-Nürnberg: Product and product related models to support the Design for X engineering design (e.g. Meerkamm 1993). This Design for X approach contains knowledge and information regarding the application domain. In the paper the focus is on Design for Manufacturing (DfM). The system contains three parts: a component model for definition of product components. The component model is again divided into four elements: a geometry element, a technology element describing tolerances, surfaces, materials, and material characteristics. Furthermore, the component model contains a function element describing the components function surfaces, forces and moments, etc. The fourth element is the organisation element assigning an identification number, a responsible person, and the status of the component. The synthesis part contains generic object oriented descriptions of the components. These are building blocks that by synthesis lead to the product components. Finally, the analysis part contains analyses of consequences for the particular solutions in relation to e.g. tools or tolerances. The analysis proposes courses for corrections.

Helsinki University of Technology: Feature modelling and product models supporting reuse throughout the lifecycle of the product (e.g. Ranta et al. 1996, Ranta & Mäntylä 1997). Mäntylä et al. have been engaged in the discussion of the requirements regarding the structure for product models supporting reuse over the lifecycle of the product model (Ranta & Mäntylä, 1997). As an analogy to design patterns used in software development, the reuse entities are categorised into three types of presentation entities, i.e. macroscopic principles for the early stages of the lifecycle containing physical

laws, mechanical structure, etc. The second type is product design patterns for the intermediate stages representing key aspects of a common structure, and microscopic features for detailed description at the late stages of the lifecycle.

Product modelling in a lifecycle perspective is an upcoming research area, whereas feature modelling is a matured area at the Helsinki University of Technology, cf. Laakko & Mäntylä (1993), Mäntylä et al. (1996), and Ranta et al. (1996).

Royal Institute of Technology (KTH), Stockholm: Feature modelling and the concept of Product Model Driven Direct Manufacturing, where the process parameters and scanning patterns are derived from the product model and from the use of a process model (e.g. Kjellberg & Carleberg 1993, Kjellberg 1995). The product model contains geometric, dimensions/tolerances, functional surfaces, and technical data. Moreover, it also refers to company specific information, product background, history, synthesis & analysis results, reasons for decisions etc.

Fraunhofer Institute, Berlin: Product and product related models containing of (1) the product model, which contains geometric description, structure description, and process description, (2) the factory model, entailing an equipment model, capacity and scheduling model, and a plant layout model, (3) the process model, which contain an operation model and a tool path model, and (4) the application model, containing application knowledge derived from service and maintenance (Krause et al. 1993).

University of Tokyo: The product modelling activities are focused on geometric constraints and geometric reasoning. Also, a generic product model for representing all types of artefacts is developed to appear in course of manufacturing and to support a virtual manufacturing environment. The product model contains description of material, intermediate products and manufacturing resources such as tools, machines, etc. Process modelling includes kinematics models, assembly models, form-feature modelling, dimensioning, and tolerance modelling, cutting process simulation, etc. (e.g. Kimura & Suzuki 1986 and Kimura 1993).

The Technical University of Denmark: The Chromosome Model is based on the Theory of Domains by Andreasen (1980), which explains product development as a synthesis of three different views on the product (domains), which are incorporated in the model: (1) Process. The process domain describes the interaction between the product, the operator and the surroundings. (2) Organ. The organ domain describes materialised design solutions, which provide the product's intended functionality. (3) Part. The part domain contains a description of the physical components and assembly structures (e.g. Andreasen 1980 and Mortensen 1998).

Institut National Polytechnique and the Université de Nancy, France: Co-operative Computer-Aided-Integrated Design (CAID) is a methodology and product model for integrated design using a multiview system.

The integrated design methodology is based on the co-operative work between all actors of a product life cycle (e.g. Tichkiewitch & Véron 1997).

Eindhoven University of Technology: The Relation-Based Product Model is suited for integrating Design and Manufacturing as manufacturability checking is embedded into the design process (e.g. Net et al. 1996). The product model is based on relations between geometrical entities with a tolerance model. For example, when assembly analysis is performed, numerical code for a machining centre, or command code for a co-ordinate measuring machine (i.e. verifying geometry) is created, then the product description is interpreted for implications in those specific applications.

University of Twente, Netherlands: Product models based on features, and product models for Model-Based Maintenance are based on Function-Behaviour-State modelling. A State aspect of a system is considered as a set of object attributes, which physically can be measured or monitored by sensors. A system's Behaviour is here defined as a set of transitions of states, and the Functional aspect is the top-level description of what the user can perceive from the system's Behaviour. Function-Behaviour-State modelling describes faults and deterioration of mechanisms in terms of user perception and measurable quantities. The product model is used as a reference for monitoring, fault diagnosis and prevention of breakdown (e.g. Houten et al. 1998).

Summing up the above mentioned schools of thought it shows that product modelling is an approach to structure knowledge and information related to a product with the purpose of facilitating the specification activities of the manufacturing company.

The various product modelling approaches differ in application domain and their level of detail. For example, the DfX tool by Meerkamm (1993) is more focused on implementation of product and product related models focusing on the particular analysis and synthesis tool, and consequently the interaction with the engineering designer, as opposed to the approach suggested by Krause (1989).

The concept of the Product Model Driven Direct Manufacturing (Kjellberg & Carleberg 1993, Carleberg 1995) focuses on the manufacturing process. The concept does provide same functionality as what is intended with the PSM of feeding realised production information forward to further production process activities – however this is limited to geometrical features, whereas the state description of the PSM may contain a wide scale of different attributes.

A product model being representative for the product throughout the production has to a product and product related model, cf. Krause et al. (1993). In order to optimise the production process, a product model should be used as a reference for monitoring. A feedback of realised process parameters Kjellberg & Carleberg (1993), i.e. from use of a process model, should be supplemented with product properties. These product properties represent the state identified of the realised product.

5. The Concept of the Product State Model

The Product State Model stores information about the product generated during production. Through a feed-forward mechanism the information can be made available in the subsequent productions steps where it can be used for adjusting the planning and control of processes. Naturally, the Product State Model describes the output quality of a certain process and thus also can be used for adjusting that same process before it is performed to the next product. The Product State Model's historical data also provides a solid basis of production information for design of new products as well as definition of production methods. However, the main idea explored in this paper is the ability to feed the product information downstream in the manufacturing process so that subsequent processes for the same product are carried out based on individual and updated product data.

The idea of the PSM is directed towards the reduction of accumulated manufacturing errors based on experiences from the development of a Product State Model (PSM) (Lynggaard 1996, Larsen 2003). The main sources of variation in mechanical assemblies are dimensional variations, form and feature variations, and kinematic variations. In particular, the manufacturing deviations caused by cutting and welding of steel plates are due to the high heat input, shrinkages and deformations (Larsen et al. 1999, Langer et al. 1999).

The PSM is designed to collect the state changes of a product or a product part at each step in the production process. Hence, it is possible to perform a geometric quality control of the production process, as the collected product state information is available for later production processes. For example, as the state of each product part is documented in the PSM after the cutting process (using a 3D vision and theodolite system), a global optimisation of the assembly process is feasible in order to improve conformance. Furthermore, the collection of state based descriptions of a product provides an automatic documentation of the product. Exchange of information between the PSM and the sources of the shop floor data collection is based on standardisation, here using the eXtensible Markup Language (XML).

5.1 Definition of the Product State Model

A Product State Model records and stores information about the product generated during production. It enables that information can be made available in the subsequent production steps where it can be used for adjusting the planning and control of the processes. The product state information is a supplement to the information provided by, or derived from, the product model, which is the specification of the product. By providing product state information along with the static product information the basis for planning and executing a process is enhanced. Here we define the Product State Model based on the following tasks that it should be able to facilitate or perform, cf. Lynggaard et al. (2001).

A product state model should

- uniquely identify individual products and parts and their assemblies/aggregations
- formalise the information about the actual conditions regarding the product
- store information from multiple sources
- collect information continuously
- enable exchange of information between applications.

In the QualiGlobe project a concept for the Product State Model has been defined in terms of a data structure and formats for describing product properties. Properties may be physical information, e.g. dimensions, surface conditions, material characteristics, position and orientation in space as well as other quality measures. It is required that this information is described in such detail that it can be applied for planning and controlling processes. E.g. the actual edge geometry of one plate is measured after the cutting process, so that it is possible to estimate the gap measure by use of the information about the two plate surfaces that constitute the joint. See the example in figure 1.

Figure 1: Gab between plate surfaces.

6. The Case study of the QualiGlobe Project

6.1 The Architecture of the PSM Environment

The basic approach taken in the QualiGlobe project was to document the actual conditions of individual parts throughout the production process. The general scenario is described in the following.

In a given process for a given part, the state in terms of output quality is registered. The information is stored in the Product State Model, which also holds product state information about that particular part, collected during previous processes. Then the part is transported to its next processing operation. Before it arrives and starts processing, detailed information about this particular part has been fed from the Product State Model into the process-planning loop where processing parameters, processing time, etc. are determined. The processing time has also been fed into the production-scheduling loop in order to update the current schedule. When the part arrives at its processing station, detailed information about this particular part again has been fed from the Product State

Model into the process control system so that the processing station is configured exactly to the conditions of that particular part.

This approach allows process planning and control as well as detailed production scheduling to take the actual conditions of each part into account. Thereby the processing is improved, i.e. higher quality at lower cost and with shorter throughput time, and the scheduling nearly becomes deterministic because the estimated processing time is more precise.

A range of modules has been defined and developed in the QualiGlobe project. Table 1 describes the individual models, whereas Figure 2 illustrates the modules and their interaction on an architectural level.

PPM	Product Part Measurement (PPM) refers to different types of measurement systems used for determining the characteristics of parts and products. Examples are vision and laser systems for dimensional measurements. Any type of measurement systems could be adopted depending on the type of product state information required.
PPD	Prediction of Process Data (PPD) is a process planning application. As opposed to other types of process planning applications it is able to take information from the Product State Model as input. For example, this means that it is able to divide a welding line in segments and applying different process parameters to each segment.
OPC	The Online Process Control (OPC) module is used to adapt the welding process parameters to the current conditions and hence adjust for smaller deviations, while the welding is taking place. It is similar to existing adaptive sensor systems, except the fact that it applies more advanced algorithms and that it resides outside the robot controller. The latter means that it can be used for different types of robots.
PS	The Power Source (PS) is similar to existing welding power sources, except for improved interfacing capabilities. The interface is used for improved reading and writing of power source parameters when controlling and monitoring the welding process.
DAS	Data Acquisition System (DAS) refers to the sensors and acquisition device, which collects physical signals from the equipment involved in the welding process.
QM	The Quality Monitoring (QM) is an application, which visualises and analyses the data collected by the DAS. It is able to detect some types of welding errors automatically.
QAR	Quality Assurance Report (QAR) refers to an application used on top of the Product State Model (PSM). It is used to document the quality of a welded part with respect to the requirements of the quality assurance procedures.
CE	Compensation Estimation (CE) is another application used on top of the Product State Model (PSM). It is used in the production scheduling loop because it provides information on the required extra work on a certain work piece due to insufficient quality.
RC, CAD, OLP	The Robot Controller (RC), Computer Aided Design (CAD) and Off-Line Programming (OLP) are existing systems involved in the PSM Environment. However, these systems are not directly involved in

	any QualiGlobe project developments, although they are necessary modules of the manufacturing process.
--	--

Table 1: Module description of the PSM environment in the QualiGlobe Project.

The architecture of the PSM Environment is described below. A file from the CAD system (i.e. the Product Model) in IGES standard provides the input for the Product State Model (PSM). The IGES standard was chosen for the prototype, as it was sufficient to use a 2D wire frame model instead of a 3D solid model. The PPM is the interface with the measurement tools from where the detailed geometrical representation is coming, unless it has been collected previously in the process. Measurements of out of plane, i.e. how wavy the plate has become as result of previous production process (here welding), and the fluctuation from a straight line of the edges of plates that are going to be welded on the part block is available from the PSM already. In this way the fit between block and plates can be evaluated.

The OLP plans the welding sequence and distribution of welding capacity on the welding tasks, and generates robot programs and a configuration file for the robot and welding equipment. Furthermore, the OLP provides data for the PSM for later analysis of the realised goodness of the planned quality. The QM is calculating the quality of the product part. Moreover, the QM organises the information received from the RC and DAS into a product state report and stores the information in the PSM for later analysis.

As a part of the near environment, the RC co-ordinates the movements of the robot and the setting of power source parameters, whereas the OPC assures that the welding parameters are according to the input from the OLP, and on basis of the immediate signals of the measurement of the gap from of the (arc-) sensor. During the welding process, the DAS measures and collects data about the welding process via sensors and directly from the RC in order to evaluate the quality of the weld. DAS forwards the signals onto the QM for evaluation.

The architecture of the Product State Model Environment is summarised in the following figure.

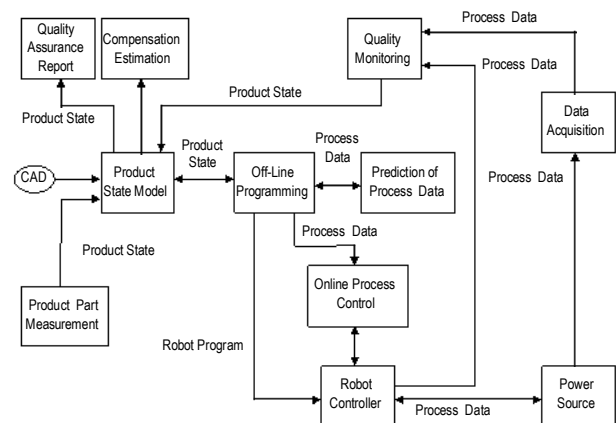

Figure 2: Architecture of the PSM Environment in the QualiGlobe Project.

The foundation for optimising the subsequent production processes based on product state information is that the PSM continuously contains updated data from the feedback from PPM and QM.

6.2 Module Dynamics of the PSM Environment Architecture

In order to illustrate the dynamics of the PSM Environment Architecture, the following section describes a typical example of robot welding of ship elements. The example contains five steps, which are:

- Step 1 – Measurement of product state
- Step 2 – Processing planning of welding and rescheduling
- Step 3 – Welding of the work piece
- Step 4 – Determine the output quality from the welding process
- Step 5 – Reporting of quality and compensation work

The individual steps are described below.

6.2.1 Step 1 – Measurement of product state

Step 1 involves measurement of the output quality of one or more processes. E.g. plate edge measurement of two plates to be joined, or the edge of one plate and out-of-plane deformation of the surface of another plate. The information from each measurement is transferred to the product state model. This step involves the PPM and PSM modules from the PSM Environment architecture.

Alternatively the two plates could be erected and tack welded and measured immediately after. This would give a more precise measurement and it would include information about the tack welds as well. However, it would delay the product state information and thus prevent more precise scheduling.

6.2.2 Step 2 – Processing planning of welding and rescheduling

Based on the part measurements the gap can now be estimated. This provides us the opportunity to perform process planning including generation of robot programs based on more precise part information. This again gives us the possibility to calculate a more precise robot welding time based on process parameters, which are derived from the actual state of the part.

This step involves the PSM, OLP and the PPD from the PSM Environment architecture.

6.2.3 Step 3 – Welding of the work piece

Upon configuring the robot and its process controller with the newly generated robot program, the welding process is carried out. Still, inaccuracies in the prediction of the groove geometry from a Product State Model or a measurement system necessitates that the process is adapted in real-time. Also deformation due to heat input

while processing results in changes of the product properties during the process. Therefore the process is controlled in real-time with a seam tracking-module and an advanced module for adaptive process control.

At the same time, while welding, a range of parameters is acquired and stored from the process for further analysis.

This step involves the RC, PS, OPC and DAS from the PSM Environment architecture.

6.2.4 Step 4 – Determine the output quality from the welding process

After completion of the welding process it is required to know the result. This is in order to determine whether the result is in accordance with quality requirements, whether the output quality has any impact on subsequent manufacturing processes. The first aspect is to some extent handled by automatic evaluation of parameter sets from the welding process. In this way we are able to determine some types of possible errors automatically. Hence, not all types and instances of common errors are necessary successfully identified.

The second aspect is performed by collecting data from the process itself and by performing structural 3D measurements of the work piece after the welding process.

Again, all product information is stored in the Product State Model. This step involves the QM, PPM and PSM modules from the PSM environment architecture.

6.2.5 Step 5 – Reporting of quality and compensation work

Based on the output quality measured in the previous step, conclusions are drawn and relevant reports are generated. One report generated is defining the compensation estimation, i.e. in case the weld requires repair or results in other types of compensation, the type and amount of repair work including additional required lead-time are reported. This report is used for production managers in relation to production scheduling. Another report is used for documenting the quality, and is thus used in the quality assurance procedures.

This step involves the CE, QAR and PSM modules from the PSM Environment architecture.

7. Discussion of Results and Benefits

The QualiGlobe project is a research project and therefore full scale benefits remain to be seen. However, as described below some commercial products are already made available based on the research results.

7.1 Results

A result of the QualiGlobe project is the identification of, description of and relation between all the modules described in this article. In addition, the concept of basing the manufacturing on a Product State Model (PSM) has been developed and tested in a small scale. Nevertheless, the concept may not in its entirety be viable at this time.

One reason alone is that Product State Models that are mature and feasible for industrial applications remain to be seen. The PSM in the quality project is a dedicated and limited pilot system, which may be used accordingly, in industrial applications. Another approach, in order to implement this concept, is to add product state data structures to existing product modelling systems.

Some of the other results of the Qualiglobe project are immediately ready for manufacturing applications. The Data Acquisition System (DAS) is today a commercially available product; Robotiker (Spain) as well as Migatronic (Denmark) have improved their Power Source (PS) products with an open communication interface developed in the project.

Yet some modules, e.g. the Quality Monitoring (QM) and Online Process Control (OPC) developed by ISF (Germany) are examples of industrially applicable systems that improve the current level of process control and monitoring.

Finally, the quality monitoring and process control applications at Fincantieri (Italy) and Odense Steel Shipyard (Denmark) have adopted some of the results.

7.2 Benefits

The experiences and benefits gained from the QualiGlobe project are:

- experience on how to implement a Product State Model, which can be used in future development initiatives
- several vision and laser measurement technologies developed and adapted for shipyard applications
- improved process planning for robot welding applications, resulting in better quality
- improved online process control for robot welding applications, resulting in better quality
- an enhanced welding power source technology for integrated control and monitoring applications
- a data acquisition system, ready to use, for robot welding applications
- a quality monitoring application that is able to detect some types of welding errors
- a quality assurance report generator based on production data collection
- a support application for production scheduling using information from quality monitoring

The Product State Model approach, and related technologies, as described in this paper has been developed in order to reduce the direct and indirect cost of lack of quality in manufacturing processes. In terms of benefits provided by this new concept, it is relevant to mention the increased focus on quality, not only as a measure of output from processes and awareness among employees – but also the consequence of quality as an input to subsequent processes. Thus adapting all processes to the real conditions is making sure that the correct

process is being applied – as opposed to a robust process that will work, though this is not without undesired side effects such as unnecessarily high heat input.

Another benefit is in terms of logistics. By preplanning processes based on measured part data, the processing time is calculated more precisely. Thereby, production schedules can be made more precise and are likely to be observed. Finally, the QualiGlobe project is providing applications for improved process control and automated documentation of quality.

8. Conclusions and Perspectives

The paper provides a review of product modelling approaches as well as empirical insight from the efforts on reducing the accumulated manufacturing errors based on enriched product information. Hence, the article contributes to the design structure for a PSM environment identifying the interacting modules as a basis for information sharing in the shipbuilding industry.

This paper has presented a new manufacturing concept based on a Product State Model. An architecture for the PSM Environment is suggested determining a set of relevant application modules and their relation. In theory, this concept leads to shorter lead-time, improved product quality and reduced production costs in shipbuilding and similar production environments.

The QualiGlobe project has validated central elements of this new concept by developing and testing prototypes. In addition, several technologies that are improving current monitoring and control of welding processes have been developed.

In perspective, standardisation and digitalisation of information is of increasing interest as Odense Steel Shipyard, Ltd. is in the middle of outsourcing part production activities, primarily to the Baltic region.

The Product State Model opens new possibilities for e.g. process planning. In fact several systems involved in industrial process planning, control and quality monitoring applications need to operate in a new way when adopting the Product State Model (PSM) approach. Therefore the QualiGlobe project has developed new applications for process planning, control and monitoring.

Acknowledgement

The authors acknowledge the employees at Odense Steel Shipyard, in particular those related to the QualiGlobe project (BRITE-EURAM Project BE97-4510), and in particular the dedication of J. Joannes (OSS, OPI), and B.A. Taranger (Det Norske Veritas), for their time and efforts in case descriptions, and analysis and design of the PSM.

Tracks: collaboration commerce, e-commerce management

Abstract

To collaborate with partners a company must reengineer its business processes for information and knowledge sharing, and for operations coordination. Digital technologies have proven very effective in supporting such collaborations. Companies may collaborate vertically with their suppliers and customers, or they may collaborate horizontally with other manufacturers. The benefits of collaboration would obviously depend upon how the partners, together, extract economic value from the market. This value would be different in different demand and/or cost scenarios. The decision to invest in collaboration technologies, on the other hand, is usually made by individual companies. There is clearly a tradeoff between the capabilities a company may create through investment in digital technology, and the market benefits it may obtain from collaborating with partners. In this paper we explore (1) how markets can be leveraged to create economic values in collaboration, and (2) how optimal investment (in technology) can be made using these collaboration values.

Personalizing Quantitative Homework Assignments To Facilitate Student Learning

vberardi@kent.edu

Abstract

Electronic business tools, technology, and approaches have enabled organizations to reach new customers and markets more effectively and efficiently than ever before. A parallel process has occurred in the education industry. In many of these educational ventures, the desire to reach underserved populations is a primary motivation. In others, efficiencies and cost reductions are paramount. Still other e-learning and innovative teaching initiatives have been initiated by the sincere and direct desire to improve existing educational effectiveness.

The project described in this paper is focused on educational effectiveness of teaching operations management to college students. The idea is to have a student-friendly approach to developing customized homework problems where each student has the same problem type but unique values, answers, and decisions. In this way, we seek to encourage student interaction and discussion of the problems while minimizing the risk of cheating through rote copying.

1. Introduction

Electronic business tools, technology, and approaches have enabled organizations to reach new customers and markets more effectively and efficiently than ever before. Just a few short years ago, people interested in buying a book had to travel to their local bookstore to physically sift through inventory on the shelves. If the book they were looking for was not available, they were forced to settle for an alternative selection, place a special order and wait days or weeks for delivery, or leave empty handed. Booksellers, most notably Internet-based Amazon.com, have helped to revolutionize the customer purchase process by changing the very mechanisms with which the customers access and acquire books. Geographic limitations of customers have been eliminated while inventory searches are completed electronically in seconds where relevant results and independent evaluations readily available. Even the special order process has been reengineered. Customers of some Borders Books stores, for example, can have their hard to find texts custom printed, cut, and bound in minutes while they wait.

To most customers, the e-business phenomenon seems to have occurred at these very visible levels. In actuality, though, these front-end capabilities require sophisticated

back-office processes built around an electronic infrastructure predicated on integrated business systems. Reaching new customers, better serving existing customers to increase their purchase quantities and qualities, and lowering the costs of doing business are primary goals.

A parallel process has occurred in the education industry. Like business organizations, secondary and post-secondary educational institutions are finding new ways to attract and service students with greater efficiencies. The University of Phoenix is a leader in electronic learning, delivering dozens of degree programs to underserved populations primarily through Internet-based processes. More recently, on-line secondary schools have gained ground. In these high schools, virtually all curricula are delivered using electronic means where student and instructor may never actually meet face-to-face.

In many of these educational ventures, the desire to reach underserved populations is a primary motivation. In others, efficiencies and cost reductions are paramount. This is especially true in some government supported institutions where budget cuts have had a disproportionate impact. Still other e-learning and innovative teaching initiatives have been initiated by the sincere and direct desire to improve existing educational effectiveness.

The project described in this paper is focused on educational effectiveness of teaching operations management to college students. Most of these students are of traditional age and begin college directly out of high school with little professional business experience. Unlike graduate students and older individuals, who may have developed the discipline and motivation to thrive in a fully e-learning environment, these undergraduates often desire the structure and socialization that comes with a classroom setting. Distance and e-learning options are available to our students but remain a small fraction of course credit hours completed and are often utilized simply to access courses that are not offered at the time or location of the student's choosing. From a competitiveness position, though, these e-learning options will only improve and become more of a viable alternative for our student population. As instructors, our core competency must be to develop pedagogy to facilitate active learning and a community classroom.

The challenge for the instructor becomes not only how to pique student interest in this quantitatively-oriented operations management but to add genuine value to the

student's business education. At one point in time, a student grade in this course was based solely on multiple-choice exams. However, this did little to meet the needs of businesses who seek new graduates possessing computer skills that can be employed in solving problems and making decisions. As a result, spreadsheet-based homework assignments have become a more prominent component.

These assignments provide opportunity for integrated problem solving, model building, and decision making for this student population. Today, homework assignments account for up to 30 percent of our student's final grade. A student survey during the Spring 2003 semester indicates that more than 4 out of 5 operations management students viewed the homework assignments as being an important or very important component to their learning processes. Furthermore, voluntary student comments written on standardized university-level student evaluation of instruction (SEIs) are overwhelmingly positive with regards to homework. These clearly indicate that students perceive homework as a valuable addition to the course.

While these student perceptions are encouraging, as instructors we remain concerned about the loss of control that occurs with assignments completed outside of the classroom. Student interaction and dialogue on problem solving is indeed an important factor in the learning process but cheating via rote copying must not be dismissed out of hand. Indeed, published studies show that academic dishonesty is not a rare practice in undergraduate programs and student attitudes towards cheating is more accepting than it was years ago. Instructor concern with the impact rote copying of homework is especially relevant given that a gap exists between student performance on homework assignments and on corresponding in-class exam problems. Therefore, while student perception regarding the value of homework is encouraging, the efficacy of homework in student learning processes is less clear.

The goal of this project is to develop a means to develop and deliver quantitative homework problems that foster student interaction and collaborative learning while discouraging the rote copying of answers. Furthermore, the method must ensure student accessibility to the technology employed and to homework assignment delivery. In addition, instructor concerns must be addressed so that not only are effective assignments developed, but efficiency in grading facilitated. To achieve these goals, concepts of personalization and mass-customization from e-commerce and operations management were embraced.

2. Principles Used in Developing Homework Delivery System

2.1 Technology

Homework development and delivery is accomplished via a combination of Internet-based and microcomputer-based technologies. The homework generating programs are obtained by students by

downloading from the instructor's website ensuring easy access and distribution. This process is very well known to most students before they even enter the operations management course.

The homework problems are encoded using Microsoft Excel and Visual Basic for Applications (VBA), which comes standard with the Microsoft Office package. The VBA program is set to automatically launch upon opening of the Excel workbook, generates the homework files, and outputs the customized assignment in a Microsoft Word file. Students must then use Excel to solve the questions posed. Each assignment requires explanations of the decisions they made. This helps to meet the needs of future business employers who seek students with strong spreadsheet, analysis, and decision making skills.

2.2 Personalization

Personalization and mass-customization are two closely related concepts that require sophisticated back-office support mechanisms to make the user front-end appear seamlessly unique to each individual (Turban, 2002). Personalization in e-commerce is often achieved via cookie files which track and store pertinent user information so customized web pages can be rendered, tailored advertisements can be generated, and relevant related products and services or information can be displayed for consideration. Personalization can also encourage customer self-service as individuals who readily find pertinent information are willing to act upon it.

Personalization of homework problems is employed so that each student receives unique values in their assignment. Student self-service is utilized via dialogue boxes that automatically launch when the Excel file is opened. The dialogue boxes ask for the student name and the last four digits of their social security number. Error trapping routines ensure valid values are entered. The social security number entered becomes a seed to lookup one of (currently) 1000 problem variations in the database.

2.2 Mass Customization

Mass customization is an operations management process strategy that attempts to blend the efficiency of product-focused and repetitive-focused strategies with the flexibility of process-focused approaches. To achieve mass customization, organizations must excel at effective scheduling techniques, modular techniques, and rapid throughput techniques (Heizer and Render, 2003).

2.2.1 Scheduling Techniques

For organizations, effective scheduling techniques are a key because of the high variety of products made, the need to achieve high capacity utilization, and the desire to keep inventories low. In homework problems, variety is achieved by generating unique values for each student and is controlled using VBA and an instructor developed database. While current problem variety is arbitrarily set

to 1000 combinations in the database for testing purposes, utilizing random number generation routines will increase this to an essentially infinite number of combinations in the near future. A more difficult scheduling problem occurs in grading the assignments. Currently a manual grading approach is being implemented via VBA code. Scheduling in this sense occurs through logical layout of the grading key that is synchronized with the homework questions posed.

2.2.2 Modular Techniques

Modular techniques are often used in repetitive-focused processes such as assembly lines to achieve a specified balance of variety and volume. This concept often simplifies the scheduling concerns noted above. Modular techniques are also applicable in the mass customized homework assignments. Consider, for example, a forecasting problem where several forecasting techniques are applied. The homework combinations can be generated so that the decisions lead students to choose different forecasting methods as the best. As such, student interaction can be encouraged as individual analysis is required to make the correct decision in each setting.

2.2.3 Rapid Throughput Techniques

Rapid throughput techniques are a characteristic of most product focused process strategies such as making steel or paper. Very specialized equipment and facilities requiring significant capital outlays make large volumes of product with low differentiation. Customization is then achieved after manufacturing as finishing processes customize sizes and packaging. For homework problems, this issue speaks directly to the grading process. Automation of grading, where spreadsheet answers are evaluated via grading agents is foreseen. In this way, a single instructor could accommodate any number of students with little additional variable cost.

3. Conclusion

In this project, we have attempted to apply the e-business and operations management concepts of personalization and mass customization to student homework problems. The idea is to have a student-friendly approach to developing customized homework problems where each student has the same problem type but unique values, answers, and decisions. In this way, we seek to encourage student interaction and discussion of the problems while minimizing the risk of cheating through rote copying.

Planning and Specifying the Composition of Web Services

Xiang Gao
INFOLAB
Tilburg University
The Netherlands
gao@uvt.nl

Abstract

As the Web services paradigm becomes popular and more and more applications are created and deployed as Web services, the need for developing new solutions tackling the composition of Web services becomes manifest. However, emerging web service standards and existing methods are not sufficient for realizing the goal of flexible and dynamic composition of Web services, although some preliminary work has been conducted in the area of services composition. This situation has raised the interesting research points for creating and developing new approaches for the Web services composition. In this paper we separate the design and implementation phases of the composite services, and concentrate on the research of the way a composite service is constructed in terms of its constituent services. We call this way the composition logic of a composite service. We firstly propose well-defined notions “composition structures” to represent the joints among the constituent services and generate the reliable structure of a composite service, and then we provide a specification mechanism to clearly specify the internal dependencies of a composite service in terms of the notification and dataflow dependencies. Our solutions for planning and specifying the composition of Web services can effectively support the properties of modularity, interoperability, dynamic reconfigure-ability and fault-tolerance for a composite software system in the dynamic Web environments of business applications, which are a organic part of our framework for tackling the challenges of Web service discovery and composition on which we are working.

1. Introduction

Web services are becoming the prominent paradigm for distributed computing and electronic business, because they represent a novel approach and framework for creating and deploying application-to-application communication on the Web. By Web services, we refer to self-contained, Internet-enabled applications capable not only of performing business activities on their own, but also possessing the ability to engage other Web services in order to complete high-order business transactions. Examples of such Web services include bill payment, customized on-line newspapers, or stock trading services and so on. The platform neutral nature of Web services creates the opportunity for developing composite services by using existing atomic or composite services possibly

offered by different organizations. For example, a travel-plan-service-package can be developed by combining several atomic services such as booking-air-ticket-service, booking-hotel-service, making-reservation-for-restaurant and renting-car-service, etc., based on their WSDL descriptions [4].

As the Web services paradigm becomes popular and more and more applications are created and deployed as Web services, the need for developing new solutions tackling the composition of Web services becomes manifest. However, emerging web service standards (e.g., WSDL, UDDI, WSFL and BPFL4WS) and existing methods are not sufficient for realizing the goal of flexible and dynamic composition of Web services. Although some preliminary work has been conducted in the area of services composition, mostly in aspects of workflow-like service integration, service conversation, and B2B protocol definition [1, 2, 3]. However, these approaches are either not flexible or too limited, there is still a lot of research that needs to be done in this direction. This situation has raised the interesting research points for creating and developing new approaches for the Web services composition.

The real challenge in services composition lies in how to provide a complete solution that supports the entire life cycle of services composition, i.e., planning, definition and implementation. By planning, we mean that according to user's requests, a composition plan that how to complete the user's tasks which maps his requests needs to be proposed firstly, afterwards, then the candidate atomic or composite services that possibly complete these tasks need to be discovered, correspondingly. During this phase, every task from the user side needs to be mapped to each service. The outcome of this phase is the synthesis of a composite service out of desirable, or potentially available, atomic services, and the structure of a composite service is generated and formed. At the definition phase, the internal dependencies of the composite service need to be clearly defined and specified. The outcome of this phase is the interdependencies specifications of services composition. Finally, the implementation phase implements the composite service bindings based on the services composition specifications. The first two phases serve as the blueprint and reference of the third phase within the entire life cycle of services composition. Therefore, the first two phases are crucial for the implementation of Web services composition. Without the appropriate planning and definition of Web services composition, it is impossible to implement Web services composition and

satisfy the user's requests. Thus the first two phases within the entire life cycle of services composition are very important, and they correspondingly raise two interesting research points, one is how to systematically plan and model the structure of a composite service? Another is how to clearly specify the inter-relationships of a composite service? If these two issues can be properly solved, the development and implementation of Web services composition would be greatly facilitated. However, the existing standards and approaches haven't systematically addressed these issues, or are not enough to effectively tackle these issues.

In this paper we concentrate on first two interesting issues and propose the well-defined notions "**Composition Structures**" to plan and model the structure of a composite service during the planning stage of services composition, and then we come up with a specification mechanism that effectively tackles the definition stage of the entire life cycle of services composition, as it can clearly specify the internal dependencies of the composite service which effectively facilitated the implementation of services composition. In the planning stage of services composition, our objective is to easily generate the composition process and to support the composer in selecting most suitable services. Thus we modified and enhanced the task structures notions [7] and developed our new composing notions for the services composition: composition structures. These composition notions capture the most critical aspect of services composition: **joints** among the several services; and address the use of libraries of well-defined building blocks to represent the joints and connect the services, which provides a kind of reliable and lightweight mechanism for services composition. By using these notions and notations, the basic structure of services composition can be generated, afterwards, and the complete and nested structure of services composition also can be generated based on the basic structure of services composition if it is necessary. Naturally, our assumption is that the composer will prefer dealing with appropriate and fewer services where possible, which increases the security and the trustworthiness of the resulting services. During the definition stage of services composition, we would like to provide a specification approach which specifies the internal dependencies of a composite service. We view every service as an independent unit of computation. Our work is motivated by the observation that a composite Web service is constructed by composing several constituent Web services, which are executed in a heterogeneous environment. The resulting composite Web service might be very complex in structure and relations, containing many **notification** and **dataflow** dependencies among their constituent services. Furthermore, the execution of such a composite service may take a long time to complete, and may contain long periods of inactivity, often due to the constituent services requiring user interactions. In a distributed environment, it is inevitable that long running composite service will require support for fault-tolerance and dynamic reconfiguration: machines may fail, services

may be moved or withdrawn and application requirements may change. In such an environment it is essential that the clear specification of the structure and internal dependencies of the composite service need to be clearly specified, and this specification need support the properties of modularity, interoperability, dynamic reconfigure-ability and fault-tolerance for a composite software system in the dynamic Web environments of business applications.

Thus the focus of this paper is on the following:

- We propose well-defined notions and notations "composition structures" to capture the most key aspect of services composition: joints among the several constituent services; and represent these joints and connect the constituent services. By using "composition structures", the structure of a composite service can be reliably generated and formed.
- Afterwards, we come up with a specification mechanism that can clearly specify the internal dependencies of a composite service which include the notification and dataflow dependencies, and it can effectively support the properties of modularity, interoperability, dynamic reconfigure-ability and fault-tolerance for a composite software system in the dynamic Web environments of business applications.

The outline of this paper is as follows. Section 2 firstly addresses our novel notions and notations: composition structure, which has four basic building blocks such as and-split, or-split, and-join and or-join. Section 3 comes up with our specification mechanism for the services composition, and last two sections present the related work, summarize our contributions and conclude the paper.

2. The Composition Structures

As we know, the dynamism and unpredictability of the business applications and Web environment require that the Web services composition have the ability to adapt to unknown situations. We believe that some form of enhanced features from reflection and process modeling will provide the right ingredients to enable adaptability.

Reflection [5] is the act of revealing a system's implementation, and allowing changes to that implementation in a controlled manner. By inspecting internal aspects of a system, its competence may be improved, either through better performance or greater adaptability. The concepts of reflection have been applied in many areas of computing and information technology, where it has been employed as a means of building up flexible and extensible computer systems – ones that can evolve and adapt to changing circumstances and expectations [6]. In this paper we apply to the concept of reflection and inspect the internal aspects of a composite service, which includes two main parts: the structure of a

composite service and the internal dependencies of a composite service. Correspondingly, we come up with our solutions in order to tackling these two parts. We believe our solutions tackle the most critical aspects of a composite service, and satisfy the requirements of the flexibility, adaptability and reliability for a composite service.

During the process modeling of a composite service there is a vital aspect and a hard point that needs to be firstly tackled: that is how to deal with the joints among the constituent services. Here we would like to propose our notions: composition structures based on the concept of task structures. As we know, a composite Web service involves the completion of several Web services. These several services need coordinate to complete a specific task. This kind of coordination is actually the coordination of several tasks, which has the process style. For example, Flight-booking service need to be finished before Accommodation-booking service commences. After finishing Accommodation-booking service and Attraction-searching service, the composite service needs to choose one service between Bicycle-booking service and Car-rental-booking service. After that, Events-planning service takes place. Processes focus on the coordination of tasks. Any process specification language should at least be capable of capturing sequential composition, moments of choice, parallel composition, and various forms of synchronization. Task Structures [7] is notions and notations for describing the various tasks within a process, and their interdependencies. In this paper we enhance the notions and notations of task structures specifically for the Web services composition. Here we only apply to these enhanced notions and notations to generate and model the structure of a composite Web service, and use another solution to specify the inter-dependencies among the constituent services of a composite Web service. We believe this kind of treatment is more reasonable, because the composing structure and the dynamic inter-dependencies of a composite Web service are two different facets of a composite service and have their own characteristics. It deserves to obtain the different treatments and apply to the different approaches and solutions.

Thus the composing structure of a composite Web service may be composed from one or more of five particular building blocks, here we call them “**Composition Structures**”. (Naturally, we might introduce more composition structures similar to process patterns in workflow research community [8,9,10]. However, here our purpose is to generate and model the structure of the coordination of several Web services, which is different from modeling the control structure of workflow, although they have some similarities. After all, the composing structure of a composite service is different from the control structure of workflow. Moreover, over-introducing the building blocks might lose flexibility and manageability for a composite service. This aspect of research is beyond the scope of this paper).

Sequential-composition: After Service A has been

performed, only Service B will be performed. This is called **Sequential-composition** between two services.

AND-split: After Service A has been performed, both Service B and Service C will be performed. Service A is said to **trigger** the other services.

OR-split: After Service A has been performed, either B or C, but not both, will be performed. This is called a **decision point**.

AND-join: Service C cannot be performed until both A and B have been performed. This form of join is called a **synchronizer**.

OR-join: Service C will be performed whenever either A or B, but not both, have been performed. This form of join is called a **discriminator**.

The above notations are not limited to relations among three services, and they might be extended more than three services. For example, Service A can **trigger** more than two parallel services at the same time.

Please note the above notations are not only notations, but also they are notions, since they express a kind of semantics and satisfy the requirements of process specification language which captures sequential composition, moments of choice, parallel composition, and various forms of synchronization.

3. Specifying the Internal Dependencies of a Composite Service

3.1 Specification Approach

In terms of the composition structures notions, the reliable structure of a composite service can be generated and formed. In order to describe the dynamic dependencies of a composite service, and there is the second part of work which needs to be done. We need to clearly specify two vital inter-dependencies of a composite service: the **notification dependency** and the **dataflow dependency**. The notification dependency means that there exists the sequential relation between two services or two services structures. For example, Service 2 can't be started if Service 1 has not completed; the dataflow dependency means that there exist the data-flowing relations between two services or two services structures. For example, Service 2 needs the data of Service 1; Accommodation-booking service needs the data of the Flight-booking service such as the date, location and the number of clients, etc. We assume that every dataflow dependency also has the notification dependency.

Notification Dependencies. Each notification dependency takes the form:

Notification from {...}

For example, Service 2 can't be started until Service 1 is successfully completed.

Service 2

```

{
  Notification from
    {Service 1 if Service 1 success}
}

```

Dataflow dependencies. If we use the textual representation in the dataflow dependencies, each dataflow dependency takes the following form:

```

Service 2
{
  Inputs {input-X from
    {output-x of Service 1};
    input-Y from
    {...};
    ...
}

```

For example, the input-A of Service 2 needs the output-a of Service 1; and the input-B of Service 2 needs the output-b of Service 1.

```

Service 2
{
  Inputs{input-A from
    {output-a of Service 1};
    input-B from
    {output-b of Service 1}
  }
}

```

3.2 Example

Now that we have the specification mechanism to specify the composing structure and dynamic inter-dependencies of a composite service, a complete specification of a composite service can be formed. If we take the “Travel Solutions” example, its complete textual specification can be written in the following:

```

Composite-service “Travel Solutions”
{
  AND-split from beginning splitting to Flight-booking
  service and Attraction-searching service
  {
    Service Flight-booking
    Inputs {date; location; the quantity of the
    tickets; ...},
    Service Accommodation-booking
    Notification from {Service Flight-booking if it is
    successful}
    Inputs
    {outputs (date; location; the quantity of the
    tickets; ...) of Flight-booking service}
  };
  Service Attraction-searching
  Inputs {location, ...},
  AND-join from Accommodation-booking service and
  Attraction-searching service to a decision point (OR-split),

```

```

OR-split from Accommodation-booking service and
Attraction-searching service to Bicycle-booking service or
Car-rental-booking service,
  Service Bicycle-booking
  Notification from
  {Service Accommodation-booking and Service
  Attraction-searching if they are successful}
  Inputs {...};
  Service Car-rental-booking
  Notification from
  {Service Accommodation-booking and Service
  Attraction-searching if they are successful}
  Inputs {...},
  OR-join from Bicycle-booking service or
  Car-rental-booking service to Events-planning service,
  Service Events-planning
  Notification from
  {Service Bicycle-booking or Service
  car-rental-booking if one of them is successful}
  Inputs {outputs(date;location;...) of Attraction-searching
  service}
}

```

Similarly, the above textual specification also can be drawn in a graphical manner with the textual annotations. Because of the limitation of space, here we will not draw the complete graphical specification blueprint.

4. Related Work

Most of the work in service composition has focused on using workflows either as a engine for distributed activity co-ordination or as a tool to model and define service composition. Representative work is described in [14] where the authors discuss the development of a platform specifying and enacting composite services in the context of a workflow engine. The eFlow system provides a number of features that support service specification and management, including a simple composition language, events and exception handling.

The work related to Web services and co-ordination or composability can be found in [25]. In this paper the authors examine the potential of using coordination technology to model electronic business activities and illustrate the benefits of this approach.

Our work in this paper is different from the above-mentioned work. Our main idea is to separate the design and implementation of a composite service, and concentrate on the research of composition logic for the composite services. Correspondingly, we come up with our sound solutions for the service composition. We believe the advantages of this way are to greatly facilitate discovery of Web services, since the generated structure by using our approaches maps the services we need to discover. Moreover it possesses more flexibility and adaptability, and the structure of a composite service may be easily changed and adapted according to the user’s realistic needs. Our work satisfies and supports the main requirements of a flexible composite software system such

as modularity, interoperability, flexibility, adaptability and fault-tolerance and dynamic reconfiguration in the dynamic Web environments of business applications. Our concrete approaches are related to the following research fields:

Generic process models: In [27], each workflow schema is associated with a family of variants. A particular task in the schema may be viewed as the root of an extensible class hierarchy, with the hierarchy expressing allowable instantiations of that particular task.

Workflow pattern: In the work of [21], a systematic overview of process control constructors is provided. The patterns address business requirements in an imperative workflow style, but are independent of any particular workflow language. They encapsulate commonly used forms of complex workflow functionality.

Architecture Description Languages: Software architecture specification is intended to describe the structure of the components of a software system, their interrelationships, and principles and guidelines governing their design and evolution [15, 16, 17]. It is common to model an application as a set of components communicating through connectors. Typically, an application is composed from components, where a component provides services to other components. A component within an application can be either a simple component, or composed out of a group of other components. The components provide and obtain service through ports. The interaction between ports can take many forms, for example, buffered message passing, one-to-many event dissemination, or synchronous request-reply communication. Currently available ADLs however do not capture the computation unit structure of a composite application. This requires describing the structure and inter-dependencies of an application. Our approaches capture this structure in terms of composition structures notations and their dependencies by specifying input and output requirements. Another advantage of describing composite structure in terms of services is that it directly enables application level fault tolerance requirements to be specified and controlled.

5. Concluding Remarks and Future Research Directions

In this paper we come up with our sound solutions for the composition logic of the composite services, which is referred to the way a composite service is constructed in terms of its constituent services. Our ideas are to separate the design and implementation phases of a composite service, and concentrate on the research of composition logic of the composite services. The advantages of this treatment are to make the composite services have more flexibility and adaptability, which greatly facilitates the discovery of the constituent services, since the structure of a composite service we generate maps the discovery of its constituent services. Our concrete approaches are that we firstly propose well-defined notions “composition structures” to represent the joints among the constituent

services and generate the reliable structure of a composite service, and then we provide a specification mechanism to clearly specify the internal dependencies of a composite service in terms of the notification and dataflow dependencies. Our work is motivated by the main requirements of a flexible composite software system such as modularity, interoperability, flexibility, adaptability and fault-tolerance and dynamic reconfiguration in the dynamic Web environments of business applications. Our solutions and specification mechanisms satisfy these requirements and support these properties. The concrete reasons are summarized in the following:

- We view every service as an independent computing unit. Our notions, notations and specification mechanism are applied to easily generate the structure of the composite computing unit (or composition structure or service) and clearly specify the inter-relations of these constituent computing units. So our solutions support the modularity and interoperability of the composite system.
- Our “composition structures” notions and notations provide a kind of flexible, adaptable mechanism to address the composition logic of the composite system, which means the structure of a composite service can be easily and reliably adapted if the users’ needs are changed.
- Our solutions provide a reliable specification mechanism for the implementation of a composite service. We believe only we have the clear specification of a composite service in an abstract manner, then it can support the properties of fault-tolerance and dynamic reconfiguration for a long running composite service on the Web.

Based on our above work, future work might include two research directions: one is to continue to research the composition logic of Web services, specifically address the composition logic in a more formal way; another is to develop the corresponding application tools or languages for our specifications of the composite services.

Abstract

Companies, large and small, are rapidly adopting Business-to-Employee (B2E) applications hoping to improve productivity of their work force. However, most B2E applications do not provide a good sense of community and lack of collaboration and interaction among its users. Consequently, employees are not motivated to fully utilize the contents and information provided by these applications. Peer-to-peer (P2P) computing is proven to be a good platform that provides and supports community by empowering users to collaborate and interact with one another. In this paper, we propose an approach to provide collaboration in B2E applications based on a P2P platform.

1. Introduction

Business-to-Employee (B2E) applications are believed to be the next wave of the "B" technology. It is estimated that over 75% of global 2000 companies will have adopted B2E applications by 2004. Not only are large corporations adopting B2E as a means to improve communication and increase productivity of its work force, but more small and medium companies are also expected to embrace the technology [6]. In another survey conducted recently by Venkatesh Shankar, et al [8], rapid adoption of B2E applications is further confirmed: more than two-thirds of the 473 firms who participated in the survey claimed that they are using the wireless Internet primarily for B2E applications. The survey results also make an interesting revelation in addition to the finding that B2E applications are going mobile: companies adopting B2E applications are not only confined to a few industries. Instead, the surveyed sectors are quite diversified; they include banking, insurance, manufacturing, telecommunications, transportation, media, utilities, retail, health care, and government. It is apparent that B2E is gaining acceptance across the board of industries.

In this paper, we will first discuss what B2E is, the desirable features of B2E, and the deficiencies of existing B2E applications. To overcome these deficiencies, we

propose a new approach to develop B2E applications based on a peer-to-peer (P2P) platform. We will briefly describe what a P2P platform is and how B2E can be built on it. Finally, we present a collaborative B2E system that is implemented by a global IT company based on Groove Network, a commercial P2P platform.

2. What B2E is

B2E is said to have evolved from the Executive Information System (EIS) of the 1980s [5]. In an EIS, senior management of an organization can access the news, financial data, company performance, information of products, competitors and vendors etc, with a single entry point. This is supplemented by emails, customized built applications, ad hoc query tools, quick and easy report writers, etc. Others believe that B2E actually began with telephone automatic systems (e.g. integrated voice response (IVR) systems) that provided simple human resources administrative functions and evolved into fully personalized portals. While it is debatable that B2E evolved from EIS projects, lessons were definitely learned from developing these EIS. For example, developers gained understanding and experience on integrating diversified data sources of an enterprise with new IT technologies and infrastructure. In addition, developers also realized the significance of politics, company culture, commitment and support from the top management in order to secure the acceptance of EIS. These experiences influence and propel the development of B2E.

B2E is to improve the effectiveness, efficiency and productivity for both individuals and teams by simplifying administrative processes, building competitive advantages through simplified workflow, collaborating and sharing knowledge with one another. Many functions and applications such as company information, R&D programs, project teams, marketing campaigns, HR functions etc, were mostly invisible to employees before, but the advent of Internet technologies made it possible for companies to create portals that integrated all these functions within one single entry point. A company can provide the most up-to-date information to its employees.

Employees can now invoke applications within the same portal without leaving the browser. Through the portal, archives of presentations made by marketing department, status reports on new products and information regarding competitors and vendors, are all accessible through the portal. The accessibility not only makes sharing work easier, but it also makes the entire company more transparent.

2.1 Desirable B2E Features

A typical B2E scenario can be described as follows: A Sales staff logs onto his personalized portal (i.e. MyPortal) in the morning. The portal contains information on the company, updated departmental information, the latest news on products, market analysis (including news on competitors, customers and vendors) done by the Marketing dept, pricing schedule, customer info, sales order status, emails, discussion forums on topics related to sales, file repository that includes sales order forms, customer PO history, new sales training materials on product specifications, and a To-Do list which includes pending sales calls, replies and responses to customers, call list for potential future customers. He will then carry out his daily task assignments and obtain supporting information using the portal.

A B2E portal can provide abundant information for a user. However, the real issue is not all on the B2E portal contents. People can become so overwhelmed by the vast amount of information in a portal that they feel alienated by them. This presents a real problem because, above all, a B2E portal should be the platform where people can relate to their company and to one another and to build the sense of community. Furthermore, any B2E portal has to be compelling to the people who use it. Based on these perspectives, we identify the following list of desirable features of a B2E portal:

(1) Basic Features

- a. Single point of entry. A B2E has one URL that will be the entry point of all employees.
- b. Tools and applications that support daily operations such as news, events, calendar, file repository, etc.
- c. Personalization. The functional aspect of personalization is to allow an employee to select what information should be presented in what order. Psychologically, personalization gives an illusion that the portal is designed to serve just one employee. The more personalization an employee does to his portal, the higher chance that he will use the portal.

(2) Advanced Features

- a. Communication
Communication should include many modes, synchronous and asynchronous such as one-to-one (email), one-to-many (broadcast message, listserver, mass mailing list), and many-to-many (discussion groups and forums), including chat room and instant

messaging. A B2E must provide channels for employees to communicate to the management and to each other.

b. Collaboration

i. Real time collaboration.

Employees will need to collaborate and interact with each other in order to improve their efficiency, productivity, often to provide better customer services. Real time collaboration includes co-browsing, co-editing, co-annotating, whiteboard drawing, chatting, and instant messaging.

ii. Offline collaboration and synchronization.

Offline collaboration is also necessary to support team work. There will be times when team members are not connected to the Internet or the collaboration does not require real time support. A B2E should support offline collaboration mode such as discussion forums. Updates done by other team members should be synchronized with members who have been offline so that they can catch up with the activities and events at a later time.

iii. Ad Hoc Collaboration.

Collaboration mode is mostly pre-defined, i.e. establishing a virtual workspace for a specific project or purpose. However, there are often times when people need to set up ad hoc collaboration workspaces to facilitate their work. For instance, a sales staff may need to collaborate with an engineering team for a short period of time. They should be able to form an ad hoc collaboration workspace to support their work.

c. Knowledge Sharing.

A B2E should support both structured and unstructured knowledge, e.g. file repository, training materials, handbook, guidelines, company procedures and policy, chat room archives, history of document annotation and editing.

d. Multiple Channel Delivery System.

A B2E should be able to deliver to multiple devices and platforms, ranging from desktop browsers, to notebook computers connected through cell phones and Wi-Fi, to PDAs and cell phones.

e. Workflow and Processes Support,

A B2E should support workflow and processes that are tailored to the company's culture and best business practices.

f. The B2E should not be restricted to single domain or application. It should be able to

span across the boundaries within and outside of a company. It should cross departments and be exposed to external entities such as clients, vendors and suppliers.

2.2 Existing B2E applications and their deficiencies

Basic B2E solutions have been around for quite some time [2]. In the 1980s, companies used phone system automation (e.g. the integrated voice response (IVR) system) to support their employees. Most notably, it was at this time that many human resource functions, such as benefit administration, could be accessed via an IVR system. In the 1990s, client/server employee self-service applications were developed. Employees could submit benefit application forms, modify their personal information, view the status of their benefit packages, apply for vacation, etc through a client/server application within the LAN. In the late 1990s and early 2000s, the advent of technologies and the availability of the Internet, in addition to the valuable experiences in building EIA systems, B2E applications were transformed into web-based Intranet or Internet applications that allowed an employee to access information anytime from anywhere. These web-based applications were then further integrated to form a fully customizable company portal. As can be seen, the B2E portal has evolved from a traditional simple IVR to a client/server application, from a limited amount of services to a full spectrum of employee services that range from accessing information on the company, product specifications, business/market intelligence on its competitors, customers and vendors, product pricing information to employee handbook, company policies and procedures, HR benefits and to online training. It is irrefutable that these solutions do improve the productivity, efficiency and effectiveness of employees. However, there are several areas that these solutions fail to address:

- (1) Lack of communication. Communication is mostly one-sided. The company disseminates information to employees and collects specific information from employees through applications. It would be difficult for employees to pass information upward. In an efficient and ideal organization, with more people in the decision making process, people who have relevant information or ideas have a better chance than ever to influence the outcome of those decisions. Existing B2E is weak to support m-way communication among employees and management.
- (2) Lack of Collaboration and Interaction. B2E applications hardly support collaboration and with very limited interaction. However, collaboration is key to improve effectiveness, efficiency and productivity. Collaboration creates good sense of community which can be the major attraction to draw employees to use B2E.
- (3) Lack of Sense of Community. Most B2E applications do not support communities. Users of such systems will hardly get the chance to interact with other users. A good sense of community support is essential to attract and retain users.
- (4) Difficulty in crossing boundaries. Most B2E applications are separated from each other. It is difficult to traverse or integrate a specific B2E application to other B2Es or to other non B2E applications.
- (5) Lack of flexibility to support ad hoc collaboration. Collaborations in most B2E are pre-defined and do not allow users to create ad hoc collaboration when needed.

3. Peer-to-Peer Platform

In the past few years, P2P has attracted enormous media attention and gained popularity by supporting two main classes of applications: file sharing, in which peers share files with each other (for example, Napster, Gnutella, Morpheus and Kazaa), highly parallel computing, in which an (inherently) parallel application runs on available nodes (for example, SETI@home and FightAIDS@home) [9].

A Peer-to-Peer (P2P) is a set of protocols on which an IT architecture is built upon to provide a distributed computing environment (DCE) [7]. Hosts are interconnected via Internet. Each host maintains its autonomy. Every host is "equal" without the distinction between Client and Server. An individual host can have its unique abilities and can benefit from services provided by its peers. The enabling technologies of P2P are due to the ubiquitous network connectivity with available high bandwidth, combined with increased process and memory capacity. In addition to file sharing and highly parallel computing, other services such as virtual communities, real time collaboration emerge.

The major deficiency of existing B2E is the missing of collaboration and hence the sense of community. Analogous to the Maslow's Hierarchy of Needs, a Collaboration Hierarchy is depicted in Figure 1. At the lowest level, collaboration can be based on emails and supplemented with FTP. The next level of collaboration is the groupware and shared network drives. A more elaborated collaboration can be provided with web applications and portals so that employees can share and collaborate anywhere anytime. The highest level of collaboration will be the real-time collaboration based on a P2P architecture. Peer-to-Peer (P2P) is proven to be an excellent computing environment to create and support collaboration and sense of community [3, 4, 7, 9]. It is this level of collaboration we are proposing in this paper.

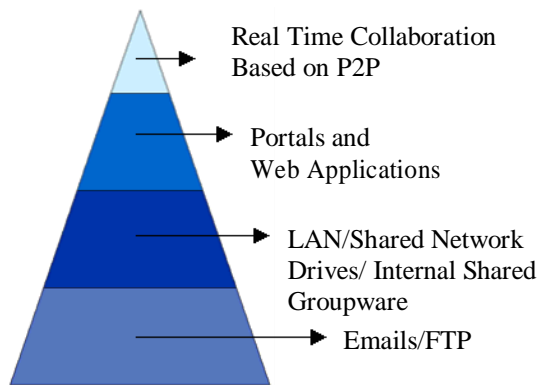

Figure 1: If Maslow was a collaborator

4. A Collaborative B2E based on P2P

A collaborative B2E can be built on top of a peer-to-peer (P2P) platform. Figure 2 depicts a high level architecture of such system.

The foundation of this architecture is based on a peer-to-peer platform. Its major services include communications, security, data synchronization, and providing components/APIs to integrate applications. For example, Groove Network is one of several commercial available P2P platforms [10].

Virtual workspaces can then be built on top of the P2P platform. A workspace is a virtual environment in which a small group of people can collaborate and interact with one another across technical and organizational boundaries. The workspace becomes a community for its members. For example, a Sales Workspace can be created and shared by sales staff who need collaboration, or just to create the sense of community. For each product development, a workspace can be created to support people who need to collaborate on that product development. An employee can belong to many workspaces at one time.

B2E Application/Portal includes those contents and applications that an employee may find in a typical company portal. The portal may include corporate directory, customer support information, e-learning system, customer support management system, marketing/sales management system, knowledge management system, etc. It can also contain other personal information and links (such as stock information, web cams to the daycare center to monitor their children, etc). The intention is to increase not only work efficiency, but also employee satisfaction and a sense of community within the organization.

Another major component is the B2E Applications Data /Documents such as customer and competitor profiles, previous proposal, etc. These are electronic records generated by B2E applications.

The B2E Integration Bridge is used to integrate B2E applications. It enables electronic records transfer between B2E applications via XML, SOAP and Web Services. The Bridge can reduce the use of emails as the primary document-sharing tool. Instead, open standard

such as Web Services based on J2EE or .NET could be used.

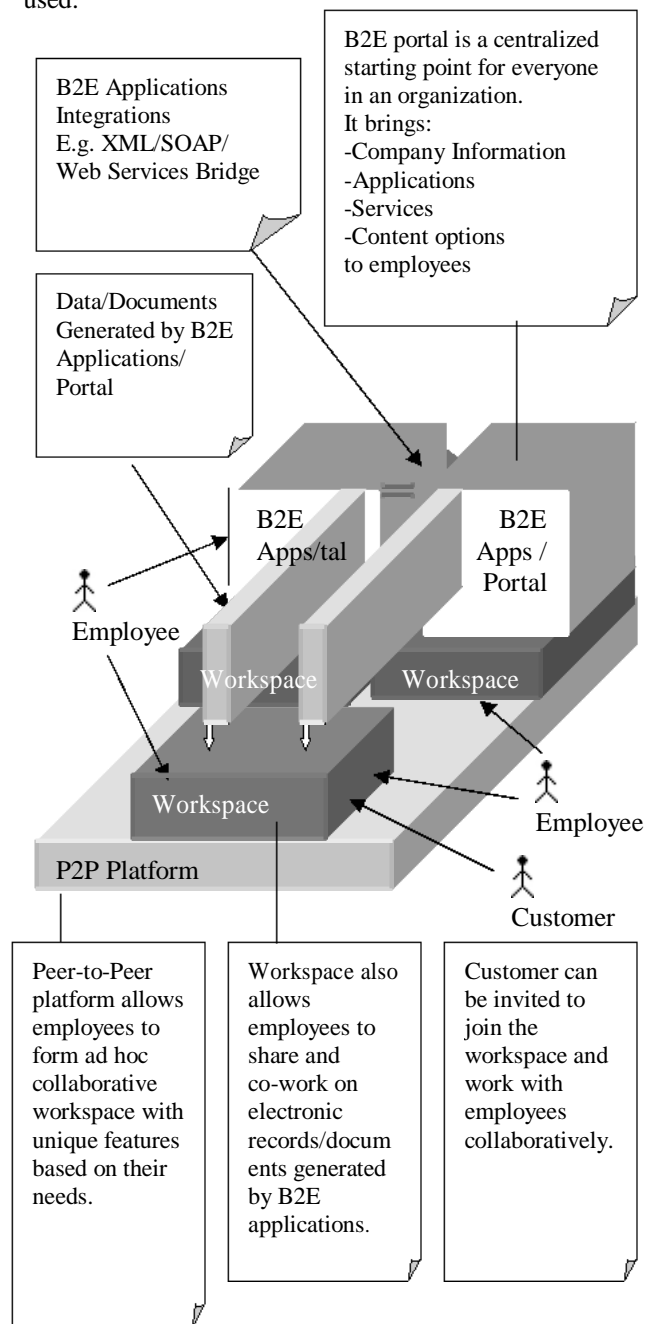

Figure 2: A high Level architecture for a collaborative B2E on P2P

4.1 Benefits

The architecture has many benefits:

- (1) A Peer-to-peer platform (e.g. Groove Network) does not require a company to reinvent itself on the existing network infrastructures. It offers a high degree of flexibility that allows applications to run across department boundaries, corporate boundaries, exposing themselves to other business partners and vendors.
- (2) Workspace can be formed easily; employees can

share and co-edit documents or electronic records generated by B2E applications/Portal. The sharing eliminates the time spending on swapping emails with attachments at the same time provides a centralized and organized way to manage the documents. Workspace can also be formed with employees and even customers from different locations or organizations.

- (3) The B2E Integration Bridge based on open technology serves all the enterprise applications integration requirements. It simplifies most of the routine data transfer between B2E applications. For those ad hoc non-routine data sharing between B2E applications and collaboration, employee can easily create workspace to facilitate the needs.
- (4) The B2E on P2P solution can be rapidly deployed with minimum custom programming needs.

5. A Case Study - B2E at KBQuest Group

KBQuest Group, Inc. is a global IT company with offices in Los Angeles, Hong Kong, and Shanghai, China. It engages in the business of software design, development, and production for its worldwide customer base.

5.1 Business Challenge

As business grew, more B2E applications were built to automate the software development processes. For example, the following applications were built to support software development process: Project Management System, Bug Tracking System, Knowledge Base Sharing System, and Configuration Management System. An Intranet was also created to enable interactions and some degree of collaboration among staff and sometimes even with the customers. The Intranet had applications such as the Online Project Tracking System and Requirements Changes Management System. Even though all of these applications were built as web-based solutions, they missed the real time collaboration capabilities. Moreover, because these applications were developed separately, it became increasingly difficult to manage and evolve to support real time collaboration. Software development requires real-time communication and collaboration among sales, development teams, and customers from different countries and time zones, but Faxes and emails with attachments supplemented with ftp sites were the only tools allowing staff from different departments and offices to share documents or electronic records.

In order to increase efficiency and to ensure the consistent quality of its creativity process, KBQuest adopted a new technology solution that would allow its teams to collaborate in real time in a virtual environment and provide a more reliable means of exchanging and working together on large programming files that were generated by B2E applications. In addition, the solution also supported mobile and offline operations with synchronization, so traveling staff could remain productive and informed.

5.2 The Solution

KBQuest built a scalable and flexible B2E based on Groove Network, a commercial P2P platform. When a user logs in his Groove space, he is able to see his personalized company portal as a welcome page. From his home page, he is able to access all workspaces that he belongs to. The B2E centralizes the entire software development process, incorporating all the B2E components, within a P2P workspace. The B2E is used primarily to support three major processes: Proposal Development, Project Development and Management and Customer Support. More processes are planned to be included in the future. These processes with examples will be described briefly in the following sections.

(A) Proposal Development

When a new client brief is received, the project team immediately creates a Groove workspace. Relevant and related managers, sales and project leads are invited to the shared workspace. Throughout the brainstorming process, the Groove workspace is the sole repository for all the information, files and data imported from other B2E applications. The workspace is the default virtual meeting place for discussion sessions, research activities and general communication.

Planning & Research

The first phase of proposal development is strategic planning and research. The project management team collects previous project information from the portal and other workspaces, including previously created proposals, analysis and design documents, and case studies. These materials are loaded into the Groove workspace shared by all members. Once all materials are shared, the team can assess the opportunity and determine a conceptual direction for the proposal. Figure 3 depicts a work in progress conceptual plan that the team is developing.

Solution Plan Development

The second phase is to develop solution plans. Team members discuss ideas through virtual meetings, draft solution plans, working on possible solutions until the right idea is achieved through chatting, instant messaging, discussing issues in the topic forum, exploring internet search by co-browsing, etc. For instance, a topic forum is depicted in Figure 4. The workspace essentially allows the team to work together on the development of the proposal, without requiring as much face-to-face time, hence reducing travel.

Proposal Generation

The final phase of the process is to generate the proposal. The sales, project managers, team leads collaborate with each other to generate a cohesive proposal by co-editing the document. Very often, client's inputs are sought at this early stage. Because Groove works easily across firewalls, the team can involve its clients throughout the proposal refinement process. The client will install Groove workspace (a free download). They will be invited to a workspace where KBQuest staff can communicate and clarify issues of the project. Once

the contract is awarded, the proposal workspace becomes the project space, where the team continues working to design and implement the system while keeping constant communication with the client.

(B) Project Development and Management

In the project space, KBQuest uses a variety of applications to manage the project and the relationship with the client. Documents and electronic records generated by B2E applications can be shared through the project space. For example, during the stage of requirements analysis, use cases can be shared and discussed by all related members (Figure 5). Design document such as domain model, data model, sequence diagrams etc can also be shared and discusses. (Figure 6). Indeed, all project-related information is now kept up-to-date automatically via the project space, including specifications document, requirements and analysis document, development documents, source code, and test cases. When a KBQuest team member makes a change, it is automatically sent to the workspace so that all other team members will see the change. Updates of workspace will be synchronized to all participants. For example, a team member can be offline or his internet connection is interrupted. Once he is back online, Groove will synchronize all missing updates, events including chat scripts that took place while the member was offline. This is especially useful in the Asia Pacific region, where Internet connections are frequently lost throughout the day.

(C) Customer Support

Customers invited to join the workspace can monitor the development process and provide instant feedback through the Project Tracking component without delay.

5.3 Results

KBQuest now has a unified B2E software process management and collaborative system that spans all of their cross-countries departments and gives their worldwide customers the ability to effectively monitor the project status. With the simple yet powerful platform supplied by Groove, the previous multiple web-based systems have been replaced or integrated by the B2E workspaces. Teams from the US, Hong Kong and Shanghai offices can communicate with each other via real-time chat, co-browsing and co-editing. All project team members work with the same up-to-date information regardless of their locations and time zones. Groove's P2P platform eliminates the network barriers between departments of KBQuest and also between KBQuest with different customers. Information extracted from the B2E portal can flow more freely. Furthermore, the Groove workspace ensures that both customers and KBQuest personnel can access the project information anywhere anytime; even when there is no Internet connection (Each local Groove workspace retains a copy of the data files). Best of all, the KBQuest staff no longer needs to login onto multiple systems just to access the same project documents.

6. Concluding Remarks

In this paper, the recent trend on B2E applications is discussed. We further identify the desirable features of B2E and the deficiencies of existing B2E systems. We show that, in order to attract and retain people to use B2E, it is essential to provide a good sense of community through real time collaboration. We further propose to implement B2E based on a Peer-to-Peer (P2P) environment that supports real time collaboration. Finally, we presented a case study to illustrate how the system is implemented and used.

Abstract

Although a variety of payment mechanisms have been developed over the years for online businesses, payment by credit cards remain the leading mechanism for online payments. For real-time online credit card processing, a merchant needs to install a third-party proprietary software in the merchant e-commerce server. However, many issues need to be resolved before integrating a third-party payment solution to a merchant e-commerce system. In this paper, we attempt to address the current state of the online real-time credit card processing models. We also discuss several factors such as cost, complexity and security issues related to implementing such a system.

1. Introduction

Over the past few years, many dot-com companies have failed; however, e-commerce is stabilizing to those companies that streamlined their online business processes [6]. According to a recent report [2], purchase of goods and services over the Internet is expected to increase from \$325 billion in 2001 to nearly \$3.5 trillion in 2006. The consumer spending of e-commerce for the year 2003 is estimated to be at \$110 billion [16]. Despite poor economy in recent years, online consumer shopping has increased from 2001 to 2002 by 43% [7]. During the 2002 holiday season, online consumers spent \$367.05 million on December 8 – an all-time high for one-day shopping; the weekly spending was about \$2 billion [8]. NACHA, the electronic payment association which develops operating rules of the ACH network, the largest network of electronic payment processors in the United States, introduced a new payment category for WEB transactions in 2001 [1]. According to their latest report, WEB transactions increased more than 300% from 2001 to 2002. Consumers are also increasingly embracing electronic methods of payment [18][21].

In the traditional retail business, the display of products, processing of payments, and delivery of goods are handled by merchants in front of the customers. In the e-commerce arena, these processes are typically handled by three different parties, and payment over the Internet is the most common concern for the consumers. Between 40 to 60 percent of Internet purchases are abandoned in the midstream, because customers do not want to compromise privacy or the security of their financial information [12]. To address these issues, various online payment mechanisms have been developed that include:

digital cash, electronic wallet, electronic check, and smart card. Most of these mechanisms have failed due to the complexity of use and implementation as well as poor customer trust. Thus, payments by credit cards remain the most prevalent mechanism for online consumer payments [13] [25].

A complete e-commerce business cycle requires interactions between several hardware and software components physically located in different geographical locations. An electronic merchant usually develops and maintains the merchant processes, while the financial institutions or software companies provide payment services to the merchants. However, in most cases, payments are not processed in real-time. For reasons of security, complexity, and cost, the payment information is typically collected from a consumer but is processed off-line like a physical store. For real-time payment processing, a merchant needs to install a third-party proprietary software in the merchant e-commerce server. However, many issues need to be resolved before integrating a third-party payment solution to a merchant system – the most important is the technical knowledge of the people who are developing the e-commerce system. For large companies, this may not be an issue, but for small companies where resources are limited, it is important to understand the challenges of implementing an online credit card processing system.

This paper attempts to address the current state of the online credit card processing system. First, we provide an overview of the credit card processing mechanism. We then focus on the various models of online, real-time credit card processing system and discuss several factors such as cost, complexity and security issues related to implementing such a system. The results can be extremely valuable to small businesses that are venturing into Internet commerce.

2. Credit Card Processing Mechanism

There are in general six parties involved in a traditional credit card processing cycle: customer, card issuing bank, merchant, merchant's bank, acquirer, and a credit card processor. The card issuing bank issues credit cards to customers and maintains their accounts. The merchant opens an account with a bank to receive payments. In order to accept credit cards, the merchant needs to register with an acquirer – a bank or financial institution that sets up an account for the merchant and provides a terminal to process credit cards. The processor is a large data center maintained by the credit card

network, and it acts as a clearinghouse for all credit card transactions.

There are two stages of transactions for any credit card purchase: payment authorization and fund capture. Authorization refers to checking the account number to see if it is still valid, has sufficient credit, and has not been reported lost or stolen. Capture refers to approval and posting of the transaction and shipment of goods. When a purchase is made by a customer, the merchant uses the terminal to send payment information to the acquirer. The acquirer contacts the card processor for authorization, which in turn contacts the customer's bank for credit availability, and if all goes well, provides a charge authorization number to the acquirer. The acquirer transmits back the authorization to the merchant. All transactions happen in few seconds and no transaction of money takes place yet.

To capture funds, the acquirer accumulates multiple payment authorizations and submits them as a batch to the processor on an hourly or daily basis. After receiving the fund, the acquirer deducts a small fee and credits the rest to the merchant's bank. Thus, all the costs associated with the credit card processing are borne by the merchants. The process of refund follows a similar set of transactions.

The credit card processing mechanism was developed by the financial institutions over a long period of time. The fundamental method of payment authorization and capture of funds are the same whether the purchase is made from a physical store or via Internet. However, the biggest hurdle for an online merchant is to get the credit card and personal information from the customer securely over the Internet.

The online payment processing becomes further complicated due to the introduction of a payment gateway that replaces the acquirer or acts in between the merchant and the acquirer. It is typically a software company or a financial institution that provides necessary software to the merchant for real-time payment processing. Most banks will not set up a merchant account for an online business because online businesses are classified high risk.

3. Methods of Credit Card Processing

A merchant can process credit card payments in a number of ways. These include manual entry through a touch-tone telephone, manual entry using a point-of-sale (POS) terminal, manual or electronic entry via a PC acting like a POS terminal, or electronic entry from a Web site [23]. Many of these mechanisms require physical interaction of the merchant with the customer or a system.

For real-time payment processing, an online merchant needs to integrate a payment processing software to the e-commerce site, so that the communication between the software tools used by the customer, the merchant, and the payment gateway are all automated. There are many variations of real-time payment processing, and recent developments include wireless technology with personal

digital assistants (PDAs), through which customers can swipe credit cards like traditional POS terminals but complete the payment transaction through the Web [3]. Since there is no standard for the Internet payment processing, a merchant needs to invest some time and money to understand various options and to implement a payment solution suitable for the online store.

4. Online Credit Card Processing Models

Several payment solutions are available for online real-time credit card processing that are implemented through technologies such as standard shopping carts, one-click buy, enterprise e-commerce package, and application service provider. These technologies require installation of some software or modification of Web pages in the merchant e-commerce server. These applications can be grouped into two broader categories of merchant-oriented applications and payment gateway-oriented applications [4][5][14][17].

4.1. Merchant-Oriented Applications

In this case, an online merchant collects customer order information including the product, personal, and credit card, from the e-commerce site, and then forwards the payment information to a payment gateway. The payment gateway in turn communicates with the credit card processor, obtains a charge authorization id to charge the customer account, and sends it back to the merchant Web server. The merchant Web server confirms the order by sending a message to the customer. After fulfilling the order, the merchant requests payments to the payment gateway. Thus, all order and payment transaction data are maintained by the merchant. As most of the processing is performed in the merchant server, these systems are sometimes referred to as local-mode. In this case, the collection of the customer information is via the Internet, whereas the sending of information to the payment gateway can be via phone lines, leased lines, or the Internet. For Internet transmissions, the Secure Socket Layer (SSL) protocol is typically used for data encryption as well as Web Server authentication.

The merchant-oriented applications typically employ a client-server approach as shown in Figure 1. The client software or plug-in is installed in the merchant Web server as a library of programs, usually in C or C++, and the server software, termed as payment gateway, resides with the software provider. The client software is a small messaging agent that uses SSL and X.509 digital certificate technology to securely communicate with the server [24]. The merchant e-commerce system typically pass payment transaction data to the client through a set of name/value pairs implemented in a merchant form at the checkout page. Depending on the fields required by the payment gateway, the code will be different. Various other Web pages and program codes are necessary to handle communication between the customer, the merchant and the gateway.

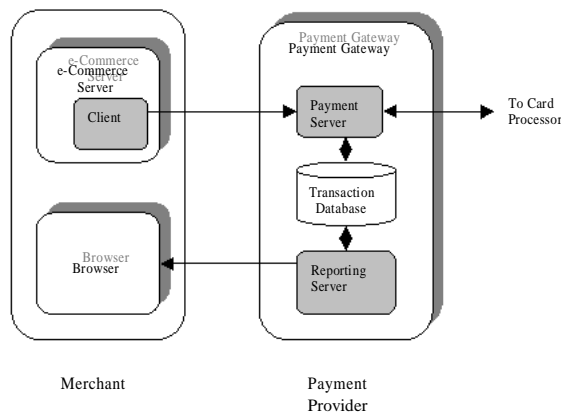

Figure 1: Client-server architecture of Payment Gateway

The payment gateway typically contains a payment server, a transaction database, and a reporting server [10][11]. The payment server accepts encrypted transaction information from multiple clients as well as routes necessary information to the appropriate processing network depending on the credit card. It also performs settlement of transactions. The transaction database contains all transaction-related information for initial orders, payment authorizations, and settlements. The reporting server is used to provide transaction reports such as settled transactions, unsettled transactions, and invalid transactions to the merchant. Thus, in this approach, all order details and some payment information reside in the merchant database, while the payment details reside in the gateway database.

Because most transaction information resides in the merchant's database server, the merchant has more flexibility in the customization of processes and transaction reports, however, strict security protocols must be maintained to protect credit card information in the database. These systems are designed to handle multiple items per transactions, more than 1000 transactions per month, and scalable up to hundreds of millions of transactions. VeriSign's Payflow Pro SDK [24] and Authorize.Net's ADC [3] are examples of merchant-oriented payment applications.

4.2. Payment Gateway-Oriented Applications

These systems are designed for merchants with limited technical capabilities and low transaction volumes. They are typically implemented through a one-click approach and they require minimal changes to the merchant Web pages. The customer usually clicks a link or a button at the checkout page and he or she is directed to a secure page hosted by the payment provider [3][9]. Transaction details (order amount, tax amount, and other parameters) that are encoded in the link are used to initialize the form. The customer then enters credit card details and personal information in the secure form in the gateway Web server.

When the order is submitted, the merchant is notified via e-mail, and the merchant can view specifics of new orders from the Web site maintained by the gateway provider. The processing of payment is same as before; however, all order and payment transactions are maintained by the gateway provider. In this case, the communication between the customer and the merchant is Internet-based, whereas that between the customer and the payment gateway is typically SSL-based. The digital certificate of a single payment gateway serves the customers of all merchants that sign-up with the payment gateway.

The gateway-oriented applications are the simplest payment solutions found in the e-commerce industry, as these systems require less hardware, less technical expertise, and less maintenance for the merchant – these are maintained by the gateway provider. In this case, merchants lose control over the payment transaction data, as they reside with the gateway provider, however, they can view these records through a password-protected Web site hosted by the company providing the payment gateway. A payment gateway provider typically supports many merchants by providing a merchant ID to each merchant and usually helps merchants to open Internet merchant accounts with banks that accept Internet payments by credit cards.

These systems are suitable for merchants processing up to 1000 transactions per month, however, the downside is that only one item can be purchased at a time. VeriSign's Payflow Link [24] and Authorize.Net's WebLink [3] are examples of payment gateway-oriented applications.

5. Issues of Online Credit Card Processing Systems

Selling goods and services on the Internet presents a set of challenges – like how to set up and maintain a secure, reliable, and cost-effective system for payment processing and managing transactions. Several issues need to be resolved before integrating a third-party payment solution to a merchant system – the most important are the security, cost, and complexity.

5.1. Security

The security of financial transactions is of utmost concern when dealing with many parties, especially over the Internet. Consumers must be able to send their financial information to an online merchant without the fear of eavesdropping. They should also be comfortable with the identity of the merchant, that the cyber-merchant is reliable and not bearing a fake identity. The merchant should also be able to send financial information securely to the payment gateway. The technology that addresses these issues is the secure socket layer (SSL) protocol, which uses public- and private-key encryption mechanisms to communicate between a browser and a Web server as well as to authenticate a Web server. If the

merchant is planning for international business, then SSL-encryption key should be 40-bit instead of 128-bit standard for the United States. In order to use SSL, a merchant needs to apply for a digital certificate to a Certification Authority (CA) such as VeriSign [24], get the certificate, and bind it to the IP address of the merchant Web server [20]. The merchant also needs to configure the Web server to accept SSL transmission and develop the payment-related Web pages such that they use HTTPS, the secure version of Hypertext Transfer Protocol.

Fraud prevention such as unauthorized credit card purchase is another important issue for a merchant, because the law provides a consumer liability limit up to \$50 if someone uses his/her credit card fraudulently. The merchant is liable for bad transactions – neither the customer, nor the credit card issuer. Thus it is important to use address verification service (AVS) which verifies key components of a customer's shipping addresses against addresses that the credit card issuer has on record for the customer. Research shows that about 65% of the time, criminals using credit card account numbers fraudulently, do not know the account's related billing address [19]. Various other security measures should be implemented for an online purchase, such as, how many times a customer can enter wrong credit card information before it is rejected. In addition, an upper purchase limit to a single transaction or the number of transactions per day by the same credit card number should be controlled.

According to a very recent report [8], about 8 million account numbers of MasterCard, Visa, and American Express credit cards have been compromised from a third-party payment processor. Thus the merchant needs to safeguard the private key used for SSL encryption as well as the consumer privacy information such as credit card numbers and personal data stored in the merchant database. The private key and the credit card number should be stored in the encrypted form, and access to these information should be highly restricted. All sensitive data should be kept behind a firewall and may be in a different database than the one used for the product catalog. To implement these security protocols and to safeguard data requires technical expertise as well as money, both of which might be limited to a small merchant.

5.2. Cost

There are several costs associated with the development and operation of a payment mechanism, and they are all borne by the merchant. Irrespective of the type of payment mechanism implemented, there is always a cost associated either with the development of the payment-related Web pages or integrating the payment software with the catalog pages. This requires in-house technical expertise or consulting service from a payment provider, where the later might cost about \$200/hour for a merchant [22]. For merchant-oriented applications, there is also a cost associated with the purchase or lease of the software, and often there are monthly or yearly fees

associated with the software license and future upgrades. For payment gateway-oriented applications, commonly there is an application fee, a monthly gateway access fee, and statements fees [15].

There is always an operational cost associated with any credit card processing whether it is performed online or offline. It arises mainly due to the charge placed by the banks and credit card network to process a transaction. Generally, there is a fixed charge for each transaction and a discount rate charged as a percentage of each order-amount. The charges for Internet transactions are often the same as the mail or telephone order transactions, and all of which cost significantly higher than the offline transactions. For example, the discount rate and transaction fee for an Internet transaction are 2.39% and \$0.30 respectively, while those for the standard swipe retail are 1.69% and \$0.20 [19]. The costs are even higher for international transaction, which are about 3.25% and \$0.30, respectively.

The above charges do not significantly vary from one payment provider to another; however, there might be additional charges from a payment gateway if it is not acting as an acquirer. Some payment gateways charge by the volume of transactions, while others provide free transactions up to certain numbers [15]. For merchant-oriented applications, there might be a batch transaction fee and it can run about 10 to 40 cents per batch. There is also a cost for charge back, which is a reversal against a sale that was an error, misunderstanding by the customer, or fraud. It can cost about \$10-\$25 per charge back [19]. For all non-card present situations such as the Internet, there might be an authorization/verification or AVS (Address Verification System) charge, which might cost about 5 to 10 cents per transaction.

5.3. Complexity

The explosive growth of payment gateways provides a variety of real-time credit card processing options available to an online merchant than can be found for a physical store. For example, all large companies such as Authrize.Net, CyberSource, iTransact, LinkPoint, PaymentOnline, and VeriSign, offer at least three different types of such solutions. In the physical store, the integration of a payment system with an existing point-of-sale system is through a standard hardware/software interface. However, in the online business, the integration is through the software and there is no standard used by various payment gateways.

All online payment applications require certain level of coding and merchant-oriented applications use various technologies such as HTML, ActiveX, ASP, JSP, XML, ODBC, JDBC, or JavaBeans to integrate payment gateways with the e-commerce servers. A merchant must have technical capabilities or means to implement these technologies. Some payment systems are also platform dependent. Thus, integration of a payment system with an existing e-commerce system might be an overwhelming effort, unless a particular payment system is considered during the design phase of the e-commerce system.

Furthermore, all payment systems require testing the whole payment cycle, including the authorization, settlement, and refund, using a valid credit card number.

Another complexity might be due to the level and type of service provided by the payment gateway provider, especially in the case of one-click approach where all transaction data resides with the provider. The merchant is limited by the way the company provides access to the database server, type of search for a particular transaction, refund procedure, audit trails, and statements.

6. Conclusion

We have provided an overview of the credit card processing mechanism and some insight into the real-time online credit card processing systems. Critical factors such as cost, complexity, and security associated with the implementation and maintenance of such systems are also discussed. No matter what method of payment processing mechanism is considered, an online merchant must realize that real-time payment processing can be highly complex – there is no one-size-fits-all solution for all merchants. Whatever payment software is chosen, it needs to be integrated with the e-commerce system, unless one can purchase an integrated e-commerce and payment system. Furthermore, choosing the right payment gateway-provider can relieve a lot of headache of handling payments and interacting with other parties of e-business processes. A payment gateway must support all aspects of payment processing – authorization, capture of funds, refunds, and reports. Products offered by selected vendors should be compared according to the factors such as complexity of the system and software, implementation time and cost, software cost and maintenance fees, transaction costs, and security features for consumers and merchants.

The Framework of Enterprise Information Processing Network for Knowledge Discovery and Sharing

Chian-Hsueng Chao

Department of Information Management, National University of Kaohsiung,
Kaohsiung, Taiwan, ROC
cchao@nuk.edu.tw

Abstract

The challenges of the global marketplace are increasingly forcing today's process-centered organizations to utilize the knowledge, capabilities, and resources to be found within their information processing networks. The issue of whether or not companies should exploit their intangible knowledge assets is far more critical than their ability to invest and manage their existing physical assets. Under this paradigm shift, information-oriented productivity depends on the sharing of knowledge and skills among workers, so that enterprise strategies can be driven by the collective intelligence and competence of the group to face today's business challenges and enable organizational learning. Management of organizational knowledge to create business values and competitive advantages is critical towards the organizational development. This paper focuses on the transformation of an enterprise information-processing network into a knowledge network for supply chain co-evolution. The ultimate goal is to develop a technological framework for a knowledge network that brings people, information, technologies, business processes, and organizational strategies together to better utilize knowledge in e-business. A knowledge network is introduced to enhance collaboration, encourage innovation, boost productivity, achieve adaptivity, and increase the information system efficiency. In tomorrow's enterprises, knowledge will be the key to release creative energies that will inspire enormous innovations and great discoveries!

1. The Emerging Business Intelligence

Over the past few decades, organizations have constantly "reinvented" themselves through a series of business and technological innovations to fit into the global spectrum of business. Manual workers and mass production schemes are not a predominant factor to today's new business. Functional integration to streamline the flow of business operations is no longer as popular as emerging process-oriented business practices. Information, such as demographics, consumers' behaviors, and numerous other business statistics, and the associated processing power are critical for the survival of organizations in business. With the global deployment of computers, uniform information architecture, and interconnecting networks, participants can work collaboratively, share networked resources, exchange

knowledge, and improve corporate or supply chain performance. Accordingly, corporate and supply chain strategies can be driven by the collective intelligence of groups to better meet today's business challenges. The increasing adaptivity of business practices has led to the role of Business Intelligence (BI) in knowledge management. BI relies heavily on the interpretation of data into useful knowledge for their trading partners within and across the supply chain to gain a competitive advantage. This same business strategy is becoming increasingly adapted by every industry, where successful ventures with a long-term competitive advantage will be characterized by their ability to create new knowledge, quickly disseminate and incorporate it into their production processes, products, and services. As we move this new millennium there will be a fundamental shifts in the prevailing paradigms and knowledge-oriented productivity will present the greatest challenge to management.

2. Knowledge Workers and Empowerment

The traditional managerial hierarchy is not addressed in the horizontal nature of collaborative or team-based communications, because of its vertical emphasis on communications and information systems. The shift from a division/functional organization to a matrix, and then to a network form arose from a desire to create organizations that utilize knowledge across processes and functions. Especially, the rapid growth of the Internet brought about a reevaluation of the old supply chain philosophy and fostered the growth of new strategic alliance and business process integration across the border of organizations, thereby enabling organizations to more fully utilize the skills, knowledge, competences, and resources found in their supply chain network. The enterprises will be able to better work together on a project across departmental and organizational barriers. Under this paradigm shift, intelligence and control are no longer concentrated in division offices. Empowered workers are actively engaged in their jobs, and they have the authority to form autonomous teams with self-defined roles and structures. The project members to form a "virtual team" can be from different divisions, departments, or even organizations. Those empowering workers will lead to radically different organizations that can cope with the ever-changing business environment. Interdependency between core knowledge workers will increase as the success of the enterprise becomes more

dependent on how well they integrate their knowledge to produce innovative products and services [1]. This is the key issue of today's knowledge-enabled organization, and many of the concepts are brought into discussions of this paper. The objective is to develop a knowledge management framework that brings people, information technologies, business process, and organizational strategy together to better utilize knowledge in business practices in a supply chain scheme. There are several factors needed to consider in order to develop a successful KM system. The first is to recognize the organization's competence.

2.1 Organizational Competence

Whenever a technological innovation is introduced, it brings both new business opportunities and new challenges to organizations. The introduction of Business Process Reengineering (BPR) in the 1990s stressed the importance of Information Technology to business practices. Most BPR issues focused on using "the power of modern Information Technology to radically redesign our business processes in order to achieve dramatic improvements in their performance" [2]. Since then, many organizations recognized IT as a key catalyst for modern business practices, and redesigned their organizational structure and business processes to improve certain critical measures of performance, such as cost, quality, service, and speed. Though IT helps an organization gain a competitive advantages, business strategies should also focus on what "value" might be created for the organization in the marketplace. BPR uses

IT to radically redesign core business processes in response to key competitive factors.

These competitive factors can be derived from the Porter's value chain [3] concept which divides an organization into a set of generic functional areas (Figure 1). According to the value chain concept, everything that a company does can be categorized into primary and support activities. Porter's value chain consists of five types of primary activities: Inbound Logistics, Operations, Outbound Logistics, Marketing and Sales, and Service. Support activities support primary activities and each other by providing purchased input, human resources, and some forms of technology to perform a given function. Porter's version of supply chain management is called a value chain because it focuses on value, where value is measured by the amount that customers are willing to pay for an enterprise's product or service. Primary and support activities are called value activities, and an enterprise will be profitable as long as it creates more value than the cost of performing its value activities [4]. Starting with the resulting generic value chain categories, an organization can further subdivide each into discrete activities, categorizing those activities that best contribute to a firm's competitive advantage. In this way, a value chain is defined and a better organizational structure and business process can then be created around those value activities that can most improve an organization's competitive advantage [5]. Technological innovations usually give companies new ideas for their organizational structure and management. This value chain thinking allows organizations to identify their competitive strengths and weaknesses and therefore

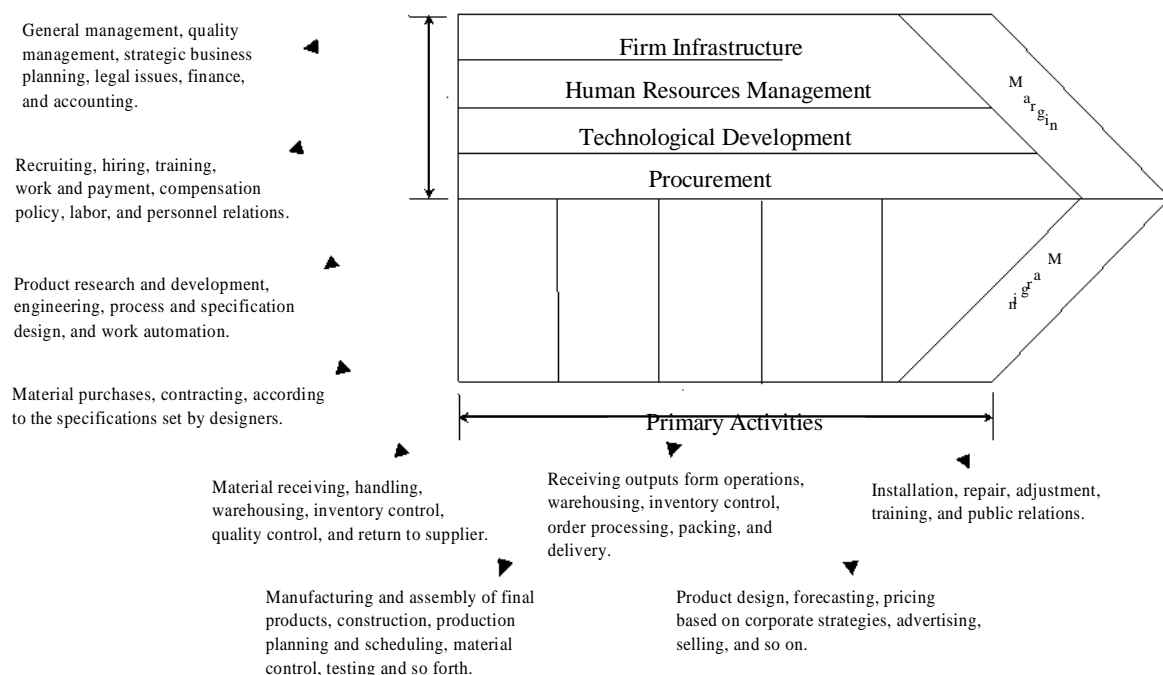

Figure 1 Porter's Value Chain and Value Activities

to reengineer their enterprise performance. All these “value-finding” processes are crucial to the development of a successful KM system. A KM system that fully utilizes an organization or an entire supply chain’s strength to take every business opportunity.

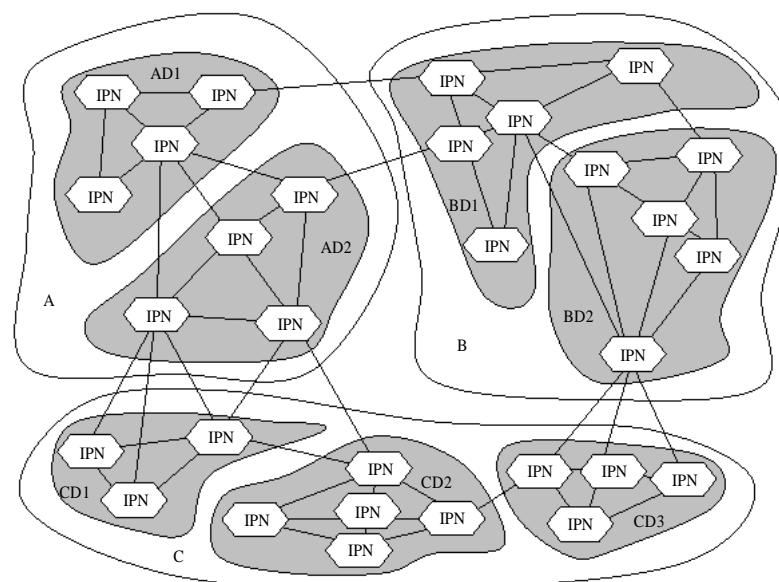

One factor worth mentioning is that value also includes all information that flows through an organization and between an organization and its suppliers, its distributors, and its existing or potential customers. Indeed, information defines business relationships. Having a relationship means that two or more companies have established certain channels of communication based on personal acquaintance, mutual understanding, shared system standards, or synchronized production results. These imply the need for stronger business partnerships, and collaborations have challenged many organizations to extend their organizational boundaries and share their visions with others.

3. The Information Processing Network and Value Chain

The information processing view of an organization has been considered one of the most influential contributions to the contingency literature [6]. In this philosophy, information processing network provides the channels for exchange and processing of information in a global system. The primary system objective of the information processing network is to provide a

communication backbone for information exchange among its subsystem, the information processing nodes. The information-processing nodes within the network are responsible for receiving, using, selecting, producing, sending, and communicating (i.e. exchange information) with other information processing nodes. As a result, the lattice of channels between the various information-processing nodes forms a physical communication infrastructure called an information-processing network.

The characteristics of information-processing nodes are much like the business components, but they conduct the actual exchange of information. The business components of the organization include people, processes, events, machines, and information that interact and combine to produce the products or output of the organization. People and information-processing machines, such as computers, are in this category. An enterprise operates as an information-processing system in a global information-processing network. Because it is an open structure, the network can be developed in a fractal pattern. The information-processing network can be expanded and connected to other organizations’ information-processing networks (Figure 2). The information-processing nodes within each network in either organization can work collaboratively to achieve strategic goals in the newly joined network. To this point, we concluded that one value chain could be linked to another value chain, because one business partner could be the other’s customer. This interconnected value chain

Business components can exist autonomously within an organization, or being shared by trading partners in a global network in an strategic alliance scheme.

Figure 2 The Information Processing Networks

system can act like a supply chain that encompass the modern business world, and participating organizations can readily extend their technologies to their partners.

4. E-Business Supply Chain Knowledge Management

Traditional business partnerships are changing in response to technology advancements and business innovations. Companies can achieve a business advantage by leveraging networking technology and the principle of supply chain integration. With network connectivity, supply chain integration is now the core strategic competence that enables many companies to act as one. Supply Chain Management (SCM) evolved several decades ago from a simple set of logistics performance tools to an inter-enterprise, and even channel-wide, operating philosophy. SCM is now a boundary-spanning, channel-unifying, dynamic, and coevolving philosophy of inter-enterprise management. The major contribution of today's supply chain model is to improve the bottom line by enhancing collaboration between businesses and their trading partners [7]. This feature is very important for the every industry, because many participants (contractors, subcontractors, material suppliers, equipment providers, and supervisors) need to cooperate/collaborate intensively throughout a project life cycle, which will change from one job to another.

Issues related to e-supply chain integration include the internal and external core business processes, the development of close linkages between channel partners, and the management of production and information as they move across organizational boundaries. For example, the manufacturing process for raw materials or the production and distribution of equipment is transparent to all members in the supply chain. The selection of processes and cooperations with supply chain partners is critical to the success of business. The selection of e-supply chain partners extends beyond choosing a trading partner or contractor and must include configuring the business-to-business collaboration among the partners. In the future, the supply chains, rather than the enterprises (contractor, manufacturer, and supplier), will compete with each other. An increase in horizontal integration synchronizes the output of the entire supply chain. There will be no isolated islands of automation, and those who can best define and reengineer their business processes in the supply chain partnership are sure to be more successful in this industry. In today's e-business, competing for knowledge requires either aligning one's strategy to what the organization knows or developing knowledge management (KM) capabilities to support a desired supply chain strategy. The ability of companies to exploit their intangible assets has become far more important than their ability to invest and manage their physical assets. Knowledge requires sharing and corporate strategy can be driven by knowledge. Knowledge management systems must to address the

strategic visions of organization. Knowledge management systems should support people to access and learn from past and present organizational business practices/strategies and to apply the lessons learned when making future decisions. Based on the above discussion, a successful knowledge-oriented business for organizations should link supply chain management, relationship management, and knowledge management to function in an adaptive way and continue to thrive in the e-business era.

5 The KM System Architecture

5.1 Knowledge Utilization

An e-business supply chain knowledge management is a new business philosophy that drives enterprises to transform their business intelligence. Organizations are becoming knowledge intensive instead of capital intensive. This new business philosophy is an integral part of the knowledge economy for today's organizations and supply chains to remain profitable, competitive, efficient, adaptive, and more intelligent. Organizations that will truly flourish can utilize IT to leverage personnel knowledge in ways that are immediately available. The design of a KM system needs to focus on the issues of data acquisition, information access/retrieval for knowledge utilization, communication, knowledge sharing, business process/information integration, document management, and most of all—collaboration. The focus on collaboration and collaborative support is perhaps one of the major distinguishing factors that differentiates knowledge support systems from other information systems. In business practices, collaborative problem solving, conversations, and teamwork generate a significant proportion of the knowledge assets that exist within a firm or entire supply chain. With network connectivity, the virtual teams can work collaboratively to share knowledge and best practices that enable supply chain “co-evolving.” In this “knowledge network,” a dedicated knowledge server and a database are required, because knowledge management must capture and retain in a central/distributed data repository the data and information that employees need. The technologies to facilitate these highly interactive communications are summarized in Figure 3. In this figure, Internet/Intranet and groupware system are the most important ones for group communications and knowledge-sharing. For knowledge sharing, the architecture of IT in the knowledge management system is concerned with organizing and analyzing information in an organization's database so this knowledge can be readily available throughout a company. To help companies organize information residing in multiple locations and deliver it to prospective users, combinations of directory service, indexing, and searching are required in the KM system. Available groupware and document management systems do an excellent job in satisfying this requirement.

Document management is a part of supporting IT, and it includes the ability to automatically develop and

classify document databases. In business practice, the project teams work collaboratively on the creation of documents and insuring that everyone has access to the latest updated version of the documents, which avoids working on the inconsistent versions of these documents. The groupware is an integrated collaborative tool that supports not only several people working together on a task, but also their different and potentially changing roles. It has email and messaging functions, document management and information sharing, collaborative authoring, conferencing, time management, and some level of structured workflow support. Its database management ability organizes, stores, replicates, and provides shared access to documents by using a hypertext scheme. It has all the functionalities to support basic business practices and knowledge management. Many groupware systems also allow the documents to be posted on the Intranet or the Internet. One of the most dominant groupware systems is Lotus Notes (now incorporated as IBM) which allows groups of users to interact and share information in an organized fashion.

With the growing maturity of Internet technology, the web can become more active. Applications can run on clients' browsers. The technological breakthrough makes the development of future web-based groupware systems (utilizing corporate Intranet) easier, because the traditional groupware and the web-based groupware have some similarities in terms of communications and

collaborations. The groupware and Internet's hypertext scheme can easily profile different categories of business information (such as from specifications and manuals to make hypertext specifications or a TQM manual) for people working on the job site, or provide them with a "hyper-trail" for step-by-step operations. Behind the scene is a complex web that links different databases residing in the project team's organizations. With the aid of hypertext, an organization's information system becomes more accessible and adaptive, and the project data can be easily stored in archives for historical reference. One of the differences between the Internet and groupware is its platform-independent advantage that makes it possible to deliver business data and streamline business processes across heterogeneous business partners in the flash of a second.

As mentioned before, a central/distributed data repository that provides/captures the data and information for employees and executive decision-making is very important in a knowledge management system. The database is the core of a KM system, the decision-making support system is the driver that consolidates and directs the overall resources of the supply chain to the most mission-critical business activities to generate profits. It is believed that the next generation of knowledge management systems will be built on the Internet backbone with "agents" that flow through the net to gather business information and display it for decision-

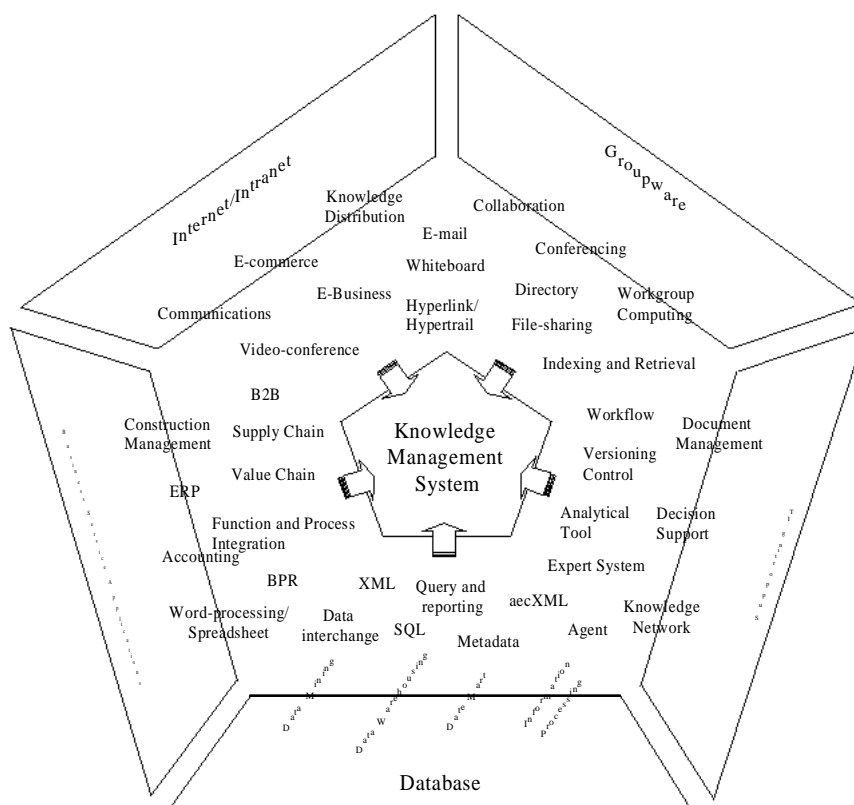

Figure 3 Knowledge Management Technological Framework

making purposes.

On the other hand, the basic business applications are necessary to conduct daily business, such as word-processing, spreadsheets, accounting, and so forth. In addition, with the growth of the Internet, e-business is rapidly expanding into a complex web of commercial activities. Many organizations have recognized this competitive advantage and have shifted their focuses from process improvement within an organization to process integration across their trading partners. This business-to-business practice transforms the traditional supply chain into a network that allows companies to work together almost as if they were one company. The key issue is the inter-enterprise processing. Therefore, knowledge management also includes business processes integration.

5.2 The Learning Organization and Smart Supply Chain

Senge in his thoughtful and provocative book [8] on system thinking described a “Learning Organization” as “an organization that is continually expanding its capacity to create its future.” A knowledge-enabled organization is a learning organization, one where all employees are using their knowledge, skills, and learning to meet today’s business challenges and to create new opportunities for the future. One thing important is that the organization also learns from customers, suppliers, and even competitors: from any and every relevant source within or outside the organization. This extended learning capability leads to a new definition of supply chain

management and customer relationship management (CRM).

In today’s e-business, companies can achieve a business advantage by leveraging networking technology and the principle of supply chain integration to improve the bottom line by enhancing collaboration between their business and trading partners. The beauty of a supply chain knowledge network is that the true value of the information surpasses the conventional boundaries that often restrict employees’ thinking [9]. The collaboration of people, processes, and technology is important, because companies can enhance customer satisfaction, improve operational efficiencies, and cut costs by leveraging a comprehensive, integrated, e-business suite of applications based on Internet technology (Figure 4). A KM infrastructure combines automation, business rules, artificial intelligence, workflow, analytical tools and advanced messaging-analysis technologies to allow e-businesses to deliver information and to respond to customer requests rapidly and accurately [10]. Therefore, in a successful k-business model, the sharing of information moves the supply chain closer to the desired goal of a demand chain. In this way, a true knowledge management system can be built and utilized by the entire supply chain community to generate profits.

6. Conclusion

Changing technology is the driving force behind the next wave of economic growth. To take advantage of this growth, organizations will have to apply both new

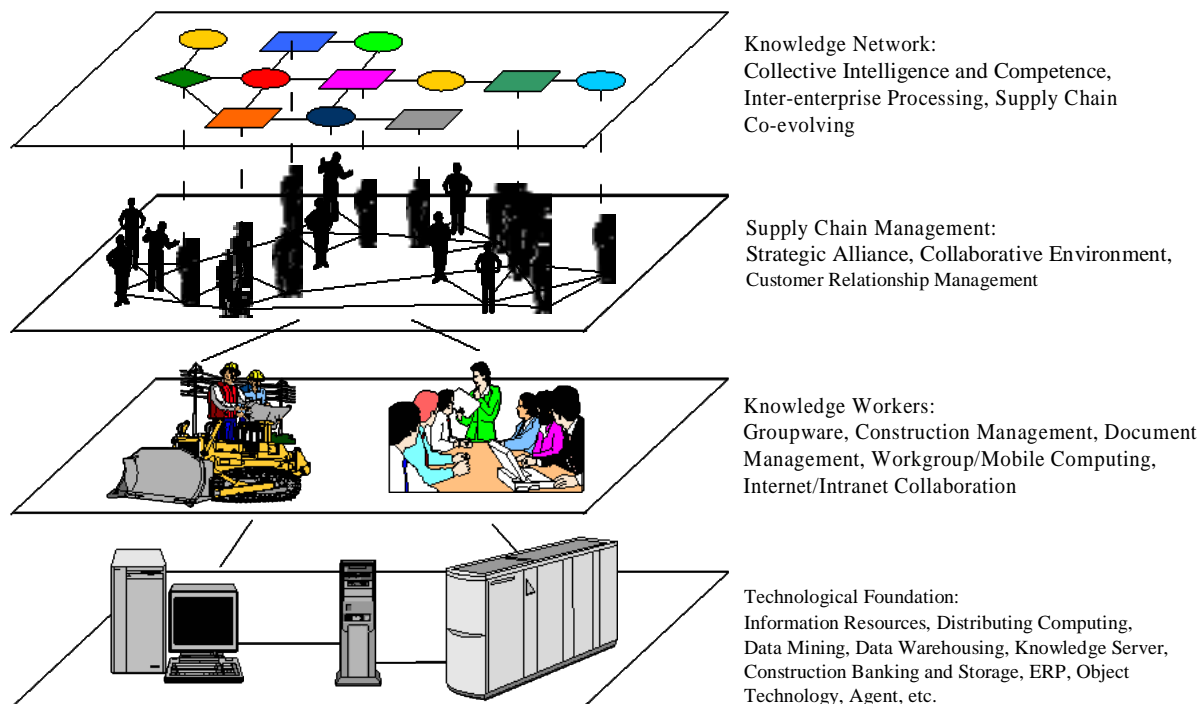

Figure 4 The Knowledge-enabled Supply Chain

technology and new thinking. First and foremost will be the ability to understand the paradigm shift in the economy from data to information and from information to knowledge. Data is the basic building block of information and ultimately of a knowledge-based business. In business practices, information is the glue that unifies businesses partnerships. Many organizations use their information processing networks and strive to become knowledge-enabled organizations to ensure that all employees are able to locate, access, and utilize the knowledge and skills they need to meet their individual and corporate goals. An organization's value chain consists of all activities performed to design, produce, market, deliver, and support its product and service. Knowledge Management is introduced to enhance collaboration encourage innovation, boost productivity, achieve adaptivity, and increase the information system efficiency. On the other hand, the challenges of the global marketplace are increasingly forcing today's process-centered organizations to utilize more fully the knowledge, competencies, and resources to be found in their supply chain networks. Optimizing parallel, rather than serial, processes is the key to supply chain management. The next generation of e-business will be built on an interconnected network which will help companies connect disparate systems, provide greater access to information, and more closely link employees and customers.

As a result, a successful knowledge management system for today's new business must provide support for the capture and communication of customer demands, as well as enable these demands to automatically trigger business events and initiate process workflows (such as launching manufacturing runs and issuing purchase requests within the enterprise and across the supply chain). A common data model will also be needed for the entire supply chain knowledge network, because the effectiveness of an e-business supply chain solution will depend largely on its ability to deliver an accurate and common view of customer demand data, as well as any subsequent events, plans, or other business data. This new "e-supply chain" offers unlimited business opportunities when enterprises fully integrated their knowledge, processes, and technology. A well-designed and well-integrated supply chain will improve existing cost-intensive processes and provide organizational agility in the event of change.

Going Wireless: Migrating From E-Business to M-Business

Chian-Hsueng Chao

Department of Information Management, National University of Kaohsiung,
Kaohsiung, Taiwan, ROC
cchao@nuk.edu.tw

Abstract

The challenge of globalization—the ability to respond quickly according to changes in market demands and competitions, is the driving force for organizations to optimize their business strategies and operations regularly. Customer preferences and needs change constantly, resulting in pressingly intense competitions. Time sensitive real-time transaction is becoming the common denominator for successful businesses. Information also needs to be available to anyone from anywhere at anytime. As the global economy shifts toward the mobile economy, enterprises need to be progressively more flexible and globalize. Mobile businesses open up new opportunities for innovative enterprises and give them new means of communications with customers and employees. In a changing business landscape, mobile business addresses new customer channels and integration challenges. This paper provides a broad discussion on the changing landscape of business: from e-business to m-business. Several issues will be addressed, such as value chain, the data access of mobile computing, m-business application framework, and the future development of mobile computing (e.g. 4G wireless). All of these efforts attempt to provide an overview and schematics for the integration of modern e-business application strategies into future m-business practices. This paper will show that any innovated business strategy should be built upon target stakeholders. With mobile technologies, enterprise applications will go beyond the four walls of organizations to a workforce on the move.

1. The Emerging Mobile Economy

Internet technology is presently changing communications to the same degree that PC technology reshaped the computing world twenty years ago. Today, e-business is rapidly expanding into a complex web of commercial activities transacted on a global scale between an ever-increasing number of participants, corporate and individual, on global open networks. A successful e-business is concerned with building new kinds of relationships with customers, employees, business partners, investors, regulators, consultants, and all other participants in business life. The most significant economic consequence of this evolution will be increased real-time interaction between organizations and their employees, trading partners, and customers. In the 1990s, a silent paradigm shift affected many business

sectors in the world economy. The emerging mobile technologies with Internet capabilities that connect numerous devices and information portals represent a new phase in enabling intelligent mobile workforces [1]. As a result, a substantial new creative cycle and innovation on the marriage of the Internet, wireless technologies and e-business is another new challenge to today's enterprises. The "mobile business" or "m-business" is an extension of e-business. The m-business is facilitated by the integration of the Internet, e-business, and the wireless world where customers can go online with any device at anytime from anywhere [2].

Today, enterprises focus on how to use mobile technology to provide customers with rich service experiences and greater satisfactions. Currently, accessing the web through a wireless device is different than accessing the web through wired connections. The mobile Internet business is in its early stages of development, so no real framework has been available to provide a systematic way to explore opportunities or problems. Nevertheless, similar to its predecessor (the e-business infrastructure), the mobile application infrastructure can be laid out easily and also include four different areas: mobile application platform providers, mobile Internet service providers, mobile application service providers, and system integrators. The usefulness of the mobile channel will be largely driven by new applications that enhance the overall customer value.

2. Defining New Market Value

The m-business is facilitated by the integration of the Internet, e-business, and the wireless world where people can go online with any device at anytime from anywhere. To embrace this vision, a new value chain is emerging that focuses on the belongings of mobile devices, wireless access, and contents. However, to create multi-channel and multi-technology solutions in a fast-moving and technologically indefinite mobile environment is difficult and extremely risky. A number of mobile devices, closed networks, disparate carrier/server systems, protocols, and solutions characterize today's wireless landscape. Currently, the fastest way to access the Internet on the move is through the IEEE 802.11b (Wi-Fi) standard. Overall, 802.11 (Wi-Fi) in its various forms (a, b, and g) has emerged as the winner in wireless LAN technology [3]. However, the problem with wireless LAN-based access is that the access points or base stations have a very short range, which means they're restricted to a few "hotspots," such as hotels, conference centers, and

airport. The situation gets more complex when the wireless LAN is mobile.

The fourth-generation (4G) cellular services intend to provide mobile data rates of 100Mbps or more. This 4G is an entirely packet-switched network that all network elements are digital with higher bandwidths to provide multimedia services at lower cost. In 4G mobile IP, each cell phone is assigned a permanent “home” IP address, along with a “care-of” address that represents its actual location. When a computer somewhere on the Internet wants to communicate with the cell phone, it first sends a packet to the phone’s home address. A directory server on the home network forwards this to the care-of address via a tunnel, as in regular mobile IP. The directory server also sends a message to the computer informing it of the correct care-of address, so future packets can be sent directly. This should enable TCP sessions and HTTP downloads to keep going as users move between different types of networks. The ultimate 4G would be full on-demand capability, Wi-Fi to WAN roaming, and have it as a true IP network. Currently, the Japanese government required all of Japan’s ISPs to support IPv6 by 2006, to coincide with the launch of 4G. Countries in Europe and Asia are considering similar regulatory action. NTT DoCoMo (provides i-mode service) also hopes that true mobile broadband will enable them to replace fixed access entirely, and they plan to have a 4G system operational by 2006. A business that creates m-business applications can benefit from the first-to-market advantage. As the wireless Internet continues to expand, first-to-market organizations will have already secured a customer base. It can be foreseen that the m-business market value will be astronomical.

3 The M-Business System Architecture

Seeing m-business processes in terms of a net value added chain is also an approach for visualizing current and identifying future competitive advantages. In short, the creation of these values depends on the enterprise’s ability to link and coordinate these internal/external activities efficiently [4]. This interconnected value chain system can act like a supply chain that encompass the modern business world, and participating organizations can readily extend their technologies to their partners. The m-business supply chain practices are just like e-business supply chain practices with the exception of mobility. This is a more real picture about business, because business opportunities occur in anywhere at anytime.

With the convergence of B2B, B2C, SCM, CRM, ERP, Business Intelligence, and real-time relationship management, the personalization of customer information is now possible. The IP convergence strategy will provide a solution that joins the two worlds of voice communications (telephony) and data traffic together. Technologies, such as interactive voice response (IVR), computer telephony integration (CTI), are beneficial to selling chain management. The fully interactive nature of the Internet changes everything in the world of self-service. The blending of Sales Force Automation (SFA) with customer self-service brings new business opportunities. Relevant information and intelligence support processes all can be aligned and implemented in real-time at anywhere. The application and technological framework of m-business to facilitate these highly interactive communications is summarized in Figure 1.

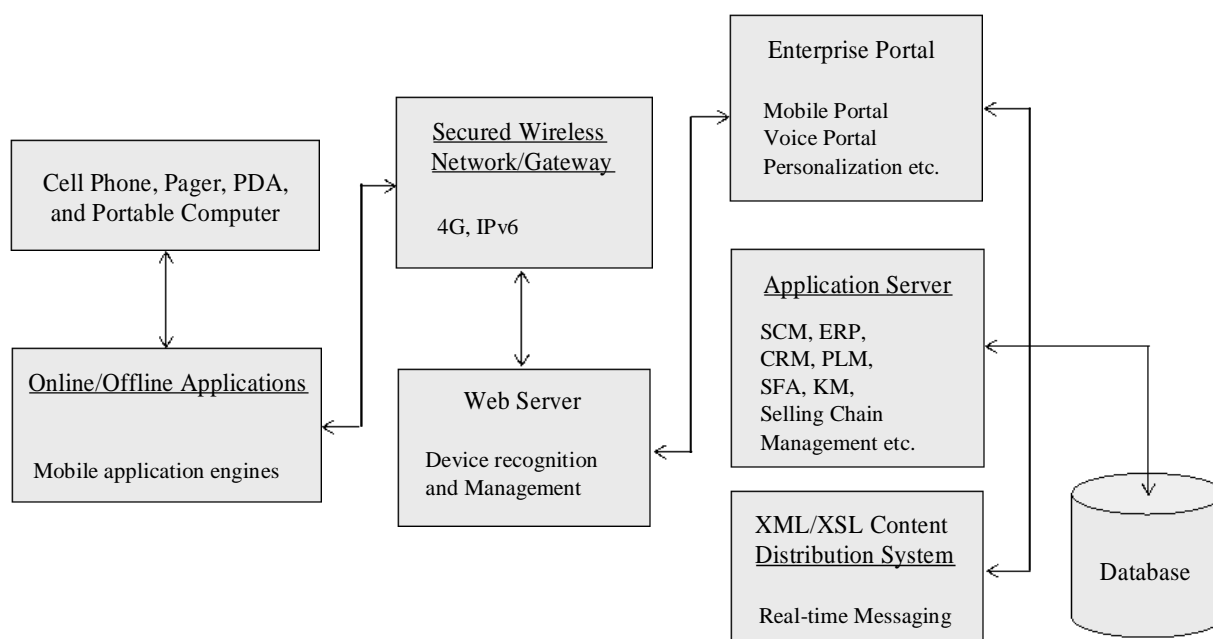

Figure 1 m-Business Application Framework

This framework extends existing business applications such as ERP, CRM, and mobile workforce applications to wireless devices.

In this framework, several dedicated servers and databases are required, because enterprise must capture and retain in a central/distributed data repository the data and information that employees need. A selling chain management suite for customer care applications enables new kinds of interactions, new kinds of information, and comprehensive access to all customers and enterprise portals. This customer care can foster joint problem-solving, and convenient self-service. Given the information customers need in the purchasing process. The reasons to stress on 4G and include in this framework are (a) it has wider bandwidths, higher bit rates, (b) it support interactive multimedia services, teleconferencing, wireless Internet, etc., (c) the global mobility and service portability, and (d) scalability of mobile networks. For knowledge management issues, the architecture of IT in the knowledge management system is concerned with organizing and analyzing information in an enterprise's database so this knowledge can be readily available throughout an enterprise. A central/distributed data repository that provides/captures the data and information for employees and executive decision-making is also very important in a knowledge management system. The database system is the driver that consolidates and directs the overall resources of the supply chain to the most mission-critical business activities to generate profits. As a result, an m-business supply chain solution must provide support for the capture and communication of customer demand, as well as enable this demand to automatically trigger business events and initiate process workflow. This application framework also takes advantage of XML. The XML now supports for developing mobile applications running on multiple devices and platforms [5]. Databases are also working with XML-structured data and tabular relational data. Therefore, the XML/XSL is very promising in m-business practices.

Effective m-business supply chain solution will need to deliver an accurate and common view of customer demand data as well as any subsequent events, plans, or other business data. This new supply chain framework will offer virtually unlimited business opportunities in the alignment of technologies and processes. A well-designed and well-integrated supply chain for m-business will improve upon existing cost-responsive processes, and have organizational agility in the event of change.

4. Conclusion

Multi-channel and multi-technology strategies represent the next frontier. Being the central platform for mobile applications, the next generation Internet must provide an infrastructure that allows data transfer to be fast and cost-efficient. The mobile Internet will open an important new channel for commerce. With mobile technologies, enterprise applications will go beyond the

four walls of organizations to a workforce on the move. Employees will be able to access the company's mission-critical enterprise applications, such as enterprise resource planning (ERP), customer relationship management (CRM), and supply chain management (SCM). This open enterprise is also extended to suppliers and trading partners so that when customers get in contact with the resources of an organization, they also touch upon the resources of the value chain. The usefulness of the mobile channel will be largely driven by these enterprise applications that enhance the overall customer values. With self-service applications in hand, customers will be able to touch the resource of an enterprise. It is the customers who drive the entire value chain (or supply chain), determining what is to be produced, when, and at what price. They will be able to interact with the entire business ecosystem and not just individual company, and this will mark the era of m-economy.

Understanding Customer Relationship Management: The Implications of CRM Fit and Customer Orientation

Jounghae Bang
College of Business Administration
University of Rhode Island
Kingston, RI 02881, USA
jounghae@mail.uri.edu

Abstract

Customer Relationship Management (CRM) has been one of the important managerial issues. The benefits of Relationship Marketing has been well recognized and new information technologies offer amazing possibilities for CRM practice.

The processes of implementing CRM, however, are expensive, and yet the failure rate of the CRM projects is also high. Of the failures, 20% end up even damaging to long-standing customer relationships.

This study focuses on explaining theoretically why huge IT investment on CRM practice does not always generate the successful outcomes to the organizations, what are the critical factors of CRM, and how the factors influence the CRM performance.

Based on the review of the previous frameworks and definitions of CRM, the study proposes an integrated CRM framework. In addition, among others, CRM Fit and Customer Orientation are addressed as critical factors of successful CRM. Although technology has been identified as a main enabler of successful CRM, many CRM experts have claimed that it is not technology in isolation that brings the success to the CRM practice. Adopting Task-Technology Fit (TTF) model, CRM Fit, not Technology, is included in the research model. Therefore, this study proposes that CRM Fit has a positive relationship with CRM performance and Customer orientation moderates the effect of CRM Fit on CRM performance.

1. Introduction

The importance and benefits of customer relationship management has been well recognized [18] [24]. Kotler (1997) [18] mentioned that the cost of acquiring new customers is from 5 to 7 times more than retaining them. Reichheld and Sasser (1990) [24] have suggested that a company can improve profits by anywhere between 25 and 85% by reducing customer defections by a mere 5%.

In addition, Customer Relationship Management (CRM) technologies and other allied information technologies offer amazing possibilities for ideal, highly satisfying customer relationship management [14] [17]. Ives and Mason (1990) [17] have introduced several conceptual tools to use information technology to improve customer service. They point out that information technology can be used to enhance customer satisfaction

by identifying and tracking individual customers; monitoring service levels by company representatives; and assisting customers in specifying, acquiring, fixing, or returning products. It is one of the main reasons why Customer Relationship Management gets substantial attention from researchers as well as practitioners.

The processes of implementing and executing CRM, however, pose difficult challenges for many organizations [1] [26]. According to one Gartner Group study, as many as 55% of all CRM projects are expected to fail during 2002-2006.

CRM systems cost an average of \$35,000 per call-center agent to deploy, and setup and maintenance of CRM sales software typically cost \$28,000 to \$40,000 per salesperson over a three-year cycle [5]. Given such high costs of deployment and maintenance, the drastic failure rates represent huge financial risks for most CRM adopters. Furthermore, It is noted that of these failures 20% lead to damage to long-standing relationships [20].

The study focuses on comprehensive understanding of CRM practice. It attempts to explain theoretically why huge IT investment on CRM practice does not always generate the successful outcomes to the organizations. This study would achieve its goals by drawing from and blending multiple disciplinary perspectives such as the Task-Technology Fit model from Management Information Systems (MIS) and Customer Orientation perspectives from Marketing and Business Strategy literatures. This study identifies factors that are critical for successful CRM implementation, how these factors work and interrelate, and what would be the effects of these factors on customer retention and satisfaction and therefore on the performance of the CRM-implementing organization.

2. What is CRM?

2.1 What/who is Customer?

To answer the question, "What is customer relationship management?" we need to first define the customer. Many different answers exist to these questions, and the broad definition of customer includes suppliers, buyers, consumers, and employees (internal customers) [11]. However in this study, the definition of customer is limited to buyers of the product or service, which a firm provides.

2.2 What is CRM?

Having narrowed the focus of the term “customer” to the product/service buyer, understanding what is CRM and what elements constitute CRM is the next step. Specific buyer-focused CRM projects need to be properly implemented and managed in each organization.

Many researchers and practitioners have attempted to define CRM in various ways. CRM has been seen as different things to different people in the different areas [14] [26] [27]. For some, CRM is understood as computer application and database marketing while for others, business strategy. Even though the definition of CRM is not consistent among researchers, based on the review of previous frameworks of CRM, three core dimensions characterize a buyer-focused CRM system: Customers in the center, Management’s articulation and tracking of customer relationship goals, plans, and metrics, and Technology, which include collaborative, operational, and analytical CRM systems. These key elements of CRM are shown in Figure 1. Each level has to be coordinated for successful CRM implementation and performance outcomes.

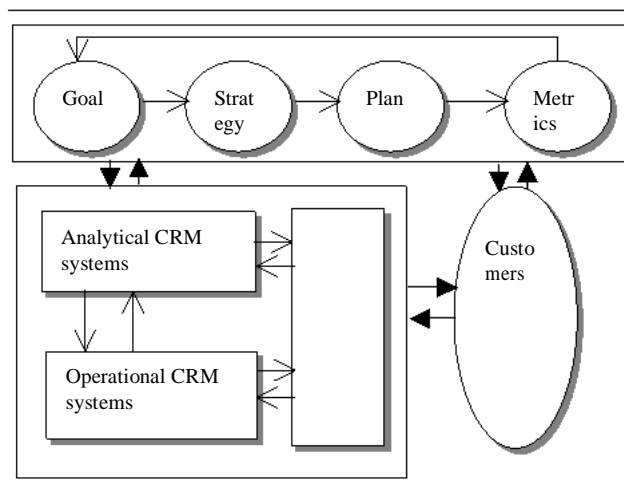

Figure 1. Framework of CRM

First, management level should be included to understand CRM since CRM has been seen as strategy of the organization [2] [7] [25]. Management level should be included in any understanding of CRM. Starting from the corporate level goals, strategies should be established to accomplish such goals. As well, the strategies have to be followed by specific plans and the performance of these plans has to be tracked and evaluated thoroughly. CRM projects have to take organizational level goals and strategy as the starting point because it is these goals, strategies, and plans that reflect the corporate philosophy regarding customer orientation and inculcate a customer-responsive corporate culture.

Second, technological structure contains analytical CRM systems, operational CRM systems, and collaborative CRM systems.

Analytical CRM systems include Knowledge Discovery in Database (KDD) concept and data mining.

KDD is outlined as a process, often iterative, of data selection and sampling, of pre-processing and cleaning, of transformation and dimension reduction, of data mining or analysis, and of visualization and evaluation [19].

Operational CRM systems entail the integration of all the front-end customer-facing functions of the business. For example, since the sales process depends on the cooperation of multiple departments performing different functions, the systems to support the business process must be configurable to meet the needs of each department [10] [15]. Business process reengineering and the integration with the ERP legacy systems [15] are included in the issues of operational CRM. It is important to note that the organization should review its business process before installing the systems.

Collaborative CRM systems refer to CRM functions that provide points of interaction between the customer and the channel [15]. It can be the communication center, the coordination network that provides the neural paths to the customer and his suppliers. It could mean a portal or a customer interaction center (CIC).

Third and finally, the *raison d'être* of any CRM system is the customer. Customer service and related issues must be included in the design, implementation, and operation of any CRM system. CRM software needs to pay attention to not only the users within the implementing organization, but also to the end customer [10]. While enhancing the operational efficiency of the organization is an important goal of using CRM technology, servicing and delighting the customers are the ultimate end-goals as well as the ultimate determinants of success.

With these components in place, CRM is defined as a core business strategy that integrate internal processes and functions and external business networks to interact, create and deliver value with personalized treatment to targeted customers to increase customer retention at a profit. It is grounded on high quality customer data and enabled by information technology [2] [7].

3. How does CRM work?

As the framework of Figure 1 indicates, information technology plays a critical role in the CRM practice. And in fact, huge investments in technology characterize the contemporary practice of CRM.

To explain how CRM systems lead to the increased customer retention and satisfaction, the framework of Task-Technology Fit (TTF) model is adopted and adapted. The TTF model highlights the importance of task-technology fit in explaining how technology leads to performance impacts [12]. TTF assumes that the performance impacts depend upon the fit between three constructs: technology characteristics, task requirements, and individual abilities. Thus it emphasizes that it is not the technology in isolation that affects performance – organizational characteristics also come into play [13]. These notions are appropriate for CRM practice study since many CRM experts have claimed that it is not just

technology that brings the success to the CRM practice, even though technology is the enabler of CRM [6].

Therefore, along with technology, organizational factors play a crucial role in the success of CRM systems. Figure 2 outlines the proposed model of factors that drive CRM performance and success.

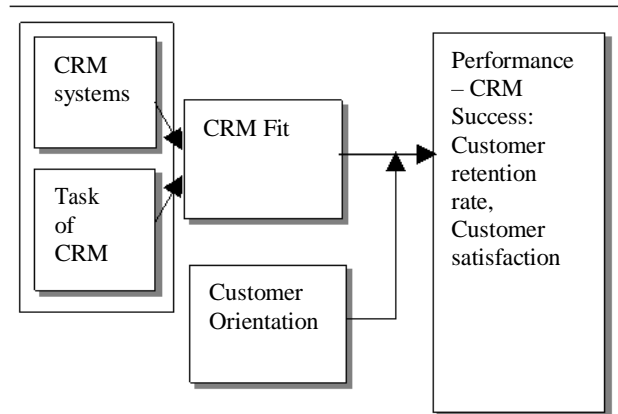

Figure 2. Research Model for CRM Fit

This model contains two main factors for the successful CRM: CRM Fit, not technology, and Customer Orientation. Based on the previous research, CRM Fit is expected to have a positive relationship with CRM success and Customer Orientation moderates the relationship. As antecedents of CRM Fit, both CRM systems, and Tasks and goals of CRM are addressed. The two antecedents are expected to have interaction effect on CRM Fit. Following is the review of each factors.

3.1 Antecedents of CRM Fit: CRM Systems

Technologies (CRM systems) are viewed as tools used in carrying out the tasks in the TTF model [12]. The tools can be computer systems (hardware, software, and data) and user support services (training, help lines, etc.).

The technical architecture of CRM can include multiple applications; performing analytical, operational, and collaborative functions. In the CRM technical structure, on the analytical side, a data warehouse typically maintains historical data that supports generic applications such as reporting, queries, online analytical processing (OLAP), and data mining as well as specific applications such as campaign management, churn analysis, propensity scoring, and customer profitability. On the operational and collaborative sides, data must be captured from the in-bound touch points, including the Web, call centers, stores, and ATMs. As outbound touch points, email, direct mail, telemarketing, and mobile devices [14].

Depending on the situation, however, a firm can choose different set of application packages with the different target. Software packages and systems tend to vary considerably. The decision on the applications and systems a firm chooses is totally dependent on the situation. Therefore, the recognition of all the possible

CRM tools seems not only impossible but also undesirable.

For this reason, the proposed study focuses on overall quality of CRM systems. Like other similar studies on TTF, identifying the quality evaluation criteria, rather than the lists of the tools used in the firm, is more suitable for the purpose of this study.

In this model, CRM systems are measured by system quality and information quality. System quality has been recognized as a measure of the information system itself [8]. For example, system characteristics can be measured by the content of the database, aggregation of details, response time, and system accuracy. Information quality has been studied as a measure of information system product [8], that is, the quality of information that the system produces, primarily in the form of reports.

3.2 Antecedents of CRM Fit: Task of CRM

Task of CRM contains the goals, depth and width of CRM, and business process design. The goals of CRM can be customization, flexibility, recovery, and spontaneous customer delight which can be delivered to the customers and those have been identified as the main drivers of customer satisfaction to be influenced by the infusion of technology [4]. CRM depth is measured by the three different targets of CRM practice [14]. The CRM targets which are applications, infrastructure, and transformation [14]. The authors explained that all those three targets are supposed to be addressed by CRM systems, but in practice, most of the companies can be categorized as focusing primarily on one of these three CRM targets. As well, the Customer Service Life Cycle (CSLC) can be used to identify the width of CRM. CSLC was initially introduced by Ives and Learmonth [16] and described a series of activities that customers would be engaged in as they purchase a product/service. The customers will traverse a life cycle as he/she first learns about it, and then learns how to specify, order, use, repair, and finally discard it. They argued that CSLC provides a powerful tool to assess opportunities to use information technology provide better service. Business process design for customers will be investigated as one of the important CRM tasks, and the focus will be how well the business process is designed to serve customers.

3.3 CRM Fit

Task-Technology Fit is defined as the degree to which a technology assists an individual in performing his/her portfolio of tasks [12]. In line with this definition, CRM Fit is defined as the degree to which CRM systems fit well the tasks and goals of CRM. The antecedents of CRM Fit are the interactions of tasks and goals of CRM and CRM systems. Eight factors were introduced to measure TTF, and the factors are Quality, Locatability, Authorization, Compatibility, Ease of Use/Training, Production Timeliness, Systems reliability, and Relationship with users [12]. These factors are used for CRM Fit in this model. Therefore, in this model, the interaction of task of

CRM and CRM systems is expected to be an antecedent of CRM Fit, and the good CRM Fit is expected to show positive relationship with the CRM performance, which is measured by customer retention rate and satisfaction.

3.4 Customer orientation

Finally in this model, Customer Orientation is included. Customer orientation has been seen as one of the three components of market orientation [21]. To date, the concept of market orientation has long been observed and extended by many researchers from Narver and Slater [21] to Nobel, Sinha, and Kumar [22]. Quite a few studies have found support for the fundamental market orientation and performance relationship [23]. Following Narver and Slater (1990)'s definition, customer orientation is referred to as "the sufficient understanding of one's target buyers to be able to create superior value for them continuously [21, p.21]" in this study. As well, it is broadly recognized that successful organizations need to have a customer-oriented business culture [3] [9]. Therefore, customer orientation is expected to influence the relationship between CRM FIT and performance in the context of CRM practice.

In sum, it is proposed that for successful CRM practice, the technology implemented should have good fit with the tasks and goals of CRM. Just implementing expensive technology is not sufficient. As well, not only the good fit between the technology and the goals and tasks of CRM, but also customer orientation is required.

4. Possible outcomes and contributions

From this study, it is expected to see the positive relationship between good CRM fit and the performance of the organization. Customer orientation is expected to moderate the relationship between the CRM fit and the performance.

This study will provide a comprehensive CRM framework and propose a model of critical factors for CRM success. Following are the theoretical implications of this research. First, the resultant conceptual frame and a model would provide a stronger theoretical basis for understanding the technology aspects of customer and market-focused research in the Marketing discipline. This is because CRM technology is examined based on theories adapted from MIS as well as Marketing. Second, the measures for CRM Fit will be based on scrutiny of CRM practices including technology and CRM business goals. The structure and dimensions of CRM Technology and CRM activities and goals will be a cornerstone for CRM conceptualization. Third, the study will theoretically shed light on the importance of customer centric management as well as information technology in CRM practice. Fourth, the factors identified from the literature will be tested empirically.

The major benefits of this study to the managers would be closer matching of CRM technology and CRM goals, leading to increasing levels of customer satisfaction and customer retention. The results of the study will provide

theoretical explanations about why huge IT investments in CRM practice do not always generate the successful outcomes desired by organizations and what factors other than technology should be focused on. Investments in CRM technology could then be planned based on careful review of business goals. Also, the measures for CRM Fit would help managers diagnose their businesses for CRM readiness and CRM technology investment. Many variables and measures developed in this study should be employable later as analytical tools for evaluating the organizations' CRM adoption, deployment, and management capabilities. In addition, the analyses of the business processes will provide guidance for better services to customers. The results will provide guidelines for using CRM systems to design customized / personalized services that delight the customers. The results of the study will guide for the smart investment to the information technologies since it will investigate the scope (depth and width) of CRM practice.

E-Commerce Skills Requirements in Online Job Advertisements

Abdulrahman A. Mirza
Information Systems Department
College of Computer and Information Sciences
King Saud University
Riyadh, Saudi Arabia
Amirza@ccis.ksu.edu.sa

Abstract

This paper presents an ongoing research to determine the most popular skills of the e-commerce workforce based on e-commerce skills requirements present in online job locator websites. A large number of online job ads for e-commerce related positions have been already identified representing different geographical areas of the United States. Data is being collected and analyzed regarding types of positions (IT vs. non-IT), salary offered for positions, required years of experience, educational background requirements, desirable non-technical (personal traits and business) skills, and, technical skills (problem solving, technology, and tools).

1. Introduction

With organizations becoming more adaptive of e-commerce as a viable business solution to augment their traditional business channels, the importance of having a capable mix of IT and non-IT e-commerce staff has become apparent. Depending on a firm's business requirements and the depth of e-commerce solutions results in a varied demand for e-commerce personnel. In line with previous research investigations of skills requirements of IS personnel [3] [4] [10], this study aims to determine the requisite skills for the e-commerce workforce. This study is seen necessary as a result of the many apparent differences that are reported between traditional IS projects and e-commerce projects [5]. Mirza and Chan [6] have identified several challenges with relation to e-business organizations that result in different skills requirements for an e-business IT workforce at different levels of the organization.

With this study we hope to answer three main research questions:

1. How different are the IT skills requirements between traditional IT jobs and e-commerce jobs?
2. How does the importance of non-IT (personal traits and business) skills differ between traditional IT jobs and e-commerce jobs?
3. How are e-commerce curriculums meeting actual skills demands of the e-commerce industry?

Methodology to be used for conducting this study and future work agenda will be described in this paper after a brief literature review of related studies. It is hoped that as a result of this study, e-commerce practitioners and job seekers will be able to determine which skills are most popular. This should help them in better preparing themselves for the e-commerce job market. Additionally, e-commerce curricula will be better developed and fine-tuned to meet the real industry e-commerce skills needs [1].

2. Related Research

Much research has been conducted regarding IS personnel skills requirements. Issues of skills portfolios, traits, training, education, skills development, and, recruitment and retention are major issues that have been extensively investigated [7]. Failure to properly manage a firm's skilled workforce may lead to a high rate of turnover, a costly, and at times, a devastating proposition for organizations [2].

With the growing complexities of organizations and the many new applications, business interactions, and technological advancements, an approach of skills portfolio managements has been recommended [8]. Todd, McKeen, and Gallupe [9] conducted a study of IT skills requirements as found in job ads of popular American newspapers from 1970 to 1990. They studied over 1,400 job ads from five-year intervals during the twenty-year period. They noticed the increase of skills requirements over the years from an average of 4 skills per ad to an average of 9 skills per ad. They also discovered that business skills were becoming more important for technical staff as years progressed. Leitheiser [4] conducted an MIS developer skills study where seven main categories consisting of fifty-four specific developer skills were identified. The seven main identified developer skills categories were: analysis & design, programming, interpersonal, business, environment, language, and application.

3. Research Methodology

This research is being conducted by investigating job ads in a popular online service for job seekers and advertisers. Of special interest are jobs that were specified as "Internet/e-commerce" positions. Eight hundred (800) job ads, posted during a two-month period

in the summer of 2003, have been collected from companies based in American states that include major cities, where a larger demand for e-commerce personnel is expected. Selected states are: California, New York, Illinois, Texas, Georgia, the District of Columbia, and Washington.

Six major categories for representing characteristics of a job ad were identified. These categories include the following:

3.1 Type of Job (IT vs. Non-IT)

Even though e-commerce can be considered as a highly technical profession, e-commerce job ads are not all necessarily looking for technical expertise. Other non-IT jobs may include marketing, sales, and accounting.

3.2 Salary

The salary offered for a certain position may be specified by the advertising company. In other cases, no salary is given. Yet in other cases, the job applicant is expected to specify their salary requirement if he/she decide to seek the position.

3.3 Years of Experience

In the current tough job market, it is interesting to determine if companies are hiring staff without any previous relevant experience.

3.4 Educational Background Requirements

The minimum level of education required from prospective e-commerce employees will be investigated. It is expected that in the current job market, more applicants will be expected to have bachelor's degrees at minimum.

3.5 Non-technical Skills

These include two sub-categories, personal traits, and business skills. Personal traits can be exemplified by "interpersonal skills," and "works well with others." Examples of business skills include "project planning," and "business function."

3.6 Technical skills

Technical skills may be divided into three sub-categories: problem solving skills, technology skills, and tools skills. An example of problem solving skills is "optimizing mathematical solutions." Technology skills include Java, XML, and HTML, while tools include "graphics applications," and "MS Office."

4. Conclusion

This ongoing study aims to determine the requisite skills for e-commerce jobs. It is believed that e-commerce, as a result of its revolutionary nature, demands different skills requirements than more traditional IT positions. An investigation of 800 e-commerce job ads is being conducted. Findings are expected to help improve the path that e-commerce professionals pave for themselves. E-commerce curricula are also expected to benefit from this study, with e-commerce programs being better developed to meet the actual skills requirements of e-commerce companies.

Mappings between Virtual Community Processes and Business Processes

Nick V. Flor
Anderson Schools of Management
University of New Mexico
United States of America
nickflor@unm.edu

Abstract

One of the new business models enabled by the Internet is the community-based model. The aim of this model is to profit from the value created by individuals interacting within a virtual community. While we know that a virtual community can be co-opted for business purposes, we do not know the extent to which a community-based business differs from a conventional one. If we are to systematically build community-based businesses, we ought to know which existing processes in a pure virtual community can be adapted for business purposes and, conversely, which processes are lacking and must be added to the virtual community in order to transform it into a business. This paper analyzes one of the largest teen-advice forums on the Internet, yesnomaybe.com, which is also a profitable, community-based business. The goal is to uncover how virtual community processes map to conventional business processes. Using representational analyses I show that a virtual community contains autonomous supply, production, and consumption processes, while lacking advertising and income processes. I end by discussing how yesnomaybe.com implements its income and advertising processes and in doing so creates a special kind of community-based business known as a programmable autonomous business.

1. Introduction

The Internet has given rise to a number of new business models, whose popular names include the storefront, auction, portal, dynamic-pricing, B2B e-Commerce, and click-and-mortar models [4]. Another emerging business model is the community-based model [16], which aims to profit from the individuals that interact within various kinds of virtual communities like chat rooms, forums, and MUDs [19]. An interesting variant of the community-based business model is the programmable autonomous business model [7] — an unmanned, automated business built entirely in software, which operates profitably and grows its customer base without any employees or managers directing it.

Although we know that virtual communities can be co-opted for business purposes, we do not have process models that describe why they can function as businesses. Existing studies on virtual communities have largely focused on design principles [20] [10] [14] [13], analyzing social interactions within such communities (e.g., [3] [15] [2]) and more recently how to support both

social capital (e.g., [5] [18]) and social processes [6] within virtual communities. There are no studies that systematically compare and contrast the processes in a virtual community with those in a conventional business.

If we are to build businesses that are based on virtual communities, we ought to understand the extant processes in virtual communities that can be adapted for business purposes, as well as those processes that are missing and must be added to the virtual community in order to complete its transformation into a community-based business. The research reported in this paper is a first step towards understanding these processes.

2. A Functional Blueprint for a Conventional Business

Businesses exist to create value for customers [11] in the form of goods—both physical and informational—and services, or products. There are as many different kinds of businesses as there are products. However, although the internal makeup, e.g., employees and equipment, as well as the external environment, e.g., suppliers, promoters, and customers, can vary tremendously across businesses, the creation and operation of most businesses can be described in terms of a very general model that I refer to as the conventional business model, which I have adapted from Flor [7]. This model depicts the main agents that a business interacts with, along with the key physical goods, information, and income exchanged between the agents (refer to Figure 1).

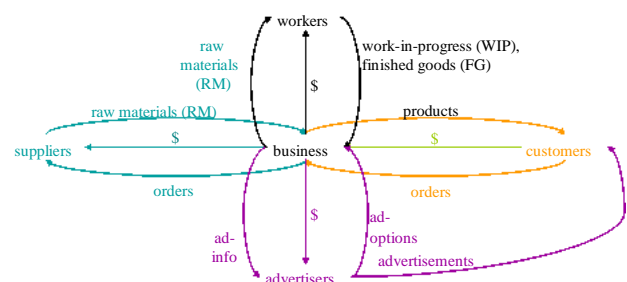

Figure 1. Functional Blueprint for a Conventional Business

Briefly, a business orders raw materials from suppliers who deliver them to the business in exchange for payment (west loop). Workers—both human and machines—take these raw materials and transform them into work-in-progress or finished goods in exchange for wages (north loop). Customers order products from the business,

which delivers them to the customers in exchange for payment (east loop). Finally, one of the major tasks of any business is to "create" customers to purchase its products or services [1]. A business works with various organizations to advertise its products to customers (south loop). These loops correspond to supply, production, consumption, and advertising processes, respectively.

If we build a similar functional blueprint for a virtual community, we can compare and contrast it with that in Figure 1, to uncover existing business processes in a virtual community as well as the processes that are lacking but necessary to make it into a business.

3. Methodology

We apply a representational analysis [8] [9] based on the theoretical framework of distributed cognition [12], to a specific information activity within a community-based business. This is an inductive method where one first charts the movement of information across the individuals and technologies (collectively "agents") that participate in an activity. By abstracting the agents and information in the chart (also known as an information activity map) one can then infer the general processes underlying the observed information activity.

3.1 The community-based business: YNM

The business whose activity is analyzed in this paper was the website YesNoMaybe.com, or simply YNM. YNM is a web-based forum developed by Mental Systems, Inc., which has been in operation since February of 2000. It is the largest teen advice forum in the Open Directory¹ (www.dmoz.org)—for both its own category Kids and Teens : Teen Life : Advice : Romance, as well as its parent category—with over 60,000 registered users who have contributed more than 300,000 postings.

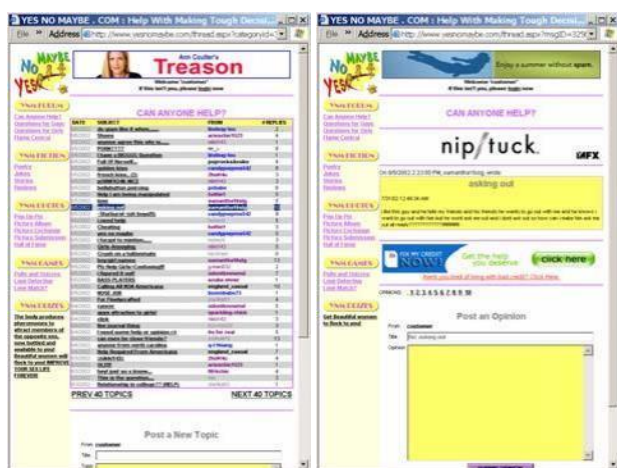

Figure 2. Screen shots: topic list (left) and topic/opinion display (right)

¹ The Open Directory is a hierarchical organization of web sites similar to Yahoo (www.Yahoo.com), but much larger and is outsourced to many of the top search engines, including Google (www.Google.com) and AOL (search.aol.com).

YNM's forum consists of ten different categories, e.g., "Questions for Girls" and "Questions for Guys." Similar to other web forums, users can browse a list of topics (see Figure 2, left screen), read the content of those topics as well as replies (see Figure 2, right screen), or post their own topics and opinions (see Figure 2, bottom of screens).

A poll of over 700 users indicates that 80% are females and 20% are males. 96% of the users are eighteen or under, with 62% below the working age of sixteen. However, YNM is more than just a teen advice forum, it is also a business that has operated profitably since its inception in February of 2000. For example in its first quarter of operation, when companies had large Internet advertising budgets, YNM averaged \$9500 per month in advertising revenues. Since then revenues have been more modest. Over the past year (8/1/2002—7/31/2003, see Figure 3), YNM averaged \$131/month in advertising revenues, with only \$15/month in expenses (fixed web hosting fee)—a simply profitability index of 777%. Besides operating profitably for the past three years, YNM continues to grow its customer base, averaging 1090 new user registrations a month over the past year.

Figure 3. YNM revenues (top line) and expenses (bottom line) from 8/1/2002 to 7/1/2003

3.2 The information activity: A help thread

Table 1 displays a topic posting (index 0) and ten opinion postings (index 1-10). In forum terminology, this is collectively known as a "thread." This particular thread was chosen because it typifies the kinds of messages posted on YNM and that one finds in other virtual community forums.

4. Analysis

The catalyst for the topic posting is some situation in Phoenix's local environment that she is not sure how to handle. Figure 4 graphs the exchange of topics and opinions between the topic poster, Phoenix, and the ten opinion posters over time.

Table 1. The thread to be analyzed

0	phoenix 3/31	I like this guy and he tells my friends and his friends he wants to go out with me and he knows i want to go out with him but he wont ask me out and i dont ask out so how can i make him ask me out all ready????????????!!!!!!
1	lilandra 3/31	..Tell him to ask you out! lol That might work.....guys like it when you take charge!..
2	kitty 3/31	You go up ta him ask him out or why he's not askin you out
3	wolverine 3/31	There's no real way to make someone else ask you out. If he wants to, there is a chance he'll eventually ask you, but there's always the possibility that he's shy, or that he doesn't knwo how you would react. The idea that you don't ask people out strikes me as a strange pne; you can't expect other people to make the first move forever, and some people would never make a move if they didn't have some indication of how you would react. If you're unwilling to ask him out, then the best thing you could do it make it known that you would go out with him if he asked you.
4	colossus 4/03	just go up to him and say 'i think your funny (or somethin like that i mena if he is) and i was just wondering if maybe u wanna go to a movie or something sometime?' and if he sasy no then well he is an ass that doesnt deserve u ne way :) lol hope i helped!
5	jean 4/03	get one of your friends to ask him out for you. hope i was helpful....always works for me.
6	rogue 4/04	u go and ask him if he likes u and then say well do u wanna go catch a movie or something on saturday (or something like that)
7	cyclops 4/05	fuck! just ask him out urself! if u like him so much just ask him out! WHY DO GIRLS HAVE SUCH A HARD TIME WITH IT!!!!!!!!!!!!!!!!!!!!!!
8	nightcrawler 4/05	Why don't you ask out already????????!!!!!! You afraid that at that point, you give him the upper-hand because you were the instigator in this matter? Or maybe you have underlaying insecurities that you haven't dealt with as of yet. You should take some time to think of this matter.
9	Professor Xavier 4/05	If I were you I would flirt as much as possible, or dress really nice for him. And if he still doesn't for awhile then you ask him. I know it's hard to get the courage to, but I have before and it worked. Not all guys are crazy about the old-fashioned saying that the guys have to ask the girls out. XXXXXXX (P.S. Need any more help email me @ xxxxxxxxxxxxxxx@xxxxxxxxxxxxx)
10	storm 4/05	Ok Ive been were you are now. The thing i did worked Ive been with my bfriend for 9 months you just talk to him till you are best friends and then he will relize ok Iam ready to go out with her and Iam just going to warn you know that you need to be careful because once you get to know him you might change your mind abort him so be careful and GOOD LUCK

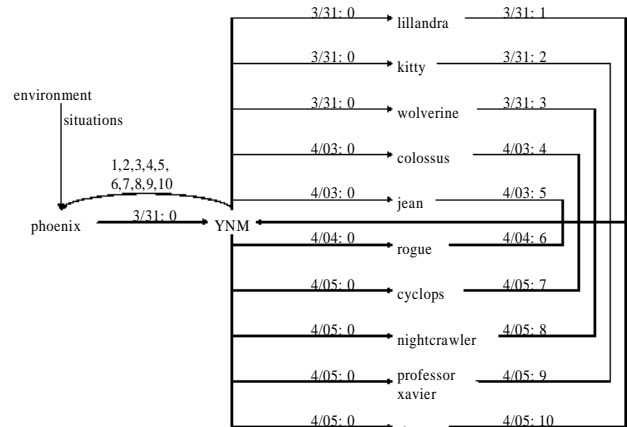

Figure 4. Information activity map for the sample thread

The arrows in the graph are labeled with a number corresponding to the content index from Table 1 and, where known, are prefixed by the date the content exchange occurred, e.g., the label 3/31: 0 denotes a topic posting on March 31st, whereas the label 4/05: 7 denotes the posting of the seventh reply on the fifth of April. She originally posted her topic on 3/31, and over the course of five days, ten other users read and responded with various opinions.

To understand how these processes get co-opted for business purposes. We first simplify the diagram by grouping the ten opinion posters into a single node labeled "opinion posters" (see Figure 5):

Figure 5. Grouping the 10 opinion posters

Next, we group the information exchanged between agents, as either a "topic" or "opinion" and generalize phoenix as a "topic poster" (see Figure 6)

Figure 6. Generalizing the information

Not shown in Figure 6 are the members of YNM that

simply browse and read threads without contributing an opinion or topic of their own. Members refer to this behavior as "lurking," which is best summarized by the following user's posting (see Table 2, emphasis mine).

Table 2. A user posting that describes lurking

Mac y	... aww spanx babe!!! dont worry theres msn for me and you! i might come back i dont know, right now im just lurking around lolz i'll hardly post or reply to anything, like i did before, but it'll be way less, ...
----------	---

Figure 7 depicts the information activity map for YNM with lurkers added:

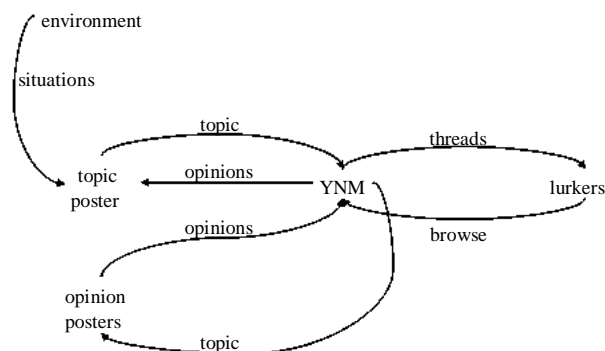

Figure 7. Functional blueprint for the thread

We are in a position now to compare the functional blueprint for the thread (Figure 7), with the functional blueprint for a conventional business (Figure 1).

5. Results

A cursory inspection of the functional blueprint for the thread (Figure 7) may not reveal the underlying business processes. However, by explicitly representing the software scripts that transform the topic and opinions into threads as well as annotating the agents and information with their counterparts in the conventional business model (see Figure 1), the business processes become apparent. Figure 8 depicts a functional blueprint for the thread with these annotations.

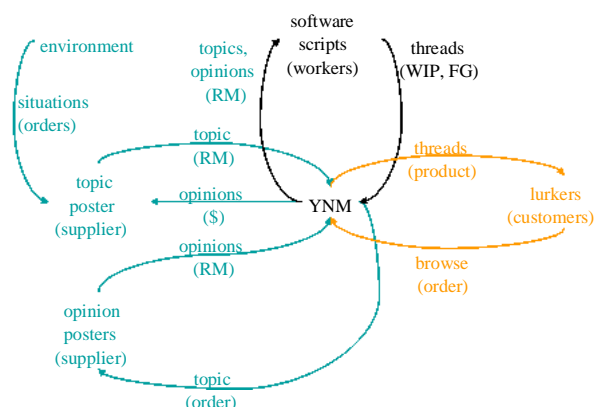

Figure 8. Functional blueprint for the thread with business labels

5.1 Common business processes: Supply, production, consumption

The thread activity, and by extension a virtual community, contains instances of supply, production, and consumption processes. Specifically, the topic and opinion posters play the role of suppliers for YNM. But unlike a conventional business where the raw materials are tangible goods, the raw materials—topic and opinion postings—are information based. Software scripts play the role of the workers in YNM, taking the topics and opinions and formatting them as threads in a database. These threads are YNM's product and are made available online to the lurkers, who correspond to business customers.

The supply process, in particular, differs from that of a conventional business in several interesting ways. First, the suppliers in a virtual community are its members, not some outside agency. Community members can and do shift roles between lurking and posting, viz., between being consumers and being suppliers. Second, they provide raw materials for free without any monetary payment—although one can view the opinions that the topic suppliers receive as a kind of information payment. Finally, the supply process is autonomous. No one within the community orders members to start supplying postings. Rather, situations in the members' environment are the catalyst for the supply process.

5.2 Missing Business Processes: Advertising and Income

The business processes missing from a pure virtual community are more apparent, namely an advertising process and an income process. To transform a virtual community into a community-based business, these processes must be designed into the virtual community. One challenge is to implement them without the virtual community having to pay any money. To do so would result in a true programmable autonomous business—a business built entirely in software that runs itself, generating income and customers, without human workers or managers directing it. In the following section, we discuss the advertising and income processes that make yesnomaybe.com a programmable autonomous business.

6. Discussion

The analysis showed that a virtual community instantiates the supply, production, and consumption processes needed by a business. The missing processes are an advertising process and an income process. While one could copy what conventional businesses do—pay some outside agency to advertise the business and charge customers for accessing content—there are several drawbacks to doing so. One obvious drawback is cost; advertising can be expensive, particularly in the national media needed to reach a mass audience. Second, it is not clear that mechanisms which work for conventional businesses will work for community-based businesses.

For example, customers are used to obtaining community content for free and may be unwilling to pay for it, especially when such content is typically available elsewhere on the Internet.

One possibility is to design low to no-cost advertising processes, as well as income processes that, paradoxically, do not require customers to pay any money to the community-based business. YNM has implemented two such processes. Figure 9 depicts the complete functional blueprint for YNM. To unclutter the diagram, topic and opinion posters have been grouped as "customers" (see west loop in Figure 9). In the following discussion, terms in *italics> reference items in this diagram.*

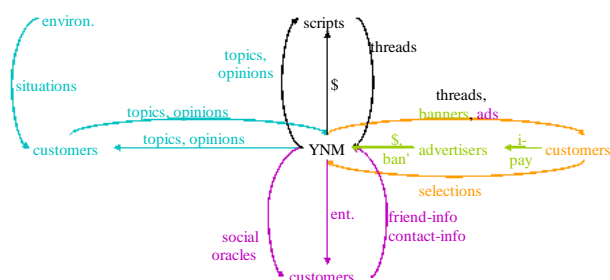

Figure 9. Functional blueprint for YNM as a programmable autonomous business

6.1 Example: YNM's income process

In YNM, customers pay indirectly via advertisers. Specifically, the advertisers give YNM banner code (*ban'*) that allows YNM to display banners along with the thread content in various locations on the web page. In Figure 2, you can see banners at the top of the page, before the thread content, and after the thread content. The advertisers then pay YNM money (\$) in exchange for the users performing some action on the banner. Different advertisers require different actions for payment. The actions include: (a) clicking on a banner; (b) clicking on a banner and then entering contact information into a form, like an e-mail address or telephone number; or (c) simply looking at a banner. The users' actions can be viewed as a kind of information payment (*i-pay*) to the advertiser, who then transforms this information into money for YNM (see Figure 3).

6.2 Example: YNM's Advertising Process

Aside from the listing on DMOZ, YNM does not appear in any of the top search engines for common search terms like "teens" or "teen romance." Moreover, keeping with the goal of autonymity, YNM's owners do not pay companies to advertise the site. As with the supply process, YNM relies on existing customers to promote the site by both word of mouth or by interacting with social oracles. A social oracle is a computer program that provides social information (*ent.*) to customers—entertaining information that users want to share with other friends and associates. YNM has two social oracles: a compatibility program, and the "love

detective" (see Figure 10).

Figure 10. Social oracles for advertising

Generally, social oracles work by taking, as input, information about a user's friends or associates and returning entertaining information about them—information that a user will want to share with others. For example, the compatibility program takes the names of two people and returns three compatibility scores along with an explanation of those scores. This entertaining information is used to construct a direct response advertisement [17]. For instance, in the compatibility game, the user is given the option of e-mailing the compatibility report to a friend. Unbeknownst to the user, only the scores get e-mailed to the friend. To receive the explanations, the recipient is told to click on a link (the direct response mechanism that sends them to YNM), and use the compatibility program.

Matching the e-mails sent out with the registration e-mails in the new-user database, shows the compatibility program has a 14.46% conversion rate. The love detective, operating on similar principles, has a conversion rate of 30.22%. Both social oracles far exceed the 2% response rate that typifies direct mail advertisements.

To summarize, YNM's income and advertising processes when combined with the supply, production, and consumption processes that result from its virtual community, allow it to generate income and grow its customer base without the owners doing any work or paying expenses, aside from the initial development and monthly web hosting costs (see Figure 3). YNM is not only a community-based business, but a programmable autonomous business as well. Future research is needed to discover how to systematically design advertising and income processes for the different kinds of virtual communities on the Internet.

7. Summary

We have seen how a virtual community instantiates supply, production, and consumption processes. To transform virtual communities into businesses, designers ought to focus their efforts on the development of advertising and income processes specific to their types of communities. As YesNoMaybe.com demonstrated, properly designed advertising and income processes can allow community-based businesses to operate autonomously and at low costs.

A New Thought about Modelling of Bilevel Programming Problems

Hai Yan Lu

helenlu@it.uts.edu.au

Abstract

This paper presents a new mathematical model for bilevel linear programming problems (BLPPs). A new kind of constraint is proposed to emphasize the pre-determined hierarchy in the bilevel decision-making process. The solution to the BLPPs based on this new model is defined. A number of simple examples of BLPPs have been solved using the new model. It has been shown that the new model is able to handle a wider range of BLPPs.

1. Introduction

The origin of the bilevel programming problems can be traced back to 1952 when they had been formulated by H.V. Strackelberg in a monograph on market economy [1]. Dempe [2] defined the BLPPs as mathematical optimization problems where the set of all variables is partitioned between two vectors X and Y , which are controlled by the upper level (leader) and the lower level (follower), respectively, and vector Y is to be chosen as an optimal solution of a second mathematical programming problem parameterized in vector X . According to Dempe, BLPPs turn to be complicated mathematical problems because (a) they are NP-hard; (b) their formulation has inherent difficulties even with respect to the notion of a solution and for many of its reformulations as one-level optimization problems regularity conditions cannot be satisfied at any feasible point. Bard [3] described the linear bilevel programming problems as a mathematical model as follows:

For $x \in X \subset R^n$, $y \in Y \subset R^m$, $F: X \times Y \rightarrow R^1$,
and $f: X \times Y \rightarrow R^1$,

$$\min_{x \in X} F(x, y) = c_1 x + d_1 y \quad (1.1a)$$

$$\text{subject to } A_1 x + B_1 y \leq b \quad (1.1b)$$

$$\min_{y \in Y} f(x, y) = c_2 x + d_2 y \quad (1.1c)$$

$$\text{subject to } A_2 x + B_2 y \leq b \quad (1.1d)$$

where $c_1, c_2 \in R^n$, $d_1, d_2 \in R^m$, $b_1 \in R^p$, $b_2 \in R^q$,
 $A_1 \in R^{p \times n}$, $B_1 \in R^{p \times m}$, $A_2 \in R^{q \times n}$, $B_2 \in R^{q \times m}$.

The solution to the problem (1.1) was described by a set of definitions as follows [3, on P196]:

(a) Constraint region of the BLPP, denoted by S

$$S = \{(x, y): x \in X, y \in Y, A_1 x + B_1 y \leq b, A_2 x + B_2 y \leq b\} \quad (1.2)$$

(b) Feasible set for the follower for each fixed

$$x \in X$$

$$S(x) = \{y \in Y, A_2 x + B_2 y \leq b\} \quad (1.3)$$

(c) Projection of S onto the leader's decision space

$$S(X) = \{x \in X: \exists y \in Y, A_1 x + B_1 y \leq b, A_2 x + B_2 y \leq b\} \quad (1.4)$$

(d) Follower's rational reaction set for $x \in S(X)$

$$P(x) = \{y \in Y: y \in \arg\min_{y \in S(x)} f(x, y)\} \quad (1.5)$$

(e) Inducible region (IR)

$$IR = \{(x, y): (x, y) \in S, y \in P(x)\} \quad (1.6)$$

In terms of the above notation, the BLPP can be written as

$$\min \{ F(x, y) : (x, y) \in IR \} \quad (1.7)$$

It can be seen from (1.7) that the solution to BLPP (1.1) can be found by solving a one-level linear programming problem in which the objective function is $\min F(x, y)$ and the constraint region is IR from pure mathematical point of view. According to Bard [3], the inducible region IR is the intersection of two sets, which are the leader's constraint region S and the region determined by the follower's optimal solution for all $x \in S(X)$, i.e.

$$\{(x, y): x \in S(X), y \in P(x)\}$$

where $P(x)$ is defined in (1.5). So it is obvious that if the leader's constraint region has no intersection with the follower's optimal solution set, i.e., the IR is empty, the problem (1.1) or (1.7) has no solution. However, this is not always the case. For example, one can expect the solution to BLPP (1.1) in a real world situation as the optimal solution for both objective functions over S or the optimal solution for the leader objective function over S . Further more, this model assumes that the information is only perfect for the leader, not the follower. This might lead to a situation in which the solution is not reasonable.

This paper presents a new mathematical model of BLPPs. The new model is developed by modifying the existing model of BLPPs defined by Bard [3] to release the above limitations. The first key point is to relax the problem's constraints by setting the follower's objective function as a reference-to constraint instead of a subject-to constraint. The second key point is to distinguish the two situations: one is when the information is perfect to the leader only and when the information is perfect to both leader and followers. A number of examples of linear BLPPs are depicted and the results show that the new model is able to handle a wider range of BLPPs and produce more reasonable solutions.

The rest of the paper is organized as follows. Section 2 describes development of the new model of BLPPs. Section 3 compares the defined solutions to a number of sample BLPPs using the new and existing models. Section 4 concludes the paper.

2. A New Mathematical Model of Bilevel Programming Problems

Refer to the model of BLPPs (1.1), we separate the problem into the leader's problem or the upper level problem

$$\min_{x \in X} F(x, y) = c_1 x + d_1 y \quad (2.1a)$$

$$\text{subject to } A_1 x + B_1 y \leq b \quad (2.1b)$$

and the follower's problem or the lower level problem

$$\min_{y \in Y} f(x, y) = c_2 x + d_2 y \quad (2.2a)$$

$$\text{subject to } A_2 x + B_2 y \leq b \quad (2.2b)$$

where (2.1b) and (2.2b) are referred as the leader's and the follower's subject-to constraint functions, respectively. Both problems are parametric linear programming problems because each level can only control one variable vector. When these two problems are combined to form a BLPP, there two possible cases: one is that the information is perfect for both levels, which means that both leader and follower know the objective functions and subject to constraints at the other level and the other case is that the information is perfect for the leader only, which means only the leader knows the objective functions and constraints of the follower. In the following sections, these two cases will be discussed separately, then a generalised model will be presented.

2.1 Case 1 -- A BLPP with perfect information for both levels

Given a BLPP with perfect information for both levels, for a possible $x \in S(X)$, the leader knows the follower's response $y(x)$ which satisfies both the leader's and the follower's subject-to constraints and will select a x^* so that the leader's objective function $F(x^*, y(x^*))$ is minimized.

The model can be written as

$$\min_{x \in X} F(x, y) = c_1 x + d_1 y \quad (2.3a)$$

$$\text{subject to } A_1 x + B_1 y \leq b \quad (2.3b)$$

$$A_2 x + B_2 y \leq b \quad (2.3c)$$

$$\min_{y \in Y} f(x, y) = c_2 x + d_2 y \quad (2.3d)$$

$$\text{subject to } A_2 x + B_2 y \leq b \quad (2.3e)$$

$$A_1 x + B_1 y \leq b \quad (2.3f)$$

This model can be simplified to a form that is the same as (1.1) by omitting (2.3c) and (2.3f) because of the perfect information for both sides. The solution to (2.3) is the same as the one to (1.1) except for the follower's feasible set, which should be re-defined as

$$S(x) = \Delta \{y \in Y, A_1 x + B_1 y \leq b_1, A_2 x + B_2 y \leq b\} \quad (2.4)$$

for each fixed $x \in S(X)$.

2.2 Case 2 -- A BLPP with perfect information only for the upper level

Given a BLPP with perfect information only for the upper level, the follower does not know the

leader's objective function and the subject-to constraints. So the follower can only response to a fixed $x \in S(X)$ over its own constraint region which is defined by (2.2b). This might lead to a situation in which the constraint region S is non-empty and compact, but the follower's response to a fixed $x \in S(X)$ does not satisfy the constraint (2.1b). The existing model of BLPPs (1.1) gives no solution in this situation. This is not always reasonable because the solution to a BLPP should be expectable in a real world situation provided that the intersection of the subject-to constraint regions from both levels is non-empty and compact. In order to release this limitation, we modify the existing model of BLPP (1) as follows:

$$\min_{x \in X} (c_1 x + d_1 y) \quad (2.5a)$$

$$\text{subject to } A_1 x + B_1 y \leq b \quad (2.5b)$$

$$\text{reference to } \min_{y \in Y} (c_2 x + d_2 y) \quad (2.5c)$$

$$\text{subject to } A_2 x + B_2 y \leq b \quad (2.5d)$$

where "reference to" is similar to "subject to" but used to combine the upper level problem and the lower level problem to reflect the pre-determined hierarchy in the bilevel decision making process.

Let S_f denote a set formed by a pair of x and y where $x \in S(X)$ and $y \in P(x)$, where $S(X)$ and $P(x)$ are defined in (1.4) and (1.5). If S_f does not belong to S , the leader will ignores the follower's responses and seeks for its own optimal solution over S . Otherwise, the leader will seeks for its own optimal solution over S_f . Consequently, the notation of solution to (2.5) is similar to the one to (1.1) and listed as follows:

(a) Constraint region S

$$S = \{(x, y) : x \in X, y \in Y, A_1 x + B_1 y \leq b, A_2 x + B_2 y \leq b\} \quad (2.6)$$

(b) Projection of S onto the leader's decision space

$$S(X) = \{x \in X : \exists y \in Y, A_1 x + B_1 y \leq b, A_2 x + B_2 y \leq b\} \quad (2.7)$$

(c) Feasible set for the follower for each fixed $x \in S(X)$

$$S_f(x) = \{y \in Y, A_2 x + B_2 y \leq b\} \quad (2.8)$$

(d) Follower's rational reaction set for $x \in S(X)$

$$P(x) = \{y \in Y : y \in \arg \min_{y \in Y} [f(x, y) : y \in S(x)]\} \quad (2.9)$$

(e) Follower's optimal solution constraint region S_f

$$S_f = \{(x, y) : x \geq 0, x \in S(X), y \geq 0, y \in P(x)\} \quad (2.10)$$

(f) Inducible region (IR)

$$IR = \begin{cases} \{(x, y) : (x, y) \in S, y \in P(x)\} & S_f \subseteq S \\ \{(x, y) : (x, y) \in S\} & \text{otherwise} \end{cases} \quad (2.11)$$

2.3 A generalised model of BLPPs

The "reference to" can also be used in the model (2.3), which is for a BLPP with perfect information for both levels, to emphasis the two levels in the problem. Since S_f is always in S in this situation, "reference to" is the same as the "subject to". Under the assumption that the leader's and the follower's constraints implicitly contains the other's subject-to constraints, the notation of solution by (2.6)-(2.11) also can be used for the case 1. Therefore, both the cases presented in section 2.1 and 2.2 can be generalised by the model (2.5) with the notation of solution definition (2.6)-(2.11), this is regarded as the new model in the paper.

3. Comparison of the Existing and New Models by Sample BLPPs

3.1 Sample BLPP 1

Given $x \in \mathbb{R}^1$, $y \in \mathbb{R}^1$ and $X = \{x \geq 0\}$, $Y = \{y \geq 0\}$, the leader's problem is

$$\min_{x \in X} (x - 4y) \quad (3.1.1)$$

and the follower's problem is

$$\min_{y \in Y} (y) \quad (3.1.2a)$$

$$\text{subject to } -x - y \leq -3 \quad (3.1.2b)$$

$$-2x + y \leq 0 \quad (3.1.2c)$$

$$2x + y \leq 12 \quad (3.1.2d)$$

$$-3x + 2y \leq -4 \quad (3.1.2e)$$

i) Case 1

Form a BLPP with perfect information for both sides as

$$\min_{x \in X} (x - 4y) \quad (3.1.3a)$$

$$\text{reference to } \min_{y \in Y} (y) \quad (3.1.3b)$$

$$\text{subject to } -x - y \leq -3 \quad (3.1.3c)$$

$$-2x + y \leq 0 \quad (3.1.3d)$$

$$2x + y \leq 12 \quad (3.1.3e)$$

$$3x + 2y \leq -4 \quad (3.1.3f)$$

The constraint region S can be determined by

$$S = \{(x, y) : x \geq 0, y \geq 0, -x - y \leq -3, -2x + y \leq 0, 2x + y \leq 12, 3x + 2y \leq -4\} \quad (3.1.4)$$

The projection of S onto the leader's decision space S(X) can be determined to be

$$S(X) = \{x : 1 \leq x \leq 4\} \quad (3.1.5)$$

Feasible set for the follower for each fixed $x \in S(X)$

$$S(x) = \{y : y \geq 0, -x - y \leq -3, -2x + y \leq 0, 2x + y \leq 12, 3x + 2y \leq -4\} \quad (3.1.6)$$

The follower's rational reaction set for $x \in S(X)$

$$P(x) = \{y \in Y : y \in \arg \min_{y \in S(x)} [f(x, y)] : y \in S(x)\} \\ = \begin{cases} 3 - x & 1 \leq x \leq 2 \\ 3x/2 - 2 & 2 \leq x \leq 4 \end{cases} \quad (3.1.7)$$

Graphically, S, S(X), S(x) and P(x) can be depicted in Fig.1. It can be seen that the set $S_f = \{(x, y) : x \in S(X), y \in P(x)\}$ depicted as a piece of line AB and BC that belongs to S. Therefore, the inducible region IR should be

$$IR = \{(x, y) : (x, y) \in S, y \in P(x)\} \\ = \begin{cases} 3 - x & 1 \leq x \leq 2 \\ 3x/2 - 2 & 2 \leq x \leq 4 \end{cases} \quad (3.1.8)$$

The problem can then be written as

$$\min \{ F(x, y) = x - 4y : (x, y) \in IR \} \quad (3.1.9)$$

According to the corollary 5.2.3 [1 on P.200], the solution to the problem can be found by comparing the F(x,y) values over the vertices of IR as shown in Table 1.

Table 1 Finding the solution to (3.1.3)

x	y	F(x,y)=x-4y
1	2	-7
2	1	-2
4	4	-12

It can be seen that the optimal solution to (3.1.3) occurs at x=4. The leader selects x=4 and the

Fig.1 Illustration of S, S(X), S(x) and P(x) for the sample BLPP 1 (case 1)

follower responses $y=4$ to make $F(x,y) = x-4y = -12$.

ii) *Case 2*

Forming a BLPP with perfect information only for the leader side will result in an identical problem as (3.1.3) because the leader has no explicit constraints.

Both cases produce an identical solution to the one obtained by the existing model [3].

3.2 Sample BLPP 2

Given $x \in R^1$, $y \in R^1$ and $X = \{x \geq 0\}$, $Y = \{y \geq 0\}$, find the solution for a BLPP formed by the following two problems: the leader's problem is

$$\min_{x \in X} (x - 2y) \quad (3.2.1a)$$

$$\text{subject to } x - y \leq 0 \quad (3.2.1b)$$

and the follower's problem is

$$\min_{y \in Y} (x + y) \quad (3.2.2a)$$

$$\text{subject to } -x + 3y \leq 4 \quad (3.2.2b)$$

i) *Case 1*

Form a BLPP with perfect information for both sides as

$$\min_{x \in X} (x - 2y) \quad (3.2.3a)$$

$$\text{subject to } x - y \leq 0 \quad (3.2.3b)$$

$$\text{reference to } \min_{y \in Y} (x + y) \quad (3.2.3c)$$

$$\text{subject to } -x + 3y \leq 4 \quad (3.2.3d)$$

$$\begin{aligned} &\text{The constraint region } S \text{ can be determined by} \\ S = \{ (x, y) : x \geq 0, y \geq 0, y \leq \frac{1}{3}x + \frac{4}{3}, y \geq x \} \end{aligned} \quad (3.2.4)$$

The projection of S onto the leader's decision space $S(X)$ can be determined to be

$$S(X) = \{0 \leq x \leq 2\} \quad (3.2.5)$$

Feasible set for the follower for each fixed $x \in X$

$$S(x) = \{y : y \geq 0, y \geq x, -x + 3y \leq 4\} \quad (3.2.6)$$

The follower's rational reaction set for $x \in S(X)$

$$\begin{aligned} P(x) &= \{y \in Y : y \in \arg \min_{\hat{y} \in S(x)} [f(x, \hat{y})]\} \\ &= \{y : y = x\} \end{aligned} \quad (3.2.7)$$

Graphically, S , $S(X)$, $S(x)$ and $P(x)$ can be depicted in Fig.2. It can be seen that S_f is a piece of line AB that is on S . Therefore, the inducible region IR should be

$$\begin{aligned} IR &= \{(x, y) : (x, y) \in S, y \in P(x)\} \\ &= \{(x, y) : 0 \leq x \leq 2, y = x\} \end{aligned} \quad (3.2.8)$$

Fig.2 Illustration of S , $S(X)$, $S(x)$ and $P(x)$ for the sample BLPP 2 (case 1)

The problem can then be written as

$$\min\{ F(x, y) = x - 2y : (x, y) \in IR\} \quad (3.2.9)$$

The solution to the problem can be found by comparing the $F(x,y)$ values over the vertexes of IR as shown in Table 2.

Table 2 Finding the solution to (3.2.3)

x	y	$F(x,y)=x-2y$
0	0	0
2	2	-2

It can be seen that the optimal solution to (3.2.3) occurs at $x=2$. The leader selects $x=2$ and the follower responses $y=2$ to make $F(x,y) = -2$.

ii) Case 2

Form a BLPP with perfect information only for the leader side as

$$\min_{x \in X} (x - 2y) \quad (3.2.10a)$$

$$\text{subject to } x - y \leq 0 \quad (3.2.10b)$$

$$\text{reference to } \min_{y \in Y} (x + y) \quad (3.2.10c)$$

$$\text{subject to } -x + 3y \leq 4 \quad (3.2.10d)$$

The feasible set for the follower for each fixed $x \in X$

$$S(x) = \{ y : y \geq 0, -x + 3y \leq 4 \} \quad (3.2.11)$$

The follower's rational reaction set for

Fig.3 Illustration of S, S(X), S(x) and P(x) in the sample BLPP 2 (case 2)

$$x \in S(X)$$

$$P(x) = \{ y \in Y : y \in \arg \min_{y \in S(x)} [f(x, y)] \} \\ = \{ y : y = 0 \} \quad (3.2.12)$$

Graphically, S, S(X), S(x) and P(x) can be depicted in Fig.3. It can be seen that S_f is a piece of line AB that is not entirely in or on S. Therefore, the inducible region IR should be

$$IR = \{(x, y) : (x, y) \in S\} = S \quad (3.2.13)$$

The problem can then be written as

$$\min\{ F(x, y) = x - 2y : (x, y) \in IR\} \quad (3.2.14)$$

The solution to the problem can be found by comparing the $F(x,y)$ values over the vertexes of IR as shown in Table 3.

Table 3 Finding the solution to (3.2.10)

x	y	$F(x,y)=x-2y$
0	0	0
2	2	-2
0	4/3	-8/3

It can be seen that the optimal solution to (3.2.10) occurs at $x=0$. The leader selects $x=0$ and the follower responses $y=4/3$ to make $F(x,y) = x-2y = -8/3$.

Table 4 tabulates the solutions to the sample BLPP 2 using the new model for the cases 1 and 2 and the existing model. It can be seen that the

solution using the new model with perfect information for the leader gives the most reasonable result.

Table 4 Comparison of solutions to sample problem2 using different models

	x	y	f(x,y)	F(x,y)
New model (case 1)	2	2	4	-2
New model (case 2)	0	4/3	4/3	-8/3
Existing model	0	0	0	0

3.3 Sample BLPP 3

Given $x \in R^1$, $y \in R^1$ and $X = \{x \geq 0\}$, $Y = \{y \geq 0\}$, find the solution for the a LBLPP formed with the following two problems: the leader's problem is

$$\min_{x \in X} F(x, y) = x - 4y \quad (3.3.1a)$$

$$\text{subject to } -x - y \leq -3 \quad (3.3.1b)$$

$$-3x + 2y \geq -4 \quad (3.3.1c)$$

and the follower's problem is

$$\min_{y \in Y} f(x, y) = x + y \quad (3.3.2a)$$

$$\text{subject to } -2x + y \leq 0 \quad (3.3.2b)$$

$$2x + y \leq 12 \quad (3.3.2c)$$

i) Case 1

Fig.4 Illustration of S, S(x), S(X) and P(x) for sample BLPP 3 (case 1)

Form a BLPP with perfect information for both sides as

$$\min_{x \in X} F(x, y) = x - 4y \quad (3.3.3a)$$

$$\text{subject to } -x - y \leq -3 \quad (3.3.3b)$$

$$-3x + 2y \geq -4 \quad (3.3.3c)$$

$$\text{reference to } \min_{y \in Y} f(x, y) = x + y \quad (3.3.3d)$$

$$\text{subject to } -2x + y \leq 0 \quad (3.3.3e)$$

$$2x + y \leq 12 \quad (3.3.3f)$$

The constraint region S can be determined by

$$S = \{(x, y) : x \geq 0, y \geq 0, -x - y \leq -3, -x + 2y \geq -4, -2x + y \leq 0, 2x + y \leq 12\} \quad (3.3.4)$$

The projection of S onto the leader's decision space S(X) can be determined to be

$$S(X) = \{1 \leq x \leq 4\} \quad (3.3.5)$$

Feasible set for the follower for each fixed $x \in S(X)$ is

$$S(x) = \{y : y \geq 0, -x + y \leq 0, 2x + y \leq 12, -x - y \leq -3, -3x + 2y \geq -4\} \quad (3.3.6)$$

The follower's rational reaction set for $x \in S(X)$ is

$$P(x) = \{y \in Y: y \in \arg \min_{\hat{y}} [f(x, \hat{y}): \hat{y} \in S(x)]\} \\ = \begin{cases} \{y: y = \frac{3x}{2} - 2, 1 \leq x < 2\} \\ \{y: y = 3 - x, 2 \leq x \leq 4\} \end{cases} \quad (3.3.7)$$

$$S_f = \{(x, y): 1 \leq x \leq 2, -3x + 2y = -4\} \cup \{(x, y): 2 \leq x \leq 4, -x - y = -3\} \quad (3.3.8)$$

Graphically, S , $S(X)$, $S(x)$ and $P(x)$ can be depicted in Fig.4. It can be seen that S_f is the piece-wise line AB and BC which are on the S . Therefore, the inducible region IR should be S_f .

$$IR = \{(x, y) : (x, y) \in S, y \in P(x)\} = S_f \quad (3.3.9)$$

The problem can then be written as $\min\{F(x, y) = x - 4y : (x, y) \in IR\}$

The solution to the problem (3.3.3) can be found by comparing the $F(x, y)$ values over the vertexes of IR as shown in Table 5.

Table.5 Finding the solution to (3.3.3)

x	y	$F(x, y) = x - 4y$
1	2	-7
2	1	-2
4	4	-12

It can be seen that the optimal solution for (3.3.3) occurs at $x=4$. The leader selects $x=4$ and the

follower responds $y=4$ to make $F(x, y) = -12$.
ii) Case 2

Form a BLPP with perfect information for the leader only as

$$\min_{x \in X} F(x, y) = x - 4y \quad (3.3.10a)$$

$$\text{subject to } -x - y \leq -3 \quad (3.3.10b)$$

$$-3x + 2y \geq -4 \quad (3.3.10c)$$

$$\text{reference to } \min_{y \in Y} f(x, y) = x + y \quad (3.3.10d)$$

$$\text{subject to } -2x + y \leq 0 \quad (3.3.10e)$$

$$2x + y \leq 12 \quad (3.3.10f)$$

Feasible set for the follower for each fixed $x \in S(X)$

$$S(x) = \{y: y \geq 0, -2x + y \leq 0, 2x + y \leq 12\} \quad (3.3.11)$$

The follower's rational reaction set for $x \in S(X)$

$$P(x) = \{y \in Y: y \in \arg \min_{\hat{y}} [f(x, \hat{y}): \hat{y} \in S(x)]\} \\ = \{y: y = 0\} \quad (3.3.12)$$

$$S_f = \{(x, y): 1 \leq x \leq 4, y = 0\} \quad (3.3.13)$$

Graphically, S , $S(X)$, $S(x)$ and $P(x)$ can be depicted in Fig.5. It can be seen that S_f is a piece of line AB that is out of S . Therefore, the inducible

Fig.5 Illustration of S , $S(x)$, $S(X)$ and $P(x)$ for sample BLPP 3 (case 2)

region IR should be S.

$$IR = \{(x, y) : (x, y) \in S\} \quad (3.3.14)$$

The problem can then be written as

$$\min\{F(x, y) = x - 4y : (x, y) \in IR\} \quad (3.3.15)$$

The solution to the problem (3.3.10) can be found by comparing the $F(x, y)$ values over the vertexes of IR as shown in Table 6.

Table 6 Finding the solution to (3.3.10)

x	y	$F(x, y) = x - 4y$
1	2	-7
2	1	-2
3	6	-21
4	4	-12

It can be seen that the optimal solution to (3.3.10) occurs at $x=3$. The leader selects $x=3$ and the follower responses $y=6$ to make $F(x, y) = -21$.

Table 7 tabulates the solutions to the sample BLPP 3 using the new model for the cases 1 and 2 and the existing model. It can be seen that the solution to the sample BLPP 2 using the new model with perfect information for the leader gives the most reasonable result.

Table 7 Comparison of solutions to sample BLPP3 using different models

	x	y	$F(x, y) = x - 2y$
New model (case 1)	4	4	-12
New model (case 2)	3	6	-21
Existing model	No solution		

4. Conclusion

The follower's objective function is modelled by a new kind of constraint, *reference to*, in the BLPPs to reflect the predetermined hierarchy of the bilevel decision making process. The newly introduced constraint is the same as the one in the existing model if the set $S_f = \{(x, y) : x \in S(X), y \in P(x)\}$ belongs to S. When S_f does not belong to S, the follower's objective function will be ignored. The new model of BLPPs can lead to a reasonable solution when S_f is out of S. Three typical sample BLPPs have been

solved by using the new model and the results have been compared against the results gained from the existing model. It has been shown that the new model can be expected to be suitable for a wider range of BLPPs and be able to produce more reasonable solutions.

Abstract

The Internet is significantly changing the strategic behaviour of many businesses that operate in the global arena. Today, many multinational enterprises (MNEs) work closely with their logistics providers to enhance their competitive positions. They increasingly outsource their non-strategic business functions, with logistics providers picking up this new source of business. The MNE is moving more towards a ‘front-end’ or customer focused operation, with their key logistics providers aligning themselves as supply chain integrators. Logistics providers may be classified as 1st to 4th party logistics providers. A 4th party logistics provider provides complete supply side solutions for the MNE, plus a degree of demand side service. It becomes an integral part of the MNEs competitive solution set. This paper proposes that integrated, fully activated, demand-supply (FADS) chains provide a mechanism to move beyond 4th party logistics provider (4PLP) solutions. It elucidates the key clusters of skills levels that must be activated by the logistics provider to operate at the 5th party logistics provider (5PLP) FADS level of outsourcing and service. The 5PLP FADS logistics provider brings a vast array of ‘added-value skills’ to the MNE, and a key innovative, flexible and highly agile partnership results, whereby pathways towards ‘sustainable’ competitive advantage may be developed. The 5PLP FADS logistics model is the next step in the progression to total logistics integration.

1. Introduction

The Internet has emerged as a powerful global force that is influencing, and sometimes significantly changing the strategic behaviour of many businesses. Some [25] [31] suggest the Internet is a new communications tool, building closer relationships with customers, suppliers, and employees. Others suggest the Internet is creating a new way to conduct business – often termed e-business [7]. The global marketplace has changed. The large MNE of the past is experiencing a dramatic change in competition from a diverse array of new global entrants [29]. Some businesses such as the book portal - Amazon.com, the auction house - eBay.com, or the automotive portal - SmartSearch.com.au, offer only an ‘on-line’ presence, yet each trades successfully. On-line Marketplaces like netbuy.com, offer extensive virtual inventories. NetBuy’s virtual inventory is four times the

size of the largest electronics components market distributor [26]. NetBuy cuts the long catalogue searching to seconds, removes inefficiencies, and links buyers with sellers. Such skilled niche operators focus on their ‘front-end’ or ‘web interface’ connectivity with the customer. Many incorporate aspects of the 8C’s of the customer web interface design - context, content, connection, communication, community, commerce, customization and characterization [15] into their business strategies. These focused, ‘on-line’ solutions are reducing both the uniqueness and the competitive advantage of the large MNE, by exploiting the unique features of the Internet [21]. This tough environment has invoked MNEs to seek lower cost solutions, whilst maintaining or improving quality [13]. Sustainability has now become a key function of cost management [26], and of strategy [7] [17] [25]. Competitive advantage has also become a key focus [12] [35].

2. Competitive Advantage

Porter, [24] proposed that 5 forces could be used to develop a company’s competitive position. These forces

1. the intensity of rivalry among existing competitors,
2. the barriers to entry for new competitors,
3. the threat of substitute products or services,
4. the bargaining power of suppliers, and
5. the bargaining power of buyers

present a key starting point from which MNEs may shape their unique competitive position. Porter’s original model displayed in Figure 1, whilst still valid, no longer covers the current global and networked environment.

Porter, [25] recognised the impact of the Internet on the business environment. He suggested new ways to create distinctive strategic positionings. Size is no longer the determining factor in success, but speed is a vital success factor. He identified two underlying drivers of profitability that transcend any technology or type of business:

- Industry structure, which determines the profitability of the average competitor, and
- Sustainable competitive advantage, which allows a company to outperform the average competitor.

Porter linked these drivers to his five forces model of competition and added the key negative (-) and positive (+) effects applicable to a specific ‘on-line’ industry. The bracketed sign indicated whether the relevant factor has a negative, or positive, effect on the competitiveness and

profitability of this industry. This Porter model, displayed in Figure 2, differs for each specific industry may exhibit different effects, and to different degrees.

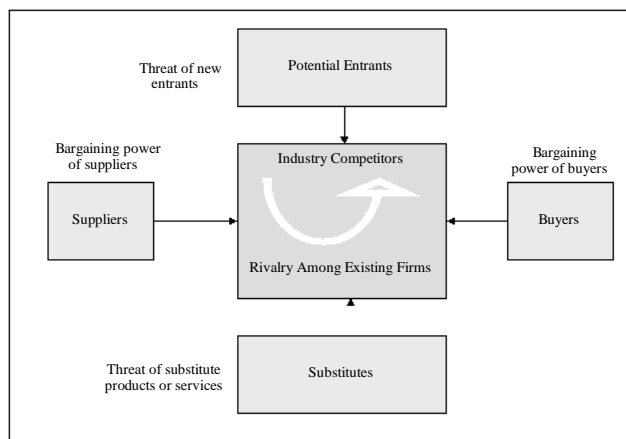

Figure 1: Porter's Five Forces Model (Source Porter, [24])

Porter suggests that, in general, Internet technologies will continue to erode profitability by shifting power to customers. This implies the MNE must move into this space and work closely with its customer base. Positive and negative effects on profitability, as a result of the impact of the Internet on the MNEs structure, can be subsequently looked at for each of the five competitive forces.

Porter suggests that, in general, Internet technologies will continue to erode profitability by shifting power to customers. This implies the MNE must move into this space and work closely with its customer base. Positive and negative effects on profitability, as a result of the impact of the Internet on the MNEs structure, can be subsequently looked at for each of the five competitive forces.

Porter believes that cost and price advantages (profitability drivers) are developed by either improving 'operational effectiveness' or 'strategic positioning'. 'Operational effectiveness' refers to 'doing the same things your competitors do but doing them better'. Here, the MNE only gains advantages if it is 'able to achieve and sustain higher levels of operational effectiveness than its competitors'. Porter concludes that 'the nature of Internet applications makes it more difficult to sustain operational advantages than ever'. As such, strategic positioning becomes all the more important, gaining cost advantages or price premiums by competing in a distinctive way. This requires a 'strong focus on profitability rather than just growth, an ability to define a unique value proposition, and a willingness to make tough trade-offs in choosing what 'to do' and 'not to do'. It involves the configuration of a 'tailored' value chain that enables a company to offer unique value. Porter states that 'when it comes to reinforcing a distinctive strategy, tailoring activities, and enhancing fit, the Internet actually provides a better technological platform than previous generations of IT'. Multinational Enterprises (MNEs) and other large firms operating in the

global arena, need to tailor their deployment of Internet technology to their particular strategies'.

Figure 2 - How the Internet Influences Industry Structure (Source Porter, [25])

Porter suggests six principles exist for establishing and maintaining a distinctive strategic positioning:

- 1.start with the right goal, which is superior long-term return on investment,
- 2.deliver a value proposition different from those that competitors offer,
- 3.operate a distinctive value chain, performing either different activities than rivals or performing similar activities in different ways,
- 4.abandon or forgo some product features, services, or activities in order to be unique at others, in other words looking at trade-offs,
- 5.strategy defines how all elements of what a company does fit together; all a company's activities must be mutually reinforcing, and

6. maintain continuity of direction, in order to develop unique skills and assets or build strong reputations with customers.

To establish and maintain a distinctive strategic positioning, and to respond to competitive pressures from start-up businesses, substitute products, new initiatives, and the like, many MNEs have moved down the outsourcing path, outsourcing commodity like areas such as transport, warehousing and the like, and then have concentrated on their core functions and competencies. [23] [34] support these ideals from both economic and price viewpoints.

3. Outsourcing

The reason(s) why a MNE decides to outsource can vary widely. Greaver 2nd, [14] offered the following reasons why an MNE may outsource an entire business function, or some elements of its business:

- Organizational driven reasons
 - Enhance effectiveness - concentrating on what you do best
 - Increase flexibility to meet changing conditions, demand for products and services, and technologies
 - Transform the organisation
 - Increase product and service value, customer satisfaction, and shareholder value
- Improvement driven reasons
 - Improve operating performance (increase quality and productivity, shorten cycle times, and the like)
 - Obtain expertise, skills, and technologies that were not otherwise available
 - Improve management and control
 - Improve risk management
 - Acquire innovative ideas
 - Improve credibility and image by associating with superior providers
- Financially driven reasons
 - Reduce investments in assets and free up these resources for other purposes
 - Generate cash by transferring assets to the provider
- Revenue driven reasons
 - Gain market access and business opportunities through the provider's network
 - Accelerate expansion by tapping into the provider's developed capacity, processes, and systems
 - Expand sales and production capacity during periods when such expansion cannot be financed
 - Commercially exploit existing skills
- Cost driven reasons
 - Reduce costs through superior provider performance and the provider's lower cost structure
 - Turn fixed costs into variable costs
- Employee driven reasons
 - Give employees a stronger career path
 - Increase commitment and energy in non-core areas.

Almost always the MNEs driving forces to outsource are to satisfy its strategic aims, to respond to global

competition, to utilize technology, to focus on 'sustainable' competitive advantage, and/or to drive down costs. [13] [19] [25].

3.1 Levels of Outsourcing

Initially, legal firms and others outsourced single functions like the mail room to first party logistics providers (1PLPs). In the early 1990's large second party logistics network players (2PLP) like TNT and UPS, commenced global operations, and in the late 1990's third party logistics providers (3PLPs) like FedEx, emerged offering added value full web tracking services. In 1999, the US logistics industry was estimated to be USD 920 billion, whilst globally the logistics industry was estimated at over USD 2 trillion globally. Significantly, less than 5% of this industry was outsourced worldwide [32]. A skilled logistics provider, capable and experienced in operating within the global arena, has genuine new opportunities to successfully enter this broad area.

For example, the software MNE Oracle, now offers a wide range of computer packages to support the transport industry. These software solutions include: load tendering, ratings (TL, ocean, air and rail), transportation infrastructure (route, carrier and vehicle definitions), intelligence and reports (flexible shipping document generation), inbound freight management, freight payment and audit. Many unexpected players (for example, integrated IT suppliers, management consultants, financial services) have also entered the logistics market. Today, many integrated functional areas, especially those deemed non-core, are outsourced to 3PLPs including: transportation, sub-assembly, and the like. These 3PLPs share resources between their network members, sometimes outsourcing certain activities to second or third tier providers, (who join the value adding process as complementary providers). Thus, both horizontal and vertical integration develops between these optimized 3PLPs and their value chains. These value chains find new ways to generate efficiencies and profits. They utilize their innovative on-line and marketing talents, incorporate latest information and communication technologies, and create new drivers in their service delivery. In addition, the MNE, with its supply chain efficiently managed (and costs controlled) by its 3PLPs, can divert its attention to developing its own internal core business efficiencies, increasing its sales and revenues, and delivering its quality assured products to the marketplace in a rapid, reliable manner [4]. The Internet, along with its off-shoots - Intranets (communication and electronic links throughout and across the MNEs functions) and Extranets (communication and electronic links between and across the MNEs supply network), provides a new medium for detailed information sharing and collaboration throughout the MNEs partnership network. As such, the Internet is a key enabler of outsourcing processes.

3.2 The Affect of the Internet

The Internet has moved outsourcing processes into a new dimension. It has allowed the MNE and its supply chain partners to share information, rationalize components, 'stock-in-process', and stock holdings. Most of the large logistics companies have acquired software, such as warehouse management systems and transport management systems, to manage their warehouses, transportation and other activities.

More recently electronic data interchange and the Internet have allowed 3PLPs to provide higher value added services for their clients through the ability to support software systems like 'Vendor Managed Inventories', 'Supply Hubs' and 'E-fulfillment'. It has also enabled 3PLPs to bridge the gap between the private and the public sector, in areas such as customs procedures.

Services such as Profit Zone's GPS tracking, NetRaker's tracing, PeopleSoft's efficiency programs, and Vodafone's 'churn-rate' (loss of customer to another competitor) programs, deliver definite value to customers in planning their operations better and reducing their working capital locked up in unused inventory and work-in-progress.

The MNE may determine which functions may be treated like commodities and outsourced. The MNEs decision makers may choose to dissect each function into its components, and then decide which activities are strategic, and/or critical. Such activities normally remain 'in-house'. Other non-core options may then be defined and possibly outsourced to logistics providers.

3.3 The Two Clusters of Logistics Outsourcing Skills Model

A rich aggregation of desirable skills has emerged for international logistics outsourcing. Voss [33] termed these 'logistics improvement skill levers' and divided them into two clusters. Voss's clusters are displayed in Table 1. These clusters encompass the outsourcing levers developed by others including [18] [35]. The 'technical' cluster encompassed the areas of supply chain management along with its recent interconnective developments. Whilst the need to enable powerful information technology and communication infrastructures (technical equipment), and technical skills has now become indispensable [6], technologies and technical skills on their own are not sufficient to attain economic success [3]. Consequently, Voss defined a second cluster – the 'soft skills' cluster. This 'soft skills' lever set is more complex than the technical lever set due to its immateriality [33] but it delivers hard results. For example, in logistics services, there is a need to interact and manage relationships, and for 3PLP's this requires the use of a broad range of soft skills [1], as reflected in areas such as the criteria (and requirements) for job candidates Voss's lever set clusters link to many of the Greaver 2nd [14] outsourcing drivers. For example, organization, improvement and employee drivers occur at both the technical level and the soft skills level, whilst

revenue, finance and cost drivers are embedded in the use and management of knowledge.

Today, MNEs and their associated 3PLP's, still primarily focus on the 'technical' levers, but the importance of soft skill levers is undeniable, [1] [28]. The world market is heavily intercultural [11] [28], stresses the importance clearly: 'while the technological advances allow an instantaneous global communication across enormous distances, there has been no comparable breakthrough in bridging psycho-cultural distance between people with different cultural frames of reference'. To reach such this market the 3PLP must acquire all the skills and abilities necessary to build bridges between people of different cultures [6]. This soft skill set uses personal, communicative, psychological and cultural sensitivity in conjunction with mental flexibility and corporate agility, thereby enabling intercultural encounters to be successfully negotiated. The MNE and its globally operating 3PLPs may then utilize these two clusters of outsourcing levers to enhance their competitive position.

Table 1: The Two Clusters of Logistics Outsourcing Skills Model (Adapted from Voss, [33])

Cluster 1: Technical Levers	Cluster 2: Soft-Skill Levers
<ul style="list-style-type: none"> • Information Technologies • Communication Technologies • DSS Technologies • Organization Technologies • IT-Infrastructure • Logistics Assets • Technical Ability • Logistics Knowledge / Know-how • SCM Knowledge • IT-Knowledge 	<ul style="list-style-type: none"> • Social Competency • Intercultural Competency • Interpersonal Competency • Communication Skills • Organizational Skills • Problem-Solving Skills • Leadership Skills • Team Orientation • Empathy • Integrity • Self-Assurance / Self-Awareness • Motivation / Creativity • Politeness / Diplomacy • Mobility / Flexibility

3.4 The Three Clusters of Logistics Outsourcing Skills Model

Voss's two clusters of logistics outsourcing skills may be further enhanced to include a third cluster with its own set of levers - the Institutional levers. The three clusters of logistics outsourcing skills model is displayed in Table 2. These additional levers encompass the drivers required to incorporate the rigorous business management, the Internet and its competitiveness into the logistics framework. The Institutional cluster of skills encompasses the legislative and governance frameworks within which the MNE operates. The logistics provider then integrates these into its operational frameworks, ensuring all external compliance related areas (financial, legal, operational,

regulatory and the like) are incorporated within its solutions.

The Institutional levers are important logistics considerations. For example, US MNEs wishing to trade in China must understand that the Chinese government and its sanctioned trading companies have blocked third-party foreign trading companies and distributors from direct participation in the Chinese market, and from providing a complete range of trading and distribution services [5]. This Chinese legislation greatly inhibits a logistical competitive advantage for non Chinese MNEs. Thus, a 3PLP company, working in China for a US MNE, must have detailed knowledge of the specific Institutional levers that apply, and must establish (or have) a mechanism within which it may operate competitively.

Table 2: The Three Clusters of Logistics Outsourcing Skills Model (© Gunesh and Hamilton, 2003)

Cluster 1: Technical Levers	Cluster 2: Soft-Skill Levers	Cluster 3: Institutional levers
<ul style="list-style-type: none"> • Information Technologies • Communication Technologies • DSS Technologies • Organization Technologies • IT-Infrastructure • Logistics Assets • Technical Ability • Logistics Knowledge / Know-how • SCM Knowledge • IT Knowledge 	<ul style="list-style-type: none"> • Social Competency • Intercultural Competency • Interpersonal Competency • Communication Skills • Organizational Skills • Problem-Solving Skills • Leadership Skills • Team Orientation • Empathy • Integrity • Self-Assurance / Self-Awareness • Motivation / Creativity • Politeness / Diplomacy • Mobility / Flexibility 	<ul style="list-style-type: none"> • Government Legislation • Industrial Policies • Company Laws • Financial Services regulation • Intellectual Property and Copyrighting Policies • Competition and Antitrust legislation • Corporate Governance and Transparency • Transport Policies (Road, sea, air & Rail) • Political Stability • Economic Growth

3.5 The 3PLP Model and Sustainability

The third party logistics provider absorbs all the three clusters of levers into their logistics solution(s) for the MNE. They then use their specialist skills to enhance the overall operations of the MNE and themselves. The 3PLP aims to position itself with a unique set of competitive and reverse logistics skills [22], thereby allowing an avenue towards sustainable competitive advantage. Companies like, Menlo worldwide (www.menloworldwide.com), Ryder (www.ryder.com), SmartSearch (www.SmartSearch.com.au), and Schneider (www.apldirectlogistics.com) each utilize combinations of technical, soft-skill, and institutional levels to develop their unique competitive solutions[2] [12].

3.6 The 4PLP Model

Over the past few years, key MNEs have sought to outsource some (or all) non-core supply chain areas of their business to a series of 3PLPs or even to one master PLP, termed a 4PL™ by Andersen Consulting. Andersen Consulting's model [10] for the evolution from a single function MNE outsourced task, such as the mail room (to a 1PLP), up to complex, fully integrated MNE outsourced solution delivered by a 4PLP is displayed in Figure 3.

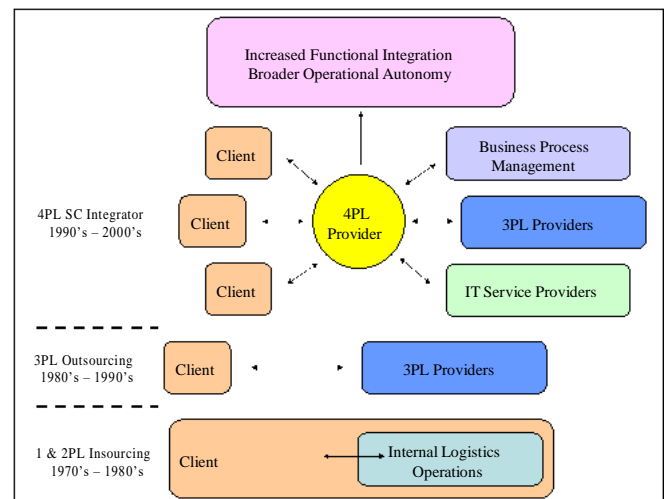

Figure 3: Evolution from First to Fourth Party Logistics Providers (Adapted from Docherty [10])

The range of activities undertaken by the 4PLP is almost identical to the role of a consultant on a long-term contract. In addition to business process reengineering; systems support and supply chain management planning; relationship management between 3PLPs and the client; and design, implementation, management and operation of the logistics facilities; the 4PLP can assist the MNE with entry into unfamiliar markets, especially those where it has extensive expertise. The 4PLP also offers a one-stop shopping experience for supply chain planning, systems selection/integration, project management, operational expertise, combined with the very latest in solutions and execution technologies. The 4PLP often works with a series of MNEs. In this environment it learns from its various MNEs and incorporates these skills into its knowledge base. It then applies this acquired knowledge to create and enhance the competitive positioning of itself and its MNEs.

In 2000, Andersen Consulting applied its 4PL™ model to Sears Roebuck's US equipment repair centres [10]. They utilized GIS, Simulation, and other tools to study the supply chain. They developed iso-cost curves, and determined regions of high and low total service cost and profitability. They used these graphic displays to establish the best US locations for the Sears Roebuck repair facilities. This model has since been adapted to many leading organizations.

The true 4PLP provider is really a super-service, cyber-corporation. For example, Nistevo (www.nistevo.com) sources and delivers the world's best items or pre-assembled component blocks. These globally

sourced items are then assembled by the MNE, and efficiently delivered to the customer. This allows the MNE to retain its competitive advantage. The UPS Logistics Group (www.ups.com/bussol/logistics) can also deliver a similar service, (and not just ship the MNEs products). Ian Chong, UPS Logistics Group's Business Development Manager estimated over 50% of CISCO's product was never touched by its employees in 2002. Thus, the MNEs 4PLP provider coordinates the timely component sourcing, manufacture, and delivery. The 4PLP functions like a virtual enterprise. It uses the global communications networks to minimize the barriers developed by geography, and sources world's best practice ingredients for the MNE, and delivers competitive advantage. [27] explains the uptake of outsourcing. In 2002, 75% of the Fortune 100 companies and approximately 45% of the Fortune 500 companies in the US used a 4PLP solution.

Currently, many MNEs like IBM, Phillips, Newscorp, and Sears Roebuck, use 3PLPs or 4PLPs, to innovate, and revolutionise their business solutions. Innovation is encapsulated via the seamless, vertical and horizontal integration of processes, and generally involves several players. This has led to increased competitiveness, particularly production, service and response speeds.

Many 4PLP 'end-to-end' management issues are related to time reductions [9]. An on-line business approach assists these improvements. For example, rapid electronic fund transfers speed-up the 'cash-to-cash' cycle [13] [30]. If interconnected with a demand-chain driven, fully networked, supply-chain enabled, integrated, on-line e-business system, a faster, more flexible, efficient service may be provided. The utilization of the embedded ordering and office automation systems facilitates a more economical, 'continuous' replacement system, where small, frequent orders permit supply chain members to hold reduced inventory levels. In addition there is direct, quick, efficient interaction between suppliers, the 4PLP, and the MNE. By analysing and connecting additional customers, appropriate 4PLPs. and appropriate suppliers, dedicated, service-related e-business sites including, www.epiphany.com, www.peoplesoft.com, www.seibel.com www.oracle.com, www.salesforce.com, and www.commerceone.com, can provide additional value to the on-line service business system. Thus, the web enabled 4PLP has several key competitive tools - time, flexibility, efficiency, cost, inventory, connectivity, customer analysis, and the like, by which it may enhance its value creation and positioning – and each is related to its on-line presence via the Internet.

3.6.2 Profitability

MNEs competing in the global environment face pressures to improve value and profitability. Investors expect MNEs to adopt value-based management frameworks where its activities and resources focus on increasing shareholder value. The MNE may identify and improve their key 'services and facilities' value drivers by enhancing operating performance (to increase quality

and productivity, shorten cycle times, and the like). The MNE may incorporate revenue management and dynamic pricing strategies, as well as development of new services (reverse logistics, service chain management and design for logistics). It may develop new expertise, skills, and technologies that were not otherwise available. It may develop new cost management, control and risk management systems, or it may outsource non strategic functions to 3PLPs or to a 4PLP [32].

3.6.3 Lean Supply Networks

The 3PLPs and 4PLP endeavour to maximize efficiencies throughout the MNEs supply chain. This has led to a shift towards leaner supply networks [13]. It has made MNEs more vulnerable. With fewer inventories in the system to 'buffer' against interruptions in supply, any disruption can have significant impact on the supply chain. For example, outsourced logistics services such as cargo delivery and postal services (which generate tangible savings of at least 10%), are possible terrorism targets. Other types of disruptions include external factors like the Kobe earthquake or foot and mouth disease, or business related factors like employee strikes, or operational breakdowns. These risks must be assessed and minimized. Thus the MNE may require logistics service providers to have special certification as 'secure' deliverers. Hence, when outsourcing the MNE must consider, the robustness of the supply chain to handle disruptions, risk management capabilities, particularly those relating to public health and safety [32]. In developing such 'risk' strategies the MNE may require the logistics providers to incorporate its latest innovative ideas in a cost conscious manner, and to create relationships with credible and sometimes superior providers.

3.6.4 Value

Without value, sales and market share don't happen [8] [19]. As businesses become more and more connected through the Internet customers may buy from anyone around the globe. Price differentials begin to disappear, with many buyers aware of the 'best' prices. Product quality differentials disappear and those with inferior products often lose market share. Customers talk to each other via chat rooms, email and bulletin boards, and the like. They are well informed as to which products and services offer the best value. Geographical location doesn't matter in today's globally connected world, as the next service provider is only one 'click' or phone call away, and global shipping networks are able to move items rapidly. Hence, the market consists of businesses with similar prices, and products, trying to differentiate themselves through whatever value attributes remain for differentiation. For many businesses this difference is their 'service' component, and the processes their customers must go through to obtain their desired outcomes [17].

3.6.5 Supplier Relationships

[20] recognises the relationship focussed customer does not engender the supplier to be stringently price conscious, whilst the price conscious customer, who does not readily perceive product value, may leave the supplier feeling abused, resentful and less focused on product quality. He links customer cooperation and a commitment to lower prices, suggesting the ‘balanced sourcing’ (high-high) quadrant should be the key target area. Thus, for maximum competitiveness, a 4PLP and its MNE’s should position themselves within this area. This requires high levels of collaboration between all parties. The 4PLP must seek to maximize the capabilities of each component of the supply chain, whilst minimizing overall ‘end-to-end’ risk. Laseter [20] suggests the ‘balanced sourcing’ (high-high) quadrant, as displayed in Figure 4, offers the best option in today’s highly competitive market.

Today, the MNE and its logistics partner(s) increasingly concentrate on delivering customer satisfaction. The MNE is acting more as a service organization with its core functions shifting from full manufacturing towards final assembly, sales, strategic positioning, and research and development conceptualization. It has generally outsourced its logistics costs (normally around 15% of the finished product cost) to 3PLPs or a master 4PLP. The logistics provider then instils innovation throughout sections of the supply chain. The vested interests throughout this virtual corporation act together chasing competitive advantage for the entire alliance team.

	Trust Based Partnerships	Balanced Sourcing
High	Supplier dominated Unclear rationale for improvement Assumes congruence of supplier goals Supplier may capture all of the value creation	Uses supplier capabilities fully Drives improvement at customer and supplier Requires high capability customer
Low	Unleveraged Purchasing Unmotivated, unstructured Traditional ‘clerical’ mentality of purchasing ‘Price taker’ Leaves lots of money on the table	Darwinian Rivalry Adversarial Customer dominated Requires purchasing clout Eliminates lethargy, but may cause resentment Does not result in improvement
	Low	High
	Commitment to competitive pricing

Figure 4 Supplier Relationship Matrix (Adapted from Lasseter [20])

Today, the MNE and its logistics partner(s) increasingly concentrate on delivering customer satisfaction. The MNE is acting more as a service organization with its core functions shifting from full manufacturing towards final assembly, sales, strategic positioning, and research and development conceptualization. It has generally outsourced its logistics costs (normally around 15% of the finished product cost) to 3PLPs or a master 4PLP. The logistics provider then instils innovation throughout sections of the supply chain. The vested interests

throughout this virtual corporation act together chasing competitive advantage for the entire alliance team.

3.7 The 5PLP Model

Hai and Yirong [16] present the Morgan Stanley Consulting Co. Ltd. China Logistics 5PLP model as the apex of a logistics relationship with the MNE. This model is displayed in Figure 5. They believe the 5PLP model focuses on providing overall logistics solutions for the entire supply chain. They further define the supply chains management (SCM) as a truly integrated approach managing flow and transforming goods in respective logistics networks. This supply chain management hinges on a common collaborative performance measurement framework that yields close, collaborative and well coordinated network relationships. The aim is to establish a competitive advantage across the supply (and demand chain) by constantly exchanging information with alliance partners, and driving further reductions in cycle times, life-cycle turns, and the like[1]. Hai and Yirong assert this delivers what consumers want, where and when they want it, and it does so in an efficient manner. They, like Morgan Stanley believe that by linking outsourcing to strategic alliances ‘win-win’ productivity situations (encapsulating faster running loops) arise for supply chain members.

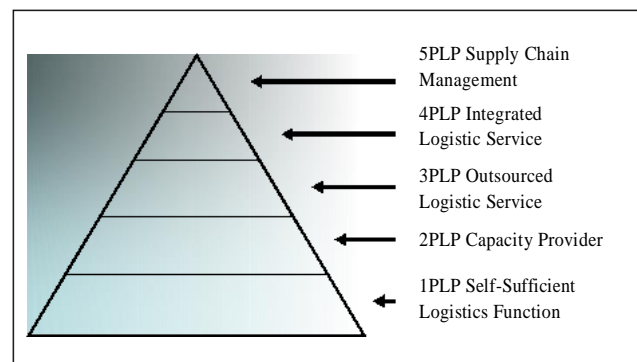

Figure 5 – The Morgan Stanley 5PLP Model (Adapted from Hai and Yirong, [16])

The Morgan Stanley’s 5PLP model is merely a re-badged 4PLP. It is not a ‘customerized’ or ‘characterized’ logistics solution. It does not provide targeting to specific individual customers needs. Thus the demand chain is not seen as a key logistics driver. For example, a current 4PLP model offers a complete set of supply side solutions for the MNE. It covers the logistics of entire supply chain, and even some basic demand chain parameters. This is the same as the Morgan Stanley 5PLP model. Without the full integration of both the demand and supply chain, and this structure being both highly flexible and agile, the apex of a logistics relationship cannot be reached. Hence the Morgan Stanley model does not represent the ultimate logistics solution, and it cannot be conceived as the apex of the logistics relationship with the MNE.

3.8 The Four Clusters of Logistics Outsourcing Skills Model

The three Cluster model developed from Voss, and incorporated into the previous (1PLP to 5PLP) models can be further expanded to include a final cluster with its associated set of levers. This additional cluster is termed the ‘characterized’ cluster. Here, for example, the web site’s ability to adapt and modify itself (based on tracking information and business intelligence software) is used to provide the customer with the impression of a made-to-order site that targets the customer’s requirements. This allows a new set of levers to be activated. This set of levers specifically targets the individual customer in an approximate ‘one-on-one’ relationship. The four clusters of logistics outsourcing skills model is displayed below in Table 3.

Table 3: The Four Clusters of Logistics Outsourcing Skills Model (© Gunesh and Hamilton, 2003)

Cluster 1: Technical Levers	Cluster 2: Soft-Skill Levers	Cluster 3: Institutional Levers	Cluster 4: Characterization Levers
<ul style="list-style-type: none"> • Information Technologies • Communication Technologies • DSS Technologies • Organization Technologies • IT-Infrastructure Assets • Technical Ability • Logistics Knowledge / Know-how • SCM Knowledge • IT Knowledge 	<ul style="list-style-type: none"> • Social Competency • Intercultural Competency • Interpersonal Competency • Communication Skills • Organizational Skills • Problem-Solving Skills • Leadership Skills • Team Orientation • Empathy • Integrity • Self-Assurance / Self-Awareness • Motivation / Creativity • Politeness / Diplomacy • Mobility / Flexibility 	<ul style="list-style-type: none"> • Government Legislation • Industrial Policies • Company Laws • Financial Services regulation • Intellectual Property and Copyrighting Policies • Competition and Antitrust legislation • Corporate Governance and Transparency • Transport Policies • (Road, sea, air & Rail) • Political Stability • Economic Growth 	<ul style="list-style-type: none"> • Agile Customer Relationship Management • Reliable Communication Technologies • Integrated Organizational Technologies • Database, Web Interface and Knowledge Management Technologies • Responsive Database, Web Interface and Activated Business Intelligence • On-line ‘Customization’ and Management • Responsive Flexible Demand Chain

By incorporating the four sets of levels into a MNE and its 4PLP supply chain, a flexible, agile, demand chain driven, supply chain supported, system may be developed. Here sets of ‘fully activated demand-supply’ chains, termed ‘FADS’ chains offer a means to sustainable competitive advantage.

FADS offer a means to move beyond the current proposed models to a 5PLP level. They incorporate improvement levers, competencies or skills, and important new achievements concerning ‘sustainable’ competitive advantages [18] [24]. They can absorb the current reasons for outsourcing as proposed by many authors including [13] [14] [32] [33].

4. The 5PLP FADS Logistics Model

To develop sustainable competitive advantage the MNE and its 4PLP must acquire and utilize unique intelligence. They derive this sophisticated intelligence by concentrating on the customer and tracking their interactions. For example, by tracking a customer’s activities, weaknesses in communication, understanding, time wastage, and the like, better communication solutions may be developed. Provided this rectification is rapid a reduction in ‘churn’ rate (loss of customer) may be achieved. These changes require the 4PLP to move into a new relationship across the entire demand–supply chain, and to work intelligently with ‘fully activated demand-supply 5PLP FADS chains.

A new logistics model – the 5PLP FADS logistics model, is proposed. The 5PLP FADS logistics model incorporates the four clusters of logistics outsourcing skills into the current ‘state-of-the-art’, or ‘revised’ 4PLP Model. This new logistics model is displayed in Figure 6. The current 4PLP brings its own specific values and skills to the business equation, thus providing a new competitive edge to the MNE. For example, the 4PLP may be a highly skilled on-line web operator with outstanding IT innovation, network skills, and on-line marketing skills. This may add an entirely new dimension to the MNEs operational skills set, or it may be a superb financial negotiations house that seeks to expand its sphere of influence. The combination of these specific skills, along with an agile, flexible, individual customer activated sensory system, opens new pathways for possible ‘sustainable’ competitive advantage. Such a mix of skills provides reduced scope for direct competition. This solution is delivered by a 5PLP FADS logistics provider.

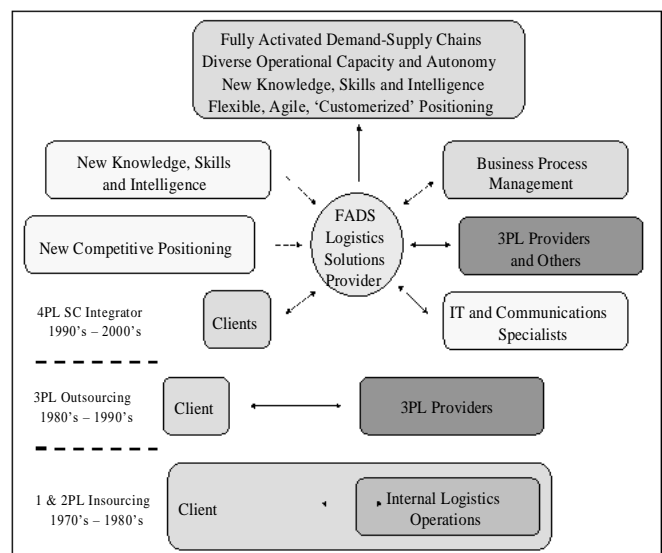

Figure 6: The 5PLP FADS Logistics Provider Model (© Gunesh and Hamilton, 2003)

The 5PLP FADS logistics provider and its MNEs are singularly focused to deliver ‘customerized’ (one-on-one) products such as a uniquely combined or ‘customerized’

set of web site pages, and helpful hints, combined with intelligent expert system software support to adapt to the customer's changing views.

To attain 5PLP FADS level logistics support the 'characterization' [15] cluster, must be fully incorporated. This fourth cluster of skills levers occurs when the MNE and its FADS logistics team are directly connected to the customer. Here the demand-driven customer-focused MNE combined with its logistics partner becomes instantly and highly responsive (agile and flexible) to the specific need of its individual customers. It requires its 5PLP FADS logistics partner to develop features specifically targeting 'what' each customer wants, along with the 'when's', the 'how's', and the 'specific' product personalization of 'where' and 'for whom'. This new economic focus has positive implications and demands across the entire demand-supply chain. In contrast, a 4PLP and its supply chain can capably deliver tangible products in a tightly managed way. Indeed, with MNEs moving more to a final assembly and a front-end, or customer sales focus this has been achieved – consider firms like UPS (www.ups.com). However, such a structure only partly satisfies the customer's demands. In addition, in the service related, or intangibles area there is great benefit, and competitive positioning possibilities, if a logistics provider can deliver a true 5PLP FADS logistics system. To deliver a 5PLP FADS logistics system the 4PLP must move to a higher level of logistics provision. It must master each of the four clusters. It must have a broad skills base and must overcome its own inadequacies including - knowledge and understanding deficiencies; appropriate IT, software and communication integration; web interface 'customerization', and the like. A 5PLP FADS logistics provider must bring new knowledge to the partnership, and the partnership must be lean, efficient and profitable for all parties.

In the future, logistics and outsourcing will approach the total logistics provider solution. The authors suggest this to be a 5PLP FADS model that delivers all the MNEs non-strategic (and even some strategic) requirements. In Australia, the major airline Qantas is one of many businesses that is segmenting their MNE, with each strategic business unit (SBU) capable of being outsourced, or being a logistics provider in itself. The 5PLP FADS model offers a new model applicable to such a move. It offers a future integrative and development path for logistics.

5. XYZ.com.au – An Example of a FADS Logistics Solution

The Australian company, termed XYZ.com.au for confidentiality reasons is a highly skilled Australian web portal company, founded in 1998. It is currently producing a leading edge FADS logistics solution for a major printing firm. It is now offering a new solution to an Australia-wide magazine. This on-line company has taken on all aspects of the magazine, and has added 'value' by combining it with its own leading edge web infrastructure and knowledge, on-line marketing and

distribution network and innovative flair. It now runs all aspects of this magazine, providing both the printing firm and the magazine shareholders with their required returns. XYZ.com.au is using its great skills mix to enhance the magazine, its reach and its on-line presence, and the shareholder body is seeing the benefits of a greatly enhanced, focused product.

6. Conclusion

A new age of global competition confronts the MNE and other large global businesses. MNEs must find new avenues to maintain competitive advantage. Past outsourcing moves have generated savings, but, as more and more businesses move along this path, opportunities for sustainable competitive advantage appear to diminish. There will always be logistics outsourcing improvements, especially in international settings, and by reviewing and clustering related skills levers, and relating these to logistics models, further advances to the development of logistics may be defined. The current 3PLP and 4PLP models alone will not provide 'sustainable' global competitiveness, as such options are readily copied. A new model is required. This paper suggests that development of a four cluster set of skills levers, and the combination of these levers into an enhanced 4PLP model for logistics outsourcing – may allow the development of a fully activated demand-supply 5PLP FADS chain logistics model to be realized.

The 5PLP FADS logistics provider must bring a unique, comprehensive skills-set (covering the four clusters of skills levers) to the MNE. A pathway towards 'sustainable' competitive advantage may then be forged between the 5PLP FADS logistics provider and its MNE partners. The 5PLP FADS logistics model is the next step in the progression to total logistics integration.

Delivery in Online Sales: The Role of Communicating Quality and Price Positions

Abstract

E-retailing, though growing rapidly, is still a very small proportion of total retail sales. One issue inhibiting sales over the internet is delivery. Many customers are not happy paying what they often perceive to be excessive delivery charges. However, the average customer on the internet is not highly price oriented, so resistance to paying delivery charges may occur because customers do not believe that they are receiving any value for this additional cost. Our research looks at the impact on willingness to pay delivery charges of different price levels and a message informing the customer that the delivery time specified is considered good service by industry standards. This simple message seems to focus customer thinking on value received (better quality service), and lowers resistance to paying delivery charges. Thus, explicit reference to the quality of the delivery service, where companies actually have good delivery, seems to be a useful message to include when customers are considering information about delivery charges.

1. Introduction

E-retailing (B2C) is growing rapidly, but the proportion of on-line retail sales still constitutes only a small percentage of total retail sales, and is likely to remain a small part of the total for some time. Frequently services, particularly delivery, are a problem. Some observers claim that e-retailers offer consumers better service than stores, but they may be talking mainly about “service” in terms of using customer information to get the sale [22], rather than more traditional after-sales service elements such as delivery, returns, etc. Anecdotal evidence indicates that many consumers are quite unhappy with service by many e-retailers [6].

Some observers have begun to point out that this service element may be a critical issue in adoption of interactive shopping [5, 11, 17]. Certainly, in other distance shopping formats, service plays an important role. For example, catalog purchasers typically report that they are concerned about service attributes such as delivery time, handling of complaints and problems, and order placement [4, 9, 15]. Clearly, understanding consumer views about service issues such as delivery will

be important as e-retailers work at improving sales over the internet [7, 12, 13].

Although delivery is a critical element of B2C retail services, only a few studies look at delivery issues in much detail. One survey shows that Dutch consumers are more likely to use the internet for product reservation than for purchase of products which require delivery, even though all the products in the study could be delivered digitally over the internet [21]. For physical products which require delivery, the tendency against actual purchase is even stronger [14]. Price may be an issue, since generally, once delivery charges are included, stores are cheaper than online retailers [1].

This study in Singapore looks at customer willingness to pay for delivery of products available on-line. As a managerial issue, this is important, because internet B2C suppliers have not yet found ways to make delivery cheap. They either have to charge customers a relatively high delivery price, or absorb a lowered margin. Which strategy works better depends on customer willingness to pay – if customers are highly price sensitive, as some discussions on e-retailing claim, then charging customers higher delivery prices will not work very well. However, some work indicates that consumers on the internet do not seem to be highly price sensitive [e.g., 3]. Then a proper strategy would be to demonstrate to them why the high prices are worth paying – if they see value, they are more willing to pay.

2. Delivery, Value, and Price Sensitivity

Service is a key element in consumer choice in retail buying, and much modern retailing is based upon the concept that consumers buy service as much as products when they purchase from a retailer [2]. Certainly, consumer demand for better service has played an important role in development of the modern retail sector in the more advanced economies of East Asia [e.g., 8, 20]), as well as in developing economies [e.g., 19]. Thus, one important reason for dissatisfaction among consumers who have tried buying over the web, and for discouraging non-buyers from trying, is the service component.

Frequently, service on the web is not up to standards that consumers expect from fixed stores, and consumers who want good service as a component of what they buy may not choose to shop online because of this. For

example, Van den Poel & Leunis [21] showed that consumers reported much higher likelihood to purchase either a small radio or a TV in specialty stores, which provide high service levels. Supermarkets and internet came out about equally, far behind specialty store, and catalog sales were very unlikely to be used for these products. Specialty stores (first) and catalog sales (last) did not change their relative positions among heavy vs. light internet users.

In Singapore, some studies indicate that consumers generally expect fairly low service performance from internet retailing, including poor perceptions of the delivery service component [17]. For example, one survey showed that prompt delivery of books and CDs ordered over the internet was not considered very likely. Of course, this would not be very critical if it was not important to consumers, but prompt delivery scored moderately highly in their list of concerns. Another survey cited in that report showed that delivery was a top concern for clothing ordered over the internet. Asked about whether better services would encourage more on-line purchase, most consumers said yes [17].

Eastlick & Lotz [5] demonstrate that attitudes toward service are one element which influences adoption of interactive shopping. Karlsson and Rosen [7] note many cases of internet stores that have failed primarily because of inability to meet customer expectations about delivery. In Singapore, Speece [17] shows that perceptions of delivery, among other service issues, differs strongly among respondents who bought books / CDs on the internet and those who did not. Shoppers who did not order over the internet had lower expectations of prompt delivery than those who did, but were more strongly concerned about delivery.

Given that consumers want high quality delivery if they buy over the internet, would they be willing to pay for it? Generally, Asian middle class consumers are strongly value oriented [e.g., 16, 18], which means they are willing to pay reasonable prices if they perceive that they have received some benefit. In other words, "Value (unlike quality) involves a tradeoff of give and get components" [23, p. 14; parentheses in the original]. Components of value include intrinsic product or service attributes, as well the extrinsic attribute price. Discussing value segments, Lichtenstein, Ridgway, and Netemeyer [10] note that price plays a negative role, but is not the most important thing considered.

In value oriented service evaluation, a buyer may set an acceptable quality level, then look for the best price within that level. Or, buyers may decide a budget, based on their ideas of price points representing required quality, then look for the best quality at that price. On the surface, it may sometimes be difficult to distinguish value orientation from either strong quality or strong price orientations. When value consumers have a large budget, the weight of price seems to decline. People buy higher quality and are willing to pay more. With smaller budgets, price assumes a correspondingly larger role. Nevertheless, value oriented consumers are still making the tradeoff, not simply choosing highest quality or

lowest price. In addition, when consumers perceive several options to be very similar, price may be the only criteria on which they can distinguish. They do not insist on lower prices because they are highly price conscious, but rather, because they do not perceive it at they are gaining any value for the higher prices.

The profile of customers on the internet is usually strongly middle class and above, making it unlikely that most such consumers are truly strongly price oriented. Rather, they are probably value oriented, but may not like to pay much for delivery because they perceive delivery service quality on the internet to be poor. Karlsson and Rosen [7], for example, show that customers of online grocery stores are not willing to pay much for delivery alternatives which they perceive as being unattractive, but they are willing to pay more for preferred delivery modes.

Delivery time is one key issue. For example, Persson and Wikstrom [13] quote a customer in an in-depth interviews as saying "the delay is the biggest drawback with the internet ..." (p. 4). Many customers expect lower prices to compensate for the perceived poor service: "... for a good price, I am willing to accept a wait of a couple of days or more" [13 p. 4]. Noack [12] cites examples showing that customers are willing to pay for what they perceive as good delivery service. Frequently commentators on internet delivery view such data and recommend that internet companies should minimize delivery time [e.g., 13], and one strategy is to set up logistics to get very rapid delivery [12].

However, simple communication with customers during the ordering process may have some impact on their perceptions of delivery service quality, and thus, on their willingness to pay delivery charges. If consumers compare access to products in a physical store, when they get it right away, to purchase over the internet, delivery quality may be perceived as poor, because they do not get the product immediately. Pointing out the quality of delivery time relative to most other internet sellers may be able to shift the comparison, so that consumers feel that they are getting some value (additional quality in delivery) compared to most internet stores. To demonstrate that simple communications may indeed be able to influence willingness to pay in this way, we looked at this issue in a consumer survey in Singapore.

3. Methodology

While developing the survey instrument, we conducted in-depth interviews with three consumer stores selling common consumer goods on the internet in Singapore. Each had online sales which managers considered to be growing well, but which still constituted only a few percent of total retail sales for the store. They all stressed that delivery costs were relatively high, and considered that prices were probably higher online once delivery costs were factored in. These stores talked about delivery times ranging from 1 to 3 days normally, but more likely to be around 3 days rather than quicker. Thus, the time which was considered pretty good by

industry standards in the experimental manipulation was determined in this consultation with online retailers.

The key elements affecting consumer decisions to buy online were developed from the literature, as noted above. One questionnaire section asked respondents to rate the importance on a 1 to 5 scale of a number of elements including delivery, price, and other service elements. Another section asked about willingness to buy given a delivery time and a delivery charge. Respondents were asked this for both local and overseas orders, taking 2 days and 1 – 2 weeks, respectively. Delivery prices were stated at three different price levels, each one in a separate questionnaire, so that any one respondent only ever saw a single price for local and a corresponding single price for overseas delivery. (E.g., the low local delivery charge was listed with the corresponding low overseas delivery charge.)

Half of the questionnaires at each price level included a message informing the respondent that the stated delivery time is considered fast by industry standards, vs. a control with no comment about delivery time. Thus, there were six questionnaire versions (Table 1). Each had a quota of 50, so that a total sample of 300 was obtained by mall intercept at several locations in Singapore. A screening question eliminated anyone who was not an internet user. The sample is relatively young, mostly under 30, with high education on average, and is fairly consistent with the characteristics of heavy users of the internet according to other surveys.

Table 1: Six Questionnaire Versions

	delivery charges		
	low	medium	high
local purchase	S\$ 3	S\$ 4 – 8	> S\$ 8
overseas purchase	S\$ 15	S\$ 16 – 20	> S\$ 20
no message version: Assuming that for local delivery a product costs S\$ 50, and takes 2 days to deliver. How willing are you to pay S\$ 3 for delivery charge?			
with message: Assuming that for local delivery a product costs S\$ 50, and takes 2 days to deliver, which is considered fast by industry standards. How willing are you to pay S\$ 3 for delivery charge?			
the overseas versions say 1 – 2 weeks delivery.			

Consistent with the profile of internet users usually cited in most Asian countries, the sample was predominately young and male. Sixty percent of the

respondents were men. The age group from 18 – 24 accounts for two thirds of the sample, and another twenty percent were between 25 – 30. Ninety-five percent of the sample was ethnic Chinese, which under-represents other ethnic groups in Singapore, but is perhaps consistent with strong internet usage.

4. Results

Security of the transaction, delivery reliability, and convenience were considered the most important issues. Delivery time was of mid-level importance, not much different from a set of issues also including return policies, reputation of online stores, low price, and modes of payment. Physical viewing of products was considered the least important of the issues listed in the questionnaire, but even this was considered somewhat important, scoring above the midpoint of the 1 to 5 scale toward the important (Table 2).

Table 2: Importance of Elements in Decision to Purchase Online

	mean	standard deviation
security of transaction	1.52	.87
delivery reliability	1.61	.84
convenience	1.68	.85
return policies	1.90	1.01
reputation of online stores	1.92	.98
delivery time	2.01	.96
low price	2.09	1.04
modes of payment	2.22	1.00
physical viewing of goods	2.43	1.19

scale: 1 = very important; 5 = not important at all

notes: differences of approximately .14 are significant ($p = 0.05$). A blank line separates means which are significantly lower than the mean above ($p = 0.05$).

Table 3 indicates that the means of willingness to pay for delivery of orders from overseas follows a standard demand curve. There is more resistance when delivery charges are higher. However, resistance to the charges is significantly reduced for high and medium level delivery charges when the message is included pointing out to customers that the delivery time is considered good by industry standards. In other words, the message seems to focus customer attention on the value that they receive for the price, and they are more willing to pay when they explicitly see the value.

Table 3: Mean Willingness to Pay Overseas Delivery at Three Price Levels, by Message about Delivery Quality or Control

delivery prices	no message		with message		row sig (no-with)
	mean	std dev	mean	std dev	
low	3.00	1.20	2.88	1.26	.626
medium	3.90	1.07	3.20	1.05	.001
high	4.02	.98	3.44	1.21	.010
column sig. (low-med)	.000		.176		
(low-high)	.000		.019		
(med-high)	.582		.310		

scale: 1 = very willing, 5 = not willing at all.

Table 4 shows similar results for local delivery charges. The same downward sloping demand curve is evident, with more resistance to higher prices. Here, since local charges are lower, resistance only becomes large for the high level of delivery charges, but again, at this high level, including the message reduces resistance to paying. Clearly, willingness to pay, at least at higher price levels, depends on customers explicitly recognizing that they gain some value for what they pay. When it is explicitly pointed out to them that the delivery service is high quality, they are more willing to pay.

Table 4: Mean Willingness to Pay Local Delivery at Three Price Levels, by Message about Delivery Quality or Control

delivery prices	no message		with message		row sig (no-with)
	mean	std dev	mean	std dev	
low	2.50	1.13	2.48	1.18	.931
medium	3.16	1.06	2.98	1.08	.401
high	4.10	1.07	3.46	1.01	.003
column sig. (low-med)	.003		.024		
(low-high)	.000		.000		
(med-high)	.000		.030		

scale: 1 = very willing, 5 = not willing at all.

To test the joint impact of message and price level, as well as to control for price sensitivity, ANOVA was run, with willingness to buy as the dependent variable. Price level, message, and the importance of price (noted in Table 2) were the independent variables. Results indicate that price level for delivery charges is significant ($p = .000$, and $p = .000$) for both local company delivery and foreign company delivery, respectively. In each case, the results show a standard downward sloping demand curve, consistent with basic economic theory. The parameters indicate more willingness to pay as delivery charges decline, and more willingness to pay local charges, where the amount is lower than for overseas (Table 5).

Price importance was also significant ($p = .037$ and $.011$ for local and overseas delivery, respectively). The similar negative coefficients in each case indicate that more price sensitive customers are less willing to pay the delivery charges. This, of course, is consistent with the definition of price sensitivity and most other research.

The key issue here is that the message about delivery quality was also significant in each case ($p = .029$ and $p = .000$, respectively, for local and overseas delivery). The positive coefficient for no message indicates less willingness to pay. Thus, a simple message pointing out that the delivery time is considered high quality in the industry was able to reduce resistance to paying delivery charges.

Table 5: ANOVA Results of Joint Impact of Message, Price Level, and Price Importance on Willingness to Buy

	local		overseas	
	sig.	parameter	sig.	parameter
model	.000		.000

low		-1.005		-.592
medium		-.518		-.288
high		0 *		0 *
price importance	.037	-.127	.011	-.159
R squared	.225		.147	
adjusted R- sq	.209		.129	

* signifies the statistical base category; other categories are relative to the base.

5. Conclusion

Although delivery is a critical element of B2C retail services, only a few studies look at delivery issues on the internet in much detail. This study in Singapore focuses customer willingness to pay for delivery of products available on-line. It examines three different price levels, each one in a separate questionnaire, and information informing the respondent that the stated delivery time is considered fast by industry standards, vs. a control with no comment about delivery time. Results clearly show that customer willingness to pay can be influenced by the message that they see at the time they consider the delivery charges.

These simple results have important implications for e-retailers. Delivery has been a barrier to the development of ecommerce, partly because customers frequently resist paying extra delivery charges. However, this resistance is frequently misinterpreted as strong price sensitivity. It is not. Rather, the resistance to delivery charges seems to represent unwillingness to pay when customers see no value in what they are paying for. They are willing to pay when they see some value received in exchange for the price. This is characteristic of value oriented middle class consumers throughout Asia.

Thus, the e-retailer's task is to shift the customer's focus when they consider delivery charges. Frequently, the comparison may be: "slow if ordered online, compared to fast if bought in a store." Resistance to delivery charges is bound to be high in such a comparison. The consumer is being asked to pay more for worse service. A simple message about the quality of delivery time can apparently shift the focus more toward "faster delivery at this site, compared to slower delivery at other sites." Here, the consumer is being asked to pay for better quality, something which many value oriented consumers are quite willing to do. In fact, given that delivery charges might be similar for various delivery times on different sites, the consumer may perceive this as similar price for better service – a very attractive proposition to value oriented customers.

Of course, additional research is needed to confirm that such results would hold in a variety of e-retailing situations. And it would be very useful to examine how to best present messages to get the customer to shift focus from the web – store delivery time comparison to the better quality web – worse quality web contrast. Nevertheless, these results do suggest that one relatively simple way to help reduce resistance to delivery charges in e-retailing is to include a message about the quality of services at the time when consumers consider the delivery charges.

An Adaptive e-KANBAN System and Its Characteristics

-Controlling the numbers of KANBAN by monitoring demand fluctuation-

Abstract

This paper discusses methods to revise the numbers of e-KANBAN for parts procurement operations from supplier factories. Three policies, i.e. Fixed Interval Review (FIR) Policy, Demand Average-monitored Review (DAR) Policy and Demand Average & Variance-monitored Review (DAVR) Policy are proposed to absorb the fluctuation of parts consumption level, which is created by the downstream shop floor of the production line. The performance of each policy is evaluated by simulation experiments and quantitative trade-off relations between criteria, i.e. Ratio of Line Stops (RLS) and Frequency of e-KANBAN Resetting (FKR), are clarified. Obtained characteristics suggest that DAVR and DAR Policies dominate FIR Policy but each of the former two policies do not hold superiority from the other.

1. Introduction

These years, because of rapid progress of globalisation and information technology in every sector of industry, assets of operations management are transferred among companies without serious obstacles. The same phenomenon also happens in each business function such as in supply chain.

Looking at Just-In-Time technology born in a Japanese car manufacturer some decades ago, many competitors utilize this toolset as so-called lean technology. In addition, information infrastructure starts to absorb this engineering asset into its own domain and modifies it. An example of such diversification is electronic version of KANBAN system called e-KANBAN system. However, according to such a drastic change, traditional know-how becomes obsolete and necessity of new technological development emerges. In this paper, based on the above argument, a new problem on a powerful engineering tool for supply chain

management, called KANBAN system, is focused to study.

A contemporary problem surrounds this technology is how to determine the numbers of KANBAN in the recent volatile demand environment. Generally, the numbers of KANBAN are quite sensitive for performance of production-logistics system, e.g. manufacturing system often stops if numbers of KANBAN are not enough, and contrary, work-in-progress inventory will exceed the capacity of buffer space if it is too much.

As both globalisation and information infrastructure are the major causes of demand instability, operations managers and researchers in this area have to cope with this problem. One effective way to overcome this difficulty is to revise the numbers of KANBAN more often than before. And, ironically, e-technology can contribute this subject as it provides quick repetitive response with low cost.

As a matter of research contribution, this paper discusses the way to revise the numbers of KANBAN for parts procurement operations from supplier factories and proposes some policies for reviewing the numbers of KANBAN to absorb the fluctuation of parts consumption level created by the downstream shop floor of the production line.

2. KANBAN System and Its e-version

The mechanism of typical KANBAN system between final assembly factory and parts supplier factory is illustrated in Figure 1. For simple explanation, let us suppose the lot size of parts transportation is one. Each part is transported from supplier factory with its KANBAN, which describes part specification, supplier site, frequency of transportation etc. Then this is qualified and accepted by quality assurance (QA) division of final assembly factory followed by transfer to line side. When each part is required by assembly line, the part and attached KANBAN are separated and assembly operation proceeds for the former.

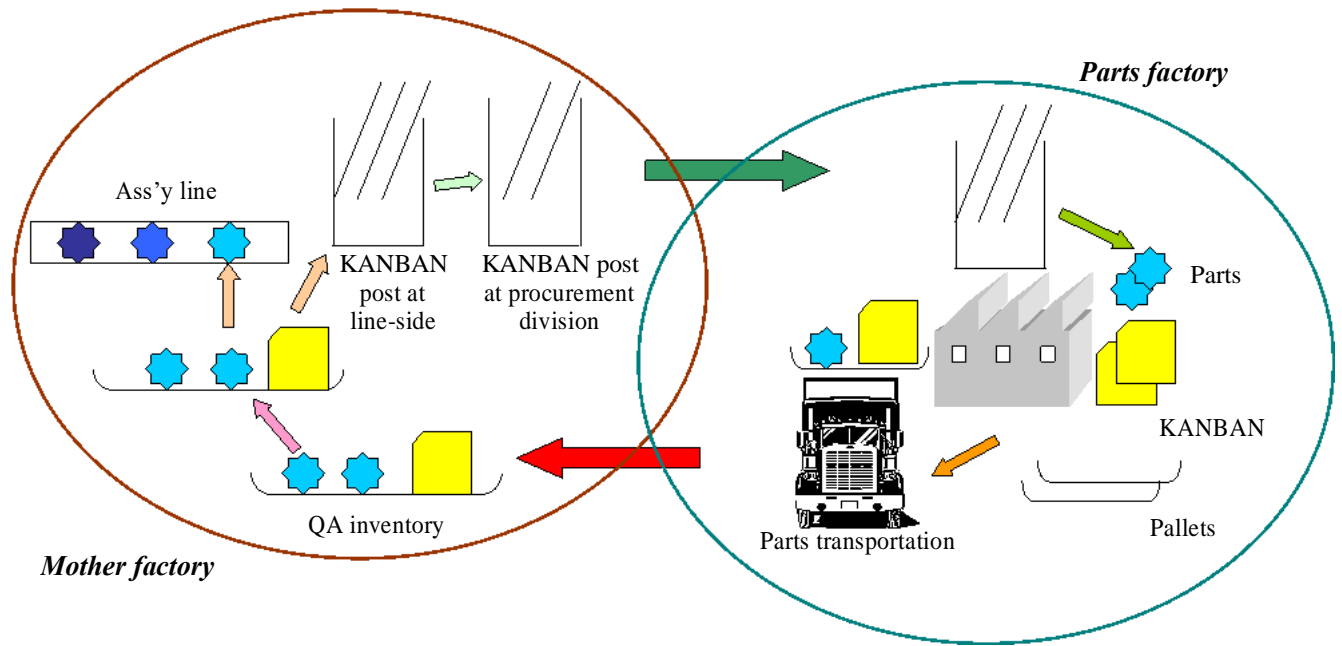

Figure 1. Mechanism of KANBAN system

The latter is thrown in KANBAN post at line-side and assorted into every supplier sites to prepare procurement operation at the division in charge.

KANBANs in the KANBAN post at procurement division are periodically transferred to appropriate suppliers and attached to the parts ready to deliver at supplier factories. Then, these are transported to QA division of assembly factory again through periodic delivery operation.

During the entire operation cycle, quick response or lead-time reduction is one of the key subjects for better performance of the production logistics system and substantial efforts have been made on this matter by launching continuous improvement activities as well as information technology implementation.

Typical example of the latter activities is electronisation of KANBAN system called e-KANBAN that is quite simple and natural attempt. Essential idea is to realise zero transfer lead-time of KANBANs in every operation phase such as their separation from parts at line-side, assortment, transfer to suppliers and coupling with deliverable parts. Concerned technologies for actualise this idea include parts database system, low cost peripheral facilities for data capturing in each phase of operation, infrastructure for data transfer such as web-based systems, monitoring and analysing systems of demand or requirement data from downstream function (assembly line in this case) etc.

Some of these technical issues have been developed, revised and implemented in some extent by the companies operated based on KANBAN systems and all of these attempts indicated that information technologies were relevant for KANBAN system refinement.

Recognising the above fact, in this paper, the last issue is focused to discuss in terms of consideration of way to revise the numbers of KANBAN.

3. Related Research and Consideration

Traditional way to determine the numbers of KANBAN is described by formula (1) [2].

$$N_t = [(\mu_t^D L + K \sqrt{L} \sigma_t^D) / M] \quad (1)$$

Where,

N_t : The numbers of KANBAN determined at the end of t -th day

μ_t^D : The average demand quantity per day estimated at the end of t -th day

L : Lead time of parts procurement (days)

K : Parameter of safety inventory

σ_t^D : The standard deviation of demand quantity per day estimated at the end of t -th day

M : Capacity of pallet (Numbers of KANBAN to be installed on it)

The essential idea of this expression is that KANBAN must care entire demand quantity and additional quantity due to its fluctuation during procurement lead-time. For the latter issue, policy of 3-sigma guarantee is quite usual and, therefore, $K=3$ might be very agreeable. The most important point here is that numbers of KANBAN derived by this way strongly affect the performance of entire system.

It is obviously noticed from this method that numbers of KANBAN depend on every variables and parameters defined above. Parameters, i.e. parts procurement lead-time, safety inventory parameter and pallet capacity, are controllable in some extent by KANBAN system manager and they made efforts to determine or improve these values properly for many years. Especially,

procurement lead-time consists of parts transportation and/or transfer time and KANBAN management time, and substantial contribution to eliminate the latter portion of lead-time have been realised through e-KANBAN implementation.

On the other hand, variables, i.e. demand average and variance must be the target variables to estimate because these concern uncontrollable business environment issue. A traditional way adopted in some factories is periodic consideration on whether numbers of KANBAN should be changed or not. For instance, some factory in Toyota Motor Co. used to consider its modification by monthly basis. The mind behind such policy is that demand statistics, e.g. average and variance, are basically stable and downstream activities such as sales division make efforts to guarantee this steadiness. And if it does work successfully, efforts on demand monitoring can be minimised as a by-product of this attitude.

However, as the business situation has been getting volatile gradually during this decade, the above argument became tough to emphasize for many companies. And consideration on how to monitor, estimate the demand statistics and feedback such information to revision of numbers of KANBAN become an emerging subject to cope with.

As a related study on this subject, Katayama et al [1] considered two types of revision models of numbers of KANBAN described below and analysed their performance under auto-correlated demand arrivals from downstream function.

- 1) FIR (Fixed Interval Review) Policy: This policy performs reviewing procedure every predetermined interval. Key parameter of this method is length of interval (days).
- 2) AR (Adaptive Review) Policy: This policy launches reviewing procedure based on the following flow chart (Figure 2), which includes statistical test procedure for detecting the change of demand average.

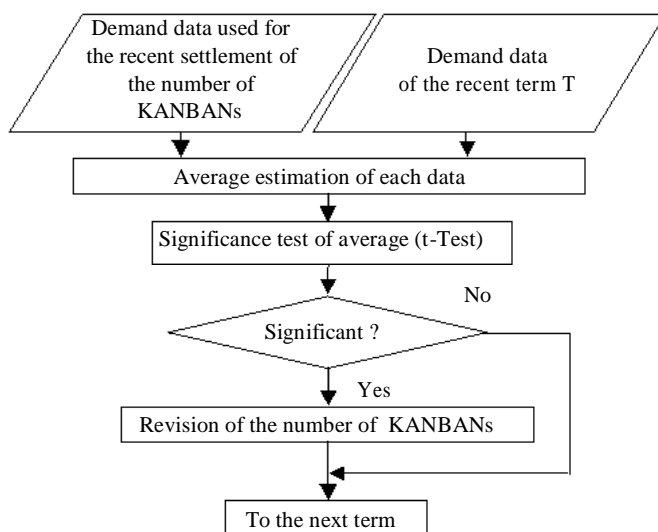

Figure 2. Flowchart of AR Policy

However, considered situations in simulation-based experiment in this study were quite limited, i.e. drastic change of average demand such as step function model and/or change of demand variance was not treated. Study on such more complicated cases is remained for further research.

4. Model Construction

Based on the arguments described in the former sections, analytical model is constructed in this section, where demand model, and some policies for revising the numbers of KANBAN and performance criteria are proposed.

4.1. Demand Arrival Model

First order autoregressive model described in formula (2) is adopted as demand arrival model.

$$D_t = \lambda D_{t-1} + (1 - \lambda) X_t \quad (2)$$

Where,

D_t : Interval of the t-th and t-1-th demand arrival

X_t : Statistically independent element of interval of demand arrival D_t . Its probability density function is supposed to be a Normal Distribution $N(\mu_t, \sigma_t^2)$.

λ : Autocorrelation coefficient of adjacent interval data of demand arrival, i.e. D_t and D_{t-1} .

From this expression, it is noticed that mean and variance of D_t are μ_t and $\frac{1-\lambda}{1+\lambda} \sigma_t^2$ respectively.

The cases to analyse include changes of mean and variance of D_t by step functions.

4.2. Structure of Lead-time

As mentioned in section 3, structure of lead-time is very important in KANBAN system, which consists of parts transportation and/or transfer time and KANBAN management time.

Based on some case investigation of car factory that operates under e-KANBAN system, certain fixed lead-time is assumed for the former portion, i.e. physical transportation lead-time of parts. For the latter portion, i.e. KANBAN management time, the ultimate ideal case, i.e. zero lead-time, is supposed because of e-KANBAN.

4.3. System Criteria

Two criteria, i.e. RLS (Ratio of Line Stops) and FKR (Frequency of the numbers of e-KANBAN Revisions) are considered as key performance indicators, which were also examined in the past study [1]. Namely, the first

criterion RLS is a reliability measure of the system that evaluates risks of line stoppage or malfunction. On the other hand, the second one, i.e. FKR, is an efficiency measure that evaluates necessary operational efforts to manage KANBAN system. Where, some man-hours for indirect work such as redefinition of e-KANBANs have to be consumed if revision is launched.

$$RLS = \frac{\text{Overall line stoppage time}}{\text{Overall available time of the line}} \times 100(\%) \quad (3)$$

$$FKR = \frac{\text{Number of revisions of number of e-KANBAN}}{\text{Total production terms}} \quad (\text{Times/Term}) \quad (4)$$

4.4. Proposal of Revision Policies of The Numbers of KANBAN

In the past research discussed about AR Policy [1], only demand average was focused to estimate and its variance was ignored despite of the σ_t^D in expression (1). This means that AR Policy cannot adapt the structural change of demand fluctuation, which tends to become large due to volatility increase of the market.

Therefore, as a new revision policy of the numbers of KANBAN, variance test procedure for detecting the change of demand variance is added to the flowchart given in Figure 2. Detail of this logic named Demand Average & Variance-monitored Review (DAVR) Policy is described in Figure 3.

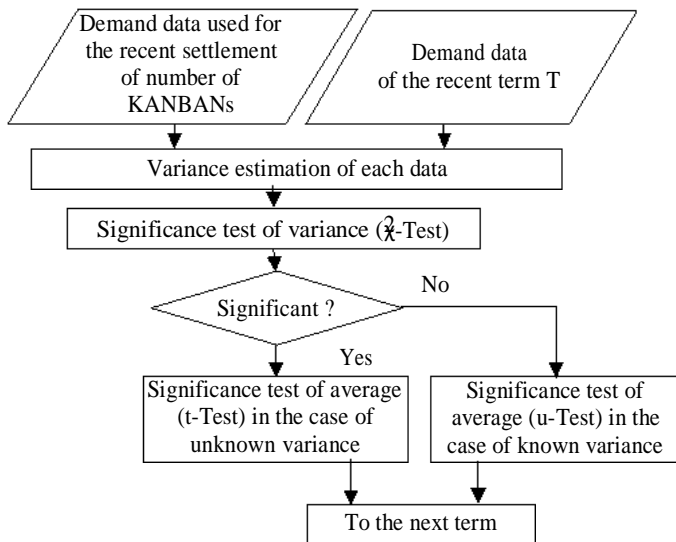

Figure 3. Flowchart of DAVR Policy

Based on demand arrival data, i.e. interval of the adjacent demand arrivals, used for setting current numbers of KANBAN and that of recent term T, e.g. interval data of demands in recent 10 days, each variance is evaluated by using the formula of definition of variance.

From this procedure, their point estimates are obtained.

Then, these point estimates are examined whether these are significantly different or not. The logic of the significant test of variance, which is performed in terms of χ^2 -Test, is applied for this procedure.

If the result is significant, demand average is checked whether it changed or not. This procedure, the followed step of variance test, can be performed by t-Test of average as same as Figure 2 because this is the case of unknown variance. On the other hand, if the result is not significant, checking procedure of demand average is performed by ordinary u-Test of average because this is the case of known variance.

When entire procedure is executed, the same procedure is iterated again after the shift of unit time.

As the summary of this section, following three revision policies are considered to examine in this paper. Where, FIR Policy and DAR Policy is the same policy as the policies in the former research [1]. Especially, DAR Policy is the same policy as AR Policy (See Figure 2) and is renamed for easier distinction from DAVR, the proposed policy.

- 1) Fixed Interval Review (FIR) Policy
- 2) Demand Average-monitored Review (DAR) Policy
- 3) Demand Average & Variance-monitored Review (DAVR) Policy

5. Performance Analysis by Simulation

The mission of this section is to analyse the chain relation between accuracy of demand monitoring, revision policy of numbers of KANBAN and system performance. This analysis is performed through simulation experiment in which simulator developed by C++ language is used. Summary of some relevant characteristics is also given based on the obtained result.

5.1. Simulation Condition

Some assumed conditions for simulation experiment are summarised as follows.

- 1) Simulation horizon: 150 days
- 2) Working hours of production line: 16 hours/day
- 3) Parts procurement lead-time L : 0.125 day
- 4) Parameter of safety inventory K : 3.0
- 5) Capacity of pallet M : 1
- 6) Autocorrelation coefficient of adjacent interval data of demand arrival λ : 0.8
- 7) Cases of demand parameters: Following five cases are considered.
 - a) μ_t ; 12→8, σ_t^2 ; 1
 - b) μ_t ; 12→8, σ_t^2 ; 2.5
 - c) μ_t ; 12, σ_t^2 ; 1→2.5
 - d) μ_t ; 8, σ_t^2 ; 1→2.5
 - e) μ_t ; 12→8, σ_t^2 ; 1→2.5

For instance, case a) means that μ_t changes 12 to 8 by step function. Where, timing of parameter

change is determined randomly and total numbers of simulation for each case are 148 patterns. On the other hand, σ_t^2 is fixed to 1

- 8) Revision interval of the numbers of KANBAN R for FIR Policy: 29 cases, i.e. 2~30 days
- 9) Length of the term T for statistics calculation regarding DAR and DAVR Policies: Three cases, i.e. 3, 5 and 10 days
- 10) Necessary time to remove or attach KANBAN from or to appropriate parts: Immediate (zero)
- 11) Time interval of collection of KANBANs from KANBAN posts: Immediate (zero)
- 12) Revision point of the numbers of KANBAN: KANBAN post. This means that necessary numbers of KANBAN are added to KANBAN post when revised numbers are bigger than the current amount. Otherwise, appropriate numbers of KANBAN are removed from there. If there are not enough KANBANs in the post, KANBANs are waited to arrive to remove.

5.2. Results and Consideration

Obtained results through simulation experiment are summarised in Figure 4 and 5. These figures represent the relationship between two criteria, i.e. Average RLS and Average FKR, in terms of trade-off charts, which are obtained by 148 iterations of simulation.

Figure 4 illustrates comparative performance of three revision policies considered in this paper, i.e. FIR, DAR and DAVR, for specified parameter conditions. Where, μ_t changes from 12 to 8 and σ_t^2 is stable as 1.

Figure 4. Performance comparison of three policies (in the case that μ_t ; 12→8, σ_t^2 ; 1)

In case of FIR Policy, FKR becomes small whereas RLS gets large according to longer revision interval and it is observed there is an inverse proportion between two measures. Looking at the performance of DAR and DAVR Policies, both show quite superior performance to FIR Policy and do not hold superiority from the counterpart. Namely, both of these policies have quite close but different trade-off characteristics. According to decrease of T, i.e. length of the term for statistics calculation, RLS values of both policies are improved substantially but FKR values are not sacrificed very much. In comparison with DAR Policy, DAVR Policy indicates its strength on reduction of RLS whereas weakness on FKR. Improvement rates of average RLS of DAVR from that of DAR are positive and smaller T values create better improvement. These might be because of the effect of its variance test procedure.

In case that both of demand parameters are changed, i.e. μ_t change from 12 to 8 and σ_t^2 change from 1 to 2.5 by step function, characteristics illustrated in Figure 5 was obtained. This figure just focuses on the performance of DAR and DAVR Policies and illustrates that superiority of DAVR Policy against DAR Policy becomes bigger for small T, which is the same trend as Figure 4. However, the improvement rates indicate better scores. This feature is quite reasonable as DAVR Policy tries to detect the change of variance σ_t^2 in the supposed situation. On the other hand, FKR measure gets worse as DAVR tries to revise the numbers of KANBAN more frequently in this case.

Figure 5. Performance comparison of DAR and DAVR policies (in the case that μ_t ; 12→8, σ_t^2 ; 1→2.5)

For more detail in the case of μ_t ; 12→8 and σ_t^2 ; 1, Table 1 summarises the joint characteristics of both FKR and RLS measures of FIR and DAVR Policies. Here, average FKR values are the points read from each

performance graphs that attain the same RLS performance.

It is noticed from this Table that DAVR Policy provides smaller average and variance of RLS than FIR Policy. That is, DAVR adaptive estimate/control offers more servile characteristics than static FIR Policy.

Table 1. RLS performance comparison of FIR Policy and DAVR Policy (μ_i ; 12→8, σ_i^2 ; 1)

Average FKR	Policy	Average RLS	Variance of RLS
0.051 or 0.053	FIR	7.169	5.443
	DAVR	2.933	0.451
0.046 or 0.047	FIR	9.169	13.43
	DAVR	4.459	1.203
0.031 or 0.033	FIR	11.74	21.62
	DAVR	6.601	4.069

6. Concluding Remarks

This paper argued about three revision methods of the numbers of KANBAN for robust and efficient parts procurement operations in some volatile demand environments. The performance of each policy is evaluated by simulation experiments and quantitative trade-off relations between considered criteria are obtained. These characteristics indicate that proposed policy in this paper (DAVR) dominate traditional simple method (FIR) in terms of both criteria and provide more reliable feature than the other semi-advanced method

(DAR).

Acknowledgements

This research has been accomplished with the support of Grant-in-Aid for Scientific Research of Japan Society for the Promotion of Science [JSPS] and Ministry of Education, Culture, Sports, Science and Technology of Japanese Government for 2003-2005. Also, Toyota Motor Corporation kindly supported our research by suggesting their way of KANBAN management. The authors sincerely express deep acknowledgement to these organisations.

An Exploratory Study of Critical Issues in Online Securities Trading: The Hong Kong Perspective

Jane S.Y. Ong
Division of Computer Studies
City University of Hong Kong
83 Tat Chee Avenue, Kowloon, Hong Kong
dcsyong@cityu.edu.hk

Abstract

The advancement of technology enables more and more people to do their business activities online. This has threatened the businesses of the traditional intermediaries. Among the various form of electronic commerce, online securities trading is one that will stand a better chance for wide adoption and success. Online securities trading penetration rate has remained on a steady upward trend [39].

The development and adoption of online securities trading have been slow in Hong Kong as compared to other Asian counter parts such as South Korea, Japan and Singapore. Past research on online securities trading in Hong Kong has been lacking. The objectives of this study are to explore the critical issues, impacts, problems and barriers of online securities trading in Hong Kong, and what can be done to facilitate local online securities trading.

This paper will first provide the background of online securities trading in Hong Kong, followed by literature review on online securities trading, self-service technology, electronic commerce, and review of studies of online securities trading in other countries.

In-depth interviews were also conducted with senior personnel in local brokerage firms that offer online trading to gather their expert opinion and to explore the critical issues, attributes, benefits and barriers of online securities trading in Hong Kong.

Recommendations to managers and future research of an empirical study will be discussed in the last section.

1. Introduction

The term 'Online Securities Trading' is the same as 'Online Trading', 'Electronic Trading' or 'Internet Trading'. It refers to any use of electronic means of sending orders (bids and offers) to the market, electronic order routing, automated centralized execution and subsequent dissemination of price and volume information [13].

We will use the term 'Online Trading' as a short form of 'Online Securities Trading' through out this paper.

One of the fastest growing online businesses is Online Trading. It is inexpensive, convenient, and supported by a tremendous amount of financial and advisory information. Trading is very fast and efficient, almost fully automated, and it is moving towards 24 hours of global trading. Day trading is rising rapidly and the traditional brokers are

disappearing slowly [37].

In recent years many companies have adopted the Electronic Commerce model in their businesses, but many of them have failed. Online trading is one of the successful Business-to-Consumer models of Electronic Commerce. Putting a securities brokerage online is a very smart move, since the business itself is simply an information-based business, and there is no logistic problem related to physical delivery. There is no better way to pass information through other channels than the Internet [3]. Online securities trading will be one of the potential winners of the Internet. The arrival of wireless application protocol (WAP), third-generation mobile phones and WAP-enabled personal digital assistants will mean even more flexibility and access.

The aim of this research is to investigate the reasons behind such low penetration rate and to find out the barriers, benefits, issues and impacts arising from the adoption of online securities trading in Hong Kong. The management of this industry can make use of such studies to strengthen and improve their business. The government and regulatory bodies can make use of such studies for policy making and amendment to existing policies so as to provide a better environment for suppliers and consumers to participate in such business. The key factors that affect the Hong Kong consumer adoption and consumer barriers of online securities trading will be investigated. These factors could be used as variables for empirical studies of consumer behavior, adoption and diffusion of online securities trading in Hong Kong.

2. Literature Review

Literature on online trading is very limited; however we may review the literature in the following related areas to gather the attributes and issues that are associated with online securities trading.

2.1 Characteristics of Online Trading

Online trading has the following characteristics [6]:

- directly connect buyers and sellers;
- support fully digital information exchange between them;
- suppress time and place limits;
- support interactivity and therefore can dynamically adapt to customer behavior;
- can be updated in real-time, therefore always

up-to-date.

2.2 Self-service Technology and Online Trading

Traditionally, securities trading were done by broker, but the new online technology allows customers to perform securities by themselves. Therefore it is worthwhile to do a review of literature on self-service technology.

There are five attributes associated with the technology-based self-service option, namely, speed of delivery, ease of use, reliability, enjoyment and control [15].

Electronic Data Interchange (EDI) is an inter-organizational system, which transmits standard business documents electronically between trading partners. EDI is quite similar to online trading in nature. Ratnasingam [33] states that the driving factors to adopt EDI are:

- cost savings (increase productivity and profitability by reducing costs);
- simplification of business processes (via automation) that eliminated the use of paper;
- speed from savings in time;
- increase productivity.

2.3 Electronic Commerce and Online Trading

Some of the issues in Electronic Commerce may also be applied to Online Securities Trading since Online Securities Trading is a form of Business to Consumer Electronic Commerce. Turban et al. [37] have made a detailed study on issues in Electronic Commerce, and now we summarize those issues that are applicable to online securities trading:

Benefits to Organizations

- Globalize and borderless markets
- Reduced cycle time
- Reduced production cost
- Reduced number of employee
- Improved brand or corporate image
- Improved customer service

Benefits to Consumers

- Round the clock trading
- More choices offer
- Lower commission rate
- Quick delivery
- Attract lower income group customers

Limitations and Barriers

- Technical Limitations
- Developing cost
- Security and privacy
- Lack of trust and user resistance
- Legal issues: Many legal issues such as consumer

protection, content control, taxation, encryption policies, cross-border transactions, intellectual property enforcement, privacy and code of ethics are as yet unresolved, and government regulations and standards are not refined enough for many circumstances.

A survey conducted by Deloitte & Touche LLP [4] asked online trading executives on what they consider to be their biggest work-related worries, and the results are listed as follows:

- concerns about system outages and mistakes;
- inability to handle a rapidly growing transaction volume;
- possibility of a bear market;
- formation of alliances between discount brokers and larger institutions.

Among the listed worries, brokerage executives find outages a top worry.

The Critical Success Factors

A study by Jones et al. [26] states that there are eight 'C' for a successful online retail business: Community, Concern (trust and confidence), Connectivity, Content, Convenience, Customer care, Communication, and Customization:

- Community: Rheingold [34] and Turban et al. [37] believe that the Web is being transformed into a social Web of communities. They think that every Web site should incorporate a place for people to chat. With millions of members, such communities could have significant effects on markets. The community brings together consumers of specific demographics and interests. This presents opportunities for transacting business and communicating messages about products and services.
- Concern (trust and confidence): customers have a wide range of doubts, worries and reservations about online retailing. Trust and confidence are central to all business relationships. Fears about the security of credit card transactions and about releasing personal and financial details are regularly cited as major reasons why consumers are reluctant to trade online.
- Connectivity: Connectivity problem such as not enough bandwidth and system outage are limiting the growth of online businesses.
- Content: Content is concerned with providing consumers with rich & up-to-date information, expert insights, lots of products to choose from, and providing it with an entertaining, visually appealing, informative and easy to use interface.
- Convenience: Convenience focuses upon the critical importance of an easy to use, easy to navigate, and logically organized site and the ability to make quick transactions.
- Customer care: Customer care is seen to be about

providing online customer support at all stages of the retail relationship.

- **Communication:** Many communication channels such as chat room, e-mail, discussion forum, etc are provided by online businesses, to facilitate communication with their customers.
- **Customization:** Products are produced in a large quantity but are customized to fit the desires of each customer. Electronic Commerce is an ideal facilitator of mass customization.

Some of the above critical success factors seem to coincide with the studies by Ghosh [17] and Turban et al. [37], who have identified the critical success factors for starting an online business as follows:

- Specific products or services traded
- Top management support
- Project team reflecting various functional areas
- Technical infrastructure
- Customer acceptance
- User-friendly Web interface
- Integration with corporate legacy systems (combine traditional and online method)
- Security and control of the online business system
- Competition and market situation
- Pilot project and corporate knowledge
- Promotion and internal communication
- Cost of the online business project
- Level of trust between buyers and sellers

2.4 Comparative Online Trading Developments

Since Online Trading is still in its infancy in Hong Kong, so it is worthwhile to have a survey on this topic in other mature countries.

In general, the use of computers and mobile phones, and access to the Internet, is in line with income, and the online trading development follows a similar pattern. From Table 2.1 you can see that the adoption rate of online trading in countries with higher income such as United States, Sweden and Germany is higher than India, China and Brazil. Even among the high-income economies, differences are evident. High ownership of personal computers, and especially high usage of mobile phones, has meant that the Scandinavian countries lead in online banking and online trading. The long-standing stock-owning culture in the United States and wide computer ownership has seen online trading become particularly popular there [12].

In Asia Pacific Region, the adoption rate of Korea, Japan and Singapore is higher than Hong Kong. Korea is Asia's fastest-growing country in online trading, with 65 per cent of trades conducted online. A number of factors, such as government support, deregulation of commissions, the rise in Internet companies and creative entrepreneurs as well as the creation of a Korean "Silicon Valley"

contributed to the explosive growth in online trading in the country [23].

From Table 2.1 it can be seen that the adoption rate of online trading in Hong Kong is very slow, approximately 1 per cent of the total trading volume. This figure is close to the survey done by HKSFC [23] in April 2000, which found that only 1.3 per cent of total trading volume is online trading.

Table 2.1: Comparative online trading developments

Source from BIS estimates based on data from the World Bank, Central Banks and Claessens, Glaessner & Klingebiel [11][12].

	Real GNP per capita (US = 100)	Internet users as % of inhabitants	Mobile phones per 100 inhabitants	Bank customers using online banking (%)	Electronic brokerage transactions: % of total
Australia	75	32	34	4	22
Finland	71	41	65		
Germany	74	18	29	12	32
Japan	79	21	45		32
Sweden	69	41	58	31	55
United Kingdom	70	21	46	6	26
United States	100	27	31	6	56
Hong Kong	71	36	64	2	1
Korea	49	23	50		65
Singapore	70	24	42	5	10
Argentina	37	2	12		
Brazil	21	2	9	4	6
China	11	1	3		3
Czech Republic	40	7	19	3	
India	7	0	0		2
Malaysia	24	7	14	<1	
Mexico	25	2	8	4	41
Nigeria	2	0	0		
Poland	26	5	10	<1	
South Africa	27	4	12		
Thailand	19	1	4		

3. Research Methodology

Senior personnel from five well-known securities houses that offer online securities trading were selected for the in depth interviews. The objectives of these interviews were to identify the benefits and problems, the issues and impacts associated with online trading.

Each interview session started with an introduction which emphasized that the participants should give their honest opinions and discuss how they 'really feel'. The interviews were carried out in a relaxed atmosphere, and to enable an open and free exchange of ideas, detailed notes were taken during the interviews instead of tape.

4. Findings and Analysis

The results reported are based upon the synthesis of the interview transcripts. Common themes that emerged have been identified.

4.1 Limitations and Barriers in Online Trading

The statistics [23] show that the number of brokerages with current online operations is relatively small as a percentage of the industry (less than 4%). The use of online trading facilities is still in its infancy and there is plenty of room for development. Online trading constituted only 1.3% of the total market volume for Hong

Kong securities in April 2000. The interviewees pointed out that the key factors for such low adoption rate were:

- geographical environment;
- social habit;
- limitation from the work place;
- connection cost and problems;
- security and privacy;
- access to computer and computer illiteracy;
- broker and client relationship;
- increased risks;
- confidence and trust;
- account settlement flexibility and margin finance; and
- regulatory policies and account opening.

The limitation factors from these findings are quite different from the studies done by Williams [41] in USA markets; which are mainly execution and technical problems. USA is the first country to adopt online trading and it is therefore worthwhile to take a look at the problems of online trading in USA. In response to numerous complaints from online investors, USA congress asked the General Accounting Office (GAO) to launch an investigation into online trading practices. They talked with 12 online brokers, who, even though they represented less than 10% of the number of firms that offered online trading, accounted for about 90% of the online trading volume during early 1999. Below is the report from this investigation. The top 10 complaints from USA consumers in descending order were:

- difficulty accessing accounts;
- failures/delays in processing orders;
- errors in processing orders;
- best execution problems;
- errors/omissions in account records of documents;
- transfer-of-account problems;
- margin position sellouts;
- problems with opening accounts;
- problems with executing cancellation orders;
- inaccurate quotes/pricing information.

Most of our findings of key factors from the interviewees are consistent with our literature review except geographical environment, social habit, and limitation from the work place; these factors are peculiar to Hong Kong. Notice that system failure is not a problem in most online brokerages in Hong Kong as the interviewees expressed that their system has been developed for quite a while and it is stable, also good contingency plan and backup are installed. Let us discuss these limitation factors in detail as follows.

Geographical Environment

The interviewees pointed out that Hong Kong is a very densely populated city and the number of securities houses is very high as compared to other cities. People are

reluctant to use online trading since it is very easy to access a securities house in their neighborhood.

Social Habit

Hong Kong people like to go to the securities house where they can meet their friends and brokers to exchange the tips for stocks; also the crowd, the noise and the atmosphere are conducive to trade. This is a similar habit for Hong Kong people where they like to go to the noisy restaurant for 'dim sum', a Hong Kong style of lunch. In contrast to online trading, they are on their own and it is sometimes lonely.

Limitation from the Work Place

Many companies in Hong Kong restrict their employees from visiting certain Web sites using filtering software. In particular, they restrict their employees from online trading during office hours.

Connection Cost and Problems

The Broadband usage is relatively low in Hong Kong due to high connection cost and dispute between property developers and service providers in cable laying. According to the report in Hong Kong Economic Journal [25], currently there are seven hundred and ninety thousand broadband households, which is about 10% of Hong Kong population. The connection cost becomes the switching cost, which limits the adoption of online trading.

Security and Privacy

There is a great deal of concern regarding the security of financial information transmitted over the Internet. If brokers' systems did not have sufficient security measures, hackers would break in and steal clients' information or assets. The security measures used by local online trading brokerages are user IDs and passwords, SSL security standards, encryption and firewalls. Online brokerages in Hong Kong generally use 128 bits SSL encryption method to secure and protect all personal information contained in online transactions between the online brokerage and customers.

Thirty-four percent of those participating in the Dataquest surveys claimed that privacy and security concerns kept their trading down [28]. Security is a critical issue, which limits the mass adoption of the Web, especially since surveys of Web users indicate that vendor reliability and security of financial transactions are important to users [19].

Access to Computer and Computer Illiteracy

Senior citizens may not know how to use a computer to do the online trading. Low-income people may not afford to possess a computer to do the online trading. Interviewees revealed that, quite a number of local investors are housewives and retired people. They do not have computers at home.

Interviewees also revealed that the customer profiles

of online trader are mostly young and educated people. Although Hong Kong is considered a developed country, the Internet penetration rate is relatively low compared to other developed countries. This is partly due to the immigration of people from China who are mostly lower income and computer illiterate. Currently the quota for China immigration is 150 people per day. A report in Hong Kong Economic Journal [24] stated that from 1982 to 1997 there were many well-educated middle class families migrated out of Hong Kong because of losing confidence in handing over of Hong Kong sovereignty to China.

Online trading would encourage the participation of younger players, as they would generally be more IT savvy. However, they may lack the funds to trade in significant volumes as compared to more established and older business people who may be more 'IT illiterate' [27].

Broker and Client Relationship

No specific broker is assigned to online client, only general customer support and hotline is available. In the traditional stock broking world, much of the value offered by brokers has been in the quality of the working relationships they developed with their clients. Brokers won their business not only by executing orders, and earning a commission in the process, but also by helping guide clients to investments that were both profitable and within the client's so-called risk tolerance profile. Whereas it is impossible to maintain such a close relation in the online trading world. This observation is consistent with the study by Wheelwright [40].

Increase Risks

The interviewees expressed the same view as Yiu [43] in that online trading has enabled investors to invest directly in the market; it has also made it easier for fraudsters to make profits. One of the most common types of online trading fraud is "pump and dump". He might, perhaps, claim on a bulletin board that the company in question was about to release news of a new product, service or alliance. His hope would be that other readers would buy the stock and pump the price. New regulations should be issued to prevent fraud and manipulation in online trading.

Financial markets are becoming more volatile as investors act on impulse or are tempted by how easy it is now to execute trades [32]. Online trading certainly has enabled millions of punters to change their minds easily and several times a day [21].

Risk assessment is the duty of stockbrokers or financial planners, who question clients to gauge their comfort level for volatility and potential losses. But with the explosion of online trading, investors have taken control of their own finances [31].

Confidence and Trust

The interviewees revealed that the loss of confidence by customers in online trading were partially due to the

dot com crisis and the closing down of many online brokerages such as 2CUBE.com and Charles Schwab (Hong Kong). Also customers do not trust a faceless broker.

Account Settlement Flexibility and Margin Finance

Interviewees expressed that customers preferred traditional trading because of the flexibility in account settlement and the availability of margin finance whereas customers need to deposit enough money before trading online.

Regulatory Policies and Account Opening

Interviewees pointed out that the requirement of 'face-to-face' account opening policy by the regulator had hindered some customers from opening the online trading account. They also revealed that the regulator is going to tighten online trading policy even further such as the minimum capital size, margin finance and system integrity.

4.2 Benefits in Online Trading

It has been suggested in our literature review that the benefits for online retail business were lower commission rate, speed of delivery, round the clock trading, global and borderless markets, control, ease of use, enjoyment, more choices, attractive to cost conscious customers, reduced number of brokers, lower production cost, improved brand or corporate image, and improved customer service. The interviewees also mentioned availability of most of these benefits in the local market and these are described in detail below:

Lower Commission Rate

Hong Kong government is going to deregulate the minimum commission rate on April 1, 2003. Currently, Hong Kong regulator requires a minimum 0.25% commission rate charged by registered online brokers. With better competition, commission rate will be lowered after the deregulation. Some interviewees revealed that they will not compete on commission rates but they will aim at middle range of commission rates in the market and compete using value added services.

Speed of Delivery and Increased Trading Volume

The interviewees pointed out that AMS/3, an Internet-based trading system that eliminates the need for orders to be input manually, should allow online brokerages to offer faster service to its clients, and increase reliability, speed and trading volume.

Online trading is foreseen to encourage more trading volume, as the facility eases the ability to buy and sell [7] [27].

Convenience, Round the Clock Trading

With online trading, you can trade any time, anywhere or any place, when you can get hold of a PC or WAP phone with Internet connection.

Global and Borderless Markets

In the past, Asian investors who wished to buy securities in other regional countries had to do so through a broker. With Internet, online trading company can reach customers around the globe. At the moment cross-border trading is not easy, the Hong Kong Stock Exchange is planning to introduce the CCASS/3 system, which will allow cross-border trading, cross-market trading, and prolong settlement period [22]. Most interviewees revealed that they had facilities, which allowed their customers to do online trading in other markets such as USA and Europe.

More Client Control, Easier to Set a Price Limit for your Stock

The interviewees shared the following views with Burton [9] and Bien [5]. One reason why retail investors have adopted online trading is that it gives them more control over their stock portfolios. Traditional stockbrokers were often suspected to buy and sell a client's securities frequently without client permission, especially in order to increase their commissions. Online trading sites allow you to set a price limit at which you buy or sell the stock. This is useful if you have an exact price in mind but haven't got the time to monitor the stock all day. You can even place orders when the market is shut, so you can make decisions in the evening or at weekends.

No Mark Up by Middleman

Online trading is system automated and no manual manipulation is necessary and thus prevents mark up by middleman. Based on information provided by brokerages as well as from actual trades, online brokers aren't marking up the prices of stocks to investors as much as done by the offline brokers [18].

Ease of Use and Enjoyment

Ease of use will improve as more Internet access channels such as digital television, personal organizers and mobile phones, become available. User-friendly Web page design and software tools had made online trading both easy to use and enjoyable.

Attract Small Investors and More Customers

The interviewees, Schroeder [36] and Bien [5] agreed that the growth of online trading opened the markets to individual investors as never before, making markets fairer for small investors. Online trading enables small investors equal access with anybody else. They don't have to rely on being a client of the right broker to find out about an issue. Strong retail demand by small investors, in turn, attracts more institutional and overseas investors to a market. Online trading could allow them to access and maintain more customers than their current offline resources allow.

Lower Production Cost and Reduced Number of Broker

Online brokerages are able to charge less than traditional brokerages because of lower expenses in terms of staff, space and other resources [10]. As with most of the businesses that migrate online, the first benefit is to reach a broader market and reduce operating costs through the disintermediation process [3]. Lower costs have caused online trading to expand rapidly in countries like South Korea and USA. Interviewees revealed that they would not lay off their existing brokers but allow them to resign naturally.

Improved Customer Service, Improved Brand or Corporate Image

Online trading makes it easier to reach and educate investors. The online trading site is full of information to educate investors on how to invest and pick a stock. Online brokerages are now competing to attract customers with the quality of the information provided. Such competition has allowed online investors to obtain stock news and analyst briefings similar to the information traditional traders possess. Online trading site serves as a forum for discussion, with topics including tips on stocks to invest in, useful investment books and government economic policies.

Information Transparency

The interviewees agreed with Lee [27] that the information provided via online trading facilities helps trader make better judgment. Investors can view the volume of buyers and sellers of any counter. This gives investors an idea of current buying patterns, and to some extent, the amount of speculation or substance a certain stock would have. In short, online trading indirectly reduces investors' risk by allowing them to be better informed and the wealth of information helps investors make better judgment.

Distribute other Financial Products, More Choices Offered

The interviewees agreed with Lo [29] that online trading company has the advantage of using the Internet platform as an efficient way to complete transactions and distribute other products to customers. Besides stock broking, online trading firms can offer other financial products, such as mortgages, personal loans, investment funds, insurance and credit cards to their clients using their existing trading sites.

4.3 Issues and Impacts of Online Trading

The interviewees also revealed the following critical issues and impacts arising from online trading:

Greater Competition

The major impact of online trading is greater competition, resulting from deregulation of commission rate, lower product cost and increased transparency. Small and foreign brokerages, which previously competed in their local markets, are now operating globally. Some

brokerages even sell below cost. This intensifies competition even further. Brokerages need to offer larger differentiation and product customization. It becomes more difficult to sustain competitive advantage in many cases. Traditional securities houses will have a better chance to survive the competition if they have an established brand name, good resources and global reach.

Threats from Online Banking

The launching of online banking (e-banking) by the local banks will boost the growth of online trading even more. The interviewees are worried about the threats from online banking, banks have the advantage of attracting their existing customers to enroll in their online trading system with the convenience of settlement and funds transfer with the customers' existing bank account. Banks have advantage over securities houses when the new regulation regarding minimum capital base is imposed, since banks have a bigger capital base.

Market Consolidation and Strategic Alliance

The interviewees expressed that there are too many small to medium-sized brokerages in Hong Kong, and they predicted that after the deregulation of commission rates more small brokerages will either close down or merge with other bigger brokerages. This is consistent with the study by HKSFC [23] which stated that more local brokerages, in particular, the small to medium-sized firms, are planning to form strategic alliances in offering online trading facilities in securities to remain competitive in the market.

Those alliances may well have been forced upon brokerages by increased competition and, they are to be welcomed, as it will strengthen the industry. The exact shape of the alliances is yet to emerge and it is unclear whether the traditional concerns about sharing client details will be overcome. There may be some regulatory and supervisory issues that arise out of these alliances and the HKSFC will monitor the development.

Disintermediation and the Changing Roles of Traditional Brokers

Direct marketing will eliminate many types of intermediaries. Online trading enables customers to place their orders without the intermediation by the brokers. The survivors will basically be providers of value-added services ranging from acting as a trusted third-party intermediary to matching special customers' requirements with brokerages' capabilities. This is also consistent with the study conducted by Bailey, Bakos [2] and Turban et al. [37].

Customer Profiles

The interviewees revealed that most online traders are young, educated and adventurous males.

Lee [27] observed that online trading would encourage the participation of younger players, as they would generally be more IT savvies. However, they may lack the funds to trade in significant volumes as compared to more

established and older business people who may be more 'IT illiterate'. Online trading is most beneficial to analytical share players who can make their own judgment from the information online.

A study by Libbon [28] showed that fifty-seven percent of online traders were less than 45 years old and 30 percent were under 35. Just 14 percent were 55 or older. Men outnumber women in online trading by two to one.

Hoffman, Novak and Schlosser [20] stated that key demographic variables like income and education drive the policy questions surrounding the Internet because they are the most likely to differentially impact the consequences of interactive electronic media for different segments in our society.

Sanchez [35] observed that online trading attracts 'shy' investors. Customers do not always prefer personal intervention to technology. Information available on stock trading sites limits the necessity for interaction with brokers. In addition, online trading sites allow investors more independence in their decision-making, while the traditional manner of investing would involve lengthy discussions with brokers.

Day-Trading Increased

The interviewees revealed that day-trading activity had increased in online trading. This is consistent with Yiu [43] which stated that the introduction of online trading services is likely to lead to a surge in day-trading, and can increase market volatility, where regulators may need to consider establishing new day-trading rules.

Best Model -- Brick and Click

The interviewees pointed out that the main reason for the recent shut down of 2CUBE.com and Charles Schwab (Hong Kong) is due to competition and lack of branch support. Therefore they think that the best model for online trading is to combine the virtual trading with the physical branch support, the so-called 'brick and click' model. This is consistent with study conducted by Committee on the Global Financial System [13] and Turban et al [37].

Expand Customer Base to China

There is a great demand from people in China to trade Hong Kong stocks because of its good regulation and mature system. Online trading is very suitable for these people because they can trade remotely from China once they have opened their accounts. Interviewees expressed that there is great potential in expanding online trading customers from China and they had done many road shows in China.

Value Added Services

All interviewees agreed that the offering of value added services is the best way to fight against competition and to differentiate themselves from competitors. They have suggested many value added services such as the followings:

Discussion Forum for Investors: Online trading site

serves as a forum for discussion, with information on tips on stocks to invest in, useful investment books and government economic policies.

Track Share Price Movements: Most online trading sites will provide function to track share price movements.

24-Hours Help lines: If you are unsure about something, you can call a 24-hour help lines without having to approach a broker.

Personalize Web: New online trading system enables customers to personalize their Web start pages and control how they view their information.

Stock-Screening: There exists stock-screening system, which will sort and filter stocks according to a set of criteria the trader enters. For instance, the trader can ask the program to show only stocks that have a certain price, volume, or P/E ratio, among other factors, and the investor can then select stocks to trade based on the results. The system can filter stocks according to specifications in many categories [38].

Real-Time Prices, Breaking News, Performance Measurement and Charting: Most online trading sites these days offer real-time prices, breaking news, performance measurement and charting. More cutting-edge are services like financial-planning tools that allow you to assess your savings needs, and tailored news. For example, if you have a portfolio of ten stocks, the system will deliver only the news that affects those stocks [8].

Portfolio Analysis and Risk Tolerance: SmartMoney is a sophisticated online asset allocation and portfolio management tool. It will ask you questions about your risk tolerance, view of the economy and the income you want at retirement. It then produces a chart that shows, in percentage terms, the categories of stocks you should consider investing in: foreign, large cap, small cap, bonds and so on [1].

Advisory Broker: Some online brokerages provide an advisory broker to give you professional advice before you place your order online.

Other Value Added Services: Free education seminars, research analysis and free use of computer facilities in the branch.

Communicating Media

The commonly used media to receive client orders are Internet and phones. Interviewees indicated that they are planning to allow customers to place their orders through wireless phone and Personal Data Assistant (PDA).

Regulatory Issues

For better customer protection and stable online trading market, government is going to tighten control for online brokerages in margin finance business, minimum capital size, system integrity and contingency plan, but it may relax the account opening policy.

System Integrity and Contingency Plans: Most of the interviewees reported that they had emergency back up for systems, power source, staffing, monitoring and technical support. Also customers may use phone to place their

orders in case of system failure. They encountered some system failures when they first offered their online trading service. However, they claimed that the problems were fixed within a short period of time. These questions of the robustness of systems, the capacity to meet demand generated by very aggressive marketing and the adequacy of contingency plans are being reviewed in the special round of Hong Kong Securities and Futures Commission (HKSFC) inspections and it indicates that the industry will need to do more to address risks in these areas.

Account Opening: The interviewees pointed out that the requirement of 'face-to-face' account opening policy had limited the number of online trading customers, but they also pointed out the government is going to relax this policy. Yeung [42] stated on 29th June 2002 (South China Morning Post Hong Kong) that the Hong Kong Securities and Futures Commission (HKSFC) had amended its code of conduct with immediate effect to allow investors to open online trading accounts without a face-to-face meeting. Those online brokerages that allow clients to open accounts without attending in person generally require clients to provide proof of identity, address and bank account details. For better control, some brokerages require their clients to have account opening documents endorsed by lawyers, accountants or a notary public or contact the clients by phone to confirm the details. However, we noted that some brokerages merely require clients to submit a copy of proof of identity without third party endorsement.

Suitability of financial products offered to clients: Almost all online brokerages rely on prior disclosure in the client agreement in relation to the risk of dealing in the products involved. HKSFC is looking into this issue by requiring clients to pass a qualification test before permitting clients to trade online in their selected products.

Impacts on Market

Online trading is more cost-efficient, accelerates trade execution and potentially expands the price information available to investors. As a result, online brokerages are finding their profit margins under pressure. Some of them may try to respond by chasing volume, others may concentrate on certain niches such as advice and research. The interviewees observed that two impacts on market are market fragmentation and market volatility. This is consistent with the study by Crockett [14]. Lower barriers to entry may mean that new online trading systems proliferate, and markets may therefore become more fragmented. Online trading leads to tighter pricing (i.e. lower bid-ask spreads) in securities markets by decreasing transaction costs. By reducing bid-ask spreads, online trading will tend to reduce the profit of active market, markets may become shallower, resulting in increased intra-day volatility. A study by research group Tempest Consultants [16] shows that 60 per cent of fund managers believed online trading had exaggerated price swings and market volatility in the UK stocks, despite having little net impact on market liquidity or company valuations.

5. Recommendations

5.1 Recommendations to Regulatory Authorities

The interviewees have recommended the following policies so as to make the online trading more conducive and healthier:

- fraud & manipulation policies;
- day-trading rules;
- systems failure and contingency policies;
- alliances, mergers and acquisitions policies;
- account opening and digital signature;
- establishment of the true and full identity of a client; and
- suitability of financial products offered to clients.

Williams [41] suggested that the regulatory authority should ensure that online trading systems include accurate and complete information on their websites in the key investor protection areas of risk disclosure, margin requirements, privacy considerations, and trade executions. This is to protect investors who are unfamiliar with online trading.

There is a trend where residents in Mainland China are using the online trading system to trade the China stocks listed in Hong Kong Stock Exchange, because of their relatively low P/E ratio. The problem for them is that they need to open a trading account personally in the local banks; they also need to deposit money into this account before they can start trading. At the moment China has strict regulation in foreign exchange and it is difficult for China residents to bring large sum of Chinese currency to Hong Kong. The large transaction volume certainly worth the regulators in Hong Kong and China to take a closer look to facilitate such trading.

5.2 Recommendations to Organizations

Interviewees have also made the following recommendations to organizations so as to promote online trading in Hong Kong. Some of these recommendations are consistent with the critical success factors in the literature review, such as methods to increase confidence & trust, communication, user-friendly Web interface, customization, customer care, etc.

Insurance for Online Trading: This is a good way to increase the consumer's confidence to trade online. Charles Schwab has introduced an insurance scheme to protect investors in case of system collapse; each client with a US stock-trading account with it would get compensation for their assets held by the broker of up to US\$100 million [44].

Celebrity Brokers in Charge: This is an effective way to attract customers as they have more confidence and trust in the well-known analysts or brokers.

Distribute other Financial Products: Online trading company has the advantage of using the Internet platform

as an efficient way to complete transactions and distribute other products to customers. Besides stock broking, online trading firms can offer other financial products, such as mortgages, personal loans, investment funds, insurance and credit cards to their clients using their existing trading sites [29].

Alliance of Online Brokerage with Online Banking: Since the biggest threat of online trading comes from online banking, the merging of online brokerage and online banking firm provides consumers the convenience of switching between the two services and freely transfer funds between the bank account and trading account. The Merger of E*Trade and Telebank is an example of such strategy [30].

Best Model -- Brick and Click (Multi-Channel Distribution): As mentioned earlier, the failure of 2CUBE.com and Charles Schwab (Hong Kong) indicated that pure online trading without physical branch support has not been successful in Hong Kong. Physical branches serve the function as 'relationship enhancers' and public trust. Combine the virtual trading with the physical branch support; the so-called 'brick and click' model will have the ultimate advantage.

6. Conclusions

In Hong Kong the population density is very high and in just about any street corner or shopping mall you can find a branch office of bank, securities agency, travel agency or property agency. The current penetration of online trading in Hong Kong is low. Due to the convenience, efficiency and cost saving of online trading, there is room for growth in Hong Kong. This paper has identified the variables and factors related to the issues, impacts, barriers and benefits of online trading in Hong Kong. These variables can be used for further empirical studies of why Hong Kong people refuse to trade online and what can be done to facilitate online trading in Hong Kong. This may also help future researchers to build an online trading consumer behavior model.

Greater competition that leads to consolidation and alliance is expected when the government deregulates the commission rate this year. The offering of value added services is the best way to counteract the competition. Other recommendations to online trading organizations have also been suggested in this paper.

In view of the developments in online services, more guidance to brokerages and increased investor education on using online trading facilities will be necessary; this paper has also made some recommendations to the regulatory authorities.

Development of Web-based Vietnamese Pronunciation Training System

MINH Nguyen Tan
Tokyo Institute of Technology
tanminh79@yahoo.co.jp

JUN Murakami
Kumamoto National College of Technology
jun@cs.knct.ac.jp

Abstract

We developed a web-based Vietnamese language learning system. A learner can hear the standard pronunciation of a Vietnamese word by inputting the corresponding word to the keyboard of the system in the Internet environment. Then the system checks the learner's pronunciation with the standard one and the score is shown on the display monitor immediately. We used the Visual C++ language to describe the system in order to provide a GUI (Graphical User Interface) environment for the users. From the results of the experiments, we confirmed that the learner could be trained to improve his pronunciation of the Vietnamese words by using our system.

1. Introduction

Vietnamese is the official language of Vietnam that is spoken by over 80 million people in Vietnam and other countries. This language is a mono-syllabic tonal language, which means that all words are only one syllable long. Each syllable of the words can be pronounced in six different tones and those tones confer different meanings on the words. If the learner pronounces a word with a wrong tone by mistake, then the meaning of the word will change completely. Therefore, the learner has to pay attention to not only pronunciation but also the tones.

We developed the Vietnamese pronunciation training system for the purpose of helping a learner of this language to enhance his skills in pronunciation. Our system gives the standard sound files by native Vietnamese speaker to the learner and compares his pronunciation to the standard one by using record-and-playback. From the results of the experiments, it is shown that the learner can be trained to improve his pronunciation of the Vietnamese words by using the system.

2. System design

We designed the system in consideration of the following conditions:

(1) For the purpose that the system can be used by many people, the system is constituted of some common elements, such as a personal computer, a microphone and an earphone.

(2) The system provides a GUI (Graphical User In-

terface) environment for users.

(3) The size of the system software has to be sufficiently small for the purpose that it can be distributed to the users through the Internet.

In order to satisfy above conditions, we used Visual C++ language to describe the system. The system works normally under following environment:

OS : Windows 98SE/2000/XP.

RAM : more than 64 MB.

CPU : more than 500 MHz.

2.1 Constitution of the system

Our system is constituted of two modules, that is, the input module and the recognition module. The former module acquires the pronunciation of a Vietnamese word which is pronounced by a user, and then analyzes this word to generate the standard pronunciation of the word. The latter module analyzes both the acquired pronunciation and the standard one, and computes the degree of a similarity between that two pronunciations by using a pattern matching technique. Figure.1 shows the constitution of the system.

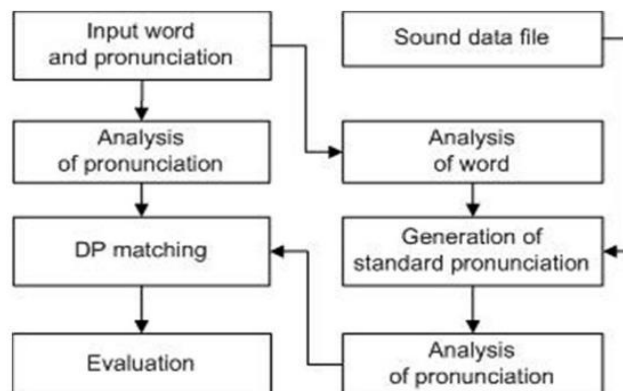

Figure 1: System construction.

2.2 Process of learning by using the system

At first, a user inputs a Vietnamese word to the system from the keyboard. Secondly, he pronounces this word toward the microphone after the standard pronunciation of the word is sounded by the speaker. Then, the system computes the correctness of user's pronunciation by comparing with the standard one,

and displays that correctness by points. The user can master the correct pronunciation of the Vietnamese word by repeating above procedure. Figure.2 shows the user interface window of the system.

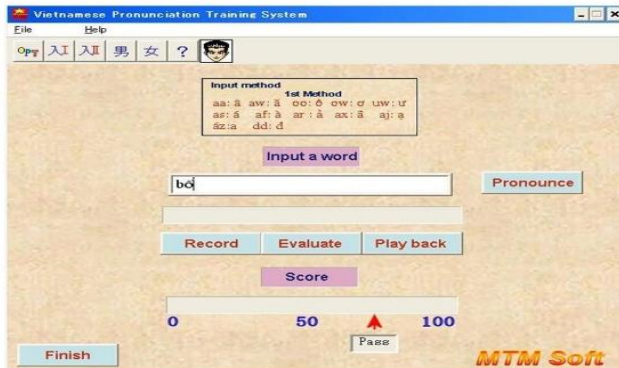

Figure 2: System interface window.

3. Making of the system

3.1 Input module

3.1.1 Speech data file

The sound data of the standard pronunciation of some Vietnamese words is stored in the speech data file. Since actual sound data size of the pronunciation is very large, that data is stored after being decomposed into vowel sounds, consonant sounds and tunes of voice.

In order to generate the pronunciation of almost all of the Vietnamese words, it is needed to store several hundred phonemes in the data file. Since the data size of a phoneme is about 10 to 15 kB when the sound data is sampled at 11025 Hz in the 16 bit monaural Wave form, the speech data file requires about the size of 10 MB.

In practice, we used two files as the speech data file, that is, wordsound.dat and wordpos.dat. The sound data of all of the phonemes are stored in the former file. In the latter file, the size and the position of each phoneme in the wordsound.dat are stored. To state how these files are used, first the size and position of a phoneme is taken out from wordpos.dat, then the sound data can be obtained from wordsound.dat by using acquired information. The construction of speech data file is shown in Figure. 3.

Figure 3: Speech data file.

3.1.2 Word acquisition process

As the Vietnamese words have six different tones, so we provided two sorts of ways to input the tones. The user can input the tones by using combinations of the alphabets and the numerals as a way. As another way, only the alphabets are used to denote the tones. Figure.4 and Figure. 5 show these ways. When a word is acquired from the keyboard by using those ways, then the system shows the word by Vietnamese letters on the display.

2nd input 1st input	1	2	3	4	5	6	7	8	9
a	á	â	ã	ä	å	â		ã	
e	é	ê	ë	ẽ	ē	ē			
i	í	î	ï	ĩ	ī				
o	ó	ô	õ	ö	ø	ô	ø		
u	ú	ù	û	ü	ū				
y	ý	ÿ	ÿ	ÿ	ÿ				
d									đ

Figure 4: One of the means of inputting a Vietnamese letter.

2nd input 1st input	a	e	o	u	d	w	s	f	r	x	j
a	â					ã	á	à	ã	ã	ä
e		ê					é	è	ẽ	ẽ	ē
i							í	î	ï	ĩ	ī
o			ô			ø	ó	ò	õ	õ	ø
u				û		ū	ú	ù	û	û	ū
y							ý	ÿ	ÿ	ÿ	ÿ
d					đ						

Figure 5: Another means of inputting a Vietnamese letter.

3.1.3 Pronunciation acquisition process

The user of the system inputs the pronunciation of the word through the microphone after he saw that word in the display. Then, the user can hear his own pronunciation any times, and he can also pronounce the same word again.

Since it is needed about 1 to 2 seconds to pronounce a Vietnamese word for the user in general, we set a time for recording a word as 3 seconds. The recorded pronunciation data is stored after being sampled in the similar way to the case of the standard pronunciation data (11025Hz, 16 bit monaural Wave format). We used the API (Application Programming Interface) functions of the Windows to describe a program for the recording and the playing back processes.

3.2 Generation of standard pronunciation

Figure. 6 shows the procedure of a generation of the standard pronunciation for the input Vietnamese word. The obtained standard pronunciation can be repeated any times in order that the user can check his own pronunciation with that one.

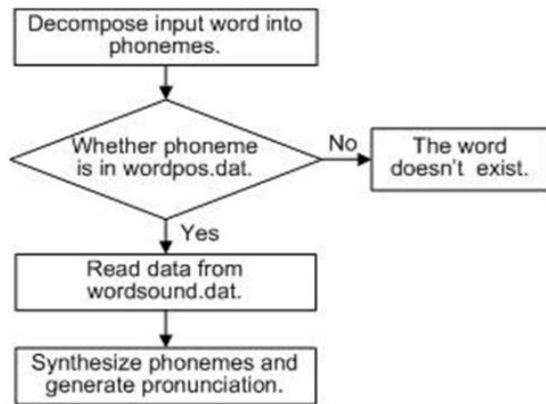

Figure 6: Overview of standard pronunciation generation process.

3.2.1 Decomposition of input word into phonemes

The Vietnamese language has following features:

- (1) Every word can be decomposed into one or two phonemes. The words which begin with a consonant are divided into two phonemes, and the other words become a phoneme themselves. There are no words which have more than three phonemes.
- (2) There are 26 combinations of consonants to appear in the beginning of a word.

The system decompose the input words into phonemes by exploiting those characters according to the algorithm below:

- (1) The system prepares a set of the 26 combinations of consonants.
- (2) In case the beginning of the word is a vowel, the word is a phoneme itself. The procedure is finished at this step.
- (3) In another case the beginning of the word is a consonant, the system inspects a part of the word from the beginning to the consonant just prior to a first vowel of the word whether that part is in the set of consonants or not. If this part is in the set, then the procedure is finished with informing the user that there is no word like such a word in the Vietnamese.

Otherwise, the accorded combination of consonants in the set is a phoneme and the rest part is another phoneme respectively, so that the word is decomposed into two phonemes. The procedure is completed in this step.

3.2.2 Synthesis of standard pronunciation

After the phonemes are obtained by above procedure, the system read the size and the position of those phonemes in wordsound.dat from wordpos.dat. By us-

ing this information, the sound data of the phonemes can be read from wordsound.dat.

In case of one-phoneme-words, the sound data can be used immediately as a standard pronunciation, the other case, two corresponding sound data of phonemes are combined to form a standard pronunciation. In the latter case, obtained standard pronunciation might sound unnaturally for a difference of each pitch of the phonemes. So we adjust the pitches of two phonemes to the pitch of the second phoneme, because the pitch of a two-phonemes-word depends on that of the second phoneme. The fast algorithm in the reference [1] is adopted as a way to adjust those pitches. The following Figure. 7 shows above procedure, and Figure. 8 demonstrates an example of which the pronunciation of the Vietnamese word [ma] is synthesized from the phonemes [m] and [a].

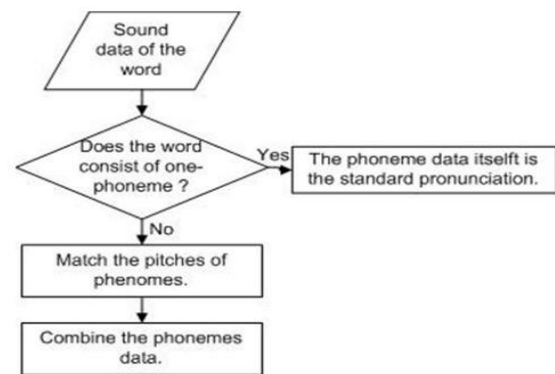

Figure 7: Segmentation and synthesis of pronunciation data.

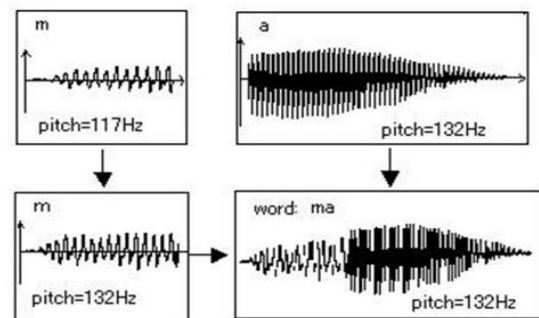

Figure 8: Example of synthesized pronunciation data.

The obtained standard pronunciation can be heard any times for the user by pressing the button from the keyboard.

3.3 Recognition module

In the recognition module, the degree how the input pronunciation of the word corrects in comparison with the standard pronunciation of that word

is computed. As the means to evaluate that degree, the cepstrum analysis [2] and the DP (Dynamic Programming) matching method [3] are exploited.

3.3.1 Detection of voice segment

At first, the section in which the voice signal of input pronunciation is exist has to be detected in order to compare with the standard pronunciation waveform. Although it is difficult to detect this voice segment exactly, we tried to do by using the energy and the number of zero cross of the voice waveform [4].

The waveform is divided into a number of frames at the period of 10 ms, and then the energy $E(n)$ and the number of zero cross $N_z(n)$ are computed for each frame, where n denotes the number of a frame. By using two threshold levels E_1 and E_2 ($E_1 > E_2$) determined from the energies, a conjectural voice segment (n_1, n_2) is detected in all of the extent as following way. That is, the beginning point of the segment n_1 is determined to the first point where the energy is greater than E_1 and besides the energy never drops below E_2 after that point. The terminal point of the segment n_2 is also determined by the same way as the case of n_1 .

The conjectural segment (n_1, n_2) is extended toward the outside of this segment by using $N_z(n)$ of each frame. The beginning point n_1 can be moved to the point where the number of frames whose $N_z(n)$ is greater than some value N_0 is more than 3 in the extent of (n_1-25, n_1) . By the same way, the terminal point n_2 can be moved too. By the means mentioned above, the voice segment (n_1, n_2) can be detected, provided that E_1, E_2 and N_0 are determined experimentally. Figure. 9 demonstrates an example of the detection. In this example, the beginning point n_1 is moved to n_1' , and n_1' is newly denoted as n_1 . On the other hand, the terminal point n_2 is not moved.

Figure 9: Detection of voice segment.

3.3.2 Cepstrum analysis

The cepstrum is obtained as a result of the inverse Fourier transformation of a logarithm of the power spectrum of a voice waveform. By using the cepstrum, we can calculate the pitch and the envelope of the

spectrum of a voice waveform.

Firstly, the voice waveform is analyzed by means of the short time spectrum analysis. That is, the frame of 20 ms long is picked out from the voice waveform, analyzing by the spectrum analysis. This analysis is performed many times to the frame which is picked out from another position in the waveform by shifting the frame 14 ms successively. Since the beginning and the terminal parts of the frame exert an influence to the spectrum, the frame is multiplied by the Hamming window function [5]. In this way, we determined the length of a frame 20 ms and the interval of the shifting 14 ms experimentally. The obtained cepstrums is treated as vector numbers and stored in arrays. Figure.10 shows the procedure of cepstrum analysis.

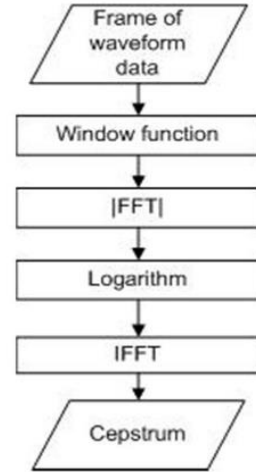

Figure 10: Procedure of cepstrum analysis.

3.3.3 Pattern recognition by DP matching method

In order to regularize some time series of cepstrums relating the time axis nonlinearly, the DP matching method is usually adopted.

By using this method, the distance between the cepstrums of the input pronunciation and the corresponding standard pronunciation is calculated.

Above two time series of the cepstrum which are obtained in 3.3.2 are denoted respectively as

$$A = a_1, a_2, a_3, \dots, a_i, \dots, a_N$$

$$B = b_1, b_2, b_3, \dots, b_i, \dots, b_M$$

where the vector a_i and b_i is the cepstrum of a frame. The distance between the cepstrum a_i and b_i is given by addtoresetequationsubsection

$$d(i, j) = \sum_k d(a_i[k], b_j[k]) \quad (1)$$

$$d(a_i[k], b_j[k]) = \|a_i[k] - b_j[k]\|^2 \quad (2)$$

where $a_i[k]$ and $b_j[k]$ are the k -th elements of each vectors. By using the equation (1) and (2), the distance between A and B is defined as

$$D(A, B) = \frac{G(N, M)}{N + M} \quad (3)$$

$$g(i, j) = \min \left(\begin{array}{l} g(i, j-1) + d(i, j) \\ g(i-1, j-1) + 2d(i, j) \\ g(i-1, j) + d(i, j) \end{array} \right) \quad (4)$$

$$i=1..N, j=1..M$$

where $g(1,1) = 2d(1,1)$, and we use the constant r under the condition of $|i-j| \leq r$.

By using this distance, the system can evaluate the pronunciation of a user. For instance, the smaller the distance becomes, the better the learner can improve his pronunciation.

4. Experimental results

To evaluate our system, experiments are performed on the following conditions:

- (1) Arrange a quiet room to avoid an influence of a noise.
- (2) A personal computer (CPU : Celeron 800 MHz, RAM : 128 MB, OS : Windows 2000), a microphone and speakers are used to make up the system.
- (3) The learners practice Vietnamese pronunciation time and again according to the way that is described in section 2.2.

Table 1 shows the scores of the experiments which are carried out to three subjects. Each subject pronounces a one-phoneme-word and a two-phonemes-word (shown in Figure. 11) five times respectively.

One-phoneme word	Two-phonemes word
a : letter "a"	na : custard-apple
o : aunt	ma : ghost
ô : stain	bô : father

Figure 11: Vietnamese words which is used for the experiments and their meanings.

Table 1. Experimental result.

Subject	A		B		C	
Word	o	na	a	ma	ô	bô
1 st time	50	30	50	80	60	55
2 nd time	70	70	40	100	70	60
3 rd time	100	60	60	90	90	80
4 th time	90	100	70	100	80	75
5 th time	100	85	100	100	95	80
Average score	82	69	64	94	79	70

From the table, we can find that the score doesn't increase monotonously, because of both the influence of the subjects' breathing sound mixed in the pronunciations and the insufficient accuracy

of the recognition process. It can be seen also that the fifth score is higher than the first one in all the experiments. This means that subjects had made progressed considerably in Vietnamese pronunciation. On the other hand, we can see that the subject could not advance his score easily for the vowels which don't exist in the Japanese language.

5. Conclusion

In this paper, we made description of our Vietnamese pronunciation training system. From the results of the experiments, we showed that the subjects' pronunciations approach to the standard pronunciations gradually by repeating a practice, while there are some room for improvement about the influence of a noise and the accuracy of the recognition process.

Abstract

This paper examines the influence of customizing banner ads to entice higher users' interactivity and sequentially builds not only positive attitudes toward the ad and the brand but also positive behavioral outcomes. It also attempts to introduce a new profiling-targeting parameter based on psychographics for customizing banner ad based on Internet user's individual differences according to their personality, types of goal-directed motives and preferred information processing strategies. Data was gathered through an online survey with a sample of 385 respondents. The Covariance Structural Modeling results supported a positive attitude-ad-brand-behavioral relationship. Positive attitude towards the ad generates more positive behavioral outcomes. Contrary to expectations, the results did not support the proposition that a positive brand attitude produces more positive behavioral outcomes. The findings provide evidence to support the proposition that customization of banner ads' creative and appeals (in terms of presentation modality, verbal versus visual presentation and information-rational versus entertainment-emotional appeals) based on users' individual differences in need for cognition, goal-directed motives and preferred information processing strategies effects positive attitudes toward the ad and the brand.

Introduction

The existing decision support systems and computer network literature have revealed that the Internet has created significant opportunity for customisation, one-to-one marketing and Internet advertising. It has also put an enormous pressure for acquiring customer information needed for such customisation.

Even though there are existing technologies to serve different and customized bundles of advertising messages to customers as they enter web sites, Raghu, Kannan, Rao and Whinston [27] argue that both profiling of the entering customers in real time and selecting the customized mix of offerings are a challenge. This is because the customer base for such customized advertisements is dynamic. That is, in order to provide individual users a customized offering, the profiling of customer preference requires a continuing basis of high level tracking of an individual customer's level of interaction when he/she surfs Web sites. Although there is a large amount of current and historical customer information available to assist the profiling a customized offering, the underlying behaviour of how Internet users process and use information from the Web remains largely unexplained.

Roehm and Haugtvedt [29] and Nowak, Shamp, Hollander and Cameron [22] have suggested the customisation of advertising messages presented to match consumers' responses. Customisation, from an advertising perspective, can be referred to as the extent of responsiveness to the consumer and the potential to facilitate interpersonal communication [13]. According to Heeter [13], the benefit of customisation involves simply personalising messages by inserting the customer's name at various appropriate points in the web page presentation. Many Internet advertising researchers highly recommend customisation or personalisation. However, there is little attention given to how customisation can be operationalised.

Several recent studies also show that changes in the nature of information communicable by Web advertising alters both consumer information search strategies and their decision-making processes [31] [14] [15]. Several studies indicate the moderating effect in the attitude-behavior relationship depends on the amount of cognitive effort required to form or change attitudes [12]. The next question is what types of

information are most attractive to Internet users, and what compels them to elaborate on particular information while discarding the remainder? In addition, what are the appropriate levels of exposure needed to impact consumer cognition, attitudes toward the ad and the brand? To address these issues, we propose a research model employing individual's need for cognition, goal-directed motives and preferred information processing strategy as a psychological mechanism to customise a banner ad design in order to understand how Internet banner advertising can lead to attitude change.

The Research Model

The model proposed assumes that customisation depends on segmenting consumers by profiling their individual differences in terms of their need for cognition, goal-directed motives and their preferred information processing strategies (known as behavioral variables). The customisation of the advertising message embraces their preference for informative and/or entertainment banner ads.

In Figure 1, the model begins with identifying antecedents that effect attitudinal and behavioral changes. The antecedents include need for cognition, goal-directed motives, information-processing strategies and personal involvement. The framework proposes a psychographics mechanism as a basis of customising a banner ad by segmenting Internet users based on their individual differences in need for cognition. Personality has been identified as one of the variables which moderates the strength of relationship between attitude and behavioral [9]. A motivational construct (goal-directed motives) is included as one of the important antecedents to explain both the direction of behaviour and in the context of brand information processing. Goal-directed motive is defined as Internet users' desire, willingness, interest or readiness to process brand information in a persuasive communication presented in a form of an Internet ad. An Internet ad with content that can satisfy a Internet user's goal-directed motive will be relatively easy to process, therefore elaboration of message may be enhanced. Bettman, Payne and Luce [4] have made a similar suggestion about ad message processing and elaboration in a non-Internet environment. Besides the type of Internet ad that an Internet user will be attracted to, an individual's reaction to an ad (e.g. ad/brand attitude) is also a function of his/her motivation.

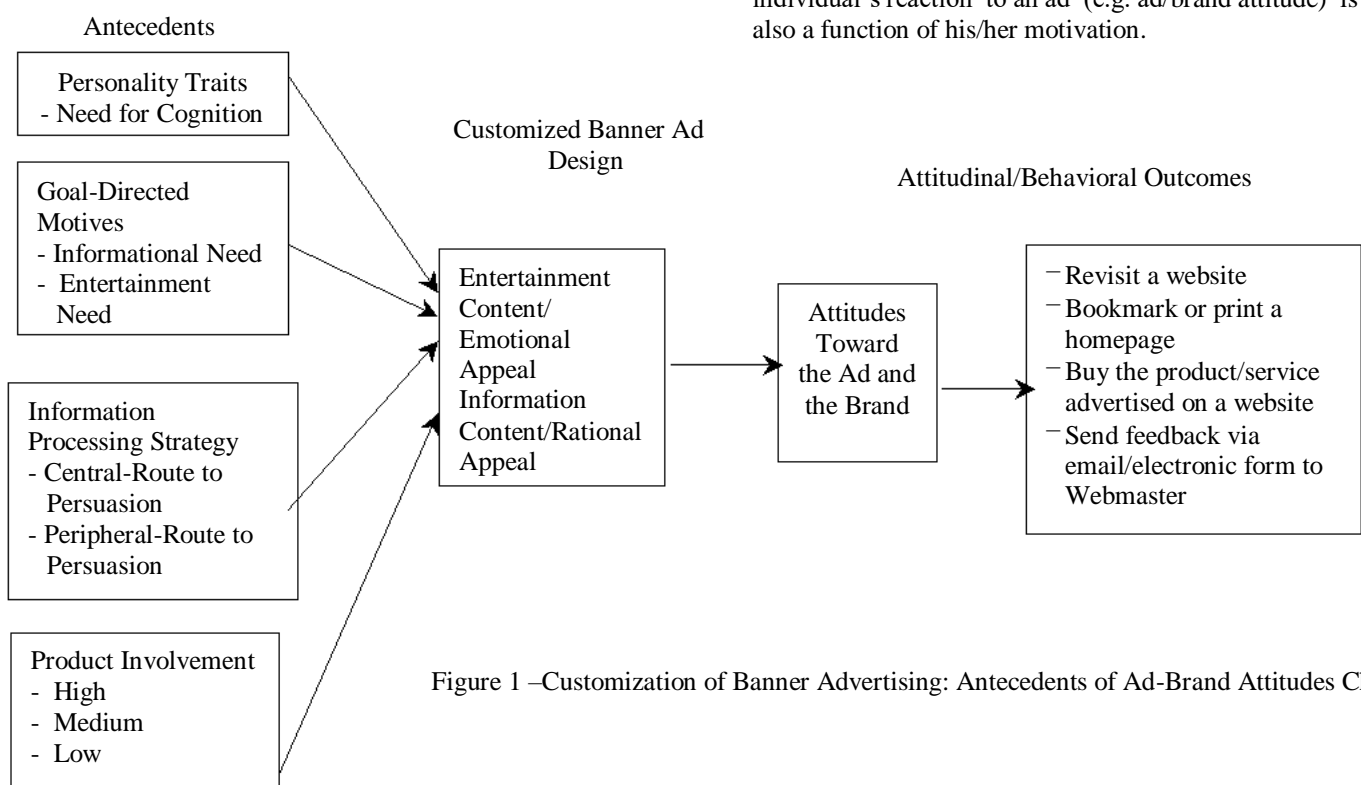

Figure 1 –Customization of Banner Advertising: Antecedents of Ad-Brand Attitudes Change

As opposed to the traditional method of customised banner advertising using demographics, the study presents a model that uses psychographics and behavioral variables to deliver the interactive advertising message and/or web site content that is tailored to the target audience.

For example, Rodgers and Sheldon [28] suggest that individuals who are driven to use the Internet for a particular reason such as searching or browsing are more likely to express favourable attitudes toward banner ads that correspond with that motive.

Cialdini, Petty and Cacioppo [7] and Petty and Cacioppo [25] have provided an explanation of the

moderating effects in the attitude-behaviour relation. These authors suggest that the moderating effects are related to the amount of cognitive effort an individual has been willing and/or able to expend in forming or changing attitudes. That is, attitudes that are formed or changed with greater cognitive effort are more predictive of future behaviour as compared to attitudes which are formed with less cognitive effort. The Elaboration Likelihood Model of Persuasion (ELM) developed by Petty and Cacioppo [23] [25] will be used as a general framework for organising and understanding the basic processes responsible for attitude change. According to ELM [25], there are two information processing strategies for attitude change - central and peripheral route processing. For example, in some circumstances, attitude formation and change results from a consumer's careful attempts to comprehend and evaluate the relevant content of an ad and to integrate this new information with his/her prior knowledge into a coherent and reasoned opinion about the brand. In other situations, consumers use peripheral factors such as their feelings about the quality of the ad, the source of the ad or their current mood state as cues to assist them to decide how they feel about the advertised brand. A motivated individual tends to engage in central processing. The persuasiveness of the message basically depends on careful and in-depth consideration of the merits of the advertised product. In this case, informational aspects of the message play an important role in persuasion and peripheral cues (animated images, graphics, music or video) are less important. On the other hand, an individual who has little motivation tends to disregard the informational aspects of the message and is likely to be persuaded by peripheral cues.

Previous studies have suggested that there is a link between product category and message strategies [8] [19]. Petty, Cacioppo and Schumann [24] and Petty and Cacioppo [25] suggest that involvement (personal relevance) with an issue was directly or indirectly related to the extensiveness of the cognitive effort that consumers expend in forming or changing attitudes. The study conducted by Verplanken [32] reported the moderating effects of involvement and need for cognition in attitude-behaviour consistency. Laurent and Kapferer [17] suggest that consumer involvement effected the extent of the decision process and information search, which in turn effected the types of media to be chosen, the numbers of repetitions of ad messages as well as the quantity of information provided by the ad.

Empirical study provided by Cho [5] claimed that Internet users who are in high involvement situations, are more likely to click ads in order to request more information than those in low involvement situations. On the other hand, those who are in low involvement situations are more likely to click a banner when it has a larger than average size banner ads. These

individuals are also more likely to click on a banner ad when it has dynamic animation. However, the study showed that there was no difference in clicking of banner ad for Internet users in the high involvement situations, regardless of the size or dynamic animation. Cho also concludes that the effect of advertising is maximized when the contents of the advertising vehicle are relevant to the product category. The effects of banner ads will be minimal where the contents of the Web site are irrelevant to the product category. Hence, a banner ad with higher relevance to the product category and the contents of the site where the banner ad is placed will generate more clicking of the banner. The study conducted by Roehm [30] confirmed that where there was matching of the tone and content of message to some aspect of a consumer then product evaluations and attitudes were enhanced and were more positive. In addition, the recent research conducted by Petty and Wegener [26] has shown that matching a communication to the functional base of an attitude that is relevant or important to a participant, can increase message scrutiny.

Recent evidence provided by Cho and Leckenby [6] suggest that simple exposure to a banner ad without clicking did not change Internet users' initial brand attitude and purchase. Furthermore, the brand attitude changes (either in the positive or negative direction) in line with their likeability of the corporate Web site, as a result of users clicking of banner ad in order to link and be exposed to the respective target ad. Furthermore, a recent study conducted by Lee and Miller [18] concluded that brand attitude would be a better measure of Internet advertising effectiveness.

Thus, in this paper, we emphasize that it is not just message content but the important combination of the message and the audience for the achievement of maximum persuasiveness. That is, the extent to which the advertising message is customised according to personality, goal-directed motives and information processing strategies of Internet users is a critical determinant of the strength of the message persuasiveness and formation/creation of attitudinal-behavioural changes. In this study, behavioural outcomes includes longer duration visit; higher frequency of repeat visit; bookmarking the web site; searching for more information about the brand; and providing feedback to advertisers or providing personal information to advertisers. This paper tests the following hypotheses, as illustrated in Figure 2.

- H₁: The greater extent of perceived customisation of a banner ad, the greater extent of change in attitude towards a banner ad.
- H₂: The greater extent of perceived customisation of a banner ad, the greater extent of change in brand attitude.
- H₃: The greater extent of perceived customisation of a banner ad, the greater extent of change in behaviour outcomes.

- H₄: The greater extent of change in attitude towards a banner ad, the greater extent of change in behaviour outcome.
- H₅: The greater extent of change in attitude towards a banner ad, the greater extent of change in brand attitude.
- H₆: The greater extent of change in brand attitude, the greater extent of change in behaviour outcomes.

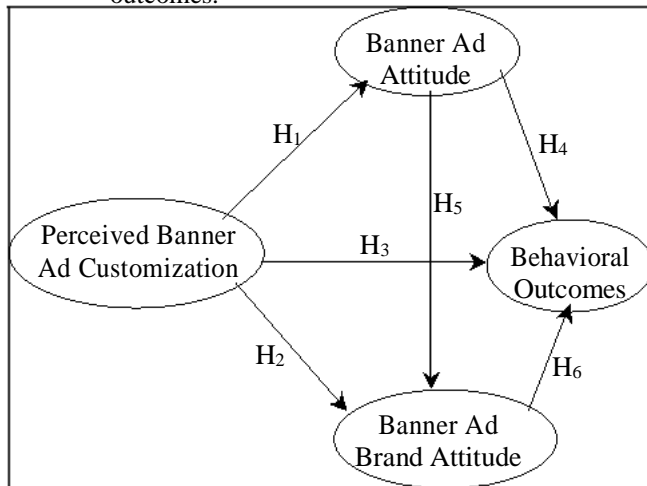

Figure 2 – Hypothesized Relationship of Perceived Banner Ad Customisation and Ad-Attitude-Brand Behavioural Relationship

In this study, familiar brands are used. A familiar brand will tend to be favored. In a previous empirical study by Ward and Lee [33], Internet users were found to be reacting more favourably to familiar brands since they prefer well-known brands. In addition, the expected click-through rate for a familiar brand was ten times higher than an unfamiliar brand. Empirical results provided by Dahlen [10] have shown that a familiar brand has a positive effect on brand attitude when exposed once or twice but wears out on multiple exposures. The author also suggests that the banner ads of familiar brands perform best on a short-term basis with relatively good initial click-through rates, but decrease rapidly after repeated exposure. The diminishing returns would likely to affect brand attitude rather than brand awareness given that in such high familiarity of the brands, brand awareness would not be expected to change. In particular, the framework showed in Table 1 was employed as guideline when designing the banner ads.

Three standard size banner ads of 460 x 55 pixels were created for this study. Each banner ad was created with different advertising theme and interactive features. The advertising objective was to determine the differences in attitudes towards the banner ad and the brand as a result of two forced exposures: first is to view and second is to click on the preferred banner ad.

Research Design And Methodology

Familiar Product/Brand	Level of Product Involvement	Goal-directed Motives	Personality Traits	Information Processing Strategies	Ad Design Principles	
					Advertising Appeal	Banner Ad
Soft drink	Low	Entertainment	Low NC	Peripheral route information processing (visual processing)	Entertainment Oriented	<u>Image site</u> Contains More Visuals and Interactive Features
Computer	High	Information	High NC	Central route information processing (verbal processing)	Informational Oriented	<u>Informational site</u> Contains More Verbal Content and Less Interactive Features
Fashion Apparel	Medium	Information and Entertainment	Medium NC	A combination of central and peripheral route information processing (Both verbal and visual processing)	More Informational and Less Entertainment Oriented	<u>Combined Informational and Image site</u> Contains More Verbal Content and Interactive Features

NC – Need for Cognition

Table 1 – Classification of Stimuli Employed In Design of Banner Ads

All banner ads contained two identical design properties with the actual company logo on the left side of the banner space and an animated actual (current) company slogan or message flashed across the centre of the banner to trigger respondent's brand familiarity. The basic structural design of the experimental banner ads was shown in Figure 3.

Figure 3— Design of Banner Ad

The background colour used for all banner ads (or dominant colour of the banner) was white. The exception was allowed for the soft drink banner ad because the background colour (red) used was the exact colour of the actual brand to project the psychological effect of warm, sense of novelty and entertainment. In addition, interactive features such as animated images were included in the soft drink banner ad to catalyst and initiate immediate reaction (clicking on the banner ad). Even though the computer banner ad was purposively designed as an informative banner, a blue animated butterfly was built-in as a means of instructing the respondent's attention of the product benefits. Similarly, as for fashion apparel banner, blinking words of the product attributes were flashed to ensure users' attention.

Operationalisation of Research Variables

The measurement scales used in this study were adapted from various sources to suit the specific context of Internet advertising. These measurement scales were based on valid and reliable measures found in previous research. In this study, for measuring attitudinal responses, this research utilised the scales developed by Gardner [11], Mitchell [21], Maheswaran and Sternthal [20], and Cho [5]. Since these scales developed by Gardner [11], Mitchell [21], Maheswaran and Sternthal [20] were originally administered to measure attitudes toward the ad and brand for traditional media, they were modified to apply in the context of Internet advertising. Cho's [5] scales were directly applied in this research to measure attitudes toward the target ad. As for behavioral responses, measurement scales developed by Baker and Churchill [3] was considered and compared to Cho's scale [5]. Modification was then made to tailor the scales to measure the purchase intent. A 7-point Likert scale measures all scales.

Sample Characteristics

The population for this study is Internet users. As such, there were no boundaries placed on the potential

respondents since the Internet can be connected anywhere and at anytime. Two samples were drawn. Data was gathered through an online survey with a sample size totalled 385 respondents who have more than one-year Internet experience. Two samples including a working adult group and a commercial online panel were used. The first sample was recruited by using advertising flyers and emails to undergraduate business students. A professional marketing research firm, AMR Interactive Australia, using their existing online panel, provided the second sample. The panel was invited via email to participate in the study. A Web URL address was then sent to those who showed interest and willingness to participate in this study in return for a cash draw incentive.

Results

The assessment of the measurement models by the means of the exploratory and confirmatory approaches. Table 2 shows that there are 4 constructs in total. Each construct is tested for its convergent validity and discriminant validity and unidimensionality is achieved. The findings indicate that the dimensions of these constructs are conceptually and empirically acceptable with multiple goodness-of-fit indices (GFI, CFI, TLI and NFI) above the 0.90 recommended level. All variance extracted for the latent constructs are equal or greater than the conventional standard of 50 per cent. The average factor loadings on these constructs are all equal or greater than 0.70. For those factor loadings of less than 0.50 were removed, the measurement is re-specified and similar CFA are conducted for level of model fit, within construct convergent validity and within construct discriminant validity including the composite reliability and the average variance extracted. Lastly, the composite reliabilities (CR) were computed. The CR results show that all constructs have reasonably acceptable reliability. Not all CR have similar reliability Cronbach's alphas. These findings confirm that the underestimation of Cronbach's alphas is insignificant [2] and therefore it is not likely to cause any practical consequences [1].

Previous research has recommended the use of multiple indices to assess the fit of the model to the data [16]. In judging the adequacy of model fit, larger CFI, TLI and NFI values (greater than 0.90) indicate good model fit. The normed Chi-square should not be greater than 5.0 [34] to indicate a good fit. Finally, the RMSEA value of less than or equal to 0.08 indicates a good fit.

In evaluating goodness of fit, the model receives a good fit to the data. The standardised regression coefficients estimated by ML estimation together with the significance tests and the structural paths are shown in Figure 3. For absolute fit measures, the model has achieved a good fit (GFI = 0.952, normed Chi-square = 2.901 and RMSEA = 0.070).

			Reliability Tests		Validity Tests			
1	Perceived Banner Ad Customization	3	0.8632	0.8690	0.6913	0.8260	Satisfactory	Satisfactory
2	Attitude Towards A Banner Ad	2	0.8629	N.A	N.A	N.A	N.A	N.A
3	Banner Ad Brand Attitude	3	0.9224	0.9232	0.8006	0.8914	Satisfactory	Satisfactory
4	Behavioral Outcomes	3	0.9066	0.9100	0.7725	0.8757	Satisfactory	Satisfactory

Table 2 – Summary of Psychometric Properties of Measures

Absolute Fit Measures

λ^2 / df	2.901
RMR	0.067
GFI	0.952
RMSEA	0.07

Incremental Fit Measures

Normed fit index	0.967
Relative fit index	0.952
Incremental fit index	0.978
Tucker-Lewis index	0.968
Comparative fit index	0.978

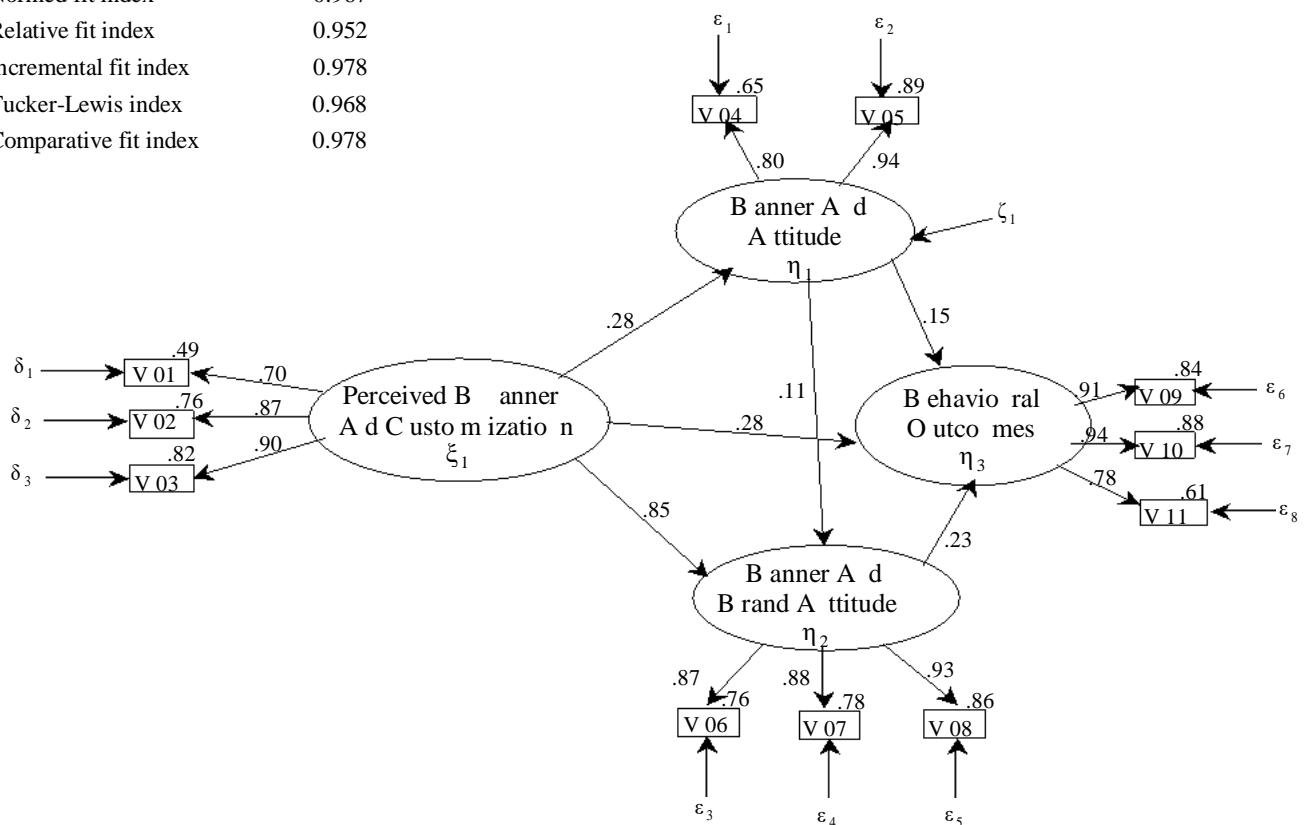

Figure 4 – The CSM Results of Estimates of Banner Ad Customisation, Attitude Towards A Banner Ad and Brand Attitude

The incremental fit measures are above the 0.90 recommended levels (NFI = 0.967, TLI = 0.968 and CFI = 0.978), therefore confirming that the model has acceptable level of goodness-of-fit.

In Figure 4, the results of the CSM show that the standardized regression coefficients of all structural paths are significant except the hypothesized relationship between banner ad brand attitude and behaviour outcomes. The extent of perceived banner ad customisation has positive and significant impact on attitude towards a banner ad ($\beta = 0.284$, SE = 0.059, p-value = 0.000), banner ad brand attitude ($\beta = 0.853$, SE = 0.051, p-value = 0.000) and behavioral outcomes ($\beta = 0.280$, SE = 0.147, p-value = 0.031). Therefore, H₁, H₂ and H₃ are supported.

The relationships between the attitude towards a banner ad and banner ad brand attitude ($\beta = 0.109$, SE = 0.043, p-value = 0.002) and between attitude towards a banner ad and behavioral outcomes ($\beta = 0.154$, SE = 0.060, p-value = 0.003) are both positive and significant. Therefore, these results support H₄ and H₅. Contrary to expectation, the findings showed insignificant but positive impact of banner ad brand attitude on behavioral outcomes ($\beta = 0.226$, SE = 0.123, p-value = 0.086). H₆ is not supported.

Discussion and Conclusion

The results show that the perceived banner ad customisation is important to effect positive attitudinal and behavioral changes. The banner ad design differs in terms of either verbal or visual representations or variation of both, and is customized based on psychographic segmentation according to personality (need for cognition), goal-directed motives, level of product involvement and preferred information processing strategy to boost interactivity and enhance elaboration, persuasion and attitudinal/behavioral changes. The perceived ad customisation and ad-attitude-brand relationship were found to be significant for banner ads. These findings support the proposition made by Roehm and Haugtvedt [29] who recommended customisation of advertising messages based on consumers' personality.

This study recommends a connection between message strategy and users characteristics. The results provide evidence to support that matching the message strategy in terms of presentation modality (verbal versus visual presentation), message appeal (information-rational versus entertainment-emotional) and inclusion of interactive features (static versus dynamic animation) with users individual differences in their need for cognition, goal-directed motives and preferred information processing strategies produces positive attitudinal responses. For example, the banner ad and its respective Web sites were designed with different creative techniques so that each layout was distinctive

according to its appeal. A rational-informational appeal (information site) with persuasive argument on the product attributes was used for computer brand. While the soft drink Web site incorporated an emotional-entertainment appeal (image site) in which celebrity video clips and news were peripheral cues, the fashion apparel used a combination of both rational-informational and emotional-entertainment appeals (text and animated images) was a more persuasive than celebrity source peripheral cues presented.

The main objective of this paper is to explore and to provide evidence relevant to the debate over whether Internet advertising works well as a branding medium. This study also aims to suggest a framework to measure Internet advertising effectiveness via brand attitude change. It includes the proposition of 'customisation of a Web site design based on Web content and form in accordance to individual differences in need for cognition, goal-directed motives and information processing strategies to the functional base of an attitude (brand attitude) to increase message scrutiny, persuasion and attitude change.

Practical Implications and Future Research

The current approach for personalised ad selection is based on the demographic information, browsing and interaction history of a particular user. The research model offers advertisers and advertising agencies a new profiling and targeting parameters for automated personalised Internet advertising. The model suggests that information about user's personal differences in terms of personality traits, types of goal-directed motives and preferred information processing strategies are better-quality user information for profiling and creating automated customized and personalised ads. User information can be requested via filling out a registration form or survey. Alternatively, the ad-server (via neural network or proprietary learning methods) can analyse the user's browsing and interaction history. Cluster technique is used to classify users into need for cognition, goal-directed motives, personal relevance or preferred information processing strategy segments. Customized ads are then selected and placed to match the relevant user.

This study also offers a comprehensive model that advertisers and advertising agencies can apply when they develop an Internet advertising plan. The research model can be employed at each development stage of a plan. For example, when defining target audiences, this model offers an alternative psychographics variables such as individual differences in need for cognition and users' goal-directed motives and preference in information-processing style as segmentation variable.

This study also recommends the use of psychographic segmentation to Internet ad design. For example, message design in terms of its 'content' and 'form' are

based on need for cognition (high or low in need for cognition), types of goal-directed motives (information versus entertainment), type of involvement (high, medium or low), type of personal relevance (high, medium or low) and information processing strategies (central-route information processing versus peripheral-route information processing). Content' embraces the variations in the ad creative based on the product category and product involvement customized according to Internet users' need for cognition, goal-directed motives (information, entertainment) and information processing strategy (central-route, peripheral route) while 'form' refers to the inclusion of interactive ad features. For example, high involvement products and services require an informational ad/site with less animation features, verbal-oriented content with textual links to satisfy information needs. Low involvement products and services require an emotional-entertainment oriented ad/site with more colourful background, graphics and images, animations, interactive features (such as chat community group and/or feedback services) to create a positive impact on Internet users' attitudes toward the ad, product and brand.

This study can be considered as an initial stage of investigation rather than a complete explanation of the phenomenon under study. The model needs further replication, extension and critical evaluation using similar product category and/or unfamiliar brands.

Abstract

Facing intensive competition in the marketplace, manufacturing companies are forced to react to the growing individualization of demands. To meet this challenge, more and more companies have realized the importance of understanding the voice of customers and recognizing customer needs. Customer needs are inherently implicit and ambiguous, resulting in barriers for customers, marketers and the designers to communicate one another and cooperate throughout the product development process. This paper studies the mapping mechanism between the customer domain and the functional domain of design. An Association Rule-Based Inference System (ARIS) is presented for the recognition of customer needs.

1. Introduction

Manufacturing companies are facing the intensive competition in the marketplace. Under such a competitive environment, more and more companies shift to the customer needs. Product definition has been considered as one of the key factors in the early stage of the product design. The success or failure of the product definition directly influences the whole product development.

Based on the Axiomatic Design theory [18], the products are specified by several functional requirements (*FRs*); and for each *FR*, there are different value options (*FRVs*). The class-member relationships for variety representation theory [12] has illuminated that for each type of product alternative (class) with a specific set of *FRs* (class attributes), product variety can further result from different *FRVs* (members). The class-member relationship for variety representation is shown as Fig. 1.

Fig. 1. Class-member relationship for variety representation

Axiomatic Design theory also indicates that the design

world is composed of four distinct domains. The customer needs and product specifications are stated in *CN* domain (customer needs domain) and functional domain [18] respectively. The customer domain and the functional domain comprise the product definition phase, from the abstract customer needs to the concrete product requirement specifications [15]. Under the philosophy of “design for customers”, the product specifications (*FRs*) should be evolved from the real needs of customers (*CNs*).

There are many difficulties when translate the genuine customer needs (*CNs*) into *FRs* because *CNs* are always originated in a verbatim format and possess the non-technical nature. On the contrary, *FRs* are always expressed with the explicit technical parameters which can be easily understood by the design engineers. Traditionally, design engineers use their experience and intuition to translate imprecise customer requirements into a clearly defined design specification, but this is a less than ideal approach, as it leads to imperfect designs, which satisfy a design engineer’s interpretation of customer requirements, rather than satisfying the genuine customer requirements [1].

Data mining is a rapidly evolving area of data analysis that attempts to identify trends or unexpected pattern in large pools of data by using mathematical tools. It could help extract useful information from large database. Association rule mining is a data mining technique that discovers strong associations or correlation relationships among data without constraining the data type and is very suited to mine the mapping relationships between the customers’ needs with the linguistic expression and functional requirements specified by the technical parameters.

This paper presents an association rule-based inference system to provide the mapping mechanism between customer domain and functional domain. Section 2 describes related research work in the field of requirement management. In section 3, an association rule-based inference methodology is represented. Section 4 represents a case study and section 5 summarizes the research work in this paper.

2. Literature review

The voice of customers (*VoC*) has received amount of interest of both academicians and practitioners [8]. The

traditional method to translate the customer needs into the corresponding functional requirement is Quality Function Deployment (QFD) [3] [7] [12]. Though QFD can help improve the product quality by providing the information about the customers [16], it is a document with a list of customer needs and functional requirements rather than a mapping tool to recognize the relationship pattern between the two.

From a design perspective, Hauge and Stauffer develop a taxonomy method of product requirements as a way to organize information [7]. Though the taxonomy method does recognize the topology of the functional requirements by classifying large bodies of information, it is too general to be a domain-independent framework. Also, because the taxonomy method starts from the engineering design perspective, it can't provide the pattern information about the customer domain and the functional domain.

In recent years, several researchers have gained achievement in the field of requirement management. Fung establishes an intelligent inference model in which the customer needs, the product specifications are both expressed in Fuzzy Sets characterized by their relevant membership functions, and the relationship between them is represented in the form of Fuzzy Propositions [5]. Though Fuzzy Set Theory excels in treating the notions that can't be clearly defined, it is not good at solving the quantitative variables because the variables must be fuzzified before they enter the inference process. It is not appropriate to translate the quantitative variables into fuzzy values.

Tseng and Jiao adopt Computer-Aided Requirement Management methodology for product definition noted as PDR [19]. This method adopts functional requirement (FR) patterns from previous product designs to map FR into desired value (FR instance). The values of FR variables are characterized by the representative center vectors. Their work focus on the FR domain, but the mapping between the customer domain and functional domain is still not recognized. A mapping mechanism to recognize the relationship between the customers' needs and product functional specifications is needed to be established to help companies provide the products to meet the customers' needs.

3. Mapping mechanism between customer needs and functional requirements

3.1 Product definition

Supposing $P = \{FRV_{jz_j}\} (j = 1, 2, \dots, m; z_j = 1, 2, \dots, n_j)$ as the generic representation of a product definition, where the product definition (P) is embodied by $FRV_{jz_j} (j = 1, 2, \dots, m; z_j = 1, 2, \dots, n_j)$ and it refers to the j^{th} FR taken with the z_j^{th} value; j refers to the numbers of FRs that the product alternatives consist of; and n_j refers to the numbers of FRVs for each FR_j .

The recognition of the mapping mechanism between

CNs and FRs to help develop the product definition then is identical to the mapping recognition problem between CNs and FRVs.

This paper proposes an ARIS system to establish the mapping mechanism between CNs and FRVs. A vivid model of customers' needs recognition is shown as Fig. 2. The FRVs are clustered and then the mapping mechanism is established between the customers' needs and FRVs. The definitions of products are described by the combinations of FRVs.

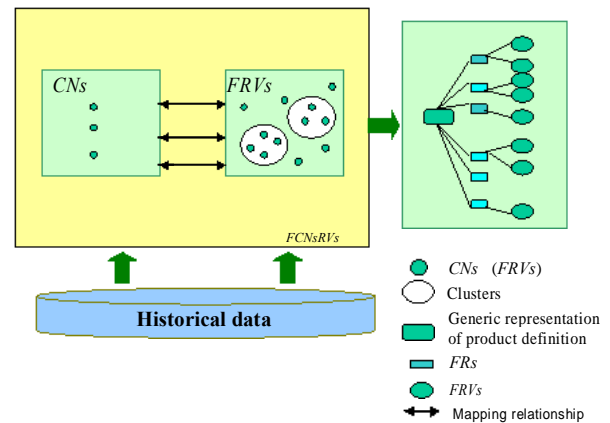

Fig.2. A vivid model of customers' needs recognition

3.2 ARIS architecture

The ARIS system consists of three parts: the user interface, the knowledge base and the inference engine. The knowledge base captures the data of CNs and FRVs. It can be partitioned into two parts:

1. $K - CN$: The knowledge about customer needs;
2. $K - FRV$: The knowledge about functional requirement values.

The architecture of ARIS is showed as Fig. 3.

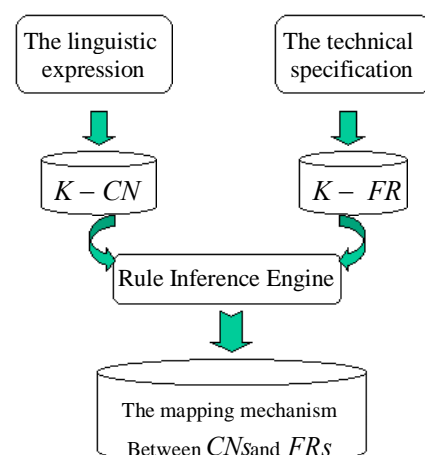

Fig. 3. Illustration of the ARIS architecture

The relational database can be established, in which CNs and FRVs are stored in two tables which are related by means of a common file. In this system, the common file

is the customer ID.

CNs are represented as $CN_{ip_i} (\forall i = 1, 2, \dots, n; p_i = 1, 2, \dots, k_i)$, which denotes the i^{th} customer's the p_i^{th} needs, where i refers to the numbers of the customers and k_i refers to the numbers of the needs of the i^{th} customer. Similarly, FRV_{ijz_j} denotes the z_j^{th} value of the j^{th} FR ($\forall j = 1, 2, \dots, m; z_j = 1, 2, \dots, n_j$), and these are what the designers design in order to meet the requirement of the i^{th} customer, where j refers to the numbers of FRs, and n_j refers to the numbers of the FRVs candidates for the j^{th} FR.

The schematic representation of ARIS can be shown as Fig. 4.

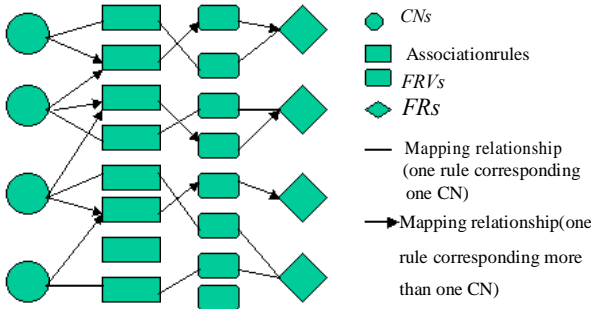

Fig. 4. The schematic representation of ARIS

3.3 Methodology

The methodology to establish the mapping pattern between CNs and FRVs by using association rules will be illustrated as following. The whole process involves two steps: data clustering and mining association rules.

3.3.1 Data clustering

Clustering is the process of grouping a set of physical or abstract objects into classes of similar objects. A cluster is a collection of data objects that are similar to one another within the same cluster and are dissimilar to the objects in other clusters. Different customers desire various FRVs. For almost all the manufacturing companies, it is impossible to meet every individual need because of the high cost. Based on the Chamberlin-Dixit-Stiglitz (CDS) Model [13], the products close together on the spectrum are better substitutes than those further apart. That is, the customers are willing to choose those products that have FRVs which are closest to their desired values if they can't find the products with their desired values are on the markets. It is wise to cluster the customers' desired values and provide the product family not only to meet the needs of customers but also reduce the cost and design time.

1. Measuring Distance

There are three types of the FRVs variables: the numerical variables, the binary variables and the nominal variables [9] [10]. The methods to measure the distances of

different types of variables are different.

1. Numerical variables distance measure

The distance measures of the numerical variables are not single. In general, the clustering methods for numerical variables include Euclidean distance, Manhattan distance, Minkowski distance and weighted Euclidean distance measure. In this paper, the weighted Euclidean distance measure is adopted:

$$d(i, v)_{\text{NUMERICAL}} = \sqrt{\sum_{j=1}^m W_j (FRV_{ijz_j} - FRV_{vjz_j})^2} \quad (1)$$

subject to

$$FRV_{ijz_j} = \frac{FRV_{ijz_j} - \min FRV_{ijz_j}}{\max FRV_{ijz_j} - \min FRV_{ijz_j}}, \quad (2)$$

where $d(i, v)_{\text{NUMERICAL}}$: the distance between customer i and customer v based on the numerical variables;

FRV_{ijz_j} : the standardized z_j^{th} value for the j^{th} FR ($\forall j = 1, 2, \dots, m; z_j = 1, 2, \dots, n_j$) held by the i^{th} customer;

W_j : the relative importance of the j^{th} FR.

Equation (2) aims at normalize the FRV variables to eliminate the effect of the unit difference.

2. Binary variables distance measure

A binary variable has only two states: 0 or 1, where 0 means that the variable is absent and 1 means that it is present. The binary variables can be grouped into two types: the symmetric and asymmetric binary variables. A binary variable is symmetric if both of its states are equally valuable and carry the same weight. The most well-known coefficient for assessing the distance measure of symmetric binary variables is the simple matching coefficient. A binary variable is asymmetric if the outcomes of the states are not equally important. For the distance measure of the asymmetric binary variables, the most well-known coefficient is the Jaccard coefficient. In this research, the binary variables in FRVs are treated as symmetric variables and thus a simple matching coefficient is adopted:

$$d(i, v)_{\text{BINARY}} = (r + s) / (q + r + s + t) \quad (3)$$

where $d(i, v)_{\text{BINARY}}$: the distance between customer i and customer v based on the binary variables;

q : the total numbers of binary variables that equal to 1 for both customer i and v ;

r : the numbers of variables that equal to 1 for customer i but equal to 0 for customer v ;

s : the numbers of variables that equal to 0 for customer i but equal to 1 for customer v ; and

t : the numbers of variables that equal to 0 for both customer i and v .

3. Nominal variable distance measure

A nominal variable is a generalization of the binary variables in that it can take on more than two states. A discrete ordinal variable resembles a nominal variable, except that the states of the ordinal value are ordered in a meaning sequence. In this paper, the ordering sequence doesn't exist, so the simple matching approach is employed to measure the distance of the nominal

variables:

$$d(i, v)_{NOMINAL} = (p - m) / p \quad (4)$$

where $d(i, v)_{NOMINAL}$: the distance between customer i and customer v based on the nominal variables;

m : the numbers of variables for customer i and v that are in the same state; and

p : the total numbers of variables.

2. Fuzzy Clustering Analysis

② Forming a fuzzy similar matrix

$$z(i, v) = \{d(i, v) - \min d(i, v)\} / \{\max d(i, v) - \min d(i, v)\} \quad (5)$$

$$d(i, v)' = W_{NUMERICAL} z(i, v)_{NUMERICAL} + W_{BINARY} z(i, v)_{BINARY} + W_{NOMINAL} z(i, v)_{NOMINAL} \quad (6)$$

$$R = [r(i, v)]_{n \times n} \quad (i, v = 1, 2, \dots, n) \quad (7)$$

$$r(i, v) = 1 - d(i, v)' \quad (8)$$

where $R = [r(i, v)]_{n \times n} (i, v = 1, 2, \dots, n)$: the similarity matrix;

$r(i, v)$: the degree of similarity between customer i and customer v ;

$W_{NUMERICAL}$: the relative importance of the numerical values;

W_{BINARY} : the relative importance of the binary values;

$W_{NOMINAL}$: the relative importance of the nominal values; and

$d(i, v)'$: the dissimilarity between customer i and customer v based on all the types of variables.

Equation (5) is used to normalize the FRV variables because the values in the similarity matrix are within the interval 0 and 1 and it is applicable to each type of $FRVs$. Equation (6) calculates the distance between customer i and customer v with the consideration of all types of $FRVs$.

③ Getting the fuzzy equivalent matrix

Equivalent matrix has the following characteristics:

- Reflexive: $r_{ii} = 1 (i, v = 1, 2, \dots, n)$;
- Symmetrical: $r_{iv} = r_{vi} (i, v = 1, 2, \dots, n)$; and
- Transitive: $R \circ R = R$

The similarity matrix generally meets the first two requests. To meet the third, convert it into an equivalent matrix by using the “continuous multiplication” method.

Multiplication in fuzzy relations is also known as the maxmin composition. Let $R(i, v), (i, v) I * V$ and $R(i, v), (i, v) I * V$ be two fuzzy relations, then $R \circ R = \{[(i, v), \max\{\min_k (i, v)_k, (i, v)\}]/i, I, V\}$ is also a fuzzy relation where r_R is an element in a fuzzy relation.

④ Choosing a threshold and perform clustering

After the equivalent matrix has been obtained, a threshold is chosen noted as l_n above which the $r(i, v)$ values validate that the customer i and customer v hold the similarity and can be classified into the same cluster. Based on the equivalent matrix, given different thresholds, different clustering results can be obtained. The clustering graph is shown as Fig. 5.

Denoting l as the l^{th} cluster ($l = 1, 2, \dots, s$) where $l[(i, v) \setminus i, v, (r_{iv} > l_n)] (i, v = 1, 2, \dots, n)$, then we have:

$$FRV_{jl} = \sum_i FRV_{ijl} / N_l \quad (9)$$

where N_l : the customers' numbers that fall into l ; and

FRV_{ijl} : the FRV for the j^{th} FR that falls into the l^{th} cluster desired by customer i .

Equation (9) calculates the average values of j^{th} FR desired by those customers falling into the same cluster. And FRV_{ijl} are then stored into the database [2].

j^{th} item in l_i where l_i refers to the i^{th} member in A_{k-1} , then members l_1 and l_2 of A_{k-1} are joined if
 $(l_1[1] = l_2[2]) \wedge (l_1[2] = l_2[2]) \wedge \dots \wedge (l_1[k-2] = l_2[k-2])$
 $= l_2[k-2]) \wedge (l_1[k-1] \neq l_2[k-1])$

In the first iteration, each item is a member of the set of candidate 1-itemsets, C_1 . Then the frequent itemset A_1 can be determined by scanning all the C_1 and selecting those items that reach the min_sup. The second candidate C_2 then is evolved by joining A_1 with A_1 and thus A_2 is determined by scanning all the C_2 and selecting those items that reach the min_sup. The iteration terminates until $C_{k+1} = \Phi$ and A_k is determined.

3. Generating Association Rules from Frequent Itemsets

Once the frequent itemsets from the database have been found, it is straightforward to generate strong association rules from them [14] [20].

7 The format of association rule

Association rules are displayed by using the following format:

$CN_{ip_i} \rightarrow FRV_{jl}$ [Coverage=value; Support=value; Strength=value; Lift=value; Leverage=value]

The left-hand-side of this rule - CN_{ip_i} is presented before the \rightarrow arrow. The right-hand-side- FRV_{jl} follows the arrow and precedes the opening bracket. It indicates that item CN_{ip_i} associates with item FRV_{jl} . That is, if item CN_{ip_i} exists, item FRV_{jl} also occurs.

7 Criteria

Only when the criteria have been met, it validates there are strong associations between the items. There are five criteria are needed to be met during the association rule inference process. They are shown as the following.

1. Coverage

Coverage is the proportion of transactions covered by CN_{ip_i} :

$$\text{Coverage} = P(CN_{ip_i}) \quad (10)$$

2. Support

Support is the proportion of transactions covered by both the CN_{ip_i} and the FRV_{jl} :

$$\text{Support} = P(CN_{ip_i} \cap FRV_{jl}) \quad (11)$$

3. Strength

Strength is the proportion of transactions covered by the CN_{ip_i} that are also covered by the FRV_{jl} :

$$\text{Strength} = P(FRV_{jl} / CN_{ip_i}) \quad (12)$$

4. Lift

Lift is the strength divided by the proportion of all transactions that are covered by the FRV_{jl} . Lift provides an indication of how much more likely is the right hand given the left hand than normal:

$$\text{Lift} = P(FRV_{jl}) \setminus P(FRV_{jl} / CN_{ip_i}) \quad (13)$$

5. Leverage

Leverage is the proportion of additional transactions

covered by both the CN_{ip_i} and FRV_{jl} above those expected if the CN_{ip_i} and FRV_{jl} were independent of each other:

$$\text{Leverage} = P(FRV_{jl} \cap CN_{ip_i}) - P(FRV_{jl}) \times P(CN_{ip_i}) \quad (14)$$

4. Case study

4.1 Background

So far, the ARIS system representation, the mathematical formulation and the algorithm have been discussed. This section presents one case that is greatly related to the above aspects to present the application of the proposed methodology. The case adopts the high variety product – the vibrating motor used as the absolutely necessary accessory of mobilephones - as an example. This is because (1) The motor products are not complex for the customers and it is easy to understand the customers' requirements for the motor products expressed in nature language; and (2) The motor products are standardized customization products which can reflect the customers' different individual needs so as to reveal the nature of ARIS system.

Since different customers have their own requirements for the mobilephone products, the motor products matched with these different mobilephones are typical customized products under mass customization. The difference in motor product design requirements results in the products characterized by a number of variations including the customers' requirements which expressed in their nature language and the functional requirement values.

Fig.6. Illustration of a motor product

The motor product is a collection of nine FRs . These nine FRs are current, pbfree, length, diameter, coating, angle, strength, weight and hardness respectively. The illustration of the real motor product is shown in Fig. 6. The description of FR_j is shown in Tab. 2.

Tab.2. Description of FR_j

FR_j	Description
FR_1	Current
FR_2	Pbfree
FR_3	Length
FR_4	Diameter
FR_5	Coating
FR_6	Angle
FR_7	Strength
FR_8	Weight
FR_9	Hardness

Tab. 3(a) Description of FRVijz_j

FR_j	FR_j Description	FRV_{ijz_j} (Encoded with jz_j)	FRV_{ijz_j} Description
FR_1	Current	11	100
		12	80
		13	60
FR_2	Pbfree	21	Y
		22	N
FR_3	Length	31	8
		32	12
		33	10
FR_4	Diameter	41	5

Tab. 3(b) Description of CNs

CN No.	CN Description
1	Feel the vibration very strongly
2	Alarmed by the vibration without vibrating suddenly
3	Sensitive to the vibration
4	Buy the expensive mobilphone to use for a long time
5	Change the style of the mobilephone occasionally at a lower price
6	Try other style of mobilephones every now and then with a moderate price
7	Portable
8	Comfortable to hold
9	Not easy to lose
10	Little noise
11	Alarmed when can't depend on vibration
12	Alarmed by both vibration and sound
13	Green environment
14	Light

4.2 Applying ARIS for the mapping mechanism

4.2.1 The data list about CN and FRV

It has been mentioned above that the motor product is a collection of nine FRs . Among these FRs , FR -pbfree is of binary type, FR -coating is of nominal type and the remaining seven FRs are of numerical types. There are 30 customers' needs derived from the company's database.

It is not surprising that there are different requirements for each FR . The historical data are composed of both customers' requirements expressed in their language and the corresponding FR values (FRV_{ijz_j}) which meet their requirements. The requirements and values bound with each customer differ from each other and are stored in the database identified by an identifier – the customer No. The description of the customer requirements (CN) and FRV are partly shown as Tab. 3.

4.2.2 Weight determination

Analytical Hierarchy Process (AHP) is used to calculate the relative importance of each FR . The pairwise

comparison scale is shown as Tab. 4. The weights (W_j) for FRs are shown as Tab. 5.

Tab. 4 The scale for pairwise comparison

Verbal judgement of preference	Numerical rating
Extremely preferred	1
Very strong to extremely	2
Very strongly preferred	3
Strongly to very strongly	4
Strongly preferred	5
Moderately to strongly	6
Moderately preferred	7
Equally to moderately	8
Equally preferred	9

FR_j	W_j
Current	0.219
Pbfree	0.304
Length	0.046
Diameter	0.031
Coating	0.019
Angle	0.066
Strength	0.157
Weight	0.095
Hardness	0.083

4.2.3 Customer clustering

1. Distance Measurement

② The numerical FRs distance measurement

There are seven numerical FRs including current, length, diameter, angle, strength, weight and hardness. The first three FRs have three levels of $FRVs$, the last four FRs have two levels of $FRVs$. That is:

$$FR_1 = \{FRV_{11}, FRV_{12}, FRV_{13}\},$$

$$FR_2 = \{FRV_{21}, FRV_{22}, FRV_{23}\},$$

...

$$FR_7 = \{FRV_{71}, FRV_{72}\}.$$

The weighted Eluclidean distance measure is adopted. The original data are input into SPSS software to be processed during which the original data are normalized automatically by computer and then the results are calculated.

The distance between customer i and customer v , i.e., $d(i, v)_{NUMERICAL}$, ($\forall i, v = 1, 2, \dots, 30$), is presented as a 30×30 matrix whose elements represent the distance between two customers measured based on numerical variables. The result is shown as Tab. 6.

② The binary FRs distance measure

There is only one binary FR namely pbfree function. It has only two states: 0 or 1, where 0 means that pbfree function is required and 1 means that it is not required. The simple matching coefficient is adopted. The distance

between customer i and customer v , $d(i,v)_{BINARY}, (\forall i,v = 1,2,...30)$, is presented as a 30×30 matrix and the result is shown as Tab. 7.

7 The nominal FRs distance measure

There is only one nominal FR namely coating. It has three states: Au, Alloy and None. The simple matching approach is adopted to measure the distance of the nominal variables. The distance between customer i and customer v , $d(i,v)_{NOMINAL}, (\forall i,v = 1,2,...30)$, is presented as a 30×30 matrix and the result is shown as Tab. 8.

2. Fuzzy Clustering

The similarity matrix is represented as R . The elements in R represent the similarity between every two customers. The result of R is shown as Tab. 9 and the equivalent matrix R^2 is shown as Tab. 10.

Because R^2 doesn't equal to R , the R^2 is not fuzzy equivalent matrix. The algorithm is required to iterate again. The result of R^4 is shown as Tab. 11.

As $R^4 = R$, R^4 is fuzzy equivalent matrix. Setting the threshold l_n as 0.84, the clustering graph is derived. It is shown as Fig. 7. Based on the clustering graph, the customers are clustered into three clusters. That is:

$$l_1 = \{1,2,7,8,11,12,14,15,24,29\},$$

$$l_2 = \{3,4,5,9,10,13,17,19,20,23,26,30\},$$

$$l_3 = \{6,16,18,21,22,25,27,28\}$$

Then the $FRV_{\mu}(j = 1,2,...9; l = 1,2,3)$ are shown in Tab. 12.

4.2.4 Mapping mechanism between CN and FRV

Since the customer requirements CN_{ip_i} and FRV_{jl} ($j = 1,2,...,9; l = 1,2,3$) have been obtained as above, the data list about the CN_{ip_i} and the corresponding FRV_{jl}^i are shown as Tab. 13.

CN_{ip_i} and FRV_{jl}^i are input as identifier-item file which is a text file that lists customers' information which is to be analyzed in identifier-item format.

Each customer has a unique identifier within which are at least two columns, one for the identifier and one for the items.

Tab. 13 The data list of CN_{ip_i} and FRV_{jl}^i

Customer ID	CN_{ip_i} (Represented by CN No)	FRV_{jl}^i (Encoded as jl ⁽ⁱ⁾)
001	1,4,7,8,12,13,14	21 ⁽¹⁾ ,11 ⁽¹⁾ ,31 ⁽¹⁾ ,71 ⁽¹⁾ ,93 ⁽¹⁾ ,63 ⁽¹⁾ ...
002	1,4,7,8,9,12,13	21 ⁽²⁾ ,11 ⁽²⁾ ,31 ⁽²⁾ ,41 ⁽²⁾ ,71 ⁽²⁾ ,51 ⁽²⁾ ...
003	2,5,9,11,13	21 ⁽³⁾ ,12 ⁽³⁾ ,33 ⁽³⁾ ,43 ⁽³⁾ ,73 ⁽³⁾ ,52 ⁽³⁾ ...
.	.	.
.	.	.
.	.	.
028	3,5,9,10,13	21 ⁽²⁸⁾ ,13 ⁽²⁸⁾ ,32 ⁽²⁸⁾ ,42 ⁽²⁸⁾ ,72 ⁽²⁸⁾ ...
029	1,4,7,12,13,14	11 ⁽²⁹⁾ ,31 ⁽²⁹⁾ ,41 ⁽²⁹⁾ ,71 ⁽²⁹⁾ ,51 ⁽²⁹⁾ ...
030	2,5,9,11,13	12 ⁽³⁰⁾ ,21 ⁽³⁰⁾ ,32 ⁽³⁰⁾ ,43 ⁽³⁰⁾ ,52 ⁽³⁰⁾ ...

In this case, the search mode is set as searching for strength, that is, the association rules are generated according to the strength value as a descendent order. The maximum number of association is set to 10000 so that the association rules can be derived completely. The minimum leverage, minimum lift, minimum strength, minimum coverage and minimum support are set as 0.001, 1.0, 0.1, 0.2 and 0.2 respectively. There are 37 rules generated. The results for the associations between CN_{ip_i} and FRV_{jl} ($j = 1,2,...,9; l = 1,2,3$) are partly shown as Tab. 14 (For illustrative simplicity, only 7 rules are listed in the Table).

Tab. 14 Association rules between CN_{ip_i} and FRV_{jl}

Rule 1: green environment\par -> pf_y\par [Coverage=0.882 ; Support=0.882 ; Strength=1.000; Lift=1.13; Leverage=0.1038]
Rule 2: alarmed when can't depend on vibration\par & not easy to lose\par & change the style of the mobilephone occasionally at a lower price\par -> h_57.5\par [Coverage=0.294 ; Support=0.265 ; Strength=0.900; Lift=2.55; Leverage=0.1609]
Rule 3: alarmed when can't depend on vibration\par & change the style of the mobilephone occasionally at a lower price\par & not easy to lose\par -> c_78.3\par [Coverage=0.294 ; Support=0.265 ; Strength=0.900; Lift=2.55; Leverage=0.1609]
Rule 4: alarmed when can't depend on vibration\par & change the style of the mobilephone occasionally at a lower price\par -> l_11.17\par [Coverage=0.294 ; Support=0.265 ; Strength=0.900; Lift=2.55; Leverage=0.1609]
Rule 5: alarmed when can't depend on vibration\par -> h_57.5 [Coverage=0.353 ; Support=0.294 ; Strength=0.833; Lift=2.36; Leverage=0.1696]
Rule 6: not easy to lose\par & alarmed when can't depend on vibration\par -> a_47\par [Coverage=0.294 ; Support=0.265 ; Strength=0.900; Lift=2.55; Leverage=0.1609]
Rule 7: not easy to lose\par & comfortable to hold & change the style of the mobilephone occasionally at a lower price\par -> w_2.42\par [Coverage=0.353 ; Support=0.265 ; Strength=0.750; Lift=1.96; Leverage=0.1298]

5. Summary

This paper proposes the ARIS system to facilitate communications between customers, marketers and designers. In evolutionary design, the historical data about the customers' needs and the functional specifications can be used to mine valuable information. The ARIS system can improve design efficiency and quality by providing the clear mapping mechanism between the customers' requirements and product specifications and enabling the design of products based on customers' needs. It also establishes a coherent framework for cooperation among marketers, designers and customers.

Abstract

Intensifying global competitions and rapid advancement of technology have promoted the needs for companies to work collaboratively with their supply chain partners in the form of a virtual enterprise, giving rise to virtual supply chain. However, given the concept was originated from the West, how to promote the application of virtual supply management concept in Asia has become an important issue to be addressed. As Hong Kong and China are leading logistics centers in the world, it is critical to identify their current situations regarding virtual supply chain management and to identify the best ways to direct companies in this region to embrace the highly collaborative Virtual Enterprise. This paper describes the different forms of enterprise collaborations and presents the result of a preliminary study on the current status of supply chain management in Hong Kong and Mainland China.

1. Introduction

Today's business environment is becoming more competitive than ever before and the global competition occurs increasingly between networks of firms [Thoreli, 1986]. Many visionary companies have been increasingly concerned with managing the business processes and activities within and between companies [Hoffner, Field, Grefen & Ludwig 2001] in order to achieve superior supply chain performance. The advancement in information and communication technology further slashes the coordination costs and enables different organizations to build up partnerships where separate firms specialize, and activities are coordinated by decentralized information systems [Strader, Lin & Shaw, 1998]. The mainstream adoption of technologies has blurred the boundaries between business organizations and it gives rise to the virtual enterprise.

Virtual Enterprise (VE) is a single business entity of globally distributed independent enterprises that participate in the different phases of the life cycle of the product or service, and work to share resources, skills, and costs, supported by Information and Communication Technologies (ICT), in order to enhance its customer value proposition and timely create and exploit complex market opportunities [Bernus and Nemes, 1999][V-Chain Project D2.2.]. The term Virtual Enterprise was originated

from a US Congress Report in 1989 on the competitiveness of the US manufacturing sector in this Century [V-Chain Project D2.2]. Strader et al. (1998) claimed virtual organizations could enjoy the agility and speed of small companies and resources of large company, in addition to better adaptation to globalization and better focus of core competence.

Though many enterprises in US and Europe have taken the lead to transform themselves into an integrative enterprise, the success of creating a single enterprise still relies on the harmonious and synergistic integration of all its capitals [Hawa 2002]. Given Hong Kong and China have dominant positions in regional logistics and manufacturing activities and their management cultures are believed to be substantially different from those in the West, it is essential to investigate the current status of supply chain management and to explore how companies in this region can migrate from existing loosely organization to highly collaborative Virtual Enterprise.

2. Collaboration in a Virtual Supply Chain

Being a virtual enterprise, all participating members in the virtual supply chain environment seek to use technology and management collaboratively in order to enhance business operations in relative to speed, agility, real-time control, and customer response [Manthou, Vlachopoulou, & Folinas 2003].

Collaboration can be viewed as the cornerstone of the success in creating a virtual enterprise and it involves two key elements: information sharing and commitment. Moving from traditional supply chains to a collaborative virtual chain networks requires the seamless flow of information amongst supply chain partners, resulting in high degree of information symmetry. Because information is power, information sharing within the supply chain promotes the shift of the power structure to high degree of interdependence. Besides, all participating organizations in the virtual supply chain environment are required to share the capitals with each other, giving rise to higher state of commitment.

3. Different Forms of Enterprises

Organizations can be categorized into different forms in the migration journey toward virtual enterprise. Higher

forms of enterprise collaboration start from Extended Enterprises (EE). Extended enterprises span organizational boundaries and possess complicated relationships between a company, its partners, customers, suppliers and market [Browne et al., 1994] [Caskey, 1995]. It is a view of an organization that takes into account of partnership and can be depicted as a globalization of exchanges, subcontracting and partnership [Martinez, 2001]. Member in the extended enterprise is required to co-ordinate its internal systems (intra-organizational activities) with other systems in the supply chain and further needs to be flexible and ready for adapting to changes [Martinez, 2001].

Extended Enterprise (EE) is better characterized as one that embodies varying network of a “dominant” company and its supporting companies (or any type of actors). Meanwhile, a virtual enterprise (VE) is a higher form of extended enterprises that has embraced the notion of inter-enterprise flow in order to sustain the agile and dynamic relationships. Both EE and VE are usually defined as virtual organizations, in contrast to those traditional organizations (called “non-EE”).

4. From Extended to Virtual Enterprise

The obvious challenge to many existing extended enterprises is how to make the successful transition from extended (EE) to virtual enterprise (VE) provided that virtual enterprise is an emergent concept with varying characteristics. According to the Report: From Extended Enterprise to Virtual Enterprise Report [V-Chain Project D2.3], migrations from the extended enterprise to virtual

enterprise will go through five stages: acknowledgement, communication, visibility, synchronization and collaboration. In migrating from EE to VE, companies need to make improve along two dimensions: Information and Communication Technology (ICT) dimension and Business Dimension. These ideas are brought together in

the migration model shown in Fig 1.

Acknowledgment can be considered the fundamental of all transformation. In order for the company to make the migration, the company must believe that VE is the future direction and acknowledge the need for moving towards the VE. This is the first stage of the transformation. This first stage needs the changes in the thinking of management and thus the improvement is mainly along the business dimension. The second stage of the transformation is labeled as **communication**. To reach this stage, the company needs to build the capability to share information and communicate with other trading partners within the supply chain. Therefore, companies mainly need to make improvement along the ICT dimension. Through this stage, companies in the supply chain are transformed from “**the knowledge islands**” to the “**the knowledge highways**”. The third stage of the transformation is called **visibility**, companies need to build trust and decide to share important information with their trading partners. The improvement needed to reach this stage is mainly along the business dimension. Through this stage, companies are transformed from “**the opaque company**” to “**the transparent company**”. The next stage of the transformation is referred to **synchronization**. Through this stage, companies within the supply chain will use the shared information to synchronize different activities through coordination and thus be able to achieve additional cost savings while enhancing service level and improving speed. A good analogy for this transformation is the change from “**the track of a discotheque**” to “**the choreography of a ballet**”. The last stage of the transformation is labelled as **collaboration**. Through this stage of transformation, the relationships between the companies within the supply chain are changed from “**the Win - Lose relationship**” to “**the Win - Win relationship**”. At this stage, companies are collaborating closely to utilize their combined capitals to explore market opportunities and provide better values to the customers. They formulate strategies jointly and share the risks and rewards with the objectives of maximizing the returns for all partners. The combined entity work like a single enterprise and finally the migration to virtual enterprise is completed.

5. Current Status of Supply Chain Management in HK & Mainland China

A field research in manufacturing companies in Pearl River Region (HK and Southern China) was conducted in Spring and Summer, 2003 to investigate the supply chain collaboration and virtual migration in this region. Manufacturing sector is appropriate for this study because based on literature reviews, manufacturing industries are keen to use SCM technology to enhance its business operations. Pearl River Region is a conducive environment where it has over 480,000 factories and 50,000 workers. Most Hong Kong manufacturing firms have moved to Southern China since 1980s. The region

contributes 40% of export values annually to China.

The field research began in Spring 2003. Data were collected through face-to-face interview and a total of 10 Hong Kong companies and 3 Chinese companies were successfully interviewed. Based on the analysis, three categories were identified – they are advanced EE (highly integrated), basic EE (partially integrated) and non-EE (non-integrated). These categories was shown in Fig 2.

Supply Chain Structure – Sharing information & Integrating Process				
	With Customer		With Supplier	
	Information Sharing	Processes Integrated	Information Sharing	Processes Integrated
Category 1	<ul style="list-style-type: none"> Supply Plan, Resultant Inventory, 18 - 24 mth sales plan, cross enterprise mater planning, EDI documents, demand forecast. 	<ul style="list-style-type: none"> VMI program, allow assessment on master sales order status inventory, integrated ordering system 	<ul style="list-style-type: none"> Future ordering plan Plan, Forecast, Production Schedule, purchase order information 	<ul style="list-style-type: none"> VMI program, out standing order status on-hand inventory status, invoice settlement, intranet shared with supplier
Category 2	<ul style="list-style-type: none"> Inventory Demand forecast 	<ul style="list-style-type: none"> Receive Purchase order through system, 	<ul style="list-style-type: none"> Demand forecast 	Upload information for material planning
Category 3	<ul style="list-style-type: none"> Shipment information Monthly Outstanding order 	<ul style="list-style-type: none"> Nil 	<ul style="list-style-type: none"> Demand forecast 	Nil

Figure 2. Key Result of the Survey

Our findings showed that most responding companies in category 1 are Multinational Corporations (MNCs). Hong Kong and Chinese owned manufacturers tend to belong to category 2 while companies at category 3 are mainly Chinese-based. Since MNCs have more resources and are more receptive to the ideas of information sharing and coordination due to the influence of their parents, these companies have higher level of information sharing and coordination with their suppliers and customers and they are closer to the VE. Meanwhile, Chinese companies are less receptive to information sharing and coordination and this they have lower degree of information sharing and coordination in the supply chain. Because the central theme of virtual supply chain is collaboration, it is therefore recommended the Hong Kong and Chinese managers to focus on developing trust and building relationships with their partners so that they can share more information with each other. With the shared information, they can also coordinate many activities with each other. These types of information sharing and coordination activities are fundamental requirements for moving towards the VE. Furthermore, companies also need to enhance their information systems so that they can link up with their suppliers and customers. The IT

infrastructure is also an essential for moving to the VE state.

6. Conclusions

The results of our preliminary study has shown that most companies in Hong Kong and Mainland China have not adopted the concept of virtual enterprise management. Migration from the current status to the Virtual Enterprise is a long journey for these companies. Companies need to carefully plan out the steps that they will have to take to migrate to the VE state. Though this subject has drawn enough attention from both academicians and industry players, virtual enterprise should not be considered as cure-for-all. Managers with the vision to embrace the adoption of virtual enterprises may follow the suggested path to migrate from the current state to the VE state. However, some companies may choose not to go through this path and decide to enhance the performance of their supply chain through other means.

Abstract

This paper describes a model of intelligent supply network that improves efficiency within the supply chain. We argue that intelligence creates efficiency and results in chain optimisation. In particular, intelligent agents technology is used to optimise performance of a beverage logistics network. Optimisation agents can help solve specific problems of supply network: reduce inventories and lessen bullwhip effect, improve communication, and enable chain coordination without adverse risk sharing. We model the beer supply network to demonstrate that products can acquire intelligence to direct themselves throughout the distribution network. Further, they gain a capability to be purchased and sold while in transit. Overviews of the supporting technologies that make intelligent supply network a reality are fully discussed. In particular, optimisation agents have the characteristics of autonomous action, being proactive, reactive, and able to communicate. We demonstrate that agents enhance the flexibility, information visibility, and efficiency of the supply chain management. Suggestions and recommendations for further research are provided.

1. Introduction

This paper presents the design of a new intelligent software system that integrates information systems developed for relationships between enterprises and the final consumer (Business to Consumer or B2C) and between suppliers (Business to Business or B2B). The proposed theoretical model uses Agent Technology and will assist both the producing firm and the customer to look automatically for an increase in the data exchange rate.

Agent technology has successfully been used in the past for in managing business processes, as described in ADEPT (Advanced Decision Environment for Process Tasks) from Jennings [10]. Based on the functionality of decision making from the company managers, the business process involves a combination of judgement and information from marketing, sales, research, development, and manufacturing and finance departments. Ideally all relevant information should be brought together before judgement is exercised. The ADEPT solves problems related to this process by

viewing it as a community of negotiating, service-providing agents. Each agent represents a distinct role or department and is capable of providing one or more services.

Within this paper the term 'agent' corresponds to the software problem-solving entities, which are situated in a particular environment, with specified functions, in order to process the inputs received related to the problem domain. The agents have the ability to control their internal state and their behaviour, to exhibit flexible problem-solving techniques in pursuit of their design objectives. The intelligent agent software system is designed to fulfil the specific purpose of analysing the information about the customers that is available currently at the retailers' databases.

Usually each software agent is a different specialist, able to accomplish certain tasks, thus providing co-operative members in a society. In this work, the scenario of knowledge co-operation on our study based on [10] will illustrate how certain components (i.e. supply agents) can be monitored from a multi-agent software system, by using intelligent specialized software agents, which will simulate the procedure of data analysis to extract useful information for the relationships between commercial partners [19]. The key aspects of this work, based on the previous research in the field [4], are:

- The identification of possible market relationships has been mapped to a 'communication' problem where different kinds of agents seek to exchange messages to satisfy and interpret data on an on-line basis.
- The agents are autonomous entities and they either work on their own or co-operate with others.
- Every aspect of the scheduling process (from initial data acquisition to the relationships' interpretation) must be available to the user, in order to understand the internal process of the software.

This study illustrates how agent technology can be used to solve real supply chain inefficiencies and optimise the logistics network. For instance, we explain how companies can use agent technology to collect data from retailers, group them into meaningful categories, and then perform different functions. As a result, the distribution chain can be managed more efficiently. Intelligent agents also make available timely data to inventory management resulting in reducing stocks and

tied capital. Intelligent agents are adoptive to changes so they are valuable in a dynamic environment where new products or partners have entered into the supply network. This flexibility gives agent technology a relative advantage which, for pioneer companies, can be a competitive advantage. The study concludes with recommendations and directions for further research.

The following sections of this paper describe intelligent agent technology, and discuss the need to re-engineer the supply network in association of technical needs and the solution of the agent-based information system is analysed. chain optimisation & re-engineering. A multi-agent architecture is described at a subsequent section and the paper concludes with recommendations and directions for future research.

2. Intelligent Agent Technology

“An intelligent agent is an encapsulated computer system that is situated in some environment, and that is capable of flexible and autonomous action in that environment in order to meet its design objectives” [22]. Agent technology has successfully been used in the past for in managing business processes, as described in ADEPT (Advanced Decision Environment for Process Tasks) [10]. Based on the functionality of decision making from the company managers, the business process involves a combination of judgment and information from marketing, sales, research, development, and manufacturing and finance departments. Ideally all relevant information should be brought together before judgment is exercised. The ADEPT solves problems related to this process by viewing it as a community of negotiating, service-providing agents. Each agent represents a distinct role or department and is capable of providing one or more services.

Within this paper the term 'agent' corresponds to the software problem-solving entities, which are situated in a particular environment, with specified functions, in order to process the inputs received related to the problem domain. The agents have the ability to control their internal state and their behaviour, to exhibit flexible problem-solving techniques in pursuit of their design objectives. The intelligent agent software system is designed to fulfil the specific purpose of analysing the information about the customers that is available currently at the retailers' databases.

In a more general way as in [22], the term 'agent' can be used, as a software-based computer system, which has the properties:

- **Autonomy:** It means simply that an agent is a computer system, which is situated in some environment, and it is able to act without the intervention of humans (or other agents), and should have control over its own actions and internal state and have some kind of control over their actions and internal state.

- **Social ability:** Agents can interact with other agents (or humans) via agent communication language (ACL).
- **Reactivity:** agents perceive their environment and respond in a timely fashion to changes that occur in it.
- **Pro-activeness:** Agents do not simply act in their environment, but they can also take initiatives. The application domain of applying agent technology is crucial as we always have to balance between risk and trust when working with software-based systems.

Usually each software agent is a different specialist, able to accomplish certain tasks, thus providing co-operative members in a society. In this work, the scenario of knowledge co-operation will illustrate how certain components (i.e. chain requirements) can be monitored from a multi-agent software system, by using intelligent specialised software agents, which will simulate the procedure of data analysis to extract useful information for the logistics network and send the appropriate messages to each level as described in the next section.

The general architecture of each individual intelligent software agent, as shown in Figure 1 includes the body, head and the communication abilities (grey box). The body contains all the centralised processes, tasks given to each agent to accomplish which can be different, depending on their role. The head includes the information provided either from the user or the other software agents and the grey box includes all the functions required in order for the agents to be able to communicate and as a result co-operate with other members of the agent society. This successful combination of several autonomous intelligent agents working together is called multi-agent systems.

Figure 1: Intelligent Agents

3. Chain Optimisation via Intelligent Agents Technology

A large array of software applications for planning and optimizing performance of supply chain is currently on market. These applications include Materials Requirement Planning (MRP), Manufacturing Resources Planning (MRPII), Enterprise Resource Planning (ERP), and Advanced Planning and Scheduling (APS). Most of these applications are focused internally within an enterprise. Inter-organisational communication is usually effected by mail, phone, fax, email, or electronic data interchange (EDI). However, EDI systems are expensive for small and medium enterprises. As a result, information flow in supply chain is normally pipelined sequentially, paused to each chain echelon, while human intervention imposes costs, delays, and errors.

The advent of the Internet has led to the emergence of new business models. Companies can now collaborate closely with all partners in the supply network. Collaboration can take place in different levels: share forecasts, manage inventories, schedule labour, or optimize deliveries. Software for Business Process Optimization (BPO) and Collaborative Planning, Forecasting and Replenishment (CPFR), is correspondingly evolving to optimise end-to-end supply networks.

Agents technology has been usefully used in automated electronic third party mediation (or brokering) mechanisms in various commerce transactions and marketplaces [18]. Agent brokers can be a non-obstructive, external dimension of existing buyer-seller relations and may only serve as a go-between and gatherer of pricing information, other service provider. Neubert et al. propose an intelligent negotiation agent, capable to assist human decision-maker supply contract negotiations, thus resolving conflict through the harmonisation of individual interests [14]. Vulkan and Jennings found that autonomous, automated agents give promising results in auction negotiations of the supply of services within the context of a BT British Telecom project [21].

Nissen explored the application of agents technology in supply chain integration of a medium-sized US government facility and found that it may have better results than web-based supply chain technologies [15]. Kimbrough et al. simulated the Beer Game having artificial agents instead of human to manage an electronic supply chain [11]. They found that agents were able to track demand, eliminate the Bullwhip effect, discover the optimal policies (where they are known), find optimal policies under complex scenarios, and add adoptability of the supply chain to business environment fluctuations. Gerber et al. presented an agent-based information and trading network (ITN) for dynamic production and sales of timber and found that simulated trading mechanism as well as matrix auction mechanisms were especially suitable for supply web co-ordination and optimization tasks [8].

4. Re-engineering supply chain using intelligent agents' technology

The main concepts of this work appear to be similar with the main concepts of the multi-agent-based technology introduced by Ferber [5]. The key aspects of this, based on the previous discussions concerning the nature of the problem are:

- The identification of certain relationships within an electronic marketplace has been mapped to a 'communication' problem where different kinds of agents seek to exchange messages to satisfy and interpret data on an on-line basis.
- The agents are autonomous entities and they either work on their own or co-operate with others under certain conditions and based on certain relationships.

The philosophy of this work is based on a dynamic multi-agent software system, which employs communication skills, with decision-making functions for data interpretation in supply chain management. The information environment within any large organisation is extremely complex. Describing who holds what information, how it is used and from where, how it can be better interpreted to derive meaningful conclusions, are very complex tasks but their importance has been accepted from all the companies in the market. Systems that can help aid the process of data interpretation and recognition of the types of information within a retailer and its value in relation to the supply chain management are therefore extremely important. In order to explore the importance of the multi-agent system development, a theoretical framework is being proposed. Specialised software agents will be able to automatically process the data and give information about the different levels of the supply network, based on certain attributes (i.e. cost, quality, safety, trace-ability, competitive advantage etc.). These will be the results from identification of the main characteristics of a well-managed process:

- Defined ownership
- Defined boundaries of each level within the chain
- Defined flow of information between the different levels
- Established control points within the whole marketplace
- Established measurements

The proposed software system overcomes today's problems, as it supports the use of more than one computational intelligence technique through agents' technology. The key function is the application area of interpretation of the available data. Considering a software system responsible for data interpretation, there can be distinguished a number of interesting characteristics as shown in Figure 2:

- The process is distributed. There can be distinguished a number of autonomous processes (data gathering from retailers, data grouping etc.), which interact with each other to end up with a meaningful conclusion.

- The distributed problem domain denotes the development of a hierarchical layered software system, which results in the construction of a structured society of agents, with different groups, each one specialised and with different functionality.
- The software system as a whole has to be easily maintained, as new agents might be included, if new products or manufacturers have entered the market.
- Finally, the requirements of such an automatic system for data interpretation in marketing are high, as it deals within a dynamic environment, where any change is possible, and the system has to be accurate.

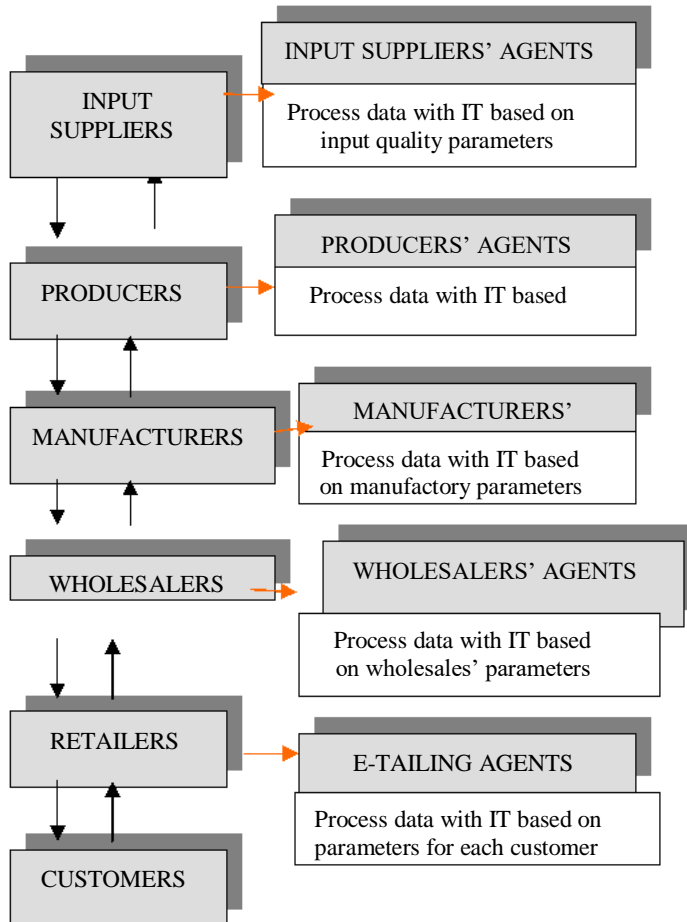

Figure 2: E-marketplace towards a multi-agent system for supply chain management

The novel idea of this framework is the construction of an agent society, in groups, based on the hierarchical reasoning during the interpretation procedure, which benefits from the agent technology in terms of decentralisation of execution, decentralisation of control and existence of co-operation. Every software component within a multi agent system has to carry out problem solving actions in order to achieve its goals. When acting on their own, their functionality determines the right actions to perform in certain situations. Within a multi-agent system though it has to consider the actions of the other software components as well, based on the principle of social rationality as given in [9]: “Within an agent-

based society, if a socially rational agent can perform an action so that agents’ joint benefit is greater than their joint loss then it may select that action”.

Based on that the expected utility of an action is given from the equation:

$$EU(a) = f(IU(a), SU(a))$$

where $EU(a)$ is the expected utility of an action “a”, which is given from the combination (based on some function f , depending on the application) of the individual utility (IU) and the social utility (SU). It means that in order for an agent to perform an action it has to consider both its own and the society’s loss (or gain). Rationality refers to the successful performance of an action. The only assumption within this theory is that the intelligent agent requires complete information and sufficient time to carry out the necessary reasoning.

The whole procedure of communication between these different kinds of agents also offers at the end the positive result of improved interpretation, a flexible architecture and adaptability.

5. Communication

In order that agents achieve their goal, they have to communicate their knowledge, which can be accomplished through the Agent Communication Languages (ACL) in a standardised way, by using communication protocols including TCP/IP, SMTP and HTTP to exchange any type of knowledge needed.

The best known ACL is that of the DARPA knowledge sharing effort, which led to the successful development of the Knowledge Query Manipulation Language (KQML) [6] and the Knowledge Interchange Format (KIF) [7]. Much research is being performed by the Foundation for Intelligent Physical Agents (FIPA), an international body that aims to set general standards for agent interoperability. FIPA have defined an ACL (FIPA ACL), which includes basic communicative actions (such as inform, request, propose and accept) together with a number of interaction protocols including the contract-net protocol.

In distributed multi-agent systems the agents themselves may be transmitted across a computer network and executed remotely. Such agents are called mobile agents. In these architectures the agent software is transmitted to the host computer, the data are processed and the final result is communicated back.

5.1.KQML

KQML is both a message format and a message-handling protocol to support run-time knowledge sharing among agents for co-operative problem solving. It employs a layered architecture of communication, where at the bottom the functionality for message transport or communication occurs and at the top the content is specified by the application. Consequently, it provides the agent designers with a standard syntax for messages, and a number of performatives that define the force of a message, while letting them decide the content of the messages. Examples of performatives include tell, inform, perform, reply and each one is associated with a

set of parameters indicated by “:”. The inspiration for these message types comes largely from speech act theory, in order to cope with problems associated with large-scale knowledge bases, which are sharable and reusable.

The performatives support the development of higher-level models of inter-agent interaction such as contract nets and negotiation. KQML provides a basic architecture for knowledge sharing and the underlying communication is asynchronous, because it assumes the message transport is reliable and preserves the order of messages, but may not guarantee delivery always.

5.2.KIF

Apart from the communication language, agents need to have an understanding and parse the content of the messages they receive. This is facilitated by Knowledge Interchange Format (KIF), which provides a syntax for message content, which is essentially first order predicate calculus with declarative semantics. This empowers the agents to understand the meaning of expressions in the representation without the help of an interpreter for manipulating those expressions. KIF is logically comprehensive, as it includes mechanisms to support the expression of arbitrary sentences in first-order predicate calculus. It also provides methods for the representation of knowledge about the representation of knowledge (meta-knowledge) and plays the role of mediator for declarative knowledge bases and knowledge representation languages (i.e. PROLOG, LISP and XML). The language description includes both a specification for its syntax and one for its semantics. For example, in order for an agent to reason based on salaries of different employees it needs to have knowledge of the employees’ id, the department they are working for and the amount of their salary:

(salary ?id ?department ?salary)

and the representation of the agent’s interest in different salaries:

(interested agent (salary ?x ?y ?z))

5.3.Ontology

Based on the domain experts’ reasoning for solving complex problems, the requirement for a domain specific vocabulary has been identified, as traditional representation languages are domain independent. Ontologies have been developed in order to provide a domain specific vocabulary for inter-agent communication. In the context of knowledge sharing the term “ontology” is used as a description of the concepts and relationships that can exist for an agent or a group of agents in a defined set of formal vocabulary. This means that in order for the agents to communicate in an efficient way, they have to use a formal context of knowledge representation so that they infer the same meaning for the same concepts referenced. The set of objects and the relationships between them are represented in a logical formalism of a vocabulary. There are certain definitions associated with the names of the different entities within the problem domain (types of entities, their attributes and

their properties, the entities’ relations and functions and any of their possible constraints) in a human readable text describing what these names mean and certain axioms that constrain their interpretation. In a multi-agent system the agents share the same vocabulary, but this doesn’t mean that they share a knowledge base. Each agent might have different knowledge to that of the others, but a shared vocabulary is essential in order to achieve their communication in a coherent and consistent manner.

6. Multi-agents architecture for chain optimisation

This section introduces the novel idea of a hierarchical decentralised multi-agent architecture developed for data interpretation and monitoring supply chain management. It employs different groups of intelligent agents to cope with the variety of application functions by using distributed problem solving. The design and functionality of the diversity of agents, along with the key issues behind the multi-agent system as a whole, are described.

The establishment of the application requirements has firstly to be considered before the software development. During the analysis of the supply chain management process, there are a number of functions specified, which indicate the need for heterogeneous groups of autonomous software entities as described in the previous section. In order to avoid any complexity issues concerning the development of the multi-agent system, the problem has been viewed from a high level of abstraction at the first stage, which as a consequence will lead to the individual agents’ specification and functionality.

The role modelling procedure is similar to the one of the GAIA methodology [22], according to which abstract roles are identified. In each one there might be other sub-roles defined depending on the specified application. As a consequence, during the design process, the roles and interactions between all the agents are identified and will be used to implement the multi agent system for supply chain management.

Within the supply chain management, the agents can be used to monitor the business units or facilities that purchase the raw material, and how these can be converted into intermediate goods and final products, which then are being delivered to the customers. The supply chain then can be efficiently co-ordinated, to ensure that the products pass through the chain in the shortest time and at the lowest cost, as agents can be used for sharing information on the network of different companies and negotiate about product prices [20].

For reasons of brevity we omit the details of the described case study and focus on the analysis and design of the software components instead. The particular application is providing customers with certain quantities of beverages. This activity involves the understanding of the system’s organisation, while viewing it as a collection of roles that stand in certain relationships to one another

and have certain interaction patterns. Figure 3 denotes the architecture of a multi-agent system for the supply chain for beverages, where the interaction between certain type of agents is predefined and the users depending on their profile have access to certain information at any time.

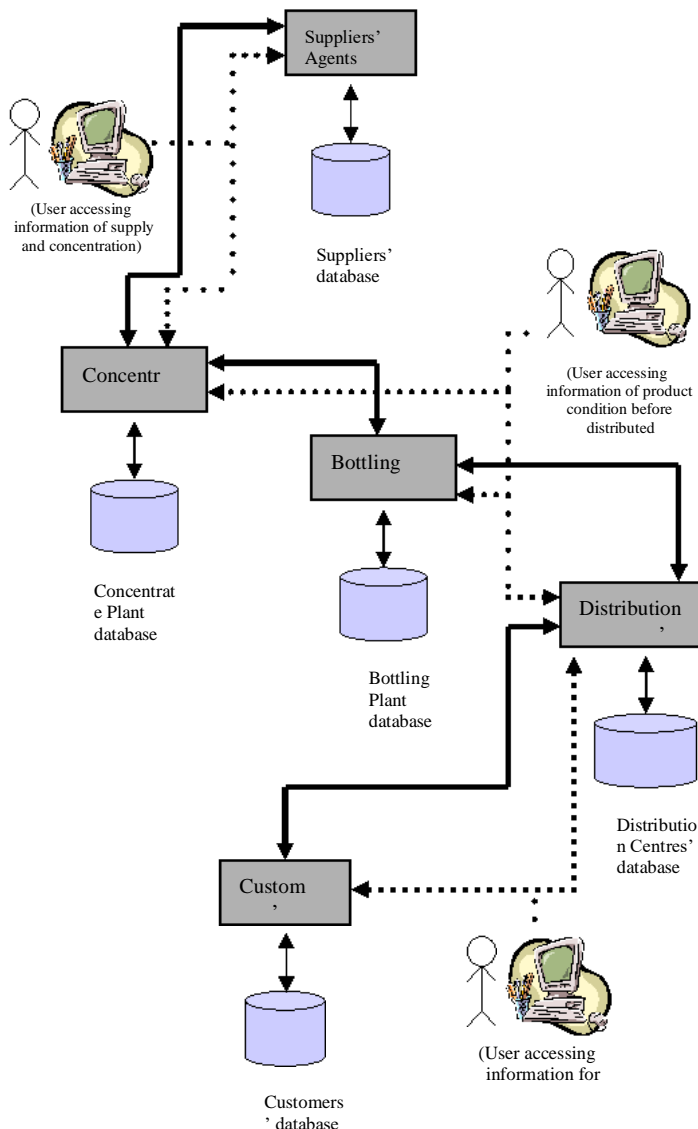

Figure 3: Agent-based supply network

Table 1 illustrates the key roles for a supply chain management multi-agent system and how these are used within the specific supply chain for beverages. The different protocol activities, permissions and responsibilities associated with each role are given, which will assist the different software components to achieve the mission of the logistics, which is to get the right goods or services to the right place and the right desired time and the right condition, while making the greatest contribution to the firm. At the same time the intelligent agents' functionality will provide one more advantage, which is to deliver the right information to the right user the right time.

Table 1: Schemata for agent roles

Role Schema: InputSupplier	
Description: Receives quote request from the producers' agents and ensures that the appropriate input quote is sent.	
Protocol and Activities: WaitForRequest, CheckQuote, InformSupplier	
Permissions:	
read incomingRequest	supplierInput
Responsibilities:	
Trust, Negotiation with supplier	
Role Schema: Producer	
Description: Receives quote request from the manufacturers' agents (Concentration Plants in our case study) and ensures that the appropriate quote is sent to the input suppliers.	
Protocol and Activities: WaitForRequest, CheckQuote, InformProducer	
Permissions:	
read incomingRequest	manufacturersInput
Responsibilities:	
Trust, Negotiation with producers	
Role Schema: Manufacturers	
Description: Receives quote request from the wholesalers and ensures that the appropriate information is sent to the producers.	
Protocol and Activities: WaitForRequest, CheckQuote, InformManufacturers	
Permissions:	
read incomingRequest	producersInput
Responsibilities:	
Trust, Negotiation with manufacturers	
Role Schema: E-tailing	
Description: Receives quote request from the customers electronically and ensures that the appropriate quote is sent to the manufacturers.	
Protocol and Activities: WaitForRequest, CheckQuote, InformDistributors, InformCustomers	
Permissions:	
read customersInput	distributorsInput incomingRequest
Responsibilities:	
Trust, Negotiation with distributors	

An example of an agents' dialogue, based on the different roles and the given ontologies is illustrated in Table 2, where a customer posts its order and two different distributors reply. At the end the customer's agent will select the distributor with the best price and time delivery. This can be specified by evaluation functions, predefined within the agents' knowledge. Based on the latter mentioned roles, the software system will be able to monitor on-line the supply chain management of beverages, which can be on-line evaluated based on the Inventory Model.

7. Discussion

There are great general benefits and savings to be gained by the use of intelligent agents for supply chain management. Initially, optimisation agents can be the building block of a correct designed simulation for an accurate representation of a supply system. The monitored supply chain can be driven temporarily beyond its maximum capacity through the knowledge of the multi agent system based on the behavior of the different layers of the supply network. Additionally the efficiency of the supply chain may be increased through the elimination of unexpected mistakes. Potential supply errors will be identified while they are still in the incipient stages.

Table 2: Example of KQML dialogue for MAS

```
Dialogue:
(orderFromCustomer
  : sender CustomerA
  : language KQML: ontology E-tailingForBeverages
  : content
    (stream-about
      : language KIF : ontology beer
      : content c1
    ))
(replyToOrder
  : sender DistributorX : receiver CustomerA
  : reply-with d1
  : content
    (stream-about
      : language KIF : ontology beerDistibution
    ))
(replyToOrder
  : sender DistributorY : receiver CustomerA
  : reply-with d2
  : content
    (stream-about
      : language KIF : ontology beerDistibution
    ))
(tell
  : sender DistributorX : receiver CustomerA
  : in-reply-to c1 : content (= (beer 500) (deliver
15.00)))
(tell
  : sender DistributorY : receiver CustomerA
  : in-reply-to c1 : content (= (beer 400) (deliver
16.00)))
```

While not directly preventing the occurrence of the system error, the unexpected element of a mistake may be eliminated and the supply can succeed with minimum losses at each layer of the chain. Some of the main contributions of the system proposed in this paper include:

- **Flexibility:** Agents technology can be non-obstructive of existing buyer-seller relationships. Trust, mostly the lack of it, has been repeatedly found to moderate of buyer-seller relationships [2] [12] [17] [16]. Typically, the application of Information Technologies alters the trade relations. Empirical studies suggest that

powerful partners take advantage of IT technologies to gain more power or impose their strategy to smaller partners. However, IT applications don't necessarily have to be obstructive in order to be effective. For example, Bakos and Dellarocas describe online reputation mechanisms as an emerging alternative to more established mechanisms for promoting trust and cooperative behaviour, such as legally enforceable contracts [1]. Das and Malek, who defined supply chain flexibility as the robustness of the buyer-supplier relationship under changing supply conditions, found that order quantities and supply lead-times are the two most common factors associated to flexibility [3]. Intelligent agents can manage orders effectively and reduce lead times thus the flexibility of the chain increases. These advantages are attributed to the following abilities of the multi-agent system:

- ¾ The analysis and design of the layered architecture has been defined and the different roles of groups of intelligent agents have been specified to map the procedure of supply chain management.
- ¾ The advanced web-based graphical user interface called the Supply Assistant Agent (SAA) will assist the users of the software depending on their user profiles to view certain information of the system and to control and if necessary interfere by sending the appropriate message to the intelligent agents of certain layers.
- ¾ A number of different intelligent agents will be able to derive information relating to the state of a product, within the supply chain from measurement data and from communication with the user and between different layers of the supply chain.
- ¾ The multi-agent system will be easily extensible due to its object-oriented design and development, which also means that it can be reused for different kind of supply chains.
- **Information visibility:** visibility of appropriate information into a distribution network is necessary in order to optimize scheduling and planning costs. Information visibility means having the right data at the right time. As a consequence, the success of any technological improvement depends on delivering information visibility into the system. Agents' technology has this advantage of having access to the different layers of information, even in cases where information has been processed from different techniques.
- **Efficiency:** Forestalling the Bullwhip effect fire-fights the explosion of many supply problems such as: excessive inventory, severe delays, poor product forecasts, unbalanced capacities, poor customer service, uncertain production plans, high backlog costs, and lost sales.

Despite the obvious advantages, there are a number of issues to be considered associated with the analysis and design of such a software system at the operational,

tactical and strategic level. We found that (a) there are data-related concerns at the operational level. Data & information sources need identification and filtering prior to processing. Problems we expect to find here are incomplete or missing data, data handling difficulties, or unreliable and inaccurate data sources. Specified security mechanisms have to be predefined as well, so that different end users have access to specific information. (b) Process-related concerns at the tactical level. In particular, process complexity, which is the speed of negotiation among the agents and the distribution of functionality to the different layer of software components, has to be specified. (c) Partner-related concerns at the strategic level. Partners should be willing to share information at tactical and operational level. Although a minimum level of trust should be expected, using optimisation agents, it is not prerequisite for business partners to share or expose strategic information (i.e. demand forecasts).

Additionally, a number of issues should be taken into account, during the software development that are of high importance for future research within the area of intelligent agents' application in supply management:

- Trust: in a web-based marketplace, it might be difficult for consumers and producers to know who is reliable and secure.
- Privacy and Security: there must be predefined access to certain type of users to certain information and there is a high concern from the consumers and producers of the security of their personal information when using e-commerce systems
- Billing/Revenue: there are no billing mechanisms so far developed for similar applications and it must be implemented over the basic web structure
- Reliability: data and connections must be reliable and with predictable performance.

It should be emphasised that agent-based systems are not a panacea for solving every type of problem. They suffer from all the problems associated with the process of gathering human expertise and converting it into a reusable knowledge base. However, the MAS development has proved to be efficient, especially in cases where there is an environment that changes over time, different distributed processes need to take place, and their results need to be correlated, like this one of supply chain management.

Future research should aim to quantify the advantages of agent technology as discussed above. We suggest the simulation of the optimisation agents effect on beverages supply network, measuring and comparing specific indicators such as inventory level, distribution costs, total logistics cost savings, life cycle time, etc. Optimisation agents can be used in supply networks with time, cost, and efficiency as critical elements. In this respect, optimisation agents can be successfully applied to sectors such as electronics and machinery, including agricultural machinery.
