Welcome Message from Conference Chairs

On behalf of Department of Decision Sciences and Managerial Economics of the Chinese University of Hong Kong, we would like to welcome you to Hong Kong and to the fifth International Conference on Electronic Business (ICEB 2005 Hong Kong). We hope you can enjoy the conference and the distinctive blend of East and West in this dynamic city.

ICEB 2005 Hong Kong is the fifth International Conference on Electronic Business which is offered by International Consortium on Electronic Business that was initiated by The Chinese University for Hong Kong, Hong Kong; National Chiao Tung University, Taiwan; Tsinghua University, China; and National University of Singapore, Singapore. The Consortium aims to be the leading forum for e-business knowledge and education in the world.

The aim of the fifth International Conference on e-Business is to foster the exchanges of research findings, innovative ideas and industrial practices in the area of e-business with particular emphasis on applications in logistics and supply chain management. ICEB 2005, the second time hosted by The Chinese University of Hong Kong at Sheraton Hotel and Towers, has more than 200 papers submitted and we collect 160 papers in the conference proceedings. The topics include decision support & group systems, Internet marketing & advertising, data warehousing & data mining, supply chain management & e-logistics, e-business models & enterprise e-service architecture, mobile commerce, Internet security & privacy, e-procurement, web intelligence, collaborative commerce, and others. We certainly hope this conference can provide a platform for exchanging the findings and issues in e-business.

The conference cannot be successful without your participation and the dedication of many colleagues. We would like to express our sincere appreciation for the support of Faculty of Business Administration, The Chinese University of Hong Kong; Centre for E-Business, National University of Singapore; Research Center for Contemporary Management, Tsinghua University; and Institute of Information Management of the National Chiao Tung University for co-organizing the conference. We would like to thank Professors Xiande Zhao and Jeff Yeung for their the great effort on serving as the program co-chairs, Professor C. C. Lee for serving as the chair for Doctoral Student Seminars, Professor Eldon Y. Li for the support from International Consortium on Electronic Business, and many colleagues for serving as international committee members. Also, the deepest gratitude to Li & Fung Limited, the sole and full sponsor, for giving us free hand on designing good quality of conference. Last but not least, we like to thanks our colleagues who dedicate to the conference, including Jessica Li, Roslind Sukendar, Kelvin Liu, Connie Vong, and many others.

We sincerely hope you can enjoy the hospitality extended by Department of Decision Sciences and Managerial Economics of the Chinese University of Hong Kong and your stay in Hong Kong.

Waiman Cheung and Timon Du
Conference Co-Chairs

Organizer

Department of Decision Sciences and Managerial Economics, The Chinese University of Hong Kong

Co-organizers

Tsinghua University, Beijing, China
The National University of Singapore, Singapore
National Chiao Tung University, Taiwan

Sponsor

Li & Fung Institute of Supply Chain Management/Logistics, Chinese University of Hong Kong

Conference Advisors

Lim Chin, Dean, NUS Business School, The National University of Singapore, Singapore
T.S. Lee, Dean, Faculty of Business Administration, The Chinese University of Hong Kong
Han-Lin Li, Dean, College of Management, National Chiao Tung University, Taiwan
Chunjun Zhao, Dean, School of Economics and Management, Tsinghua University, China

Conference Co-chairs

Waiman Cheung and Timon Du, The Chinese University of Hong Kong, Hong Kong

Program Committee Chairs

Xiande Zhao and Jeff Yeoung, The Chinese University of Hong Kong, Hong Kong

Doctoral Student Seminars Program Chair

C. C. Lee, The Chinese University of Hong Kong, Hong Kong

Publication Chair

Baoding Liu, Tsinghua University, China

International Program Committee

Paul Alpar, Philipps-Universitaet Marburg, Germany

The Study on RFID Security Method for Entrance Guard System

Y.C. Hung¹, C.W. Tsai², C.H. Hong³

¹Andrew@mail.nyu.edu.tw ²s0930316@mail.nyu.edu.tw ³chhong@csie.nyu.edu.tw

Abstract: The RFID technology has been used by industries in recent years, for examples, replacing the traditional two-dimensional barcode, logistics management, military applications, identification. In fact, RFID technology has become one of the new killer technologies. The RFID uses radio frequency to convey information which involves, however, many security problems; Current RFID guidelines do not present solutions to these security problems. The methods put forward in published paper fail to offer complete solutions, either. This study identifies RFID security method for Entrance Guard system. The algorithms used include Hash, AES, random values, XOR four item technology, and use the three-way authentication structure to solve the safety problems of the certification of Entrance Guard system. The experiment showed the algorithms provided better protection on the current RFID systems against attack methods such as Eavesdropping, Traceability, Spoofing and Replay attacking.

Keywords: RFID, RFID Smart card, AES, HASH.

I. Introduction

Since World War II, RFID technology which was used for identifying enemy's or our flights has been over 60-year evolution. Now, in the big enterprises with over 5 billion US dollars annual sale worldwide, 70% of them has create RFID technology plan. This shows RFID technology has drawn the attention from general merchandise, retail business, government, storehouse industry, and so on, so RFID technology has just become the application in the top class of the new generation. Apart from being used on the logistics management, another application of RFID is to insert RFID tag into Smart IC card. This type of application is quite extensive, for example, Taipei MRT pass card, identification card of entrance security of multi-storey buildings, work ID from government and schools, student ID, and so forth. Through RFID wireless transmission and features of non-contact, the original issues of inconvenience and fabrication on the use of contact smart card. However, due to the RFID using wireless frequency to communicate and carry information as well, its new security issue has also gradually appeared. In additional, the issue of RFID system security has not yet been fully regulated in the book of national normal standard, so this issue is quite controversial.

In this study, RFID tag frequency is 13.56MHz, and according to ISO/IEC18000-3, it belongs to Passive Tag. There is no place for batteries in the tag, and the size is

restricted, so the ability of calculation for the tag is limited with the small capacity of the memory. Therefore, the use of traditional encryption calculation and authentication mechanism cannot be applied. For this reason, it is hoped to use four technologies such as Hash, AES, Random values, and XOR with the combination of the 3-side authentication framework to bring up less calculation and high security identification mechanism to RFID smart card which is hardware restricted, for solving the security concern of the current use of RFID smart card identification and entrance guard system. Besides, with the difference of general security identification mechanism, this study has been added in active defence mechanism, for further enhancing the security of system, and reducing the opportunity of the data in RFID smart card to be eavesdropping,spoofing, traceability.

II. Background Knowledge

II.1 RFID

RFID stands for "Radio Frequency Identification" system, and it is similar to Smart card system. It is developed due to the defect of contact system by using radio frequency and carrying digital data, so the identification card and card reader do not need to contact each other but complete the exchange of data. Consequently, there is no requirement of direction under this way of carrying data, and the card could be immediately identified when it is put in the bag or purse. It's a chip of mini two-sided radio waves with card-pasted style, and only uses two connected point to connect one simple IC to another antenna, so the installation of receiving signal could be done. When the question of the electromagnetic remote wave was sent out, the card could right away to answer the required information by digital radio frequency signal, while RFID is composed of 4 parts, such as RFID tag, RFID reader, Backend database, frequency radio.[1][2]

(1) RFID tag

It is pasted or inserted to merchandise, goods, RF chips in smart card, and the main structure includes CLK circuit, AC to DC commutation wave filter, demod, codec, ip, memory.

RFID tag can be divided into two different types, active and passive:

◎ Active Tag

With one build-in small battery, the capacity of memory could reach 1MB, and there is longer radio communication distance (100 meters) by using communication, but there is limitation of deadline which is about 7 to 10 years, so the

cost is relatively high.

◎ Passive Tag

No build-in batteries, the coil inside the tag could send electric field out by readers to get energy. Due to the use of electromagnetic induction, the communication distance is short, and the cost is lower, small size, long duration with more competitive ability, so it highly possible to become the mainstream of market. There is a comparison between active and passive RFID tag in table 2-1 below.

Table 2-1 The comparison of tags

	Active	Passive
Power installation	Build-in	No Build-in
Valid period for use	Yes	No
Environment Condition	More Sensitive to high and low temperature	Can adapt to worse environment
Price	higher	Lower

(2) RFID reader

Reading, receiving past or inserting merchandize, goods, receiver of RF tag in the smart card. The main structure concludes: PLL, VCO, Demod, Codec, uP, Memory, time record generator. RFID reader can use antenna to read and write. Different RFID system has different type of antenna. For example, the reader in the entrance of supermarket: because the goods carried in different height, the antenna could be high as a person's height. The antenna do not need to activate tag anytime, but activate the transmission by cooperate the sensor in the food pad. Readers can be divided into two types: fixed and portable. The former can be place in the entrance of the supermarket, good shelves, warehouse entrance, wagons, container yard entrance, airport, and so on. The latter one is much lighter, with direction and shorter distance of interaction.

(3) Back-end database

The main function is to record details of the RF tag, when the reader received RF tag signal, it will link either by wireless or wire network to back-end database, to get the integration of details of RF tag for other application to use.

(4) Frequency radio

The frequency of RFID is to link the information transmission between tag and card readers. The frequency is sent from card readers out to tag, and the tag returns the information inside the tag. The option of frequency is mainly based on the distance between RF reader and RF tag. A lower frequency means a lower range of reading, and slower information transmission. But in the metal and humid environment, high frequency relatively has better reading ability. Besides, it depends on the frequency opened by each

country. Every country uses different frequency. Generally speaking, the information transmission and communication frequency between FR readers with low frequency and RF tag are not controlled by government, but the ultra high frequency would be restricted. Take Japanese government as an example, the frequency of 950~960 MHz has been decided to open for RFID system to use. RFID system could be categorized by frequency into four: Low Frequency (LF,125KHz ~ 135 KHz), High Frequency (HF,13.56 MHz),Ultra High Frequency (UHF , 100MHz~960MHz), Microwave(over 1GHz).

II. 2 RFID Security Issue

RFID system carry information by wireless, so if RFID system does not provide complete security mechanism, then within the available range of information transmission, the attackers can randomly access, falsify, delete, and damage the information of RFID tag. This weakness has obviously threatened the organization, enterprises, personal information security and privacy. In the following text, the weakness of RFID used by attackers and may cause security problem attackers will be indicated.

A. Eavesdropping

Because RFID system uses wireless to transmit information and communication, the attackers could eavesdrop the information and message during the communication between reader and tag. So the way of this type of attack is called "Eavesdropping". In the transmission of RFID system, it can be roughly divided into reader-to-tag(forward channel) and tag- to-reader(backward channel). Forward channel came from reader, so the distance is long and the range is big (100meter), so it is easily to be eavesdropped without being noticed easily. Backward channel came from tag, so the distance is short, and the range is smaller, so it's more difficult to be eavesdropped without being noticed easily. As Figure 2-1 shown:

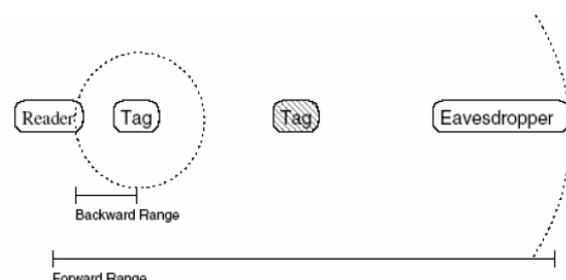

Figure 2-1 Forward、Backward range

The security issue of eavesdropping will cause two serious damages: the exposedness of personal information and business spy.

(1) The exposedness of personal information

In the aspect of the exposedness of personal information, this has been widely used in RFID smart card which save card holder's personal information. For example, health insurance card stores medical record, personal information,

and so on. For they are the information that card holder would not want to make known to the public, and necessary to be protected. However, because RFID system belongs to non-contact card, so the opportunity of being exposed is relatively higher.

(2) Business spy behavior

Nowadays, the industry of manufacture, logistics, retail, and military institute give every effort to popularize the use of RFID system, and RFID relatively brings quite a lot of benefit, convenience. However, under the tendency of RFID, the issue hidden behind would be monitored by attackers, the risk of being stole on information. RFID system could make the factory owners use the information stored in the tag memory to quickly get product name, model number, material, logistics procedure, and so on; on the contrary, the attackers could also get and monitor the product information in the same way. Therefore, the activity of business spy would become worse, and then lead to serious consequence if there is no further prevention of security mechanism.

B. Traceability

In RFID system, RFID reader could get the information and trace product through the returned message RF tag. It is also this feature that attackers could trace product and users through the returned message from FR tag, so it is called "Traceability". The main reason that attackers could trace tag is because normally the returned value from tag is fixed and unchanged. Some tag returns UID value directly, and this UID is also the unique identification value of RF tag. Therefore, attackers only have to set readers in many fixed point, then they could trace products and users. For example, sneaker factory owners want to carry out logistics and storehouse management, so they insert RF tag chip into shoes, and when customer A bought this shoes, then attackers could trace the customer A through the fixed RFID reader and make customer A's privacy public.

C. Spoofing

After the introduction of two security RFID issues of eavesdropping and trace, another issue is "Spoofing" which includes two major items: Theft and Counterfeiting.

(1) Theft

Through deceiving legal RF tag, attackers could deceive automatic book close system, entrance guard security system by RFID system features. For example, attackers could rewrite RF tag information or replace the RF tag information inside expensive goods with that inside the cheaper ones. Or attackers could falsify a host of RF tag to mess up the whole management of the supply chain.

(2) Counterfeiting

Counterfeiting is defined as can be read or intercepted to falsify the information of RF tag. Attackers could deceive RFID system through falsifying RF tag information. For

example, they could forge IC card of entrance to invade company or military institute.

II. 3 RFID Existing Security Strategy

The solution of this RFID security issue could be divided into two categories: Non-Cryptographic Scheme and Cryptographic Scheme. There will be a brief description of several important solution: "Kill tag approach" in "non-Crypto-graphic scheme" and Hash based access control, Randomized access control, Hash chain in "cryptographic scheme". [3][4][5][6][7][8]

A. Kill tag approach

In order to prevent the occurrence of security issue when users get RF tag, the solution is to delete its memory information before they get it. The way is to put one 8-bit password in every RF tag, and then run "Kill" command. However, there are two problems existing in "Kill tag approach". One is the support from the manufacturing factory is required, and the other one is that to ensure the Kill command has been actually executed is difficult.

B. Rewriteable memory

Separating memory in RF tag into ROM and RAM, ROM can store public information, and RAM can store private information. Readers have to be authenticated before accessing RAM, with the implement of cryptographic scheme.

C. Hash based access control

Irreversibility of Hash is mainly to be used for authentication. Its structure is as Figure 2-2 shown:

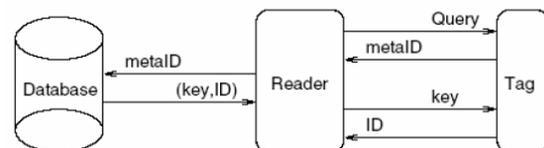

Figure 2-2 Hash based access control

In RF tag, metaID (metaID = has (key)) will be stored firstly. When readers query RF tag, RF tag would return metaID, and reader can search the back database to find the matched key value to complete authentication. This method could solve the problem of RF tag information being eavesdropped, but because the returned metaID value from RF tag is fixed, so it cannot prevent attacker's trace.

D. Randomized access control

This method is used to improve the issue of Hash based access control to be traced. Adding one random value R in the returned value, so the returned value that reader queried could be changed. Its returned value is $\{R, h(ID_k || R)\}$ and the structure is as followed in Figure 2-3:

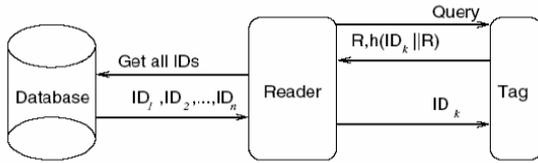

Figure 2-3 Randomized access control

E. Hash chain

In RF tag, storing on initial value $s(s_1)$, and the way of communication with readers is similar. Only the returned value changed to $a_i = G(s_i)$, and after responding to readers, it would immediately changed to $s_{i+1} = H(s_i)$ where G, H are hash function. Its structure is as followed in Figure 2-4:

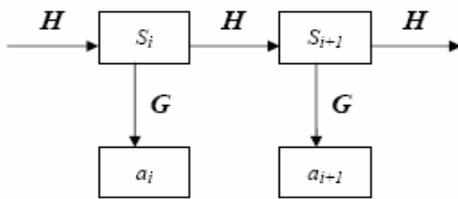

Figure 2-4 Hash chain

III. System Structure

III.1 System Introduction

In current entrance guard systems, most of them use RFID smart card for user identification. This RFID technology gives the convenience and speed for identification check but this convenience also relatively generates the security issues. In this research, we provides a symmetrical encryption method (AES, HASH, Random value) and three-sides identification in the entrance guard security system structure of RFID smart IC card. This system structure not only protects the user information privacy, counterfeit prevention, and identity theft, but also protects the card holder to be traced. Besides, different from other security system structure with focus on the passive security shield, this system also provides active detection for smart IC Card security. After the card is attacked, the system will automatically turn on the reaction procedure to increase the security level on information and privacy protection. The system structure is depicted as Figure 3-1.

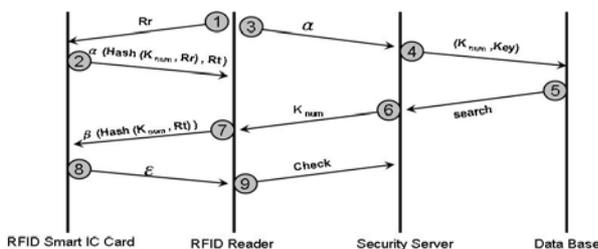

Figure 3-1 System Framework

The RFID smart IC card discussed in this research is the RF tag with frequency at 13.56Mhz. So the standard from ISO / IEC 18000 specifications should be followed. As a result, there will be some limitations for the hardware. In this research, we will embed a hash calculator, random generator and several logic gates in the RF tag, which will not violate the hardware limitation rules from the specifications. Before introducing the system structure flowchart, we can define the database structure saved inside the RF tag and security system database. {S_{count}, Key_{num}, P_k (Data)} is the database structure in RF tag. S_{count} records the scan counts for this RFID smart IC card by RFID reader. K_{num} is the identification serial number of the user data encryption key in this RFID smart IC card. P_k (Data) is the encryption code of card holder information encrypted by the K_{num} key. There are {K_{num}, Key_i} and {ID, S_C_count} in the structure of security system database, in which Key_i is one of the key used in system encryption, K_{num} is the corresponding identification serial number for Key_i, ID is the user identification code and S_C_count is the identification number of times between the record system and card holder. The system data structure is depicted as Figure 3-2 in below.

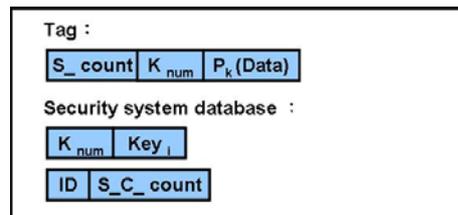

Figure.3-2 Data Structure

System flow

Here we will categorize in nine steps to explain the system flow structure from Fig3-1.

- (1) When the card holder use RFID smart card to precede the identity confirmation, RFID reader will generate question message to the RFID smart card after the card holder puts the card within the save and read range of RFID reader. This question message includes Rr value, which is a 128bit random value generated by the reader.
- (2) When RFID smart IC card is inside the reader sensor region, it will add the S_{count} value in the RF tag by the power from electromagnetic induction. Then it will generate α message as reply from the equation $\alpha = \{F_i(K_{num}, Rr) || Rt\}$. Ft is a hash function embedded inside the tag and Rt is the random number generated by the random code generator. The transfer format of question message from RFID reader and α message replied by IC card will use the standard of communication structure defined in ISO/IEC 18000-3 specification book, as illustrated in Figure3-3 and Figure3-4.

SOF	Flags	Com code	IC Mfg	UID	Signed data Rr	CRC	EOF
	8 bit	8 bit	8 bit	64 bit	128 bit	16 bit	

Figure 3-3 Query message

SOF	Flags	UID	Signed data α	CRC	EOF
	8 bit	64 bit	128 bit	16 bit	

Figure 3-4 α message

- (3) RFID reader gets the α value and sends it back to the backend system for identification comparison.
- (4) Security system searches the saved K_{num} in the backend database then it will compares $F_r(K_j, Rr)$ and α value.
- (5) The system will send the Key_i and K_i , which are generated from the IC card of the card holder, back to the system. After full search in all K_{num} , the system will send back error message if it cannot find the matched K_i .
- (6) RFID reader will send β message in order to get the card holder information from RFID smart IC card, in which $\beta = F_r(K_i, Rt)$.
- (7) After RF tag confirms β message, it will try to compare to see if K_i and K_{num} are the same.
- (8) Make sure β message is correct, feedback ϵ from $\epsilon = (P_k \text{ (Data)} \parallel S_count) \oplus F_t(Rr)$.
- (9) RFID reader will process the identification procedure though the Key_i , Rr , S_C_count value from the card holder. The identification process will get $P_k \text{ (Data)} \parallel S_count$ from $F_r(Rr) \oplus \epsilon$ and then use the key to get the value of $P_k \text{ (Data)}$.

The 9 steps in above is the passive mode processing steps for security identification system. However, we also mentioned the active mode security identification system. The procedure will be addressed in below. According to the real needs, the system will define two security entrance guard values (T1 and T2). From the security identification step (9), the security system will get the S_count value from the ϵ message. After the calculation of S_count and S_C_count difference value (n), it will compare the n value with the entrance guard value defined by the system. If n is larger than T1, the system will warn the card holder and inform that the card might be attacked. If n is larger than T2, the system will lock this RFID smart IC card and request the card holder to activate the card from the IT department. The security system administrator will use different key for encryption and change K_{num} value for card holder's personal information. By this method, the system will be able to perform the active security shield to enhance the security in the identification system.

III. 2 Security Analysis

In the second chapter, we have discussed the security problems in the RFID system. In this section, we will do the security analysis for the security identification process from the security problem in the RFID system in order to proof the security structure in this system. In this research, we assume that RFID reader, backend data transfer and communication are all inside a safe environment. Therefore, the research will not cover the discussion in security topics in RFID reader and backend data transfer connection line.

A. Eavesdrop

From the transfer structure inside this system, the data transfer (See Fig 3-1, step 8) in this identification process of RFID smart IC card and RFID reader (See Fig 3-1, step 1, 2 and 7) is protected from the hash function encryption. The hash function contains irreversibility which means that the attacker could not reproduce the original message even though this message was eavesdropped by the attacker. Besides, two random numbers (Rr and Rt) are used in this identification process which offers different message for each identification process to increase the difficulty of force methods by the attacker. During the information transmission from the card holder, the system will send the information after the data process with $F_t(Rr)$ in xor calculation. The card holder's information was encrypted and saved in the RF tag memory. Though the attacker uses the stole Rr value to calculate $F_t(Rr)$ value and crack the xor calculation protection, the cost and time will be increased for attacker to crack and get the encrypted $P_k \text{ (Data)}$ based on several different encryption key used by the system. For example, it will cost 2^{128} to crack the information from 128bits key with AES encrypted calculation. If the key number is 2^5 , the cost will increase to 2^{640} for crack. Therefore, the attacker will not be able to steal the $P_k \text{ (Data)}$ value to solve the private information from the card holder.

B. Spoofing

In the entrance guard security system, the reproduction and theft of identification IC Card is a serious security topic. In this system, the attacker is able to get the $P_k \text{ (Data)} \parallel S_count \text{ } xor \text{ } F_t(Rr)$ value by eavesdrop. If the attacker is able to analyze the interpreted $P_k \text{ (Data)}$ value to reproduce IC Card and deceive the security system, the identification procedure is required before the personal information check by the security system. At this time, the attacker must also hold this K_{num} value of the RFID smart IC card together to pass the identification procedure to the check process. However, the K_{num} value will be encrypted with hash function and random value in the transfer process. The attacker will not be able to get the K_{num} value by eavesdrop and to reach the goal of deceiving system with $P_k \text{ (Data)}$ value.

C. Traceability

In traditional RFID system, the attacker could trace the

card holder from the fixed replied message from the attacker reader's quote only by couple fix location RFID reader via the RF tag chip embedded inside the card holder's RFID smart IC card. In the security system discussed in this research, the message value from each communication transfer between the whole RF tag and RFID reader is not a fixed value due to the extra embedded hash calculator and random value generator inside the RF tag (See Fig 3-1, Step 1, 2, 4, 7, and 8). Therefore, the attacker will not be able to trace RF tag from the fix reply message.

D. Man-in-the middle attack

If the attack is sent after reproduction of legally obtained RFID reader and RF tag message, the attacker could get $(P_k(\text{Data}) \parallel S_count) \oplus F_t(\text{Rr})$ value after performing Man-in-the middle attack. However, the attacker still encounters the same difficulty in the spoofing attack as discribed above. The attacker has to cract two encryption procedure to obtain the card holder private information. So this security system structure is able to prevent Man-in-the middle attack.

E. Replay attack

If the identification is not passed either in security system side or RF tag side, the system will stop the reply message immediately. Besides, the system uses two random numbers and active security shield mode so that resending attack is not able to attack the system.

F. Active reaction procedure

Different than other security system, we added two calculated value (S_count , S_C_count) and two security entrance guard values ($T1$, $T2$) in the RF tag memory. If the attacker's RFID reader attempts to save and get this RFID smart IC card, S_count and S_C_count will generate difference once the identification process is failed. If the identification process is finished from the legal RFID reader, the system will get the information inside the RF tag memory and compare the difference between S_count and S_C_count value. If the difference of S_count and S_C_count is larger than $T1$, the system will warn the card holder that the card might be attacked. If the differenece is larger than $T2$, the system will request the card holder to the security department to update the information inside the IC card. Different keys are used to re-encrypt the private information and modify the K_{num} value to ensure the system security and card holder's privacy. The reason to use this two stage entrance guard value is due to some unexpected

issue in transfer and communication failure between RFID smart IC card and RFID reader, such as the high humidity in the rainy days or RFID smart IC card was placed inside the metallic box etc. Therefore, two entrance guard values are used to prevent these unexpectable reasons from the inconvenience of frequent changing card information.

IV. Conclusion

The development of RFID technology brings significant convenience to people but its security is also a big drawback. Without providing solutions, it will seriously affect the information security from personnel, company, military to government. This research provides an identification system for RFID smart card entrance guard system with Hash, AES, Random values and XOR technologies. Combined the identification from three sides, the goal is to resolve the security issues for RFID smart card, such as eavesdrop, traceability and counterfeit etc. In addition, the embedded RF tag hardware also meets ISO/IEO 18000-3 standard to proof the execution possibility. Besides, the active shield system was added in the structure to enhance the strength of the security systems to prevent the potential danger of system failuer from the attacker by resending attacks or Dos attacks to the system.

Abstract: The implementation of RFID had aroused discussion in every area. Experts believe that the emergence of RFID will cause another business revolution. Many industries had deployed RFID, like aviation industry, in which RFID is used in maintenance materials and baggage management. This paper discusses the implementation of RFID in MRO process and the building of a ubiquitous computing environment. We believe that our proposal has three merits to MRO (1) anti-counterfeit parts (2) MRO liability (3) efficient and effective inspection. The architecture can address the competition pressure that aviation industry faces and consequently enhance competition advantages.

Keywords: Personalized, Mobile, and Ubiquitous E-service.

I. Introduction

Ubiquitous computing, or UbiComp, first proposed by Weiser, is the method of enhancing computer use by making many computers available throughout the physical environment, but making them effectively invisible to the user [5]. UbiComp enables users to access demanded services and information under various environment, and eliminate the media break that connect the virtual world (including ERP, IS, Internet, etc.), and the physical world (objects, person, assets). The applications of UbiComp in business environment help improve business processing efficiency and eliminate human intervention during information processing. Among technologies that had been used to implement UbiComp, RFID is the most practical and feasible one. RFID is not a new technology; in fact, it was invented during World War II [8]. Nowadays, it attracts attention from various industries and academics. RFID system comprises three primary components: tag, reader, and back end database [6][8][12]. RFID tag consists of antenna and electronic circuit [6][7][8][12]. The antenna transmits data or receives data from readers. The antenna also allows tag to couple to an electromagnetic (EM) field to obtain power [6][8][12]. The electronic circuit is divided into two parts: memory and logical gate. There are two kinds of memory, ROM and RAM, and their capacities range from hundreds to 1K bits [9].

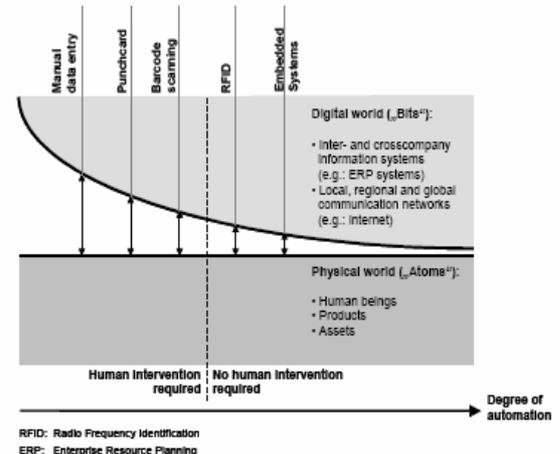

Figure 1 Media Break Between the Physical and Digital World [4]

There are about a few thousand of logical gates [12] to perform the basic computation in tag. Tag is categorized as passive or active and as low frequency or high frequency, depending on the power source and data transmission radio frequency [6][7][8][12]. Furthermore, RFID tag has many characteristics, for example, the unique identification, the basic computation, and its traceability. RFID is considered the successor of barcode. There are some applications of RFID system, for example automatic road toll collection, anti-theft systems, goods tracing and identification. The participants of aviation industry also notice this new application. Currently, the competition among aviation companies is intense due to the entering of new competitors and the stagnation of market growth. To conform to regulations, huge budget is spent on maintenance procedures. In aviation industry, aircrafts have to perform maintenance regularly. Such a process is called MRO (Maintenance, Repair, Overhaul) [1]. For safety reasons and public interests, the law enforcements, like FAA, have set up conscientious demands or regulations to make sure that the airline companies carry out MRO as requested.

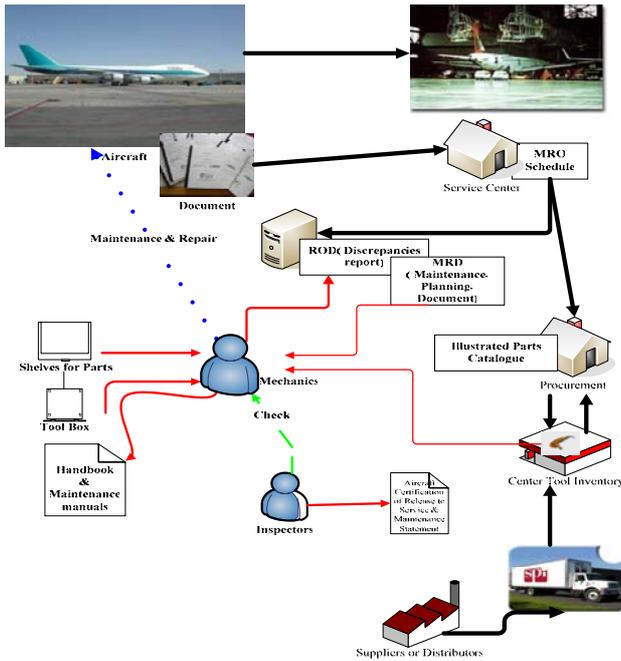

Figure 2 MRO Processes [1]

MRO is required every 650 flying hours, and it costs approximately 12% of total operation cost of an aircraft [1]. The opportunity cost of an idle aircraft is about US \$ 23,000 per hour [1]. Therefore, the airline companies are searching for solution to decrease costs and increase the MRO efficiency and effectiveness. In [1][4], the authors propose architectures that build the UbiComp environment to improve tool management and tool inventory management during MRO process by using RFID. The authors believe that this architecture will upgrade the MRO efficiency and maintenance accuracy. Not only academy, the aviation companies also perform RFID field test, like baggage tracking [11]. Boeing and Airbus had cooperated with FedEx to attach RFID tags in some aircraft parts, like onboard maintenance power. In 90-day test, all the RFID tags perform well. Boeing and FedEx expect that the RFID tags will be attached to all parts of aircraft in the future [2][3]. Delta Airline, working with Boeing, put RFID tags in components of engine. They look forward to the deployment of RFID throughout MRO process to provide better services [2][3]. Boeing and Airbus team up to set up requirements of implementing RFID and establish standards [10].

II. Motivation

We had reviewed many studies about using RFID to improve MRO. These studies all focus on issues of upgrade the level of MRO efficiency, but do not emphasize on the accuracy of MRO process [1][4]. In [1][4], the architecture aims to improve tool management and tool inventory by attaching RFID tags in tools. However, the proposed architecture cannot detect the possibilities that mechanics may skip standard maintenance procedures or miss some parts. We

believe that the accurate MRO is more important than efficiency. Besides, [1] and [4] do not address the fake parts problem, which costs the aviation industry US \$100 million each year. In our proposed architecture, we use the standard MRO procedure to sequence all replacing or repairing parts. By this means, it can hopefully ensure that mechanics follow the standard procedure to do their job and do not bypass any important step. We also introduce an approach to solve the problem of fake part, and it can be implemented in tags with limited computing power. Finally, to improve inspection process, we propose an electronic and credible certificated process. It provides the legitimate audit trails.

III. Architecture

III.1 Tag

The tag stores two types of data:

- (1) **Unique Identifier (Tag_ID):** This attribute follows EPCglobal standard and stores 96-bit electric product code.
- (2) **Manufacturer's Authentication (MAC_{manufacturer}(R)):** The Manufacturer first generates a unique random number R for each tag. Before the product is shipped to the customers, the manufactures will encrypt R by using MAC with secret key of manufacturer and then store it inside the tag. The secret key is only possessed by the manufacturer.

Tag_ID	MAC _{manufacturer} (R)
EPC	*****

Figure 3 Data Format for RFID Tag

Tag_ID	R	CustomerID	Key
Tag_ID ¹	A1111111	Northwest	123456
Tag_ID ²	B2222222	Northwest	123456
Tag_ID ³	C3333333	Northwest	123456

Figure 4 Database of Manufacturer

The Manufacturer stores each tag's EPC, R, customerID, and key in database.

III.2 Before MRO

After the aviation companies received the parts they purchased, they will perform the following actions:

- (1) **Authenticate Purchased Parts:** As illustrated in Figure 5, the companies start to authenticate these parts after the purchased parts arrived. MRO server is responsible for recording tag unique identifier (Tag_ID), which is generated by product manufacturers. The reader collects the Tag_ID and MAC_{manufacturer}(R) and then sends to MRO server. The MRO server will wrap up these collected data along with CustomerID and send to the manufacturer. After the manufacturer received these transmitted data, it uses the key (manufacturer) to examine the received MAC_{manufacturer}(R).

It also checks CustomerID to make sure that the aviation company does not receive the wrong parts. Finally the manufactures send all information, including the production date and expiration date, back to the aviation company if the whole authentication result is O.K.

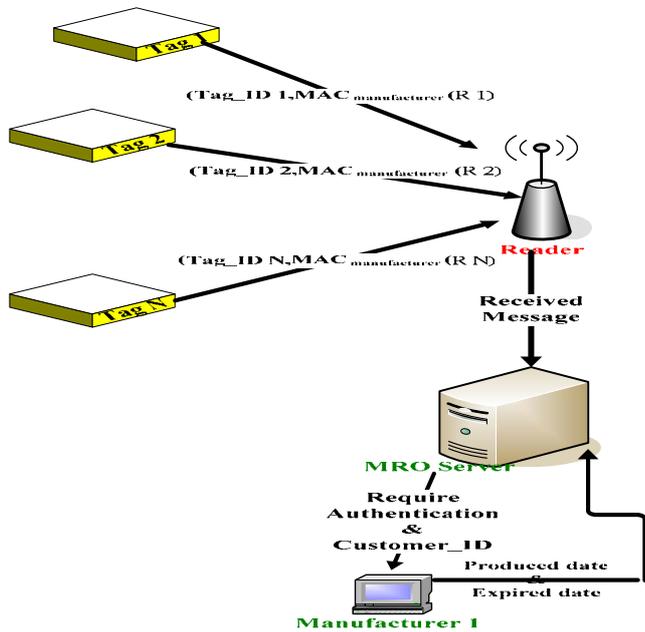

Figure 5 Procedure of Parts Authentication

(2) **Prepare the MRO procedure:** After completing the authentication process, MRO server records all corresponding information, including the production date and expiration date. The MRO server also arranges the MRO schedule, sets up standard maintenance procedure, and provides on-line technical supports to mechanics. As for MRO scheduling, the MRO server will choose the appropriate parts for some standard MRO procedure based on information of the production and expiration date. After the schedule is arranged, the sequence of usage is also set up according to the standard MRO procedure. For example, if the part of Tag_ID¹ needs to be replaced first and parts of Tag_ID² and Tag_ID³ should be installed simultaneously later according to standard maintenance procedure. Then the MRO server will monitor if the parts are used based on this sequence by using RFID reader.

III. 3 During MRO Process

As Figure 6 illustrates, the mechanics carry the mobile device, like smart phone, PDA, or notebook during MRO process. The mobile device can communicate with MRO server wirelessly by using 802.11. It is also equipped with a RFID reader to read tag information. Before the mechanics start working, the mobile device downloads the MRO schedule. Besides, the mobile device also downloads the assembly instruction from MRO server. When the mechanics begin performing MRO process, he or she scans the parts based on the sequence of usage. Meanwhile, the mobile device will compare the scanning sequence of tags with predefined assembly order, which is stored in device. If the

comparison result is not correct, the mobile device informs the mechanics that some parts are missed or the assembly sequence is wrong. This action will make sure: (1) all parts are used according to the planned schedule and designed sequence. (2) no part is missed.

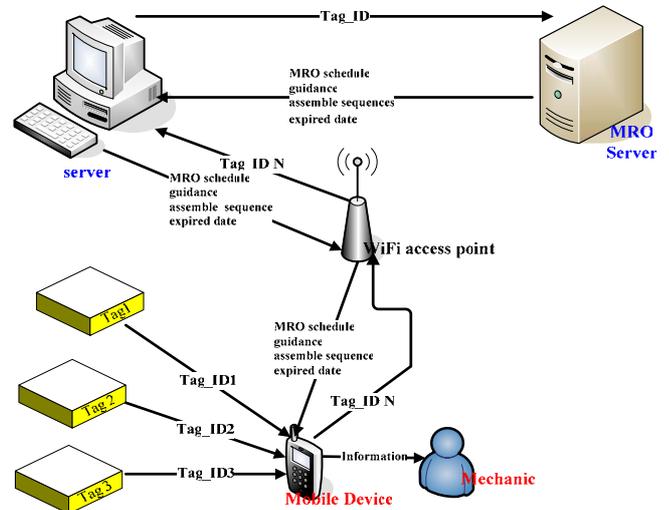

Figure 6 Process of Using Mobile Device to Run MRO

III. 4 Inspection

After the MRO is finished, the aircraft must be inspected before taking off. An inspector will do so by reading tags and checking MRO schedule and sequence with mobile device. If everything is O.K., the inspector uses mobile device to generate the e-document of “Aircraft Certification of Release to Service & Maintenance Statement”, and e-signs this statement. Then this electronic document will be sent to the database of authority along with the corresponding digital signature.

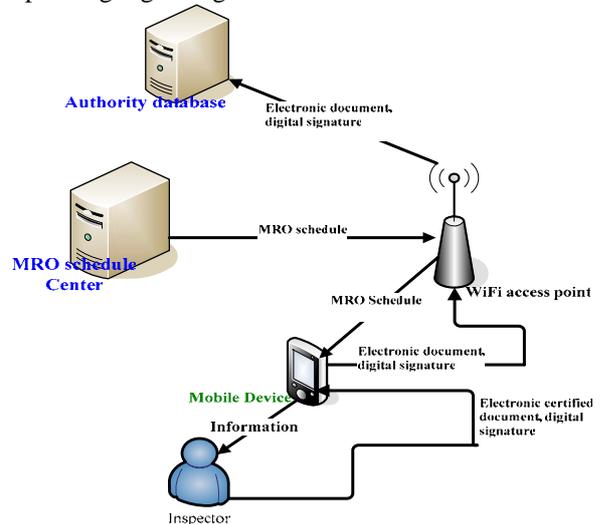

Figure 7 Process of Storing e-Document and Issuing Digital Signature

IV. Conclusions and Future Works

We believe that this architecture has the following benefits:

(1) Prevent Fake Parts: In this architecture, a tag will store MAC data for self-authentication and the secret key is only kept by manufacturer. This enhances the ability of fake-resistance.

(2) Decline Man-made Error: The maintenance schedule and sequence is stored in MRO server. When the mechanic performs MRO process, it is easy for him/her to check whether he/she uses the assigned parts and follows the predefined assembly sequence. It can decrease or eliminate human errors that may occur during MRO.

(3) Fast and Credible Inspection: The inspector issues electronic document of "Aircraft Certification of Release to Service & Maintenance Statement" with digital signature after completing the inspection. It provides an effective and efficient certification approach.

In conclusion, this architecture not only can be deployed into MRO process of aviation industry, but also is extended to other areas such as vehicle industry or delicate apparatus assembly line, in which the procedure accuracy is a critical concern.

Abstract: Wang Sheng is a developer for the RFID solution; he is interested in RFID middleware and SAP RFID solutions. He is a master student at Shanghai Jiao Tong University. From Sep.2004—Jan. 2005, he is working a RFID Demo center project in Shanghai, and this article is about a Outbound Delivery process in SAP system with RFID technology. Wang Dong is professor at Shanghai Jiao Tong University. His area of expertise is logistics solution and RFID technology. This paper will tell you how RFID make magic in outbound delivery process.

Keywords: SAP: SAP is the biggest business software provider in the world.

R/3: SAP R/3 is an ERP software powered by SAP. It is the core software of all SAP systems. SAP R/3 a great brand in ERP.

RFID: Stand for Radio Frequency Identification, a technology similar in theory to bar code identification. With RFID, the electromagnetic of electrostatic in the RF portion

of the electromagnetic spectrum is used to transmit signals. An RFID system consists of an antenna and a transceiver, which read the radio frequency and transfers the information to a processing device, and a transponder, or tag, which is and integrated circuit containing the RF circuitry and information to be transmitted.

Software and Hardware are used in the whole process.

Software: SAP R/3, CIP (Collaboration Inventory portal, a RFID Middleware), RFID Device Control

Hardware: SAP R/3 server (CPU P4 3.0*4; Memory 4G), CIP Server (CPU P4 3.0 memory 512M), RFID Reader (Alien RFID Reader), RFID tags (Class0 tag).

Outbound delivery process

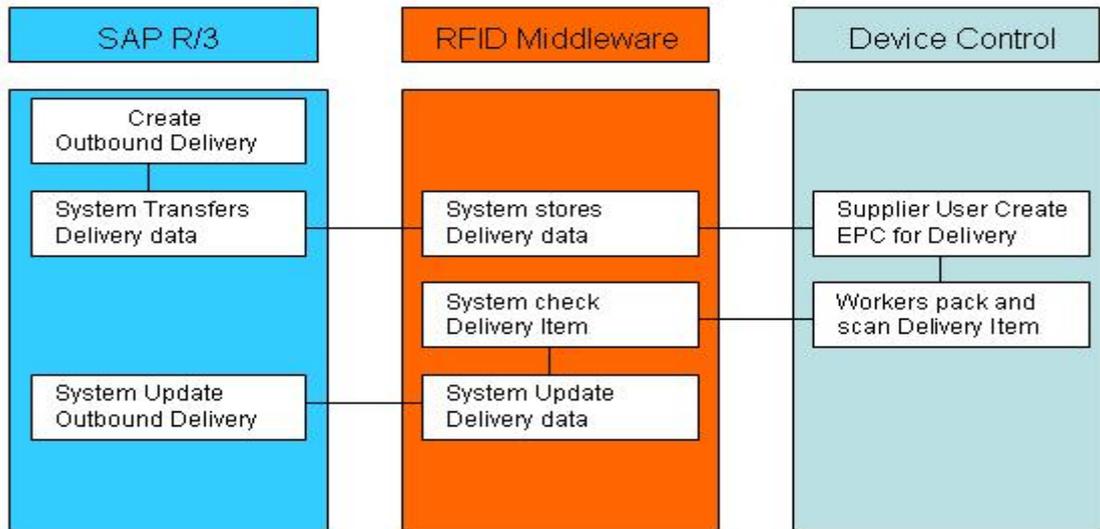

The physical view of RFID-enabled outbound delivery is like the picture.

RFID-enabled Outbound Delivery

We first paste the RFID tag to cases and pallet. This process is called “tag commission”. When the tags are print to the cases and pallet, Hierarchy of this mapping is record in the RFID middleware system. This is the process of “packing” in RFID solution. And packed goods are send out

through RFID-installed Gate, the RFID reader is mostly fixed Readers, and check out can be automatically. The third section we call this “loading”, the goods with RFID tags are loaded to the trucks and the mapping of this good issue is also recorded in both the RFID middleware and R/3 systems.

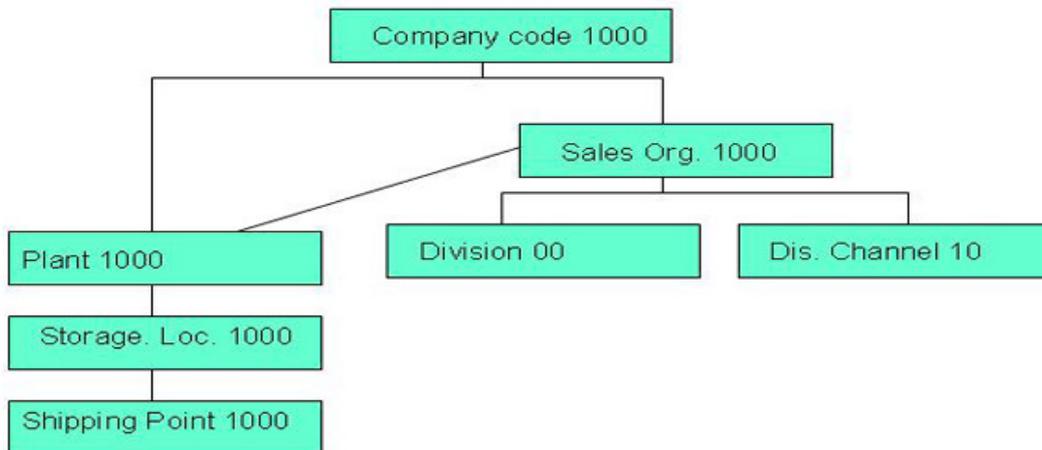

- 1) First we create a outbound delivery in SAP R/3 system, in the system we use transaction code"VL01n", and When the outbound delivery is created in SAP system, the delivery data is transfer to RFID Middleware systems automatically (a SAP technology call "BADI" is used here, it will be talked later).
- 2) The information about the EPC data are send to Device Control through XML, and Supplier user can doing tag commission.
- 3) After the tags are print to the cases and pallet, the workers pack them together. Then workers pushed the barrow though the RFID Gate.
- 4) The system gets the information from the RFID Reader installed in the Gate, then the system check the mapping of the cases and pallets with the original information stored in the system.
- 5) When the checking is OK, the RFID middleware update the delivery. And the information is transferred to system
- 6) R/3 system also updates the delivery data by BAPI calls.

Master Data Management

Master Data in SAP

There are information about Company, Plant, storage location and Material, and this information is saved the in R/3 system by customizing job.

A company with plant 1000 and sales organization 1000 is customized in SAP R/3 system. This company is a vender that will perform outbound delivery in our Scenario. The company's organization is show below.

Master Data in RFID Middleware

RFID Middleware contains information about RFID tag, RFID object, tag observation, Material and EPC mapping.

Table: STATUS

item	type	length	NULL	Prime Key	Default value
id	integer	4	NO	YES	
statusMessage	char	100	NO	NO	
timestamp	timestamp	10	NO	NO	

Table: READERID_XXX (observation table of one Reader XXX)

Item	type	length	Null	Prime Key	Default value
id	integer	4	NO	YES	
epc	char	16	NO	NO	
timestamp	timestamp	10	NO	NO	

Table: Material (Material with EPC prefix)

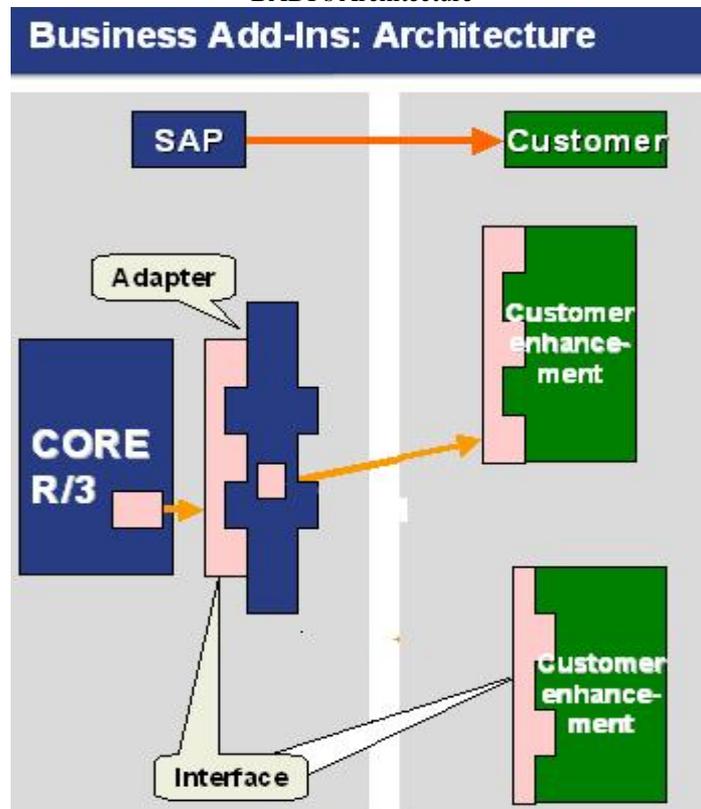

Item	type	length	Null	Prime Key	Default value
id	integer	4	NO	YES	
Material	char	16	NO	NO	
EPC prefix	char	16	NO	NO	

Interface programming

To fit this requirement, SAP BADI interface technology is been used here.

Requirement 1: Delivery transport to Middleware system automatically

BADI's Architecture

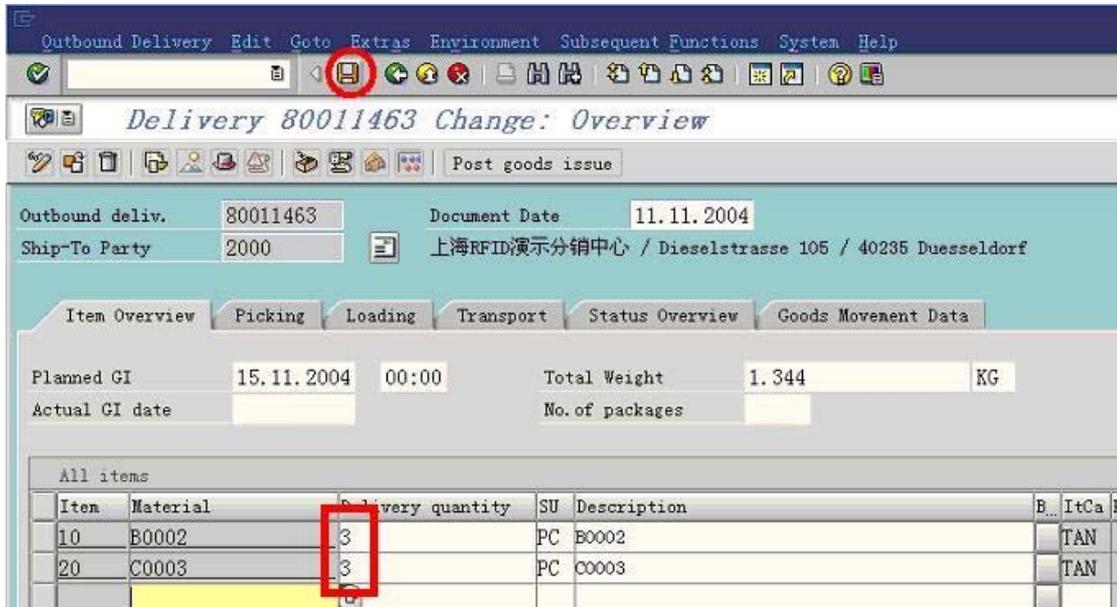

BADI (Business Add-In) is an Enhancement technology to provide connectivity to R/3 system. With BADI, SAP customer can change their software process easily and with good SAP support.

Enhancements are made possible by SAP application programs. This requires at least one interface and an adapter

class that implements it. The interface is implemented by the user.

Our Delivery process with BADI

1) When first Create or Change a delivery

2) Implement the delivery interface The method `publish_after_save` is called by the system "if_ex_delivery_publish".

```

method if_ex_delivery_publish~publish_after_save .
  data: ltab_likplips type table of zstrc_likplips initial size 0 ,
        lwa_likplips type zstrc_likplips,
        lwa_likplips_tmp type zstrc_likplips.
  .....
  .....

  call function 'Z_RFID_SYNCDOTOCIP' destination 'JCO'
    exporting
      requtext          = '0000000000'
    tables
      z_likplips        = ltab_likplips
    exceptions
      communication_failure = 1 message msg_text
      system_failure       = 2 message msg_text.
  .....
  .....
endmethod.

```

3) Function 'Z_RFID_SYNCDOTOCIP' transfers the delivery data to RFID Middleware.

Requirement 2: Post Good issue creates material back to SAP system.

BAPI (Business Application Program Interfaces) is

defined as a method of an SAP Business Objects. SAP BAPI Interface. The BAPIs in the R/3 System are currently implemented as function modules all of which are created and managed in the Function Builder. Each function module underlying a BAPI:

- 1) Supports the Remote Function Call (RFC) protocol
- 2) Has been assigned as a method to an SAP Business

Object in the Business Object Repository
 3) Is processed without returning any screen dialogs to the calling application

Our post Good issue with BAPI
 1) RFID Middleware (CIP System) post goods

2) When post goods issue at RFID Middleware, it calls BAPI “z_postdoforsap” to post goods issue in SAP system.

```

function z_postdoforsap.
*"-----
*"*"Local interface:
*"  IMPORTING
*"    VALUE(I_VBELN) LIKE  LIKP-VBELN OPTIONAL
*"  EXPORTING
*"    VALUE(RETURN) LIKE  BAPIRET2 STRUCTURE  BAPIRET2
*"-----
.....
perform import_data using i_vbeln return.
.....
endfunction.
    
```

3) Delivery status in SAP is automatically change by this way

The screenshot shows the SAP Document Flow interface. At the top, there is a menu bar with 'Document flow', 'Edit', 'Goto', 'Environment', 'System', and 'Help'. Below the menu is a toolbar with various icons. The main area displays 'Document Flow' with a sub-header 'Status overview'. The document details are: Delivery 80011463, Business partner 2000, and 上海RFID演示分销中心. Below this is a table with three columns: Doc., Date, and Overall Processing Stat.

Doc.	Date	Overall Processing Stat
. Standard Order 8208	11.11.04	Being processed
Delivery 80011463	11.11.04	Being processed
. GD goods issue:delvy 4900026813	11.11.04	complete

Benefit of RFID-enabled outbound delivery.

Wal-Mart ask his vendors to do outbound delivery with RFID-enabled. And at January 2005, 132 Wal-Mart's vendor (32 voluntary vendors) has paste RFID tag in cases and pallet. The benefits are:

- 1) When delivery information is send to Wal-Mart, they can receive the goods automatically, because RFID Readers can scan RFID tag in a long distance. Here we need an Event Management in Wal-Mart side to handle the deliveries.
- 2) With RFID technology, the cases and pallets can be easily managed and reused.
- 3) At the vendor side, post goods issue can be check by RFID instead of by workers.
- 4) Goods information can be traced at every point of the delivery.

In a word, RFID-enable outbound delivery increases the efficiency of the whole Supply Chain Process.

Abstract: Radio Frequency Identification (RFID), which uses radio waves to identify objects, was discovered in 1930s for military purposes and it transformed into commercial uses in 1980s in the United States. In this paper, we explore the research domains in RFID technology, innovation and diffusion theory, and supply chain management within the existing literature for exploring whether RFID enhances supply chain competence and e-business. This paper also forms a preliminary study base for researchers who may wish to carry on future research in this area.

Keywords: Emerging Technologies, RFID, supply chain.

I. Introduction

Radio Frequency Identification (RFID) is a term for technologies that makes use of radio waves to automatically identify people or objects [48], [25]. It was discovered in 1935 by Scottish physicist Sir Robert Alexander Watson-Watt [36] mainly for military use. It only started to become popular in commercial sector around 1980s, particular in automobile industry such as Ford, GM, Chrysler, and Toyota, with the RFID tags produced by Allen-Bradley in 1984 [45]. In this paper, we explore whether RFID would enhance the supply chain management system, and, whether it is an opportunity or a threat. We explored a number of different research domains (including RFID technology, supply chain management and diffusion theory) within the existing literature. According to Bourner (1996), there are a number of good reasons for spending time and effort on a review of the literature. Some of these reasons taken for this paper are: *to increase breadth of knowledge within a subject area*, and *to provide the intellectual context for one's own work, enabling the positioning of a project relative to other work* [10]. Hence, we organize this paper into seven sections. In the next section, it brings forth RFID fundamentals including the characteristics of RFID and a comparison

between RFID and bar coding. In Section 3, we discuss how RFID technology fits in with the Theory of Technological Innovation Diffusion. In Section 4, we present how RFID improves the supply chain management and e-Business. In Section 5, we cover the current applications of RFID in Asia, particularly in China. In Section 6, the disadvantages and problems of RFID will be outlined. The conclusions and the future research areas of RFID in supply chain management will be presented in the final section.

II. RFID Fundamentals

II.1 The Development and Characteristics of RFID

RFID is a wireless tracking technology that allows a reader to activate a transponder on a radio frequency tag attached to, or embedded in, an item, allowing the reader to remotely read and/or write data to the RFID tag [48], [25]. RFID utilizes a semiconductor (microchip) in a tag or label to store data. Data is transmitted from, or written to the tag or label, when it is exposed to radio waves of the correct frequency and with the correct communications protocols from an RFID reader. Tags can be either *active* (using a battery to broadcast a locating signal) or *passive* (using power from the RFID reader for location). Because the tag sends an electronic signal, it can transmit information when buried under several layers of products and shipping material, through concrete walls or even under water [6].

RFID has its roots dating back to WWII when British planes had surface mounted transponders installed so that radar could detect their planes from those belonging to the enemy [8]. After the 1950s, development went a little quiet until the 1960s when in the first commercial use of RFID, electronic article surveillance was used to counter theft. In the 1970s, inventors, companies, academic institutions and government all continued developing RFID applications and the opportunities afforded by the technology began to be realized. The latest generation of RFID allows the dozens of individual objects within a group to be uniquely identified at

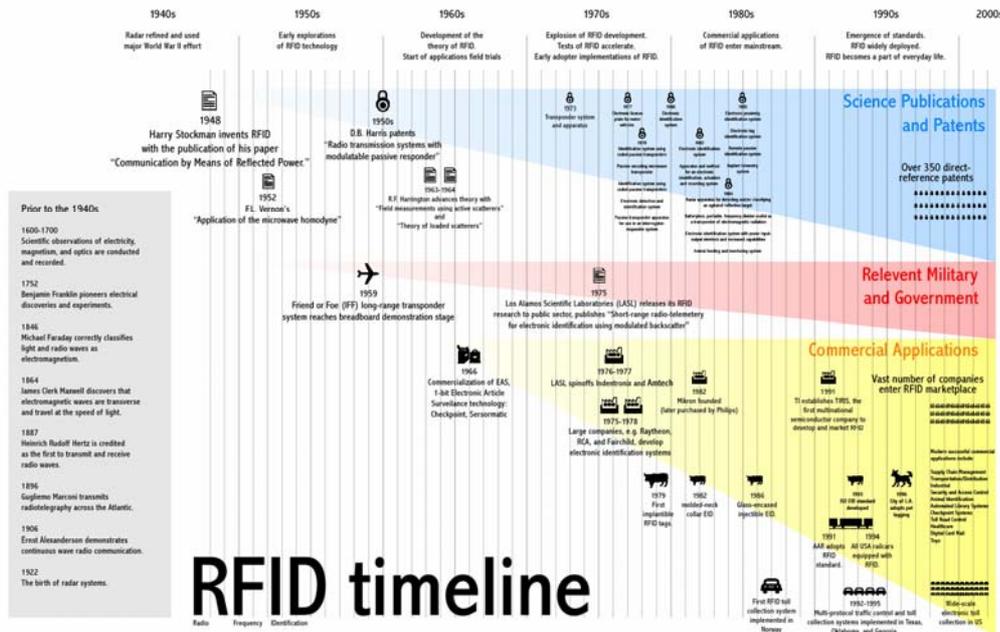

FIGURE 1. RFID Timeline
 (Source: Interaction Design Institute Ivrea 2002 [24])

	Bar Coding	RFID
Reading capability	Optical-line of sight required.	Wireless – line of sight not necessary (some environmental exceptions).
Reading speed	Bar coding can read a single label per scan.	RFID can read multiple tags in a single pass.
Durability	Labels tend to be damaged in harsh processes. Etching directly onto part has increased durability.	Tags are more durable than bar code labels, can be used during and after most harsh environments.
Amount of information	A 1D bar code can store 20 alphanumeric characters, while a 2D bar code can store roughly 2,000 characters.	RFID tags are capable of storing several thousand characters, or several kilobytes, of information.
Flexibility of information	To update information, a bar code label must be replaced with a new bar code label.	To update information, many RFID tags can have their memories updated with new information through wireless communication.
Security	2D bar codes provide encryption capability.	RFID tags have manufacturer installed identification codes that cannot be changed, thus making counterfeiting difficult.
Cost per label or tag	Bar code labels typically cost less than \$0.01.	RFID tags cost from \$0.25-\$0.50, up to \$250.
Standards	Bar coding is standardized and widely accepted.	RFID lacks complete standardization, especially in the global environment
State of infrastructure	The infrastructure to support bar codes is in wide existence.	The infrastructure to support RFID is minimal. Users would have to invest in additional equipment to support RFID.

TABLE 1. Summary of Differences between Bar Coding and RFID
 (Source: Robert W. Baird & Co. Incorporated 2004 [38])

the same time. However, until recently, RFID, which allows the tracking of individual items, has not been feasible for

many commercial applications given its high cost and technological limits. Today, companies such as Alien

Technology and Matrices are developing RFID components (e.g., tags, readers, etc.) at a much lower cost than was formerly possible, creating a wider opportunity for RFID. Figure 1 gives the timeline of RFID [24].

II.2. RFID Attributes – A Comparison vs Bar coding

As bar coding is the most established automatic identification technology and RFID can be considered the most promising. Conceptually, bar coding and RFID are similar: both are intended to provide rapid and reliable item identification and tracking information. RFID is similar in theory to bar code identification systems. Both technologies establish object identification via scanning and facilitate data collection. However, RFID offers vast improvements over bar coding. The advantages of RFID over bar code technology are summarized in Table 1.

RFID technology is “essentially a new and vastly improved barcode [33].” It has been considered a replacement for barcodes. However, it is much more than an “improved barcode,” not only because it does have high storage capacity and ability for reprogramming, but also because of its miniature size and the accompanying tracking ability. We evaluate their suitability in the different application types.

Authentication applications

RFID technology is far more suitable than bar coding for authentication type applications due to the relative ease of copying and forging bar codes. In contrast, RFID technology is considered to be almost impossible to counterfeit or copy, which makes it a valid technology for authentication purposes.

Tracking applications

In most tracking applications, bar codes will currently provide the best payback for investment. It helps to alleviate the problems of manual data handling with relatively low costs [19]. The installed base of bar code readers is extensive, as it is by far the most popular automatic identification technology [18]. However, if the deliveries are likely to require excessive handling and poor environmental conditions, RFID is a viable option as the identification technology [11] [26] [31]. The use of RFID greatly increases the needed investments, and thus easily reduces the number of tracking points in the system, as even the cheapest RFID readers with limited functionality cost around one thousand Euro [47].

Process effectiveness applications

At the moment bar code based applications are widely used in the short shelf life supply chain. Bar code scanning reduces errors associated with manual data handling, and produces visibility to aid supply chain management [19]. Also, the introduction of new bar coding standards that

enable adding the sell-by dates to the codes have helped in retaining the integrity of stock rotation and hence help solve the spoilage problem [43]. However, there are problems associated with bar code data collection. The reading of bar codes invariably requires manual handling in the supply chain. Either the packages with bar codes or the reading devices are handled manually in order to read the codes [11] [13] [26] [31]. This makes data capture difficult, especially in the retail store environment where large amounts of goods are handled in facilities not designed for effective logistics [17]. Readability of bar codes is, occasionally, problematic due to dirt and bending; resulting in reduced accuracy of reading rates, particularly in successive handling situations and in difficult environments [35] [31]. However, RFID tags with sensor functions can monitor physical conditions, like temperature and humidity and to register if the product has suffered any knocks. The greatest cost efficiency can be achieved with recyclable transport containers, as the same investments in transponders can be continuously utilized [2].

Information management applications

Currently, in license plate applications bar coding is the most cost efficient technology. When storing read-only information directly on the identifiers, two-dimensional bar codes are often the best alternative due to the amount of information that can be incorporated and the relatively low price. In applications with requirements for read-write capabilities RFID is, of course, preferable.

Even though there are differences between bar code and RFID standards, technology can overcome this and now some stand-alone devices can read from barcode and write to RFID tags [23][7].

III. Theory of Technological Innovation Diffusion

III.1 RFID and e-Technology

The use of e-technology as a means to enhance supply chain competence has been widely espoused. A brief listing of these technologies ranges from those that have existed for decades to some very recent innovations, and encompasses many of the following:

- the personal computer;
- electronic data interchange (EDI) among carriers, shippers and customers;
- bar-coding and scanning;
- advance ship notices (ASNs);
- shipment and package tracking systems;
- satellite global positioning systems (GPS) and geographic information systems (GIS);
- software agents, HTML, JAVA, XML, object-oriented programming and semantic webs;
- the Internet, intranets and extranets;

- Web-enabled relational databases, data warehouses and data marts;
- decision support systems;
- electronic signature technology;
- wireless technology; and
- Enterprise Resource Planning systems (ERP).

Technology \ Application	Authentication	Tracking	Automation	Information Management
Bar code		X	X	X
RFID	X	X	X	X
OCR			X	
Biometrics	X			
Vision recognition			X	
Magnetic ink	X		(X)	
Smart cards	X			X
Contact memory			(X)	X
Magnetic stripe	X			X
Bluetooth	(X)	(X)	(X)	(X)
GPS		X		
GSM cell location		X		

TABLE 2. Different Identification Technologies Classified By Application Types
(Source: Kärkkäinen, Ala-Risk and Kiianlinna 2001 [27])

Various technologies used to track and automatically identify (ID) people, products, and other objects in order to enhance the supply chain management are:

- Barcodes
- Optical Character Recognition (OCR) Systems
- Biometrics
- Voice recognition and ID systems
- Fingerprint ID systems
- Smart cards
- Memory cards
- Microprocessor cards

RFID combines features of several of these technologies. Like barcodes, RFID is used to identify and track objects. As with OCR and biometrics, RFID enables automatic ID and verification. RFID also can be used like smart cards, memory card, and microprocessor cards to store information and provide interactive data processing.

The most important strength of RFID technology is that when using RFID tags, no line of sight is needed with the identifier in order to identify the object. Products can be identified effortlessly, during processing and without additional handling. Tags can be read through non-metallic materials, and about 60 tags can be read simultaneously [11] [26]. Also, most RFID tags are durable and resistant to temperature and other environmental factors [15]. More detailed descriptions of the technologies can be found in Table 2 [27].

III.2 Rogers' Technological Innovation Diffusion Theory

Rogers (1983) explains *diffusion* as: the process by which an innovation is communicated through certain communication channels over time among the members of a social system [40]. He breaks the adoption process down into five stages:

awareness, interest, evaluation, trial, and adoption. The distribution of adopters of an innovation can be approximated by a normal distribution of the time of adoption. Using the mean and standard deviation of this distribution as a method of segmentation results in five adopter categories: (1) innovators, (2) early adopters, (3) early majority, (4) late majority, and (5) laggards [40] [41].

- (1) *Innovators* are the first 2.5 percent of the individuals in a system to adopt an innovation. While an innovator may not be respected by the other members of a social system, the innovator plays a gate keeping role in the flow of new ideas into a system.
- (2) *Early Adopters* are the next 13.5 percent of the individuals in a system to adopt an innovation. The early adopter decreases uncertainty about a new idea by adopting it, and then conveying a subjective evaluation of the innovation to near-peers through interpersonal networks.
- (3) *Early Majority* is the next 34 percent of the individuals in a system to adopt an innovation. The early majority follow with deliberate willingness in adopting innovations, but seldom lead.
- (4) *Late Majority* is the next 34 percent of the individuals in a system to adopt an innovation. The late majority adopt new ideas just after the average member of a system.
- (5) *Laggards* are the last 16 percent of the individuals in a system to adopt an innovation. Laggards tend to be suspicious of innovations and change agents. From the laggard's viewpoint, their resources are limited and they must be certain that a new idea will not fail before they can adopt [39].

III.3 Applications of Rogers' Theory in RFID

The RFID industry is still at the growing stage. Technical standards and customer demand will hasten maturity of the industry, favourably impacting supply capacity and cost. Some actual implementations of RFID technology are being experienced within some organizations in the U.S. and Europe. Wal-Mart, for example, the world's largest retailer, has instructed its top 100 suppliers to place RFID tags on all its pallets and cases, though not on individual items, by January 2005. Over the next decade, it is likely that nearly every Fortune 500 and Global 1000 company will join the U.S. Department of Defense (DoD) and Wal-Mart in employing so-called automatic identification technology, making RFID an essential factor in almost any business [33].

Royal Philips Electronics and IBM have announced a major collaboration, which will see the joint development of RFID and smart card applications. The two companies hope that their combined reputation and market muscle will attract customers seeking to roll out their RFID projects using well-established suppliers [4].

Woolworths involvement with RFID technology came under the Home Office's 'Chipping of Goods' initiative [20].

Tesco is currently trialing tags on DVDs at its Sandhurst and Leicester stores. In this trial Tesco is testing smart shelf technology in collaboration with MeadWestvaco, an American packaging company and Entertainment UK (EUK), that keeps DVDs stocked in 2,500 retail stores in the UK [46].

In January 2003, Gillette became the first major manufacturer of consumer goods to place a giant order, 500 million, for RFID tags.

In U.K., Argos' involvement in the 'Chipping of Goods' initiative is mainly due to the fact that they are a retailer of high value products such as jewellery, electrical equipment and furniture. Since jewellery pieces are small and easy to convey, this was the chosen product to track for this nine-month trial, which aimed to reduce shrinkage. Up to 16 per cent of the products are returned and so an improvement in supply chain transparency was also sought [22].

Organizers of the 2006 football World Cup in Germany are to issue paper tickets incorporating smart tags. With more than 3.2 million tickets expected to be issued it will be the largest deployment so far of RFID technology at a sporting event [4].

The organizations cited above are the *Innovators* of applications in RFID, and meanwhile, the number of organizations preferred to be *Early Adopters* is increasing. Rogers identifies several additional characteristics dominant in the *Innovator* type:

- venturesome, desire for the rash, the daring, and the risky,
- control of substantial financial resources to absorb possible loss from an unprofitable innovation,
- the ability to understand and apply complex technical knowledge, and
- the ability to cope with a high degree of uncertainty about an innovation.

Early adopters frequently serve as opinion leaders who can persuade others to adopt the innovation by providing evaluative information [41]. From the perspective of theory development, knowledge about the characteristics of early adopters can help researchers develop richer theoretical models that explain adoption behaviours across a range of adopter types.

Recently statistics indicate that more than four-fifths of U.S. businesses plan to use the tracking technology at some point, with 69 percent looking at RFID as in 2005 [9]. This shows that U.S. companies adopt RFID technology at *Early Majority* category.

IV. RFID Emerging Applications—Supply Chain

IV.1 Supply Chain Historical Perspective

RFID technology can help suppliers eliminate delivery lag times, determine point of origin, track orders in the supply chain, and make inventories more visible (e.g., in a warehouse, in a shopping cart, on a battlefield). Technically, RFID has the capability to increase efficiencies in supply operations by minimizing the need for line-of-sight proximity between a scanner and an RFID tag. In fact, industry analysts are predicting that within a decade, RFID technology will have matured to a point where loaded shopping carts can be automatically read as a customer moves through the store checkout, without the need to unload or manually read tags.

According to Accenture (2004), a global management consulting, technology services and outsourcing company, an RFID open systems solution can increase inventory turns by 10 to 15 percent. Greater inventory turns facilitate capital resource optimization, increased margin procurement and significant reductions in obsolete inventory levels. Supply chain managers today must be better informed with accurate real-time data to stay competitive [1]. Other potential benefits of RFID technology in the supply chain management are listed in Table 3 [6].

Explanation of P, C, I symbols:
 Tagging at various packaging levels (Pallet, Case, Item) in order of significance to achieve named benefits.

Function / Activity	Potential Benefits	Manufacturing	Warehousing	Transportation	Store Operations

Post-Sales Service	Increased warranty compliance				I, C
	Faster warranty and repairs processing				I, C

TABLE 3. RFID and the Supply Chain
 (Source: [51])

IV.2 Driving Forces of RFID Applications in Supply Chain Management

RFID Technology and Information Flow

The supply chain is the flow of both information and material through a manufacturing company, from the supplier to the customer. Information flow broadcasts demand from the end customer to preceding organizations in the network. Information has to be accurate, timely and visible before it can replace inventory. It is the integration of transportation, distribution, ordering, and production. The information can access data interchange and data acquisition at the point of origin and point of sale through inter-company and intra-company. The smoother the information flow, the earlier information can be reached to the customers. It is important that systems be designed to enhance open and rapid communication and sharing of information across the supply chain and within the organization. The flow of information has been recognized alongside the importance of materials flows in the logistics channel. Information technology has been forwarded as a means of achieving competitive advantage, and as a valuable tool used to ensure that the logistics objective of providing target services at the least total cost is accomplished.

RFID enables the user to find, track, secure, and count items faster and with higher accuracy than with other competing technologies. RFID can dramatically increase the

speed, efficiency, and accuracy of data collection by improving the linkage between management information systems directly to the various data points of the supply chain. This capability allows information to be collected, processed, shared and leveraged on a near real-time basis by virtually all members of a supply chain. It is believed that this increased communications speed will continue to enhance the management capabilities throughout the supply chain as they are adopted further. Figure 2 indicates the large number of touch points in a supply chain where RFID tagged pallets, cases and items aid in connecting the physical world with the information world. This does not just only apply to traditional distributions, i.e. from manufacturers to retailers. It can also adapt to the B2B e-business/e-commerce.

RFID is a means of capturing data about an object without the need of a human to read and recode the data. Radio frequency (RF) tracking is a current and highly beneficial technological advance that could lead to tremendous cost reduction in the future for all retailers. If the reader detects a large quantity of a certain product moving off the shelf, it automatically sends a signal to a nearby camera to take pictures and alert security to make sure that these items are not being stolen. This type of information should help stores reduce the amount of theft by not only the customers but also its employees.

Issue Pertaining to Process and Quality Control

RFID enables a number of process management and quality control innovations through real-time tracking.

Inventory expiration management

Products can be tagged for expedited processing when there are time-sensitive constraints. The technology is typically used to track assets at three levels — pallet, case/carton, and unit. Tagging at all three levels allows each to possess its own identity or to be associated with the others for tracking at various stages in the supply chain. With the associations made possible by RFID, when a pallet passes by a reader, for example, the RFID system can identify the pallet and check its location into the software system, while at the same time recognizing the corresponding cartons and units that it is carrying.

RFID's faster scanning process significantly increases inventory visibility, which enables better inventory management through more efficient staging and rapid cross docking. Improved inventory management increases inventory velocity and allows for incremental labor cost reductions. Further, as a result of the enhanced tracking, less safety stock is required.

Manufacturers can continuously track products offering verification and certification of product location, product handling, environmental conditions and processing procedures. And meanwhile, tracking a product's location, handling procedures, environmental conditions, and processing will enable quality control, improvement, and certification.

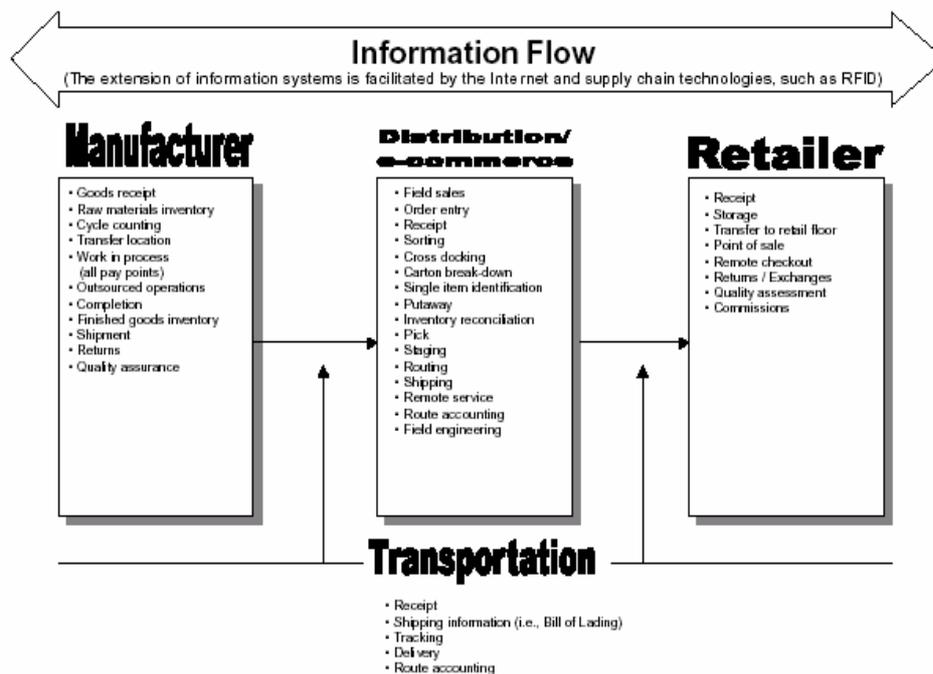

FIGURE 2. Potential RFID Touch-Points in the Supply Chain
(Source: Robert W. Baird & Co 2004 [38])

Employee management and monitoring

Quality improvement requires that line personnel improve product handling and processing. If products can be tracked through the production process, then personnel who handle the products can be better managed and supervised.

The increased reading capability reduces the need for manual intervention as RFID readers can automatically scan incoming shipments entering a distribution center or retail location. RFID's more robust scanning capability also reduces labor associated with pallet breakdown and cross docking activities. In addition, improved inventory accuracy also reduces the need for labor intensive physical counts.

Just in time manufacturing and delivery

Manufacturers can use RFID to work more closely with suppliers and customers to integrate production activities within the plant and to streamline interactions with other participants in the supply chain.

As supply chain members receive better, faster and more accurate inventory information, they improve their forecasting and plan their operations more effectively. As a result, retailers have fewer stock outs, resulting in improved sales (retail sales are said to be reduced by nearly 4% each year from stock outs), while distribution centers save through increased shipping accuracy, which lowers returns and improves customer satisfaction.

Government Regulations and Certifications

Governments can play an important role in helping to foster the adoption of new technologies such as RFID. For example, in the U.S., Department of Defense (DoD) is seeking to use RFID to transform its supply chain. Department of Homeland Security is looking at RFID to secure the nation's ports and borders. Food & Drug Administration (FDA) is encouraging pharmaceutical companies to use RFID to reduce counterfeiting and secure the country's drug supply. Government concerns over food safety have increased dramatically and they are demanding improved supply chain visibility to increase safety and efficiency. This track will have experts to talk about various Government Regulations and how plants can maintain the integrity of their brands, control product from harm, better manage product recalls, comply with government regulations and gain supply chain efficiencies using RFID. For example, in European Community (EC) 178, Article 18 [16] is, the law of traceability, "The traceability of food, feed, food-producing animals, and any other substance intended to be, or expected to be, incorporated into a food or feed shall be established at all stages of production, processing and distribution."

Governments that fund RFID projects give local companies an edge while helping to promote technology that can benefit the society at large.

We have examined the U.S. and European government's roles on RFID. In the next section, we explore RFID in the Asia region.

V. RFID in Asia

V.1 Applications of RFID in Asia

In Asia, RFID applications primarily focus on logistics, with an emphasis on warehousing, shipping, maintenance of product quality and inventory management. Japan is currently researching two approaches to reducing the cost of chips and other Asian countries are expected to follow Japan's lead. Japan has already adopted RFID for a variety of purposes, including anti-theft devices, public transportation, and supply chain management. In their 2004 white paper on the status of information and communications in Japan, the Ministry of Internal Affairs and Communications (MIC) outlined a "u-Japan" policy to promote a "ubiquitous network society [30]."

RFID has been used in South Korea primarily for tracking livestock, public transportation fare payment, highway toll collection, and postal services. The South Korean government is supporting an RFID project at the Port of Busan. It is encouraging companies to invest in an RFID research park. It is also promoting RFID to satisfy growing demand for supply side applications in South Korea and globally in hopes of becoming a leading exporter of RFID technology. South Korean electronics firms such as

Samsung and LG are heavily involved in developing RFID technology. Nevertheless, South Korea's RFID technology is currently years behind that of Japan, Europe, and the United States.

Despite Taiwan's experience in establishing supply chain models and the government's success in promoting e-business, the adoption of RFID technologies in Taiwan has been relatively slow. The government of Taiwan is beginning to assist in the development of an RFID industry and to promote the use of RFID technologies among leading industries.

The Singapore government has put up US\$5.8 million to support the development of the RFID industry in the island republic, while the Chinese government has been encouraging the use of RFID for mass transit tickets and other applications to stimulate adoption. If history is any gauge, this government-industry partnership in Asia is likely to catapult the region to the forefront of RFID adoption.

V.2 Overview of RFID Adoption Drivers in China

China, as a key manufacturing center, will be directly affected by the RFID adoption. There are several driving forces to have RFID adopted in China. Chinese businesses began with a weak foundation in the intense world trade environment, similar to the many other companies that grew from developing countries. How were these Chinese businesses able to compete with foreign competitors armed with strong capital structures and efficient communication networks?

Firstly, as China becomes one of the world's main manufacturing centres, 'Made in China' is reshaping the world supply chain structure. Consequently, China logistics is playing a key role in world business that no manager can afford to ignore. Global manufacturers supply products to many nations, but no nation plays a bigger role than China. Well over 70 percent of the more than \$200 billion worth of goods imported into the U.S. from the Pacific Rim each year comes from China [37].

Chinese government officials and heads of Chinese companies are placing an increased emphasis on the country's logistics infrastructure, which has not kept pace with the growth in manufacturing during the past decade. Because of the growth of China's logistics infrastructure has lagged, China's supply chains are highly fragmented.

China is the world manufacturing engine and the adoption of RFID in the factories and distribution centers of China is fundamental for RFID technology to deliver on its promise of product visibility throughout the global supply chain. China is also a powerful source of out-sourced manufacturing, and suppliers of RFID components, subsystems, firmware or integration services cannot afford to ignore this marketplace of suppliers.

Secondly, the Chinese government is closely watching the adoption of RFID by overseas companies, both to understand potential customer requirements and to learn best practices. The government is also acutely aware that Wal-Mart, with its RFID mandate, imports an estimated \$12

billion to \$20 billion (roughly 10 percent to 15 percent of overall US imports from china) per year directly from China.

Finally, experts suggest RFID might help China's retailers better compete against foreign rivals. They held several conferences on RFID within a couple of years. For example, the RFID China Summit 05, on March 10, 2005, was designed to present the latest news and key end-user case studies and pilots to help China-based decision-makers answer the questions about RFID they are struggling with. Shanghai and 44 other cities already use an RFID payment system for public transportation.

V.3 Opportunities of RFID Applications in China

RFID technology increases visibility and accountability in the supply chain. RFID will allow manufacturers, retailers, and suppliers to efficiently collect, manage, distribute, and store information on inventory, business processes, and security. Everyone recognizes China as a low-cost manufacturer and a huge potential market. In early 2004, China established a working group to draft and develop national standards for RFID tag technology. Some reports indicate the group is adhering to international standards, while others suggest the group is planning to go its own way.

The Chinese government starts to realise the importance of RFID. In addition to the focus in manufacturing, China is interested in anti-counterfeit solutions using RFID especially for the liquor and tobacco industries. Estimates show that more than six hundred million bottles of liquor and two billion cartons of cigarettes are consumed annually by the Chinese population. For the popular brands of liquor and tobacco, more than half are counterfeit items. To protect these industries, the need for anti-counterfeit solutions is compelling. RFID may be one of solutions to this issue.

VI. Threats of RFID Projects in Supply Chain

VI.1. Investment and Training Costs

Presently, RFID technology is expensive and the price of RFID tags has traditionally been a significant obstacle to its widespread deployment in Supply Chain Management. Cost is a factor that may hinder the widespread utilization of radio identification tags. Tags range in price from US\$0.55 to \$55 [28]. Currently the tag reader is possible to read 75 or more tags per second, it has been remarkably difficult to design systems that can read 100% of the cases on a pallet, let alone all of the individual cartons inside a case [21].

Another cost is the large investment for RFID implementation in the large scale IT infrastructure required to support the many suppliers. The cost of acquiring, installing, and maintaining an RFID system will be a major and determining factor in the deployment of RFID in the commercial sector. There appears to be great diversity and little quantitative information in the overall costs of acquiring, installing, supporting and maintaining an RFID system. RFID system cost is composed of tags, readers, and processing and supporting information technology hardware

and software. Higher adoption rates will cause system costs to drop and encourage more RFID users. Middleware (the software that runs the operation) costs vary from US\$25,000 to several thousand dollars [44]. Many expenses will be incurred – everything from the equipment to the management educating employees – without a real sense of what the benefits can be. Many expenses will be incurred – everything from the equipment to the management educating employees – without a real sense of what the benefits can be.

The cost of simple RFID tags is likely to fall to roughly US \$0.05/unit in the next several years [42].

VI.2. Authentication and Security Issues

Authentication is a fundamental aspect of manufacturing and customer interface systems' security. Once a user account has been authenticated and can access an object, either the user rights that are assigned to the user or the permissions that are attached to the object determine the type of access granted. Therefore, authentication applications are usually applied in security critical situations, i.e. granting access rights to restricted locations or providing possibilities for accessing privileged information. Therefore security aspects are highly relevant when considering the best possible technology for authentication applications.

The impending ubiquity of RFID tags, however, also poses a potentially widespread threat to consumer privacy [29]. Most privacy and security concerns about RFID involve the use of RFID at the individual customer level, at or after the point of sale, rather than in supply and inventory tracking applications. Privacy advocates are worried that if RFID tags are placed in common items, the product may continue to be tracked even after being purchased by consumers [49].

According to Cohen (2003), recent improvements have allowed the creation of RF tags that have limited read/write capability. Once authentication protocols for read/write applications have been perfected, there will be a greater chance for creating more secure tags [14].

Jeff Woods, a Gartner research analyst who researched ongoing RFID projects for over six years foresees by 2007, at least 50% of RFID projects will fail - a lot of companies will burn through plenty of money testing the new technology [9],[34]. Reasons for failure may be due to

- many companies have unrealistic expectations on RFID
- sometimes bar codes work best
- ROI is elusive

However, Woods agrees with many industry analysts who said RFID can live up to its billing in about three to five years.

VII. Conclusions and Future Research

In this paper we have illustrated that RFID technology has relatively higher potential applications through the supply

chain procedure over the other identification technology on both the physical transport products from the manufacturers to retailers; and the B2B e-business. We also discover that RFID technology in supply chain management in the U.S, is at *Early Majority* category as suggested by Rogers' Innovation Diffusion model. Similar study in the Asia region is encouraged. The aim of this paper is to explore the opportunities and threats of the applications of RFID technology in supply chain management through the literature review of the research domains: REID technology and the supply chain management.

Asia is eventually going to take the lead in RFID innovation and adoption. In China, because the government now sees logistics infrastructure as a focal point of the country's strategic position in the global economy, it is likely that its government plays a significant role in the adoption of RFID, both in the promotion of standards and the launching of pilot programs.

As is common with emerging technologies, several challenges must be overcome for RFID to mature to its full potential: maturation of RFID technology, harmonization of standards for hardware/software, privacy and security concerns, and implementation cost barriers.

The overall success of RFID technology in the mass market mainly depends on chip prices. It is predicted that by 2006, tags will cost \$0.05/piece [12]. RFID technology is not standardised. Current industry RFID standards are largely incomplete with respect to addressing a number of technology and application issues. "Barcodes have a good fifteen years left to run, but once RFID standards are fixed, it just needs some major retailers to drive supplier adoption, and the whole thing will quickly pick up critical mass [3].

The most straightforward approach for the protection of consumer privacy is to "kill" RFID tags before they are placed in the hands of consumers. A killed tag is truly dead, and can never be re-activated.

The Chinese government is beginning to take action to leverage RFID technology to benefit the country's overall logistics infrastructure and support key customers. Hence, there is a need and great interest for the research on applying RFID technology in supply chain management and e-business in China. We look forward to seeing whether RFID will enhance supply chain competence and e-business, whether this is an opportunity or a threat, in coming years. This paper should help establish the foundation of this research.

Abstract: After a nursing staff of North Town Woman & Children's Hospital made an error injection and caused one infant dead and six injured in 2002, the Taiwan government pays more attention to patient safety. Firstly, the Department of Health (DOH) established the Patient Safety Committee in February, 2003 to promote several patients' safety activities and education training. Secondly, the committee is actively planning a nationwide reporting system of patient safety to summarize the common causes of medical errors.

Most hospitals (about 70%) have not utilized information technology to construct a patient safety reporting system. The conventional reporting mechanism is to fill a paper form and circulate through out the organization. Therefore, in order to make the greater efficiency and effectiveness on a reporting system, this research develops a Patient Safety Reporting System (PSRS) used inside the hospital to solve the disadvantages of conventional reporting mechanism and enhance patient safety and medical quality.

The prototyping method was used to develop the PSRS to assure the communication between users and system designers about the actual system to be implemented. The results show that the PSRS has higher satisfaction than that of the traditional paper method. The PSRS not only save on time and man power for reporting but also improve the anonymity and security of reporting process. These advantages have a positive effect on staffs' willingness of reporting. The experience of developing this system could be used as reference for other hospitals to develop their own PSRS

Keywords : Patient Safety, Reporting System, Patient Safety Reporting System, Medical-Error, Hospitality Business & the Internet.

I. Introduction

In 1999, Institute of Medicine (IOM) pointed out the average body count of medical error is more than traffic accident which caused international attention to medical error. The Patient safety then becomes a popular topic in the medical industry recently. In order to reduce the damage of medical error, various countries established the relevant committee to deal with the issues of patient safety and medical quality in the hope to prevent and reduce medical error.

deal with the issues of patient safety and medical quality in the hope to prevent and reduce medical error.

After a nursing staff of North Town Woman & Children's Hospital made an error injection and caused one infant dead and six injured in 2002, the Taiwan government pays more attention to patient safety. Firstly, the Department of Health (DOH) established the Patient Safety Committee in February, 2003 to promote several patients' safety activities and education training. Secondly, the committee is actively planning a nationwide reporting system of patient safety to summarize the common causes of medical errors.

According to Shi's research (2003), about half of medical employees have experienced medical error events and about 70% regional hospitals and psychiatric hospital in Taiwan still using paper reporting mechanism. Studies indicate several reasons that prevent employee to report errors. Therefore, how to set up an efficient and effective yet unobstructed and secure reporting mechanism to offer medical staff first to recognize causes of errors and then to learn from the mistakes and decrease medical errors is an important issue which the medical administrators should concern. This study develops a computerized Patient Safety Reporting System (PSRS) to achieve the aforementioned goals.

II. Research Methodology

This study first reviewed reporting system related research papers to obtain some ideas about design the computerized PSRS. Secondly, a case hospital was chose for implement the system. Interviewing was used to collect the users ' needs of the systems and questionnaire was used to find out their unwilling reasons to report a medical error. The questionnaire was revised from Uribe's (2002) study. Prototyping method was adopted to develop the PSRS. Finally, an evaluation questionnaire was used to compare the traditional paper reporting mechanism and the computerized PSRS from users. At the stage of system development, suggestions from experts and scholars are used in supporting the completion of system analysis and system design. The developing steps are as followed.

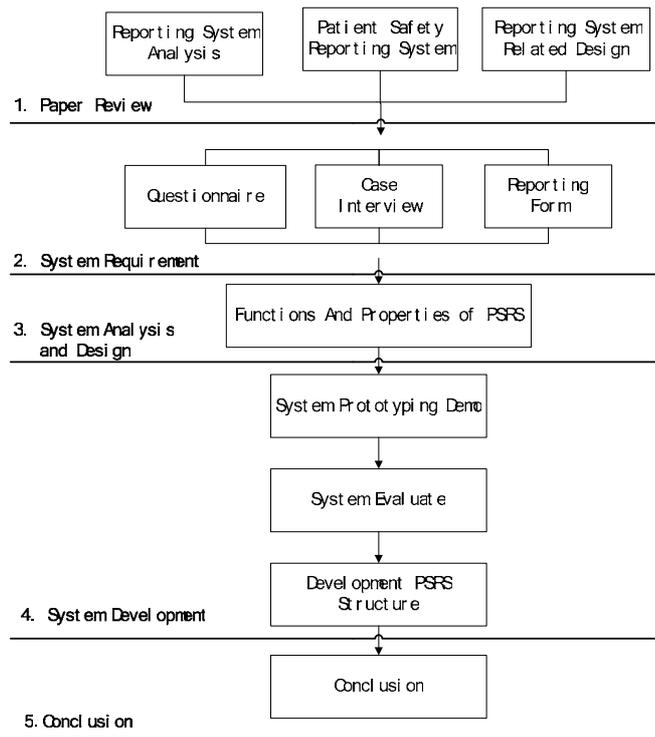

Figure 2 : Study Procedure

III. C

The research takes both the PSRS and the hospital information systems (HIS) into concern. In other words, the PSRS needs to be compatible with the existing HIS. The hardware and software structure are showed in figure 3. The system is developed by adopting Prototyping Method. Use PC to work as the system server, and SQL Server as the database. The system development tool is commonly used as ASP in HIS. Finally, Client/server structure is applied to construct the system on the internal network of the hospital.

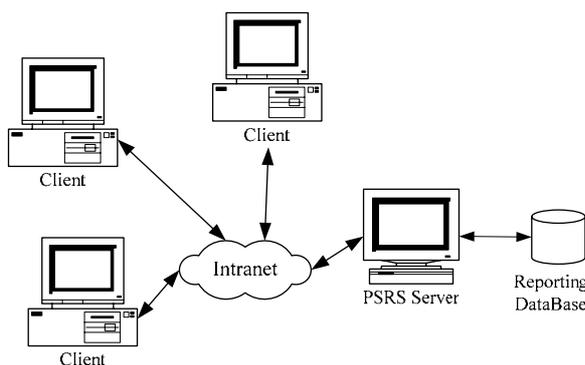

Figure3 : System Environment

SYSTEM FUNCTION

This PSRS is designed for a specific hospital by demand analysis of the interviewing, questionnaire investigation and literature reviewing. Figure 4 shows the PSRS functions and data need for the specific hospital. First, the input data

includes employee basic data, department structure data, and reporting data of medical error. Then, the system instantly deals with the reporting data as shown at the process stage. Finally, the system generates reporting events and reporting data analysis.

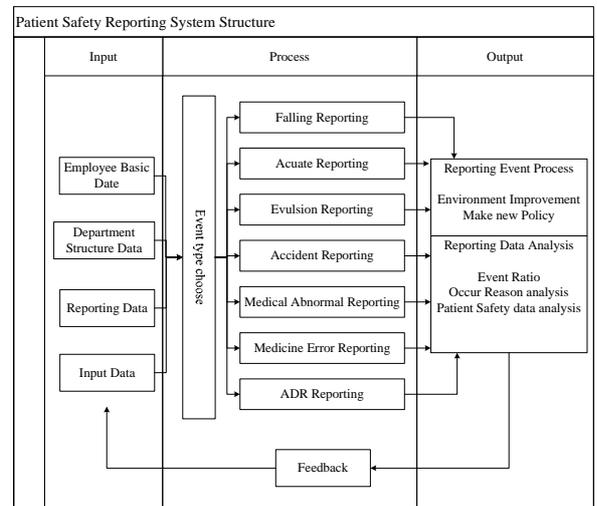

Figure 4 Patient Safety Reporting System Structure

IV. Display and Description

After logging the system (see figure 5), the reporting function page is show as figure 6. The users need to select the reporting type. Then, users have to input the needed data for the event that was intended to report as shown in figure 7. Since the description of the event is well structured, most of the inputs are just to click and check. There is a description box to enter text for anything that was not structured in beforehand. The system will store the input data automatically and send out an e-mail to notify the manager that supervises the reporter about the event. Then, the manager needs to log in the system and give suggestions or guidelines about the event to the reporter. If the event is cross departments, then the manager of the other department and the higher supervisor will be notified by e-mail automatically. In addition, the system also offers report and generates various types of statistical (see figure 8), depending on the type of report that users select. The monthly report of the events reported will be summarized and sent to the committee of patient safety of the hospital and further to the national patient safety committee.

Figure 5: User Login

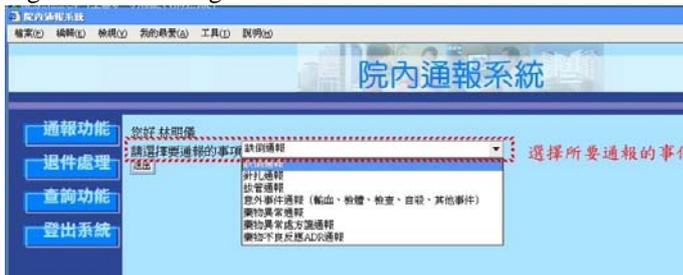

Figure 6: Select Reporting type

Figure 7: Reporting data input

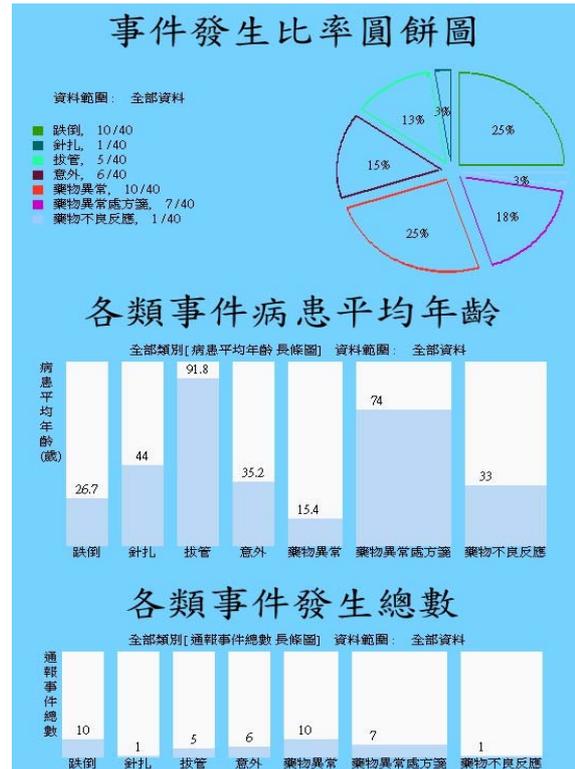

Figure 8: Data analysis and statistic

System Assessment

The assessment is done by questionnaire investigation through the internet. The subjects are staffs in the case hospital who have used the PSRS. The staffs give scores from 1 to 5 to represent first-rate to last-rate. Table 1 shows the comparison between the PSRS and the traditional paper reporting mechanism. The first-rates of paper reporting mechanism is easy to access the paper form to report while the PSRS is save on the manual distributing effort on the physical report. The best five that RSPR outperforms the paper mechanism are in the manual transferring effort on the physical report, environment protection, confidentiality, anonymity, and the efficiency of transferring the report.

Table 1: Comparison of Assessment between PSRS and paper reporting

System Property	PSRS		Improvement	
	Average	Rank	Average	Rank
Anonymity	3.39	11	0.84	4
Convenient to Report	3.42	8	0.39	13
Time Saving	3.39	10	0.45	12
Ease of Use	3.53	4	0.66	8
Transferring Time	3.55	3	0.81	5
Feedback	3.37	13	0.54	10
Confidentiality	3.41	9	0.92	3

Environment protection	3.50	6	0.96	2
Security	3.19	14	0.49	11
System Cost	3.48	7	0.78	6
Manual Transferring Report	3.63	1	0.99	1
State Monitor	3.52	5	0.74	7
Form making	3.58	2	0.65	9

According to the questionnaire results shown above, the average score of paper reporting system are all below than 3 except in the item of ease of access. Therefore, it is obvious that users were not satisfied with the paper reporting system. In the contrast, the average score of PSRS are all higher than 3 points which reveals that users are more satisfied with the PSRS. Hence, the computerized PSRS is extremely beneficial.

V. Conclusion

The result of this research shows that utilizing information science and technology to report medical errors can not only offering efficiency and reducing cost, but also improve the

shortcomings of the traditional paper reporting, such as lack of confidentiality, anonymity, security, as well as the trouble of manual transferring reports. The PSRS enhances the users' reporting willingness and forms a good reporting culture inside the institute. One observation is worth mentioned that the reporters of paper reporting mechanism were most nurses and medical staffs the rest while the reporters of PSRS even include janitors. Moreover, after the reporting culture inside the hospital is formed, staffs can learn to prevent medical errors from previous experiences. From the aspect of information science and technology, more data analysis can be carried out when more data are accumulated, such as Data mining, Neural Network, and OLAP analysis, in order to find the unexpected pattern related to causes. This study is to develop a specific information system for a case hospital. The external validity may not be satisfactory. However, the experience of developing the PSRS can serve as a reference for other hospitals that intend to build their own computerized reporting system. With more hospital establish inside-hospital reporting system, the national patient safety reporting system then can have true and solid data to analyze. Then the government can set up policies or regulations based on the analysis and enhance the medical quality nationwide.

Adoption of Wireless Handheld Technology: A Case of Queensland Healthcare

Raj Gururajan¹, Abdul Hafeez-Baig² and Clint Moloney³
The University of Southern Queensland^{1&2}
Queensland Health Department³
Toowoomba, Queensland, 4350 Australia
gururaja@usq.edu.au

Abstract: Wireless technology is considered to a component of emerging technologies due to its relative newness in business. The mobility offered by this technology has influenced the introduction of this technology in healthcare, especially for nursing profession as nurses are always moving between patients and wards. The main advantage provided by this technology is collection of patient data at point of care, to manage patient schedules and to manage pharmaceutical information as these are the tasks performed by nurses in their workflow. Further, the technology offers flexibility and mobility to nursing staff to enable them to access data while they are moving between wards and patients. Despite many comments, it appears that user opinions on the adoption of technology specific to nursing are not prevalently available as current studies are focused on the technical aspects. This study, through a grant won from the Queensland Nursing Council in 2004, conducted a set of 30 interviews with nursing staffs to identify adoption factors. A qualitative technique, namely interviews, was used for data collection purposes and the adoption factors were identified using an NVivo analysis. The outcome of the interviews is reported in this paper.

Keywords: Mobile Commerce & Business, wireless technology, health care, IS

I. Introduction

Prior studies indicate that wireless applications using handheld devices can provide significant advantages by providing solutions to some of the existing problems that healthcare professionals face. These advantages include the reduction in transcription errors arising from paper based documents (Sausser, 2003), data collection at point-of-care (Simpson, 2003), considerable reduction in the amount of paper work required (Sparks et al., 2001), administering medications by having text based alerts using these handheld devices (Dyer, 2003), remote monitoring of patients and connecting to other systems such as patient care (Yacano, 2002).

While prior studies have highlighted the advantages of handheld applications, they have not yet ascertained factors that determine adoption of such a technology. This study is

designed to determine these factors. Once the factors of adoption are ascertained and appropriate solutions put in place, healthcare providers can enjoy the benefits of the application of this technology by providing solutions to staff associated with any crises encountered (Davis, 2002), managing the increasingly complex information challenges (Yacano, 2002), complying with the rigorous regulatory framework (Wisnicki, 2002), reducing the medication errors (Turisco, 2000), generating affordable applications that allow for greater mobility (Athey & Stern, 2002). In addition to these, wireless applications would also provide benefits to healthcare due to its flexibility and mobility in providing for better data management (Wisnicki, 2002), including complex patient data requirements (Davis, 2002), proper integration of data to existing systems (Craig & Julta, 2001), and improved access to data from anywhere at any time (Stuart & Bawany, 2001).

II. Literature Review

In healthcare literature, the concept of wireless technology is discussed by many studies (Wisnicki, 2002; Dyer, 2003; Simpson, 2003; Sausser, 2003; Hu et al., 2002). For example, Wisnicki (2002) provides details of how broadband technology, a component of wireless technology, can be used in healthcare. The discussion provided by Wisnicki (2002) involves the high cost of setting up wireless technology in a healthcare setting, improvements to patient care using this technology and potential cost-effective quality of service to patients. Sausser (2003) provides information on how to improve clinical quality using wireless technology including challenges for maintaining security and privacy. Sausser (2003) also discusses the concept of portable devices for data collection purposes by providing an argument on benefits that can be realised using these devices. Simpson (2003), while critiquing the nursing domain, stresses the need for the innovative use of IT to improve patient care. He points out those new IT technologies can help address some of the chronic problems encountered including saving nurses time, skilled nursing care and home health care. He also provides details on the expended time per every hour of nursing care and suggests that new technologies would provide solutions to some of the acute problems of nursing due to this time factor. Dyer (2003) on the other hand provides details of how text messaging using wireless devices can be effectively used to remind patients of their appointments. He reports the idea behind a radically new

system of managing patient care in conjunction with modern telecommunication applications using wireless devices to improve the quality of patient care. Common to all these studies is the use of emerging technologies in healthcare and potential benefits that can be achieved.

While many other studies reviewed in the healthcare literature echo similar sentiments, none of these studies have examined the potential problems in data collection methods using wireless devices. It appears that almost all studies have taken this crucial aspect for granted. While some studies have indicated existing problems in collecting patient data and provided some theoretical solutions, these studies have seldom analysed the changing nature of information systems using wireless devices.

To understand the issues associated with data collection using wireless devices, the Information Systems literature is also reviewed. Such a review indicated that this area is not fully researched. For example, Redman (2002) states that the wireless technology is in its infant stages and warns of the potential pitfalls when IT providers rush to implement the technology; Shah (2001) warns of the slower speed of wireless networks compared with the desktop computers and highlights the potential problems that could be encountered by healthcare; the relative high costs to initially set up these wireless networks is highlighted by Shroeder (1999); lack of real time connectivity due to the mobility of the device and the problems associated with such mobility is highlighted by Stevenson (2001); the size of the screen and hence the problems that may be encountered to display data due to screen size while capturing data is stressed by Toms (2000); the problems that may be encountered due to the lack of provision for high quality graphic display on wireless devices is highlighted by Atwal (2001), and Bevan (2001) discusses the potential problems of capturing data using wireless devices due to the 'hard-to-see display' nature of these devices. While the above mentioned studies warn that problems could be encountered while using wireless devices, they also tend to agree that the usage capabilities of these devices are growing and hence these hardware related problems will disappear in a few years time.

What can be realised from this review is that the majority of the studies have focused on the 'hardware' or 'physical' component of wireless devices as this appears to be a focal point of interest to many authors now. Other studies can be grouped into the 'implementation' or 'management' of wireless technology in healthcare organisations as the cost appears to be a determining factor in such implementations. None of the studies reviewed appear to have examined the 'usage' aspects of wireless devices. While studies such as Davies et al. (1989) have examined the 'Technology Acceptance' in organisation and derived a model for such acceptance, the outcomes of such studies can't be generalised for wireless technology as the technology is radically different from the traditional desktop technology. With desktop technology, users source data by accessing them using wired and fixed devices. On the other hand, with wireless technology, the data comes to the users

via the hand held devices and this new paradigm gives users a lot of mobility and hence access to data.

While healthcare organisations are keen to save money, they are also keen to provide high quality services to their patients. Crucial to this high quality care is data collation and analysis for decision making. The raw data collected at point of care by nursing staff is converted into information by feeding the raw data into various organisational databases. Current literature highlights the importance of incorporating wireless devices in organisations without discussing how nurses are able to collect data effectively. Limited information is found on the factors of adoption and inhibitors associated with such devices. Therefore, this study conducted an investigation into the factors of adoption of wireless applications for data collection by nurses. The adoption consists of facilitators and barriers. The facilitators are the positive influence and the inhibitors are the negative influence. By doing so, this study will fill-in the gap in the literature and provide insights into those factors that need to be given priority while using wireless handheld devices for data collection purposes.

III. Research Plan

III.1 Research Problem

This research aimed to identify factors that determine the adoption of wireless handheld applications in hospitals for data management by nurses. This research examined potential challenges in adopting wireless handheld devices due to the rapidly changing nature of technology and associated legislative framework. Based on the initial literature reviewed, the following research questions were asked in this study:

1. What are the factors of adoption of wireless handheld devices in healthcare for nurses?
2. What are the emerging challenges in adopting wireless handheld devices in nursing?

III.2 Research Design

The focus of this research study was to investigate the factors of the adoption of wireless applications. Inference from the literature revealed that this was an under explored area which demanded investigation into the role of technology and that of human context in using the technology. Although prior studies in Information Systems and Health indicated that a quantitative approach would suffice, recent studies recommended that a combined approach (mixed methodology) of qualitative and quantitative methods would provide strength to the research outcome. Experienced researchers indicated that there was a need to include qualitative approach to study the human social and psychological factors (Remenyi et al., 1998).

The research study investigated human psychological factors such as training, ease of use, motivation, culture, causal ambiguity, absorptive capacity, and retention as factors influencing the adoption factors of new technology.

Factors identified for this research were limited and needed to be expanded further to accommodate other unknown factors that affect the adoption of wireless technology in a given setting. Hence this study included a qualitative approach with the use of interview methods to strengthen the research outcome.

This research was designed to capture a cross-sectional snapshot and a dynamic longitudinal picture of the acceptance of wireless handheld devices and their applications in hospitals. The data were collected using a qualitative technique, namely interviews. The data were collected from nursing staff involved in patient care and focused on their behavioural patterns of adoption and usage of current technologies and their opinion on the usage of wireless technologies. The interviews focused on understanding nurses' changing views and behavioural pattern. Three specific hospitals were identified for this purpose where wireless devices are used for data collection purposes. The hospitals were derived from government, private and regional sectors respectively.

The qualitative method employed in this study included semi-structured in-depth interviews to gain a sufficient understanding on the topic from nurses using wireless technology in hospitals. These interviews helped to identify any unknown factors that affect the adoption of wireless technology.

III. 3 Data Collection

The data collection involved two specific stages. In the first stage we reviewed the existing literature in order to identify various issues impacting the healthcare domain where handheld devices can be used. This is called as the 'exploratory' stage. The main purpose of this stage was to identify factors in order to derive an interview instrument. The second stage involved actual data collection. These two stages are explained below.

Stage 1 – Literature Review (exploratory):

Extensive literature review was carried out at this stage to integrate the materials available into the interview questionnaire. The questionnaire consisted of over 20 themes and an information sheet was prepared after this comprehensive literature review. The specific purpose of this stage of the study was to ensure that nursing staff were comfortable in answering the technical aspects of wireless technology as appropriate to their working environment. This stage did not identify any mediating factors and only main factors influencing the adoption of technology were the focus of this stage.

Stage 2 – Interviews (evaluative):

In order to extract opinions about technology in a specific domain such as healthcare, the choice of sample is crucial. This is because the opinions expressed by nurses should be unbiased and should pertain only to technology and not the effects of technology on their current workflow. The samples for this project were drawn from the

Queensland health department and each of the samples is currently holding a practicing license. Further, the participants chosen are working in wards and people with administrative roles have been eliminated from the interview.

While Information Systems research identifies a range of sampling techniques such as random and clustering, the sampling technique used for this study is classified as 'purposive' sampling. As we need healthcare staff with special knowledge of technology, this approach was followed in this study. The samples were chosen through the local medical district on their advice as their opinions on wireless technology was extracted based on their knowledge. Therefore, the samples needed to exhibit certain attributes that are related to technology adoption. This approach has been followed in many health studies.

In the second stage of the research a set of 30 interviews were undertaken. In order to ensure the interviews were conducted on time, the local health district was approached through one of the authors of this paper and suitable candidate groups were identified. After obtaining ethical clearance from both the principal university and the Health District, a research associate from the Health District was contracted to undertake the interviews. The interviews were conducted in such a fashion as to minimise any disruption to nurses' work schedule, ensure comfort of nurses in answering questions, minimise any travel time by interviewees, synchronise the 'interview' language with participants and to prompt nurses when unknown aspects were encountered by participants.

Prior to the interviews, the line managers were approached for permission to release staff for interviews. Initially a consent letter was distributed to obtain consent for interview and the list of people interviewed was provided to the Health District. The interview was recorded using a digital recorder and catalogued as per ethics requirement. These interviews were then transcribed for data analysis.

Participants for the interview were selected from the nursing staff in Queensland Health. The participants were initially screened for suitability as only nurses working with technology were considered for this purpose. Any nursing staffs involved with administration only were eliminated from the interview to avoid any unforeseen bias. Nurses with a vast background were chosen (pharmacy, oncology and emergency departments). As the nurses belonged to the Health Department, no further screening was employed for sampling.

The instruments of this research consisted of two broad categories of questions. The first category of questions was related to the adoption and usage of wireless devices in hospitals for data collection purposes. The second category consisted of demographic variables. Open ended questions were included in the instrument to obtain unbiased and non-leading information. Prior to administering the questions, a complete peer review and a pilot study were conducted in order to ascertain the validity of the instrument. A two stage approach was used in administering the instrument, where the first stage would gather information about the key

factors influencing users' decision to use wireless applications and the second stage on the importance of those key factors. This approach was followed in this study in order to complement the open ended questions so as to determine the importance of the individual factors determining the adoption and usage of wireless devices and applications.

III. 4 Data Analysis

The data was analysed using NVivo software application. Prior to the analysis of data, the interviews were transcribed using university services. The transcribed interviews ranged from 8 pages to 17 pages in length, covering a total of 260 pages of rtf format file. Two experienced transcribers were involved in the process of converting the interviews into a computer file.

Once the files were transcribed, they were read while listening to the conversation in order to verify accuracy of transcription. Any bits that were missing during the transcription process was filled in as the researchers possessed sufficient knowledge of various technical terms used in this domain. The files were then printed and scanned for facilitators and inhibitors. These themes were identified on paper and then used as nodes in NVivo while examining the text files.

Once the themes were identified as free nodes using NVivo, the text snippets were examined again to aggregate the nodes into groups. Initially over 200 free nodes were realised and they were grouped into facilitators and inhibitors by examining the text passages again. They were grouped into the two major categories as trees and a simple correlation analysis using the table facilities was also performed on the various nodes.

III. 5 Results

The analysis using NVivo confirmed that the following facilitators and inhibitors can be extracted from the data collected from nursing participants. Our aim was in identifying the factors impacting wireless technology adoption. We did not attempt to classify them in an order of priority. However, we will be conducting more data analyses to classify them in proper groups and this exercise is beyond the scope of this project. The following tables list the facilitators and inhibitors of wireless technology adoption in nursing.

Table 1: Organized facilitators of the adoption of wireless hand held technology

Facilitators 1=Facilitators 2=volumes of information 3=user friendly 4=user friendliness 5=reduction of documentation 6=quicker response 7=more timely recording 8=mental health
--

9=medication schedule 10=medication errors 11=managing data 12=intensive activities 13=Health policy 14=handover reports 15=fantastic benefit 16=falls 17=cut down on the paperwork 18=current competence 19=benefits 20=avail lability of more time 21=alert clinicians 22=adverse event 23=advantages 24=access massive amount of information 25=remote monitoring
--

Table 2: Organized inhibitors of the adoption of wireless hand held technology

Inhibitors 1=Inhibitors 2=user friendly 3=user friendliness 4=unreliable 5=testing 6=short staff 7=secure 8=reliance 9=problems 10=schedule 11=How does it work 12=Health policy 13=coverage 14=confidentiality 15=awareness

III. 6 Specific comments on the factors

Facilitators – this factor indicates the positive influence of wireless technology on nursing. This factor also indicates that due to the positive mind frame, nurses will be keen to adopt the new technology in their setting.

Volumes of information – nurses indicated that wireless technology will help them manage the volumes of information. This can be realized due to the mobility and flexibility offered by the technology. This factor also correlates with data management, more timely recording and medication schedule.

User friendly – participants indicated that user friendliness of mobile applications will enable them to get their work done better. The distinction between user friendly and the next factor user friendliness was not clear. However, the term ‘user friendly’ was discussed while we were probing the technical aspects. Therefore, we believe that participants are referring to the applications used to conduct their daily work schedule and predominantly

indicate IT systems.

User friendliness – this factor was seen as a driver and was discussed while the management of technology was discussed. Therefore, we assume that the participants refer to the management of IT applications and the resources provided to them to conduct their jobs.

Reduction of documentation – this factor has been identified as a major driver by almost all interviewees. The nursing participants felt that wireless technology can provide the greatest advantage in this domain. This factor was linked to hand over reports.

Quicker response – this factor was mentioned in three specific contexts. The first one was accessing information in order to respond to various queries. The second aspect was in terms of various care management procedures. The third aspect was in terms of hand over reports and any query arising at this point of hand over. Participants believed that wireless technology in conjunction with better access would provide significant benefits in this domain.

More timely recording – participants felt that the mobility offered by the technology would enable them to record events in a more efficient manner than the paper based system. This factor was stated in conjunction with quick response and reduction of documentation.

Mental health – this factor was not recognized by all participants. We believe that this may be specific to a domain and highlighted in that context. Participants felt that wireless technology can help to track mental health issues such as monitoring patient movements using a handheld device. They expressed that wireless technology in conjunction with other technology such as Geographic Information System will accomplish tracking of patients specific to this domain.

Medication schedule – this is another area where participants felt that wireless technology can bring in significant benefits. Participants felt that handheld devices can help to track various details of medication schedules pertinent to patients. This factor was also linked with a reduction in paper work and timely recording.

Medication errors – this factor was almost agreed as a driver by all participants. The greatest benefit of wireless handheld technology appeared to be a reduction in medication errors. Participants commented that by introducing proper validation checks in the computer systems running on the wireless devices, instant validations can be facilitated leading to reduced medication errors.

Managing data – this factor emerged as a strong driver due to the mobility offered by wireless technology. Participants expressed their view that handheld devices will enable them to carry data as they move. This is also seen as a major paradigm shift in the way data is handled now. This factor is strongly correlated with a medication schedule and reduction in documentation factors.

Intensive activities – this factor was considered to be a less significant driver by the participants as they feel that the advantages provided by the wireless technology may be able to minimize the burden placed by their intensive schedule of

activities.

Health policy – this factor emerged as a driver despite the fact that certain participants questioned the current health policy. The consensus appears to be that if there is a proper health policy then the technology can deliver promises. Due to the positive perception exhibited by participants, we classified this factor as a driver, rather than an inhibitor.

Handover reports – participants expressed this as a major driver as almost everybody agreed that the wireless handheld devices can provide significant benefits in this domain.

Fantastic benefit – this aspect is categorized as a factor because the term ‘fantastic benefit’ emerged in many conversations. While participants were not able to clearly identify benefits, there is a positive feeling that the technology would be able to deliver benefits.

Falls – this factor was identified as a driver with a very specific cohort of participants coming from the aged care sector. We believe that these participants are already familiar with the handheld device to monitor aged care patients’ falls details.

Cut down on the paperwork – this factor emerged as a strong driver with links to reduced paper work and improved medication schedule. Participants agreed that handheld technology can definitely cut down paper work due to timely digital recording of data. Further, they also felt that this may reduce the errors such as transcription errors.

Current competence – this factor was discussed in a multitude of contexts. Some participants expressed that nurses are already handling a variety of technology and are therefore, competent enough to handle handheld technology. Others expressed that they are familiar with computing systems and hence possess necessary competence to manage handheld devices. This factor clearly indicates that nursing staff are not afraid of using new technology in their work.

Benefits – this factor was stated by a few participants while discussing the handheld technology. While this is a driver, the factor needs to be investigated further to identify what the actual and perceived benefits are.

Availability of more time – this factor emerged strongly with a number of people agreeing on this factor. The perception was that participants felt that they will be able to have more time to perform core functions because wireless handheld technology can assist them with data management.

Alert clinicians – participants felt that by using wireless technology, it may be possible to alert physicians in a more sophisticated way than the current ‘pager’ systems. They also felt that physicians can view various data associated with patients in a better way using the handheld technology.

Adverse event – this factor emerged as a driver because participants felt that wireless handheld technologies can provide more information in regard to adverse events because it is possible to store aspects of adverse events and retrieve them using this technology.

Advantages – this factor needs more investigation as participants stated there are advantages using wireless handheld technology. We were not able to glean more details from the interview schedule beyond this word.

Access massive amounts of information – this factor emerged as a major driver due to the perception that currently nursing professionals have to handle massive amounts of information which is carried in folders adding to the burden. Participants felt that the use of handheld technology may alleviate varying voluminous files and also provide access to data that is not available on hand while handling patients.

Remote monitoring – participants felt that wireless technology can facilitate remote monitoring using sophisticated methods. This emerged as a major driver because the majority of participants agreed that this be a driver. However, the concept of remote monitoring was expressed from monitoring a patient from their chairs to managing a patient in regional locations using this technology. This has a weak correlation with management's policy factor.

Inhibitors - this factor indicates the negative influence of wireless technology on nursing. This factor also indicates that due to the negative mind frame, nurses will NOT be keen to adopt the new technology in their setting.

User friendly – this factor indicates the technical component of wireless applications as applicable to nursing. Participants indicated that applications and computing systems should be user friendly in order to be adopted. It appears that current systems are not very user friendly and hence the negative bias in adopting new technology.

User friendliness – this factor was discussed by participants in terms of management support. Participants expected the supporting environment to be friendly in order for them to receive the necessary support.

Unreliable – this factor emerged as a major barrier because a number of participants discussed this under varying contexts from technology to management. The technical reliability of wireless coverage within health appears to be an issue. In addition, some participants also questioned the robustness of health policies in the wireless technology domain leading to major skepticism of the adoption of this technology.

Testing – this factor assumed minor importance as a barrier, as users insisted that wireless systems should be thoroughly tested prior to adoption. This factor was also correlated to education aspects.

Short staff – this factor emerged as a major barrier as many participants highlighted this issue. Participants highlighted the shortage of staff in health and its impact on technology adoption. One area that emerged here was the necessity for training and the impact it can have on staffing issues. This was weakly correlated to the policy framework.

Secure – this factor also emerged as a major factor as participants were concerned about this issue. The security factor was also discussed in terms of privacy and the impacts on their job. This factor had perhaps the most negative influence on the adoption of wireless handheld technology as it impacted performance.

Reliance – this factor was discussed by participants in terms of technology failure and their concern to resume

health activities without reliable technology. This factor was correlated with a number of facilitators such as access to information in a wireless environment.

Problems – this factor was categorized as a barrier because of the technical problems that can impact wireless handheld technology. This factor correlated with user friendliness in terms of support warranted when systems fail. Participants have again highlighted the need for robust policies in this domain and sufficient back up options.

Schedule – this factor was somewhat confusing as this was discussed under a variety of themes. The main negative feeling merged because of a proper schedule of wireless implementation in the participants' working environment. This has introduced a lack of direction as many participants encountered many different schedules for wireless implementation through varying policy statements.

How does it work – participants expressed this factor as a barrier due to the lack of training provided in the wireless technology domain. This factor was stated with the need for training.

Health policy – the lack of clarity in developing a rigorous policy framework has introduced a barrier to the adoption of wireless handheld technology according to the participants. They felt that a clear policy framework is essential as to the procurement of devices, usage framework, training, measurement etc.

Coverage – participants were uneasy as to the coverage aspects. This was discussed in technical terms and correlated with the policy framework.

Confidentiality – this factor emerged as a barrier when discussing access to information aspects. Participants highlighted that they were unclear as to the various confidentiality clauses and the impact on these clauses by using technology that is not well governed. This was considered to be a significant barrier by participants.

Awareness – this factor emerged as a result of the relative newness of the technology in the domain area. Participants expressed their concerns due to the newness of the technology in health and the need to raise the awareness as relevant to their profession. This also appears to be a major barrier in the adoption of wireless handheld technology.

IV. Discussion - Factors of Adoption & Emerging Challenges

Once these facilitators were identified from the interview notes, an effort was made to group them based on some arbitrary common themes among factors. While the interview data was analysed based on context, it was possible to extract four broad themes namely: ocumentation, information management, advantages and benefits. The documentation theme refers to any incentives to reduce paper work encountered by nursing staff. Information management refers to access to information and associated aspects. Advantages refer to positive and direct influences encountered in their daily operations. Benefits refer to

influences at organisational level as viewed by nurses. Themes that fitted these groups were identified and clustered under these four factors and a model was derived using NVivo.

Previous studies have already indicated that information management (Sparks et al., 2001) is a significant advantage using wireless technology. This was discussed by previous studies in terms of time management due to reduced information load (Sparks et al., 2001), reduction in medication errors (Sausser, 2003), and reduced documentation (Yacano, 2002). This study agrees with the previous notion that information management can be made easy by using wireless technology adoption. The new factors such as user friendliness, quicker responses, timelier recording and availability of more time for routine work appear to be the facilitators of the adoption of technology for healthcare professionals. Other comments indicate that healthcare professionals believe that the reduction in documentation and the quicker responses associated with the technology would be significant drivers of adoption. If adoption is slow, it may be more an indication of implementation problems rather than the perceptions of the relative advantage of the technology.

The inhibitors reveal details that are not found in the literature yet. For instance respondents considered the surrounding infrastructure to be a barrier to enable the technology. This is reflected in their statements to the effect that short staff, policy and work schedules are all considered inhibitors in adopting the wireless technology. This needs further investigation. The lesson from this exclusive exercise is that the factors of data management will drive the adoption of wireless technology in healthcare as this is where significant advantages can be gained. While some factors reported in this study are already highlighted by previous studies, this is perhaps the first attempt to extract views from users in a systematic manner. In addition to wireless technology, work settings appear to be impeding the adoption of technology. The implication of this aspect is that, in addition to the introduction of wireless technology, healthcare managers should consider the working conditions of their staff as these conditions enable the use of technology. In terms of theories used in the Information Systems Domain, there are five dominating aspects to technology adoption in any given setting. They are (i) relative advantage, (ii) compatibility, (iii) complexity, (iv) trialability and (v) observability. These five themes are well justified in this study. For instance, the theme 'Relative Advantage' is justified by the information management concept as expressed by the healthcare people in this study. 'Compatibility' is established through various discussions on access to resources including technology and devices. 'Complexity' is discussed by the participants by the information overload and the benefits that technology can bring in terms of time savings. 'Trialability' is highlighted by the fact that 'the technology is here to stay' and their implied willingness to trial new systems. Finally, the 'Observability' is mentioned in terms of various benefits that

can be provided by the technology.

In essence, while some factors correspond to the literature, emerging new factors indicate the benefits that this technology can bring to healthcare and associated facilitators of adoption. The next level of this research will look at the factors outlined by Rogers using an in depth analysis of the interviews and relate them to the factors identified by the nurses during their interviews.

V. Significance to Nursing

The study is significant to nursing for many reasons including the mobile nature of nurses, heavy data access when on the move, hand over reports, etc. Literature indicates that handheld devices can provide significant advantages to nursing by providing solutions to some of the existing problems such as the reduction in transcription errors arising from paper based documents (Sausser, 2003), data collection at point-of-care (Simpson, 2003), reduction in considerable amount of paper work (Sparks et al., 2001), administering medications by having textbased alerts using these handheld devices (Dyer, 2003), remote monitoring of patients and connecting to other systems such as patient care (Yacano, 2002). While prior studies have highlighted the advantages of handheld applications, they have not yet ascertained factors that determine adoption of such a technology. This study is perhaps the first attempt in Australia to identify these advantages by talking to nurses using an interview instrument.

VI. Conclusions

We found out that the adoption of wireless hand held technology by nursing staff received mixed feedback. While the facilitators are more than the inhibitors, issues such as security and awareness indicate the concerns to adopt new technology.

The driving force behind the adoption of wireless technology in a nursing domain appears to be the access to information and the management of volumes of information. While these two factors emerged strongly as facilitators, participants also felt that these two factors can reduce errors and paper work. We recommend that further research is now conducted on the issue of access to information, inclusive of an impact analysis.

In terms of inhibitors security, confidentiality and policy framework appear to be inhibiting the adoption. It can be noted that these factors are directly related to the management of technology rather than functional aspects of technology. These factors when combined with awareness and education issues indicate the reluctance of nursing staff to use the technology as the direction is not clear to them. If security, confidentiality and policy framework have effective corporate governance in raising staff awareness, this should overcome the barrier.

In essence, the data indicates that the facilitators are facilitated by the potential this technology can offer and the

inhibitors are the lack of management direction provided by the department or by the operating environment. In our opinion, while there is considerable enthusiasm to adopt new technology such as this, the participants are reluctant because they were not provided with comprehensive information as to how this technology can benefit them. This can be highlighted as an awareness issue, which is easy to rectify.

We believe that the effect of inhibitors can easily be minimised by adopting a training and education framework. This training framework will inform the nursing staff of the benefits, the policy framework and regulatory framework in their working environment. Once this is covered, a simple trial pushed from the top will enable staff to actually experience the benefits. This coupled with better technical support will influence users' decision to adopt wireless technology in their working environment.

We recommend that when considering the implementation of wireless technologies into the nursing profession that the adoption factors outlined in this report are taken into consideration.

In summary we believe that we have generated through this research an effective implementation model that will assist nurses considering the acquisition of such technology.

Collaborative Forecasting under CPFR[®]

Henry C. Co and Juanita Roxas
College of Business
California State Polytechnic University
3801 W. Temple Ave, Pomona CA 91768
hco@csupomona.edu

Abstract: Collaborative Planning, Forecasting and Replenishment (CPFR[®]) is an inter-industry initiative driven by the Voluntary Interindustry Commerce Standards Association (VICS) to improve partnership between manufacturers and distributors/retailers through the exchange of information. This paper examines the assessment, communication, and reconciliation of forecast errors under CPFR[®]. A basic spreadsheet program is used to demonstrate how to facilitate analyses. Instructors can use this exercise to demonstrate examples in the classroom.

I. Introduction

Collaborative Planning, Forecasting and Replenishment (CPFR[®]) is an inter-industry initiative driven by the Voluntary Interindustry Commerce Standards Association (VICS) to improve partnership between manufacturers and distributors/retailers through the exchange of information. Its mission is to increase visibility along the supply-chain, thereby reducing the variance between supply and demand.

CPFR[®] evolved from CRP (continuous replenishment process), or better known as the vendor-managed inventory program (VMI). Successful VMI initiatives have been trumpeted by many companies, including Campbell Soup, Johnson & Johnson, European pasta manufacturer Barilla SpA, Shell Chemical, General Electric, Intel, and many others. However, inaccurate forecasts and undependable shipments have been major obstacles to higher performance.

Using decision support tools and standardized data formatting and communications, trading partners take equal roles in developing and managing a plan for "what is going to be sold, how it will be merchandised and promoted, in what marketplace, and during what time frame," based on the category management practices created as part of Efficient Consumer Response.

By eliminating procedures such as order processing and exception processing and taking into account factors such as the manufacturer's supply constraints and the retailer's promotion plan, both parties can use all the information available to make the best possible joint decisions.

CPFR[®] changes the relationship paradigm between trading partners. CPFR[®] requires redefinition of a company's goals and direction. It requires trust between partners. The sharing of product information, point of sale (POS) data and market intelligence among trading partners, usually through EDI or exchanges, is the building block to

CPFR[®]. Periodically, the retailers and their vendors would hold manual collaboration meetings to make their forecasts more accurate. With forecast collaboration, the vendors not only see the demand patterns of their immediate customers (the retailers), but also the demand patterns of the end-users. Thus, their forecasts reflect the actual consumer demand. Periodic collaboration meetings provide proactive decision making and adjustments, thereby improving replenishment orders execution.

This paper examines the assessment, communication, and reconciliation of forecast errors under CPFR[®]. A basic spreadsheet program is used to demonstrate how to facilitate analyses. Instructors can use this exercise to demonstrate examples in the classroom.

II. Forecast Errors and Accuracy

The calculation and communication of forecast error (or accuracy) measures among trading partners is crucial to the evaluation of demand planning activities. It is therefore important for trading partners to understand the parameters and alternative formulas for calculating and reporting these metrics.

II.1 Forecast Errors

Forecast errors are most often reported as absolute values. Regardless of whether forecasts are high by 8% or low by 8%, forecast error is still as 8% error. However, a source of confusion is in the calculation of the percentage forecast error. Some organizations measure the deviation of their forecast from observed (actual) values, while others measure how actual events deviated from their forecast. Both calculation approaches are widely used, and the only difference is the denominator:

- Deviation of Forecast from Actual: % Forecast Error = $(|Actual - Forecast| / Actual) * 100$
- Deviation of Actual from Forecast: % Forecast Error = $(|Forecast - Actual| / Forecast) * 100$.

If the deviation of forecast from actual is being measured, then the actual value is used as the weighting factor. Otherwise, the forecast value is used as the weighting factor. If a trading partner prefers results in terms of forecast accuracy, computing the forecast accuracy is straightforward. Subtracting the % forecast error from 100% yields the forecast accuracy, e.g., instead of reporting a forecast error of 8%, the corresponding forecast accuracy = $100\% - 8\% = 92\%$.

There are caveats in using the formula above to calculate the forecast error (or forecast accuracy). An obvious shortcoming is that by using an absolute error in calculating forecast accuracy, it is not possible to see whether there was an under-forecast or over-forecast an event without referring to the detailed data.

Another problem is that it is possible for the forecast accuracy to become negative if forecast error is over 100%! Since negative forecast accuracy is difficult to conceptualize, by convention any forecast accuracy value below zero is reported as zero (i.e., dead wrong!).

II. 2 Aggregating Forecast Errors

Frequently, forecast errors are reported not for a single item, but for a number of stock keeping units (SKU) across a number of locations. In this case, the relative weight of each individual item must be considered in calculating the error of the next level of aggregation. In practice, aggregation may occur across product, location, and time as follows:

- Product Dimension: SKU, Item, Brand, Category, Cross-Category
- Location Dimension: Store, Customer distribution center/ Store Group / Store Format, Customer, Channel
- Time Dimension: Day, Week, Month, Quarter, Year

In the following examples, it is assumed that the deviation of the actual value from the forecast is being measured. Hence, the forecast value is used as the weighting factor.

II. 3 Illustrative Example

The calculation and communication of forecast accuracy is fundamental in appraising demand planning activities. Unfortunately, the same reported result could indicate excellent or poor performance, depending upon how it was calculated.

Consider the following example. A product category consists of two SKUs, the forecasts and actual sales are shown below:

	Forecast	Actual	Absolute Error
	<u>Forecast</u>	<u>Actual</u>	<u>Absolute Error</u>
SKU 1	100	80	$ 100-80 =20$
SKU 2	80	100	$ 80-100 =20$
Category	180	180	$ 180-180 =0$

The % accuracy of SKU 1 = $100\% - 20/100 = 80\%$ and the % accuracy of SKU 2 = $100\% - 20/80 = 75\%$ (Note: the denominator used is the forecast). At the category level, the forecast is $(100 + 80) = 180$ units, and the actual is $(80 + 100) = 180$ units. This may lead one to think that the forecast accuracy at the category level is 100%!

The forecasts for SKU 1 and SKU 2 are 100 and 80 units respectively. The total forecast for the category is 180 units. Thus SKU 1 accounted for $100/180 = 56\%$ of the category total forecast, and SKU 2 accounted for $80/180 = 44\%$ of the category total forecast. Hence, the weighted forecast accuracy for the category is $(56\% * 80\%) + (44\% * 75\%) =$

78%.

Is the forecast accuracy for the category 100% or is it 78%?

When a forecast is calculated at the distribution center (DC) level, the calculated category forecast accuracy can be much different.

Suppose there are two DCs. The forecasts and actual sales of SKU 1 across all DCs are shown below:

	Forecast	Actual	Absolute Error	Forecast Accuracy
SKU 1 at DC 1	50	30	$ 50-30 = 20$	$100\% - 20/50 = 60\%$
SKU 1 at DC 2	50	50	$ 50-50 = 0$	$100\% - 0/50 = 100\%$
SKU 1 Total	100	80		

The forecasts for SKU 1 at DC 1 and SKU 1 at DC 2 are 50 and 50 units respectively. The forecast for SKU 1 across all DCs is 100 units. Thus SKU 1 at DC 1 accounted for $50/100 = 50\%$ of the total forecast for SKU 1. Likewise, SKU 1 at DC 2 accounted for $50/100 = 50\%$ of the category total forecast. Hence, the weighted forecast accuracy for SKU 1 across all DCs = $(60\% * 50\%) + (100\% * 50\%) = 80\%$.

The forecasts and actual sales of SKU 2 across all DCs are shown below:

	Forecast	Actual	Absolute Error	Forecast Accuracy
SKU 2 at DC 1	40	70	30	$100\% - 30/40 = 25\%$
SKU 2 at DC 2	40	30	10	$100\% - 10/40 = 75\%$
SKU 2 Total	80	100		

SKU 2 at DC 1 accounted for $40/80 = 50\%$ of the total forecast for SKU 2. Likewise, SKU 2 at DC 2 also accounted for 50%. Hence, the weighted forecast accuracy for SKU 2 across all DCs = $(25\% * 50\%) + (75\% * 50\%) = 50\%$.

Since SKU 1 accounted for 56% of the category total forecast, and SKU 2 accounted for 44% of the category total forecast, the weighted forecast accuracy for the category is $(56\% * 80\%) + (44\% * 50\%) = 67\%$.

The above example highlights the need for trading partners to have a consensus on the method of calculating and reporting forecast accuracy. That way, trading partners can better understand the performance being measured, and can duplicate the calculations from source themselves, if they desire. They can also request that a trading partner calculate a metric based upon data in their systems.

III. Negotiating and Reconciling

Companies conduct customer studies and competitive analyses to get a pulse on the marketplace. They also scan the environment for demographic trends, regulatory climate, technological developments, economic conditions, and so forth. Like internally generated data, this external

information most likely is continuously collected and monitored.

For example, manufacturing sees demand by SKU/plant, distribution sees demand by sales category/region, and retailer sees demand by cash versus credit sales. Different views of forecasts inevitably lead to different forecasts. The figure below acknowledges the different forecast views in a typical enterprise. The bottom level is the most detailed, typically with forecast for each stock keeping unit (SKU), region, channel, and brand. The higher levels represent aggregate forecast data at increased levels of summarization. These diverse working views are reconciled with one another to ensure that forecasts are consistent across the whole organization

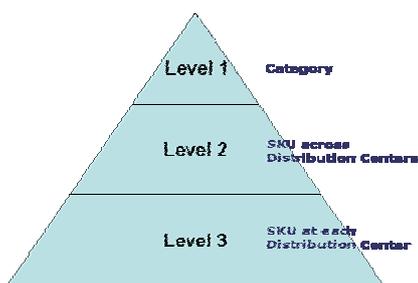

Figure 1. Hierarchical Forecasting

To produce a single unified statement of expected demand, the forecast has to incorporate and reconcile information from diverse sources inside and outside the corporation. To illustrate, consider the following example:

Level 3 (SKU at each DC) Forecasts. SKU 1 is sold to customers through distribution centers (DC) 1 and 2, while SKU 2 is sold through DC 3, DC 4, and DC 5. For the coming year, sales forecasts from DC 1 and DC 2 are:

SKU 1	Units	Price	Value
DC 1	8,200	\$20.61	\$169,002
DC 2	4,845	\$10.00	\$48,450
Total SKU 1	13,045		\$217,452

The sales forecasts from DC 4, DC 5, and DC 6 are:

SKU 2	Units	Price	Value
DC 3	7,000	\$20.50	\$143,500
DC 4	12,600	\$18.50	\$233,100
DC 5	8,400	\$21.80	\$183,120
Total SKU 2	28,000		\$559,720

These forecasts correspond to Level 3 Forecasts in Figure 1. The forecast for SKU 1 and SKU 2 across all DCs are \$217,452 and \$559,720, respectively.

Level 2 (SKU across all DCs) Forecasts. Suppose the forecasts of the product managers of SKU 1 and SKU 2 are \$250,000 and \$475,000, respectively. These correspond to Level 2 Forecasts in Figure 1. From Level 3, the forecast for SKU 1 across all DCs is \$217,452. How should one adjust the forecasts for SKU 1 at DC 1 and DC 2?

What about the forecasts for SKU 2 at DC 4, DC 5, and DC 6? The forecast for SKU 1 across all DCs at Level 3 is

\$559,720. Should they be proportionately reduced?

Level 1 (Category) Forecast. Suppose management has set a goal of \$750,000 for the category. This goal is \$25,000 over the sum of the sales targets (\$250,000 and \$475,000 = \$725,000) at Level 2. The category forecast of \$750,000 corresponds to Level 1 Forecasts in Figure 1. How should the product managers increase their forecasts, to be consistent with the goals of the category manager?

Adjusting Proportionately As a first pass, consider adjusting the forecasts proportionately.

First, the Level 2 forecasts (SKU across all DCs) should be revised to make them consistent with the Level 1 forecast (Category). To do this, the Level 2 forecasts must be adjusted by $(750,000-725,000)/725,000 = 3.45\%$ (an increase). The revised Level 2 Forecasts are \$258,621 for SKU 1, and \$491,379 for SKU 2

Next, the revised Level 2 forecasts are used to adjust the Level 3 forecasts. The forecasts for SKU 1 at each DC must be adjusted by $(258,621-217,452)/217,452 = 18.93\%$ (an increase). The forecasts for SKU 2 at each DC must be adjusted by $(491,379-559,720)/559,720 = -12.21\%$ (a decrease).

The revised Level 3 Forecasts, SKU 1 at DC 1 and SKU 1 at DC 2, are 9,752 and 5,762, respectively. The revised Level 3 Forecasts, SKU 2 at DC 3, SKU 2 at DC 4, & SKU 2 at DC 5 are 6,145, 11,062, and 7,374 respectively.

Figure 2 summarizes all the calculations above. The data was entered into an Excel worksheet which shows the sum of forecasts at Level 2 (cell D18) = \$725,000. This is less than the Level 1 forecast of \$750,000 (cell D22). To reconcile the forecasts, the forecasts at Level 2 for SKU 1 and SKU 2 are increased by 3.35% (cells I16 and I17), respectively. The Excel formula for cells I16 is $I16=(D22-D18)/D18$. The formula is copied and pasted onto cell I17. The revised forecasts are shown in cells H16= $D16*(1+I16)$ and $H17 = D17*(1+I17)$.

To revise the Level 3 forecasts, the pertinent Excel formulae are:

- $I3=(H16-D5)/D5$
- Copy and paste onto cell I4
- $H3=D3*(1+I3)$
- Copy and paste onto cell H4
- $I8=(H17-D11)/D11$
- Copy and paste onto cells I9:I10
- $H8=D8*(1+I8)$
- Copy and paste onto cells H9:I10

	A	B	C	D	E	F	G	H	I	J

Figure 2. Adjusting Forecasts Proportionately

$J12 = \text{SUMSQ}(I3:I4, I8:I10)$. SUMSQ is an Excel function. SUMSQ (I3:I4, I8:I10) computes the sum of squared % changes (I3:I4, I8:I10) in Level 3 forecasts. It is a summative measure of the amount of changes in the forecasts for each SKU at each DC.

Optimization Model Collaborative forecasting is iterative. To adjust the forecasts proportionately across the board, the original forecasts for SKU 1 at DC 1 and DC 2 must be increased by almost 19%! The managers in these DCs may not have the necessary resources to attain the revised sales goals. Even if they have the resources, the market may not be strong enough to sustain a 19% increase in sales.

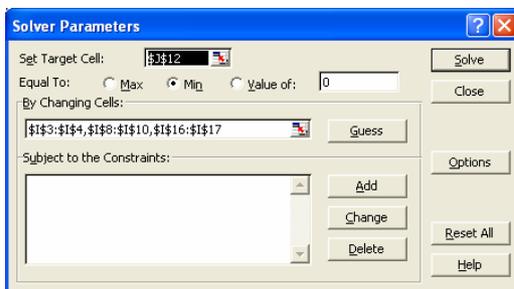

While DC 1 and DC 2 are expected to increase their sales target, DCs 3, 4, and 5 are actually asked to revise their forecasts downwards by -12.21%. If like most business organizations where performance is tied to the ability of attaining sales targets, this may become a sticking point among the managers in the organization.

The following exercise shows how an Excel worksheet can be used to demonstrate how the various organizations in the business can collaborate to arrive at an executable single forecast.

Level 3 (SKU at each DC)			Level 3 (SKU at each DC) Revised				
	Units	Price	Value	Units	Value	% Change	
DC 1	8,200	\$20.61	\$169,002	8,578	182,907	8.23%	
DC 2	4,845	\$10.00	\$48,450	4,959	49,591	2.96%	
Total SKU 1	13,045		\$217,452	13,534	\$232,500		
Level 2 (SKU across all DCs)			Level 2 (SKU across all DCs) Revised				
	Units	Price	Value	Units	Value	% Change	
SKU 1	7,000	\$20.50	\$143,500	6,477	132,789	-7.47%	
SKU 2	12,600	\$18.50	\$233,100	11,340	209,796	-10.00%	
Total Category	8,400	\$21.80	\$183,120	7,600	165,674	-9.53%	
Total SKU 2	28,000		\$599,720	25,417	\$508,250		
						Sum of Sq % Change	-30.03197%
Level 1 (Category)			Level 1 (Category) Revised				
	Units	Price	Value	Units	Value	% Change	
SKU 1			\$250,000		\$232,500	-7.00%	
SKU 2			\$475,000		\$508,250	7.00%	
Total Category			\$725,000		\$740,750	2.00%	
						Limits on % Change	
						Level 1	± 2.5%
						Level 2	± 7.0%
						Level 3	± 10.0%

Figure 3. Adjusting Forecasts Using Solver

First, notice that the % changes in Figure 3 are different from those found in Figure 2. The cells, highlighted in yellow, are called the decision variables. A tool in Microsoft Excel called Solver can be used to change the values of these decision variables. To use Solver, click Tools on the menu bar, and choose Solver. On the pull down menu, enter the following Solver parameters:

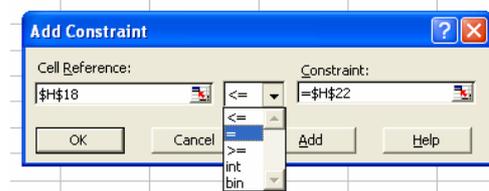

The Set Target Cell is J12, the objective function. Recall that cell J12 a summative measure of the amount of changes in the forecasts for each SKU at each DC. Solver is directed

to help minimize this value. On Equal to, choose Min, to minimize.

In the By Changing Cells box, enter \$I\$3:\$I\$4, \$I\$8:\$I\$10, \$I\$16:\$I\$17, \$I\$22. Solver is instructed to change the original values of the % changes (cells highlighted in yellow). These are the decision variables. Next, Solver has to be taught how to solve for the decision variables. We do this by introducing constraints in the Solver menu.

To reconcile the forecasts, the forecasts at all levels should be consistent. Therefore, the sum of forecasts at Level 2 (cell H18) must equal the category manager’s forecast (cell H22). Likewise, the total forecasts for SKU 1 at Level 3 (cell H5) must equal the forecast for SKU 1 at Level 2 (cell H16), and the total forecasts for SKU 2 at Level 3 (cell H11) must equal the forecast for SKU 2 at Level 2 (cell H17). These constraints must be entered one at a time as follows:

On the Solver Parameter menu, click Add to add the first constraint (Level 2):

After entering the first constraint, click Add to add the next constraint (SKU 1 at Level 3):

Again, click Add to add the next constraint (SKU 2 at Level 3):

In order to complete this task, additional information more information is required. In intra-organization collaborative forecasting, sales targets are to be adjusted based market outlook, and the resources available to the managers in each DC.

Collaborative forecasting requires hard work, high commitment, and willingness to give and to take. Suppose it is agreed that % change at Level 3 should not exceed 10% in either direction, and the % change at Level 2 should not exceed 7% in either direction. Furthermore, the category manager’s forecast is constrained not to exceed 2.5%. This information must be translated into Excel formulae, and entered in the “Subject to the Constraints” box in the Solver

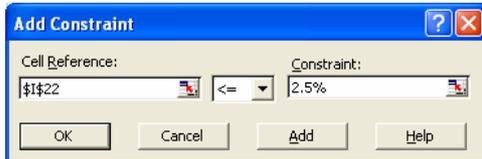

menu.

At Level 1, the constraints are $I22 \leq 2.5\%$ and $I22 \geq -2.5\%$.

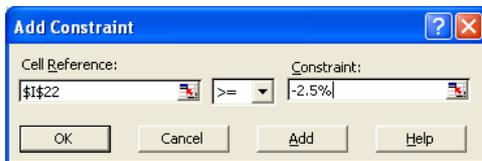

At Level 2, the constraints are $I16:I17 \leq 7\%$ and $I16:I17 \geq -7\%$

For SKU 1 at Level 3, the constraints are $I3:I4 \leq 10\%$ and $I3:I4 \geq -10\%$. For SKU 2 at Level 3, the constraints are $I8:I10 \leq 10\%$ and $I8:I10 \geq -10\%$.

Now, click Add to add more constraints:

Click Add to add another constraint:

Repeat, until all constraints have been added. Click OK when done.

Finally, on the Solver Parameter menu click Solve. This is how the optimal % changes in forecasts are all levels (Figure 2) were determined.

The above example, albeit an abstraction, stresses the process of integrating the planning activities across all functions in the organization into coordinated processes.

As shown in Figure 3, the category manager's forecast (Level 1) is to be adjusted downwards by 1.23%, from \$750,000 to \$740,750. This is within the 2% limit. At Level 2, SKU 1 will be decreased by 7% while SKU 2 will be increased by 7%. These adjustments are within the 7% limit. Finally, we see adjustments ranging from a 10% reduction to an increase of 8.23% at Level 3. Again, these changes are within the 10% limit.

The process appears to be straightforward.

Unfortunately, disconnects often occur within the corporate wall, coordinating activities of distinct legal entities along the supply chain often poses a much more formidable challenge.

IV. Conclusion

This paper illustrates the complex procedure involved in implementing CPFR. It shows the various levels of forecasting and highlights pitfalls in attempting to coordinate the activities of different levels of the firm and its Supply Chain partners. Instructors may find this exercise useful as a classroom example demonstrating how the use of a basic spreadsheet program (e.g. Excel), allows the possibility of reconciling many diverse perspectives from different levels of management into one coherent forecast.

Future studies can examine the imperative for

interorganization collaborative demand planning, and what industry is doing today to accomplish it.

Contextual Bundling and E-Commerce: Strategizing for Online Bundle Formulation

Gaurav Mittal
Nokia Corporation

Abstract: Bundling has emerged as a key issue in current marketing and online business thinking. By extending contemporary conceptualizations, this paper proposes a new approach to bundling for both marketing of products and services in E-commerce. It reviews the literature on both bundling and consumer product evaluations and puts forward a new approach. It demonstrates that contextual bundling can constitute the strategic core of a company utilizing E-commerce for its business; at least if the firm's primary goal is to maximize the opportunities of attracting valuable customers, online content purchase and its consumption. This research carries forward some results from previous studies, while it finds other prior results to be questionable. Shows that strategic implications of online bundle formulation is only partially explained in terms of a price or product focus, which is where most of the previous research has concentrated on. A context specific price or product bundling focus can have more strategic implications than a simple price or product focus on consumer purchase evaluations. Businesses must define bundling through an in-depth appraisal of the actual contextual experience of the customers, rather than focusing solely on reservation prices, which is where previous literature has put maximum emphasis.

Keywords: Collaborative commerce, Consumer perceptions, Bundling (marketing), Strategy.

I. Introduction

The notion of electronic commerce (E-commerce) has been gaining in popularity with the rise of commercial activities on digital networks, especially on the Internet. In the academic world as well as in commercial organizations, many analyses see the Internet as a way to re-engineer the relationship between the producer (manufacturers and service providers) and the final consumer, leading to major productivity progress in transactional activities. Bundling product with services and dedicating assets and learning capabilities to their production allow transaction costs to be reduced along with more customer satisfaction. Internet is often analyzed as a medium that will enable the establishment of a direct electronic relationship between producers and manufacturers.

Millions of technology products are/can be distributed via the Internet. The technology continues to advance with breathtaking speed, yet existing theory and practice fail to

provide clear guidance on how these technology products should be packaged, priced, and sold. At one end of the spectrum are technologies such as on-line market clearing [4] where transactions are made in a continuous setting, transaction possibilities may pass and information about future possibilities may be incomplete or unknown [4]. In on-line market clearing, buy bids and sell bids are matched to maximize some value, such as seller profit or market liquidity. This paper draws attention to the opposite end, on-line bundle formulation. Here the task is to match a buyer's needs with items offered by suppliers so that a single complete bundle is purchased. Excess supply and market liquidity are not concerns here. The sole focus is on the satisfaction of the buyer.

The approach proposed in this paper makes use of *expected utility theory* to facilitate the decision process [16, 31]. Basing purchasing decisions on expected utility maximization (as opposed, say, to expected cost minimization) seems appropriate because it is sensitive to the decision-maker's attitude toward risk and preferences for such attributes as item quality, compatibility with other items, and supplier reliability.

With the high volume of purchasing options available on Internet today, strategic tools that can cleverly ascertain the true value of several different options are becoming important. More businesses are turning to web-based pricing tools that sift through large volumes of data on product revenues, inventory levels to determine how much to charge for items during certain periods [15]. Still others are resorting to dynamic pricing, whereby prices can change in time as well as across consumer markets and across packages of goods or services [13]. Dynamic pricing is utilized not only to maximize profit by responding to changes in supply and demand, but also to discourage the use of price-comparing shoppers by rendering them unreliable. These pricing strategies translate into higher profits for business, mostly at the expense of the consumer.

The focus of bundling literature till now has been on price discount. The literature on consumers' perceptions of price discounts is grounded in prospect theory [12] and mental accounting [30]. This literature suggests that in risky situations, consumers are more sensitive to possible losses than to possible gains, and that they are likely to accept more risk when potential losses are aggregated. Losses are aggregated when several losses are summed and presented as a single unit. For example, if an investor sees losses in a portfolio only once after three months (e.g., in a quarterly financial statement), he/she will be more willing to take risks than if he/she saw the same losses with greater frequency (e.g., by reviewing the portfolio daily or weekly). The

principle of aggregated losses suggests that bundling several otherwise risky products together might reduce perceived risk, as the bundle would offer several distinct benefits (gains) for one price (loss).

Bakos and Brynjolfsson [3] conclude that the economics of aggregation are in many ways similar in effect to economies of scale or network externalities. A marketing strategy that employs large-scale bundling can extract greater profit and gain competitive advantage from a given set of goods. Economies of aggregation will be important when marginal costs are very low, as the case for the (re)production and delivery of information goods via the Internet.

Recent research has found that consumers who buy a bundle of products at a bundled price consume less of the bundle than do consumers who are presented with separate product prices [22,27]. Consumers who buy a bundle of products at a bundled price perceive far greater ambiguity on the cost of their purchase than do consumers presented with separate product prices. This greater ambiguity "decouples" the cost of the purchase from the extra benefit of consuming the entire bundle. In other words, consumers who are presented with a bundled price will account less for the costs of their purchase than will consumers who are presented with separate prices [29].

This approach questions, among other things, the role of price and product bundling as the primary and only means of an online bundle formulation. The importance of product bundling is not questioned as such, but bundle formulation is rather seen as a measure of overall value offering to the consumer. More room and insight is required to listen to the consumer voice and taking his views, needs and opinion into account in strategic decision-making.

This paper addresses the online-bundle formulation (OBF) problem. The task of OBF is to decide which of many satisfactory combinations (bundles) of items should be formulated to maximize the buyer's overall satisfaction. Satisfaction, formalized as multi-attribute utility, includes product experience, consumer valuation, reputation, price, information and risk. This paper extends the contemporary conceptualizations about online bundling and proposes a new approach to bundling for both marketing of services and products in E-commerce.

II. Contextual Bundling

Contextual bundling is all about bundling to optimize the end user experience in a specific context, says Mittal [19]. An illustration of this phenomenon to offer "complete" product bundles is wireless operators initiative to integrate handsets, networks, content and services to produce an end-to-end, easy to use mobile Internet experience. The customer experience is transformed by ease of use, tailored packaged services for communication, organization, entertainment and information needs of the consumers on the move, improved quality of sound and content, encouraging increasing adoption and usage of online services. This is supported by a

new, easy to understand pricing model, designed to ensure customers receive simpler bills and to encourage usage through increased cost transparency.

Bakos and Brynjolfsson [2], find that when different market segments of consumers differ systematically in their valuations for goods, simple bundling will no longer be optimal. However, by offering a menu of different bundles aimed at each market segment, bundling makes traditional price discrimination strategies more powerful by reducing the role of unpredictable idiosyncratic components of valuations. Their findings appear to be consistent with the markets for Internet and online content, and copyrighted music.

A mobile Internet service provider or vendor, for example, is able to offer (alone or by matchmaking or through partnership) a variety of different offerings to a consumer. The service provider, in an effort to favorably affect the online content purchase and consumption may combine and optimize a-set of offerings to make the whole package work in a plug-and-play fashion. This takes the effort away from consumer; the package works optimally for the intended service(s) and enhances the consumer perception and hence increased content consumption. For example, an online-package with integrated Music player device, listening to Music service, installed settings to access the content and ready songs (content) on the move. This can be defined as *contextual bundling i.e. bundling of offering in a particular context*. In the above example, the context is "music on-the-go". The service provider or vendor in this case does not offer (n multiply n) offerings to the consumer. Other similar examples can be "TV on the go", "Click as you go", etc. The offering is focused in a particular context and experience for the consumer. In its most simple and basic form, contextual bundling can be considered as product bundling.

In the never-ending quest to gain and sustain a lead over competition, online businesses in a wide range of industries are turning to integrated solutions. They see integrated solutions as an *integrated chain* that is listening and responding to customer needs. According to Poirier [23], businesses see this chain as a mechanism for transforming their companies into enterprises that are more efficient and more responsive to customer demand.

Integrated solutions can result from both internal focus and external collaboration when the internal strengths do not match the other more skilled party. Poirier [23] has made a study of more than 300 global firms engaged in similar practices. This study revealed four levels of progression. The first two levels, where the vast majority of companies are situated, are internally focused. The two higher levels, embrace an external focus. Poirier also found that businesses continue to concentrate their efforts on internal excellence, ignoring the advantages external alliances bring. Higher level, by contrast, leverage shared resources to satisfy customers, resulting in increased consumer purchase and consumption. Needless to say, content consumption is the key for an online business.

Many organizations are building ‘value-chain constellations’. These are organized networks of businesses that are working together, utilizing Internet, sharing resources and rewards in pursuit of targeted markets and consumers. Working as integrated units and focusing intensely on the targeted opportunities, these constellations are outperforming the less integrated units. Only a few companies in the lower level have managed to improve customer satisfaction.

The shift in power from sellers to buyers in digital economy has given the phenomena of co-engineering where customers cease to be product and price takers and instead become co-creators of product and price. Kotler et al. [17] refer to the roles that customisation, customerization and collaboration play in preparing market offers. Customisation occurs when companies offer solutions in response to unique demand, as when a doctor cures a sick patient. In this case the company takes the lead in designing the offers. Customerization describes the situations in which the customer, rather than the company, takes the lead in designing an offer. For example: Dell computer’s online configuration tools allow customers to design their own computers. Collaboration occurs when a company and its customers actively dialogue and work together in co-customizing the offering. Many companies use extranets to dialogue with important suppliers and customers. Hence, the growing power of consumer makes dual-track communication with the consumer a major precondition of strategic success, and even more so when the aim is to win new customers.

Contextual bundles can also be understood in the context of widely accepted and proven concept of supply chain logistics. The two, partly share the goal to meet the demand for enhanced services by supplying more to the same customer and thus annulling the customers need to shop down the lane. Sussams [28] describes logistics as the science that integrates all the activities. It does not look at the individual parts of a system in isolation but looks at the ways in which the parts are connected and suggests better connection.

Complementarities can obviously create additional incentives for bundling, and thus can lead to the bundling of goods for reasons that have nothing to do with the reshaping of demand [7]. In addition to the goods being complements or substitutes, there may also be costs and benefits associated with producing, distributing, or consuming the bundle as a whole, such as economies of scale in creating a distribution channel, administering prices, and making consumers aware of each product’s existence. Such economies underlie most large “bundles” of physical goods. For example, technological complementarities affect the collective valuation of the millions of parts flying in close formation that constitute a Boeing 777. Similarly, it is cheaper to physically distribute newspaper or journal articles in “bundles” rather than individually [2].

One of the effects of the emerging information infrastructure is to dramatically decrease distribution costs

for goods that can be delivered over networks. As noted by [5, 18] and others, this may be enough to make it profitable to “unbundle” certain goods, such as magazine and journal articles, packaged software and songs, to the extent they were formerly bundled simply to reduce distribution costs. The opposing effects on bundling of lower distribution costs because of networking and lower marginal costs due to digitization were first noted by Hanson and Martin [11] and are applied to the analysis of bundling, site licensing, and subscriptions by Bakos and Brynjolfsson [3].

Even with zero additional costs, the benefits of context specific bundling may be eliminated if the bundle includes goods that have negative value to some consumers (e.g., pornography or advertisements). Same goes with asymmetric bundling, while technology is rapidly reducing the costs of reproduction and transmission, the time and energy a user must spend to identify the “desired product” can present a barrier to the limiting result of contextual bundling. For example, the research found that the many users found Phonebook “Backup” service with mobile phone purchase as very valuable but the same users felt annoyed when their new mobile just had a “Sync” icon with no service behind it (eating the menu space in their mobile with it being of no practical use to them).

Thus, on-line companies can achieve a higher market penetration and deepen the value for its customer by creating market offers to match the customer’s contextual experience. This can be achieved by offering context specific bundles to the customers.

III. Empirical Evidence

The research approach of this study is best described as action analytical, with clear orientation towards understanding the effect of bundling on consumer purchase intentions. The “action” in this study is represented by intentions and experiences related to on-line bundling, which provide a new point of analysis and understanding consumer purchase intentions.

The action analytical analysis in this study is a methodological combination of interpretative study of concepts, theme analysis [8] and Alasutari’s [1] factist perspective. Research method is defined as consisting of those practices and operations, through which the researcher produces *observations* and those rules according to which those observations can be further *interpreted* as possible leads in solving the problem [1]. The phases, producing observations and interpretation, are partly integrated, describing the process through which the mystery is solved [1].

As a part of research, the author conducted a survey of the consumers utilizing digital technology products like a mobile phone, digital camera, Internet services etc as a part of their day-to-day life. The aim of the survey was to study the consumer evaluations for different forms of bundling, giving practical real-life examples.

The target group was selected at random and no specific

prior condition is laid down to pre-select the survey respondents. At the same time, to ensure wider geographical coverage respondents from North America, Europe and Asia, who could understand and communicate in English, were approached to fill the survey. The survey was conducted both in electronic and paper form. The preference at all times was to have the survey conducted in electronic form and participants were encouraged to send the reply of survey in electronic form.

The main topics of the survey are identified based on the preliminary theoretical framework, but the language and variable scales were justified with a pilot round done with few respondents. Once satisfied that the respondents are able to understand the questions and complete within 10-12 minutes, the survey was sent with a possible deadline of 3 weeks. Within the deadline of 3 weeks, 104 filled-in forms were received.

The survey responses were partly analyzed with the SPSS® 13.0 program and in an exploratory manner. According to Olkkonen [21], this kind of approach is often used for new problem areas, in order to find out what the problem is actually all about. Typically, the empirical material in this approach is collected and analyzed according to the researcher's personal understanding of the problem area. The explorative method usually, and also in this study, serves well as a basis for future research in the area.

III. 1 Summary of Empirical Results

The respondents had the most favorable attitude towards the "Availability of Right mix of features". It is a significant finding that more than half (62%) of the respondents feel that availability of right mix of features as the most important characteristic that affects their purchase decision involving a bundled product. Here, the availability of right-mix of features can be understood in terms of what consumer feels is the right mix, meaning providing the experience to the consumers in their own specific context. The consumers value the product most in their own specific context and the consumer valuation comprises of experience from the product, positioning of product, reassurance to the viability of concept, relative advantage of the product as perceived by the consumers. Figure 1 shows the consumer responses during the survey.

The next important characteristic that affects consumers purchase decision involving a product bundle is availability of price discount. Thirty-five (35%) of the survey respondents feel that availability of price discount as the second most important characteristic that affects their purchase decision involving a bundled product. This can be understood in terms of price promotions, product consumption and number of (loss) transaction involved in the purchase. The literature shows that consumer perceive each transaction as a loss transaction [12, 30]. Price discount, higher consumption and reduced transaction costs are typical elements in price bundling.

The third important characteristic that affects consumers purchase decision involving a product bundle is availability

of wider features. Survey results point that thirty-five (35%) of the respondents feel that availability of wider features as the third most important characteristic that affects their purchase decision involving a bundled product. This can be understood in the light of product bundling. Typical elements that define a product bundle are risk mitigation, innovation, brand and a higher user base when involving new, technology, such as Internet, product bundles.

The least important of the four characteristics that affects consumers purchase decision involving a product bundle is availability of custom build product. It is a significant that about half (44%) of the respondents feel that availability of custom build product as the least of four important characteristics that affects their purchase decision involving a bundled product. This can be understood in the light of information needs of the consumer, information search efficiency, complexity of the decision-making environment. Such bundles are effective when the product is fast becoming a commodity and the capability of differentiation is minimal.

IV. Discussion and Conclusions

Adoption of new products can be influenced by economic constraints. Consumers may delay adopting a new product because they feel its price is too high [24] or they expect its price to fall [10, 20]. Under such conditions, consumers prefer to wait and see results from others who can afford to take economic risk [26]. Previous research suggests a relationship between price and perceived risk in two directions. Roselius [25] suggests that consumers may buy a more expensive product because they perceive less risk based on price-quality association. Alternatively, others argue that price acts as a constraint to purchase and represents a financial risk [14].

Marketers typically rely on price promotions to induce trial among nonusers for new products, to increase purchase volume, and/or to retain current consumers who might otherwise switch brands. Despite the broader implications of bundling, previous research has examined bundling primarily as a promotional vehicle that marketers use to sell two or more products together at a discounted price. The mention of consumer experience is totally absent in bundling strategies. It is clear from the consumer experience and valuation will drive the consumer to higher satisfaction and hence also higher purchase and consumption. We need to extend the meaning of *bundling* and decrease the ambiguity about the concept by understanding the core concepts of consumer valuation and purchase process.

Dhebar [6] suggests that technology markets are characterized by high levels of uncertainty related to product standards, product compatibility, availability of complementary products, and vendor credibility/reliability. Such uncertainties stimulate anxiety felt by consumers, which can manifest itself in hesitation to purchase, deferment of purchases, and in extreme cases, exiting the market altogether.

While increasing the rate of market acceptance is important to all products, it seems to be particularly important to increasing-returns-based high-tech products, where the need to jump-start the user base early in the product life cycle is critical. This argument suggests the value of acquiring and retaining early adopters (as opposed to later adopters) on the overall profitability of a new high-tech product [9].

Hence, from the consumer's perspective, newer, technology rich products present greater adoption due to high uncertainty related to product reliability, product compatibility, availability of complementary products and vendor credibility. In addition, consumers are concerned about rapid obsolescence and depreciation of technology products. Such high degree of uncertainties often causes apprehension, which can result in consumer hesitation to purchase, prolong decision-making complexity, deferment of purchases, and in extreme cases, canceling the purchase altogether.

A holistic concept of purchase intention is related to "determination or act to purchase", which also deal with the potential to experience, consume and satisfy. The consumer purchase research looks at things *from the payment perspective* of the consumer. In a complex, socially constructed consumer thinking, it is logical to assume that a bundling of a superior experience inevitably results in higher consumption and better satisfaction. With this logic, this study *challenges the unintentional assumption that price discount is a value as such*, inevitable and equal to better consumer experience. In order to question bundling as a means for higher market penetration, we need a feasible framework for analyzing the consumer purchase intentions. Figure 2 provides us with a combined framework bundling and consumer purchase intentions. What the figure above illustrates is the indispensable knowledge that consumer purchase intentions are defined by the total product experience.

The framework is a synthesis of the extant understanding in selected fields of consumer research that have addressed the issues of consumer psychology. To the framework's credit, its dimensions (consumer valuation, price discount, innovation and risk, and consumer information need elements) are *intuitively descriptive, conceptually independent, and do not lead to circular reasoning*. Each of the four dimensions is *grounded in well-established research*, rather than superficial management research applications. The framework leaves the prioritization for those applying the framework in their specific context.

The study proposes a new approach to bundling in the relation to contextual marketing. It also shows that strategic implications of bundling are only partially explained by price or product focus, whereas previous research has focused mainly on this aspect. A specific price bundle can have more strategic implications than a different specific product bundle, due to associative power of bundling and its interactive capacity. The study demonstrates that the distinction between transactional and contextual is key to

understanding the strategic relevance of bundling and the consequences to companies. Whereas transaction bundling is a promotional tool, contextual bundling is more strategic in that it greatly facilitates the consumer experience.

Consumers often do not use products to their true potential. Major cause for the same is the lack of understanding of the product and how the product can be used in certain situations to make their life smarter and easier. One of the purposes of bundling is to make consumer understand the product and its benefits more clearly. Today's consumer is often very busy and confused between the products and thus clear positioning and fit of product in consumers mind is often necessary. As a result businesses can effectively connect consumers with services, giving them possibility of recurring revenues. Bundling in a specific context, contextual bundling does exactly that; it educates the consumer about the various faces of the product related to different situation giving them a holistic experience and hence improved positioning of product in consumer's mind driving higher consumption and repeat online purchase.

V. Limitations and Future Research

This study has limitations that could be overcome in future extensions of this research. Future research could further test the findings of this study with respect to age and geographical location. For example: context specific experience can change to a great extent in different age groups.

It was noted during the course of this study that younger age group (20-25 yrs) were more price sensitive than older age groups (30+ years). Such an age-based analysis of consumer purchase intentions was considered outside the purview of this study; however, further research can be helpful to create more targeted bundles for specific age groups.

Similar to the above, it is possible that consumer preferences can vary with respect to geographical location and the state of economy where the consumer is residing. It is possible that consumer preferences in developed economies can vary to the preferences in developing economies. Further research can be helpful to create more targeted bundles for specific geographical locations.

The consumer purchase intention framework looks promising, but calls for more detailed and profound research. Answering the following questions would allow cause-effect and longitudinal studies:

Are the dimensions and elements of consumer purchase intention valid, and are there missing elements?

In this study, I examine only four factors influencing consumers' intentions associated with a purchase of a product bundle. Future research may include additional factors such as consumer innovativeness, purchasing power and risk aversiveness. Innovators might react to a bundling strategy differently than other consumers would. Since many

product categories from software to communication services are considered new-technology, future research might address how bundling strategies affect consumer decisions in different product categories. Future research might also explore marketing tactics that might be used to influence consumer perceptions of bundle positioning (i.e., which product is treated as anchor or tie-in; see [32]). Finally, I hope this study will stimulate further research in the areas of bundling, consumer purchase intentions and new product introductions in new technology markets.

Managing Coordination Costs of Interorganizational Relationships: An Analysis of Determinants

Geng Zhang, Zhenyu Liu

Department of Management Science, Xiamen University, Xiamen, P.R.China, 361005
zhanggeng001@126.com, zhenyliu@xmu.edu.cn

Abstract: This paper presents a framework of the determinants analysis of the control of interorganizational relationships (IOR). While drawing on transaction cost analysis and resource-dependency theory, the authors analyze the effects of asset specificity, environmental uncertainty, level of dependence and trust on coordination costs of IOR. The explanatory power of the framework is assessed by a case study of buyer-supplier relationships from manufacturing industry in China. The findings from the case study suggest asset specificity, environmental uncertainty, and trust are the main determinants influencing coordination costs of buyer in IOR.

Keywords: Collaborative commerce, Interorganizational relationship, Coordination cost.

I. Introduction

Interorganizational relationships (IORs) are hybrid organizational forms which contain elements of both markets and hierarchies. Market exchanges are transactions between separate organizations, and hierarchical relationships are coordinated among organizations. IORs coordinate the activities of multiple organizations that are separate entities but cooperate with each other about their common concerns [15].

One important characteristic of IORs is cooperation, it refers to an agreement, relationship or exchange between two or more actors that is conducted by each of the participating parties. In past researches, many scholars highlighted the opportunities for mutual gains as the key motivation for IORs cooperation, including the gains as inter-learning, efficiency profitability, competent advantages, risk-resist ability and scale economic effect [15][10][8]. On the other hand, some authors have reported high failure rates of IORs. From a survey of year 1995 of Australia manufacturing organizations, Williams [15] find that approximately 38 percent of all respondent firms indicated that they had at some stage abandoned a cooperative arrangement, the main reasons being loss of control and lack of trust followed by the growing coordination cost of the arrangement. The wish to remain independent and remain control of their business operation was also the main reason of the failure.

A second characteristic of IORs can be described as the interdependence between partners. To create the transaction

value of common goals, partners should pool their resources together as well as determine the division of labor and the interface of activities between them. The resulting interdependence between the subtasks the partners agree to perform subsequently needs to be coordinated across organizational boundaries to ensure a fit between their points of contact [5].

Gulati and Singh [7] have stressed the importance of using coordination for managing task interdependence by arguing that "concerns about anticipated coordination costs are particularly salient in alliances, which can entail significant coordination of activities between partners". As the IOR's tasks become more interdependent and more uncertain, the need for coordination and decision making increases. Upon that, successful control of coordination costs becomes a key point on this cooperation relationship.

This paper develops a framework to analyze the determinants on the control of IORs in China, which is built on transaction cost analysis (TCA), resource-dependency theory (RDT) and notions of social control. We explain the framework from a case study of four buyer-supplier relationships on the manufacturing industry. Considering the availability of data, we will investigate the case from the buyer's perspective. In respect of the complexity and difficulty of measure on coordination costs, this paper does not try to examine the structure or measurement of coordination costs. Rather, we will focus on the inner relation between coordination costs and those influential factors.

This paper, in the next section, provides an analytic framework for measuring the determinants on interorganizational coordination costs from the TCA and RDT perspectives. Next, to explain the power of the framework, we employ a case study of buyer-supplier relationships from manufacturing industry in China. The paper ends with conclusions and directions for future researches.

II. Theory and Hypotheses

Detecting determinants on coordination costs of IOR can be studied from TCA perspective and RDT perspective respectively. The TCA has focused on the appropriation concerns in IORs, which originating from pervasive behavior uncertainty and contracting problems [3][11]. The basic assumption underlying the TCA perspective is that the specific governance form is based on an economizing on transaction costs. As asset specificity becomes substantial, interdependency is deepened and coordination is needed for

safeguarding the appropriation concerns.

RDT is a theory rooted in an open system framework, it focus on the ability that a firm must obtain necessary resources from external organization to survive prosper. The premise in RDT is that, firms confronted with an unpredictable environment will try to establish interorganizational relationships as a strategic response to uncertainty. The RDT perspective addresses the importance of the resources exchanged and the parties' ability to control the flow of input- and output resources [4].

When considering the management and control of IORs, we think the crucial concern is the magnitude of coordination cost. This paper considers both dimensions from TCA and RDT as potential detriments on coordination costs. Besides the common premise of uncertainty dimension, we focus on examination of asset specificity from TCA as well as other dimensions from RDT and social theory, including level of dependence and trust.

II.1 Coordination costs

Many researchers argue that the coordination cost outweighs the benefits that an alliance can provide. How to control the costs is the key to allow a firm to realize the potential gains from alliance involvement [2][7]. The problem lies in the difficulty to measure it, as coordination costs can not be reflect from financial data. Considering business exchange is based on contract, Artz and Brush [2] suggest that coordination costs should be measured through contracting costs. They argue that IOR creates two types of contracting costs: the ex ante costs of initially establishing the contract, and perhaps more significantly, the ex post costs of periodically renegotiating and adjusting those contracts.

We also adopt the perspective of Artz and Brush and use the latter type of costs to measure coordination costs occurred in IOR. Therefore we use a similar approach as that suggested by Artz and Brush [2] and use the amount of time a buyer spends preparing for and actually negotiating supply contracts and the extent of conflict in the negotiation as indicators of coordination cost. In detail, we consider three aspects here: the amount of preparing time before negotiation, actually negotiating time and bargaining sessions, and the extent of conflict in the negotiations.

II.2 Independent variables and hypotheses

Asset Specificity. Asset specificity refers to physical assets, production facilities, tools and knowledge tailored to a specific relationship that cannot be re-deployed for other purposes without the sacrifice of productive value. When entering an IOR alliance, participants usually have to invest on assets with specific use only in this alliance. As regarding the manufacturing industry, a firm should, which is looking for appropriate supplier, make great effort on searching and evaluating the potential partners. This may consume a lot of capital, labor and time to establish and maintain the cooperation relationship. Besides, the participants should be locked in by special production equipment, computer technology and related interorganizational systems that link the buyer and supplier production and scheduling activities.

Substantial asset specificity creates bilateral dependence and may reduce the buyer's control over supplier. Therefore the buyer's coordination costs may rise. Accordingly we propose:

H1: In a buyer-supplier alliance, the association between buyer's asset specificity and buyer's coordination costs is positive.

Uncertainty. According to TCA, uncertainty refers to the condition of being able to predict relevant contingences surrounding the transaction. There are two types of uncertainties. One type is referred as environmental uncertainty which means circumstance surrounding an exchange cannot be specified ex ante. Artz and Brush [2] define environmental uncertainty as the inability to predict changes in relevant factors surrounding the buyer-supplier exchange, such as the changes in price of product input and the demand for end product. Therefore the environmental uncertainty makes it more difficult for the buyer and the supplier to negotiate contracts.

Another type of uncertainty is referred as behavioral uncertainty which means performance cannot be easily verified ex post. The effect of behavioral uncertainty is a performance evaluation problem, that is, difficulties in verifying whether compliance with established agreements has occurred [6][14].

When anticipated the supplier may have motivation to behave high behavioral uncertain, the buyer should consume more time and effort in negotiating contract for safeguard purpose. Accordingly we propose:

H2a: In a buyer-supplier alliance, the association between environmental uncertainty and buyer's coordination costs is positive.

H2b: In a buyer-supplier alliance, the association between supplier's behavioral uncertainty and buyer's coordination costs is positive.

Resource-dependency. As RDT provides a holistic approach with explicit recognition of economic and social-political dimensions of IOR [12], Ratnasingham and Kumar [13] argue that RDT is concerned with: (1) external forces such as e-commerce environment within which the dyad operates, (2) internal organizational dimensions that structure and shape written policies and procedures, and (3) trading partners' interactions in their general exchanges.

Similar to the descriptions above, this paper takes the suggest that these structure arrangement may be embedded whining socio-political characteristics of dyad, so we use level of dependency and trust as the dimensions of resource dependency.

Regarding the level of dependency reflects the extent that the buyer relying on suppliers for the resources they cannot produce themselves, so we suggest that:

H3a: The greater the level of buyer's dependency on supplier exists, the more coordination costs the buyer should use.

Sociologist viewed trust as an individual's confidence in the intentions and capabilities of a relationship partner and the belief that a relationship partner would behave as one hopes. In IOR's research, Ratnasingham and Kumar [13] indicate trust as a key factor for successful long term trading partner relationships, because high extent of trust between partners can increase cooperation, thus leading to communication openness and information sharing. Furthermore, they identified three types of trust existing in IOR: competence trust, predictability trust and goodwill trust.

Competence trust emphasizes the trust in trading partners' skills, technical knowledge. Predictability trust emphasizes the trust in trading partners' consistent behaviors that provide sufficient knowledge for other partners to make predictions and judgments due to past experiences. Goodwill trust emphasizes the trust in trading partners' care, concern and honesty that allow other partners to further invest in the cooperation relationships.

Summarily, we can view trust as a very lubricant that can help mitigate risk and coordinate interactions in business relationships. Hence, we argue trust may be an important mechanism to reduce the coordination costs, and suggest:

H3b: The greater the trust between the buyer and the supplier exists, the less coordination costs the buyer should use.

The hypotheses are summarized as figure 1.

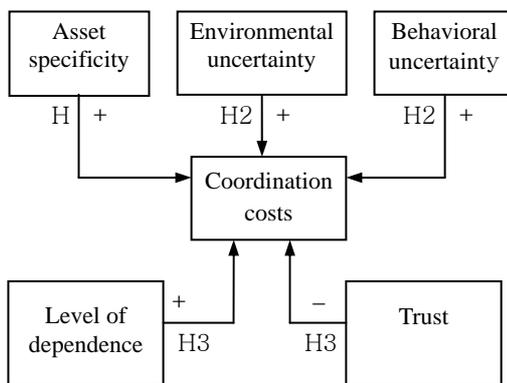

FIGURE 1: Determinants on coordination costs

III. A Case Study

On purpose of comparative, we select two electronic firms and two machine-making firms located at Xiamen city for in-depth study. These four firms are all stated owned firms listed on China Stock Exchange.

At first stage, we designed a survey based on buyers' perspectives of asset specificity, environmental and behavioral uncertainty, level of dependence on supplier and trust between the trading partners. Each dimension includes several items recorded on 1 (strongly disagree) to 5 (strongly agree) Likert scale. Next, we chose the interviewees as the managers of purchasing department or managers being responsible for R&D. Then we sent the surveys to interviewees beforehand and asked them to choose a supplier for certain product. Latter we arranged the interview with them separately for detailed discussion. The summary data in this case study is provided in table 1.

The electronic firms are Amoi Electronic Corporation and ABC Electronic Corporation. AMOI is a multinational electronic enterprise, which highly focuses on developing and manufacturing products from telecommunication, digital video & audio to IT industry. Nowadays Amoi has been an internationally well-known leading manufacturer and supplier of mobile phones in China. In 2003, this firm has employed about 20,000 persons and the total sales reached 850 millions US dollar. The interviewees chose the supplier producing screens used in mobile telephones.

The other investigated electronic firm is ABC which is an anonym. ABC is the leading professional manufacturer of Plastic Film Capacitors in China. Its current total annual capacity has reached 2.5 billions pieces, which can be ranked first in China and sixth in the world. The total employee is less than 2000, and the total sales are about 36 millions US dollar. The interviewees chose the supplier producing metal materials used in capacitors.

The machine-making firms are Xiamen King Long United Automotive Industry Corporation (XMKL) and Xiamen Engineering Machinery Corporation (XMEC). XMKL has taken up a leading position among domestic coach manufacturers and has hired 3500 employees with the total sales reached 542 millions US dollar. The interviewees chose the supplier producing engines used in coaches.

XMEC is the key enterprise of large scale for producing wheel loaders of the state. The company had been the birthplace of the first loader of China. The total employee is 2000, and the sales in 2003 reached 313 millions US dollar. The interviewees chose the supplier producing diesel engines used in wheel loaders.

We firstly compare the negotiate session with their own supplier between the two electronic firms. On average, both of them respond some extent of complexity in negotiation with their suppliers. To reach an agreement with suppliers on contract items, it often requires extensive preparation time and numerous separate bargaining sessions. This should belong to drastic competence and homogeneity of products existing in electronic industry. Therefore, electronic firms are always tried to strictly control the costs and quality of their product to gain competitive advantage in the market. This results tough negotiation with suppliers and increase the coordination costs of buyers. Investigated data shows that the two electronic firms received a same mean value of 3.6 on coordination costs. Rather, the average value of coordination costs for the two machine-making firms is much less, which is respectively 1.8 and 2.2. Both of the two firms attribute the relative easy bargaining process with suppliers to mature market of machinery industry.

Asset specificity. Amoi has gotten a greater value of 3.4 on asset specificity, and the value for ABC is 2.2, which is separately the max value and min value among the values of the four firms. The reason is that the supply of screen for mobile phone demands high customization, while the material for capacitors is high standardization. The engine and diesel engine used by two machine-making firms must comply with national standard, which make the asset specificity lower. As a whole, higher levels of asset specificity increase the difficulty the electronic firms experience in negotiation supply contracts. Although the coordination costs of ABC do not seem positive to asset specificity, this may be influenced by environmental uncertainty which increase the coordination. However, from the analytical perspective of industrial difference, this result can support the positive relationship between asset specificity and coordination costs.

Environmental uncertainty. As expected, the levels of environmental uncertainty of electronic firms are obviously higher than those of machine-making firms. ABC gets the greatest value of environmental uncertainty, which is not only two times than those of machinery firms but is also much greater than the value of another electronic firm. There are two causes can explain: first, the market price for

capacitors usually fluctuate violently. Second, the investigated component procured by ABC is metal material, which has been floated frequently in recent years suffered from international supply. In general, electronic industry confronted with drastic competence as well as fast technology innovation. Consequently the product prices and purchasing costs change frequently, along with the life cycle of product shorten. Suffering greater environmental uncertainty than machine-making firms, hence, electronic firms need more deliberately negotiate a contract. As a result, it suggests that higher levels of environmental uncertainty increase the coordination costs of buyer.

Behavioral uncertainty. Except for the lower value of Amoi, the levels of behavioral uncertainty of other three firms are almost the same. On account of the tiny distinction of these values which is nearly medial value, from this investigation we cannot get any conclusion on the relationship between behavioral uncertainty and coordination costs.

Level of dependency. Our data reflect that all of the firm present high levels of resource dependence on their suppliers for investigate. The primary reason is that the interviewees of the four firms have happened to choose the focal suppliers of their core products as investigating object. Among the firm, the level of dependency of ABC is lesser. Because there exist many manufacturers can supply metal material, in the other hand, ABC may find some other substitute if possible. In general, the distinctions among the levels of dependency of the four firms are not obviously. As all the values are distributed between 3 and 4, so the results suggest that the negative between level of dependency and coordination costs is not significant.

Trust. From table 1 we can see, the trust between buyers and their focal suppliers is reached a high level in the range of 4.29 and 4.57. Considering the greater value of trust dimension in the case study, we can conclude that all the four firms have tried to establish strong trusty cooperation relationships with their focal suppliers. Hence, to some extent of degree they have reduced the behavioral uncertainty of their trading partners and make the negotiation proceeding smoothly. As result, this finding support for Hypotheses 3b.

IV. Discussion and Conclusion

This paper contributes to focus on the determinants of coordination costs in IORs by considering the dimensions of TCA and RDT. Our model indicates that when studying the control of IOR, the economic dimensions and relational norms should be putted into consider simultaneously. There is little empirical study on such topic based on relationships of Chinese organizations, and this study also makes a valuable contribution by filling up this gap.

In this study, we investigate four manufacturing firms located in China belonging to different industry. The result shows that the Hypotheses 1 and Hypotheses 2a in our model have been significantly supported by the empirical data. That means in the context of China, the traditional TCA research is also useful in study of interorganizational relationships. We find that both asset specificity and environmental uncertainty directly increases the coordination cost of interorganization exchanges. And this finding is clearly consistent with previous TCA research [2]

[1] [9].

As the dimensions of RDT, this study supports Hypotheses 3b significantly. Therefore this finding indicates that trust can reduce buyer's coordination costs by mitigating behavioral uncertainty. Besides, trust between trading partners also plays a direct role in reducing buyer's coordination costs. On considering the effect of dependency level, distinction of the investigated data is quite tiny, and our study does not significantly support Hypotheses 3a. One possible explanation for this non-significant finding may be that the dependency level between trading partners in this study are too similar to manifest the different influential level.

While the findings of this study provide valuable insights, several future studies need research into the selection of determinants of IORs. For instance, our study has provided insight from the buyer's perspective, lacking of supplier's choice. Since the IORs are bilateral relationships, the successful control of IOR rely not only the action of the focal firm, but on actions of all the participants. Therefore, future research would analyze the determinants from the supplier's perspective. Finally, considering the shortage of case study method, it requires quantitatively methods using a number of IORs from a wide extent. This also remains an important challenge for future research into the management of IORs.

Abstract: This paper attempts to integrate concepts of a collaborative commerce and inter-organizational relationship to build a framework for influencing factors of e-Taiwan collaborative commerce partnership and empirically explore it. The importance for five dimensions of the Research Model based on seven top representatives of interviewed six Taiwanese companies engaged in E-Taiwan is summarized. Statistical analysis is used to decide which factors are vital for the success in three phases of partnership in e-Taiwan. Data are collected through a survey of organizations that are actively involved in the planning or operation of E-Taiwan collaborative commerce. The result has been shown the influencing factors are not the same in three phases of partnership in this collaborative commerce. It implies that to manage a collaborative commerce must have different strategies to select, develop, and maintain participants.

Keywords: Collaborative commerce, Partnership.

I. Introduction

In the past years, many organizations have tried to expand or broaden their supply chains in collaborative commerce. However, successful collaborative commerce is a challenge among the industry around the world, it maybe partly dues to the slow world economy making financing much more difficult for collaborative commerce, but organization behavioral adjustments should be also considered. Transitioning from traditional transaction approaches to an e-business model and adopting new technology present many organizational challenges. Building an Internet infrastructure and attracting more participants initially may not ensure the longevity of a collaborative commerce.

Therefore, this research tries to cover the findings of studies on collaborative commerce and organization behaviors. The research methodology is comprised of three approaches:

- (1) Literature review for building a Research Model.
- (2) Interviews with top-level executives in leading Taiwanese companies engaged in collaborative commerce to validate and justify the Research Model.

(3) Questionnaire survey based on the research model and statistical analysis to explore the influencing factors of e-Taiwan collaborative commerce partnership.

II. Literature Review

Within the literatures, it is shown that appropriation of information technology such as e-marketplaces justifies organization behaviors [6, 11]. As to the relationship styles of business partners, scholars propose many types such as arm's length, joint venture, supply chain and so on [2, 3, 8, 9, 12, 15]. Two major schools of thought have pursued the study of information technology and organizational changes. The decision-making school [17] emphasizes the cognitive processes associated with rational decision making and adopts a psychological approach to the study of technology and change. Institutional school [13, 16] emphasizes the role of ongoing discourse in generating social constructions of technology, with a consequent emphasis on human interaction in studies of technology effects. Several theoretical views synthesize these competing schools to form the social technology perspective. Adaptive Structuration Theory (AST) proposed by DeSanctis and Poole [6] in 1994 provides a model that describes the interplay between Advanced Information Technology (AIT), social structures, and human interactions. AST focuses on social structures, rules and resources provided by technology and institutions as the basis for human activities.

The constructs of AST [6] are (1) structure of AIT including structural features and spirit, (2) other source of structure including task and organization environment, (3) group's internal system including styles of interacting, knowledge and experience with structures, perceptions of others' knowledge and agreement on appropriation, (4) emergent sources of structure including AIT outputs, task outputs and organization environment outputs, (5) new social structures including rules and resources, (6) social interaction including two subsets: (a) appropriation of structures including appropriation moves, faithfulness of appropriation, instrumental uses, and persistent attitudes toward appropriation, and (b) decision processes including idea generation, participation, conflict management, influence behavior and task management, and (7) decision outcomes including efficiency, quality, consensus and commitment.

AIT brings social structures which enable and constrain interaction to the workplace. META Group) [1] proposed collaboration commerce into four functions as Design Collaboration, Marketing/Selling Collaboration, Buying Collaboration, and Planning/Forecasting Collaboration. According to the definition of META Group, E-Taiwan collaborative commerce can be treated as one type of AIT for the modern organizational market; it combines computing, communication, and business trading decision support capabilities to aid in buyer-seller groups idea generation, planning, problem solving and decision making. This research attempts to explore “E-Taiwan Collaborative Commerce” proposed by Ministry of Economic Affairs of Taiwan, including plan A, B (Industrial Automation and e-Business Promotion Program, iAeB), C (Cash), D (Delivery) and E (Engineering Collaboration). They are collaborative operations to link with business process, content and domain knowledge exchanging that includes e-procurement, e-financing, e-payment, e-global funding, e-logistic, transportation planning, synchronization, design change and information sharing etc. The scope of “E-Taiwan Collaborative Commerce” denotes “the Center of Knowledge/Processing Transaction” of collaborative commerce. According to the definition of our functions of META Group, “E-Taiwan Collaborative Commerce” can be classified as a kind of collaborative and AIT.

Structural features are the specific types of rules and resources, or capabilities offered by the system. Features within “E-Taiwan Collaborative Commerce” might include anonymous recording of business transactions, periodic data collecting and analyzing, and negotiation within business groups. Those features govern exactly how information can be gathered, manipulated, and managed by members in E-Taiwan Collaborative Commerce. Features of e-marketplaces bring meaning and control to group interaction. There currently is burgeoning interesting in e-marketplaces and their potential role in facilitating organizational and social changes. Once Collaborative Commerce is applied, the technology should bring productivity, efficiency, and satisfaction to individuals and organizations, but the social evolution of structure within industrial and human institutions are also changing. Social technology perspective as AST can be an analytic principle to explore the influencing factors for “E-Taiwan Collaborative Commerce”. Based on the meaning of each construct in AST, initial dimensions for the Research Model are listed as Table 1.

III. Research Model

Researches related to E-Taiwan collaborative commerce focus on finding characteristics and functions. The findings in literatures include information transparency, cost reduction, interdependence, partnership compatibility, low logistics costs, etc [4, 5, 7, 10, 14]. The influencing factors of each dimension are summarized in Table 2. The relationship styles of buyers-sellers in organizational.

Table 1. Initial Research Dimensions inspired from AST

Major Constructs of AST	Initial Dimensions for the Research
Structure of AIT	Characteristics of E-Taiwan
Other Source of Structure	Initial Leader of E-Taiwan
Group's Internal System	Members of E-Taiwan
Emergent Source of Structure	Industrial Environment
New Social Structure	Derivative Problems of E-Taiwan
Appropriation of Structure	Functions of E-Taiwan
Decision Process	Phases of E-Taiwan

Markets proposed as five relationship styles of partnership in e-marketplaces are also defined. They are (1) arm's length, (2) buyer-seller relationship, (3) trusted partnership, (4) joint venture and (5) value chain [9].

Expert depth interview is employed to validate the Research Model. Then a primary questionnaire survey is conducted to analyze which influencing factors are vital for the success in three phases of partnership in E-Taiwan Collaborative Commerce, including a question about the relationship styles of partnership in E-Taiwan Collaborative Commerce in order to exploit participants' perspectives. Six top representatives of Taiwanese companies related to E-Taiwan are selected for expert depth interview to validate the Research Model. The companies interviewed are MiTAC International Corporation (plan B, C, D, E), Hewlett-Packard Development Company (plan A), Futaba Technology Development Corporation (plan D, E), China trust Commercial Bank (plan C), Systex Corporation (plan A,B, C, D, E) and Advanced Semiconductor Engineering, Inc.(RossettaNet). The importance of each research dimension based on opinions of seven executives of the interviewed companies is summarized in Table 3. The importance of All research dimensions are bigger than 75% that is set to be significant (i.e. significant dimensions must have three out of four interviewees mention at least). Based on the importance voted by six executives, the Research Model is proposed as Figure 1. Business model is an additional factors proposed by these seven interviewed representatives.

Table 2. Influencing Factors of Research Dimension

Research Dimension	Influencing Factors
Characteristics of E-Taiwan Collaborative Commerce	(1) information transparency (2) capability of information integration (3) ability of improving for transaction quality (4) cost reduction
Initial leader of E-Taiwan Collaborative Commerce	(1) credibility (2) *business model
Members of E-Taiwan Collaborative Commerce	(1) information sharing (2) ability of communication (3) exceptional management (4) commitment (5) trust (6) strong partnership (7) coordination (8) interdependence (9) compatibility of partners (10) performance expectations met
Industrial Environment	(1) e-business capability (2) standards setting
Derivative Problems of E-Taiwan Collaborative Commerce	(1) reform of business procedures (2) reform of organizational structure (3) degree of information transparency (4) compatibility among systems (5) security (6) *consistence of standards
Functions of E-Taiwan Collaborative Commerce	(1) inventory reduction (2) improvement of purchase order forecasting (3) accurate customer demand (4) e-payment (5) e-financing (6) e-global funding (7) reducing the financial cost (8) transparency of transportation (9) low of logistics costs (10) improving the quality of delivery (11) inventory control (12) transportation planning (13) quality of delivery (14) management of design change (15) reducing time-to-market (16) reducing the cost of design (17) development (18) computer-supported (19) collaborative design

* proposed by seven interviewed representatives.

IV. Primary Questionnaire Survey and Research Findings

Since the Research Model is justified and validated, the questionnaire survey is deployed next. In the questionnaire, questions (36 items for plan A, 39 items for plan B, 42 items for plan C, 46 items for plan D, and 38 items for plan E) are developed to related to the forty influencing factors of seven

dimensions in the proposed Research Model. Items appearing in the question are measured in five-point Likert-type scales. Data are collected through a survey of organizations that are actively involved in the planning or operation of E-Taiwan Collaborative Commerce. Thirty-four questionnaires are delivered and all recycled and considered effective after examination. For avoiding bias from extreme values, the geometric means instead of average means to evaluate answer values of questionnaire surveys. This research is hence used it to decide which factors are vital for the success in three phases of partnership in E-Taiwan Collaborative Commerce. The geometric mean of opinion values to each question is converted into percentage form. Questions with the percentage bigger than 75% are considered significant in this research. Influencing factors related to those significant questions are the crucial factors this research aims to find. According to the primary analysis, the crucial influencing factors of three phases of partnership in E-Taiwan Collaborative Commerce are summarized in Table 4.

Table 3. Importance of Research Dimension

Research Dimension	Number of factors mentioned by experts	Sum of importance among factors	Importance of dimension
Characteristics of e-Taiwan	27	28	96%
Initial leader of E-Taiwan	13	14	93%
Members of E-Taiwan	69	77	90%
Industrial Environment	14	14	100%
Derivative Problems of e-Taiwan	106	112	95%

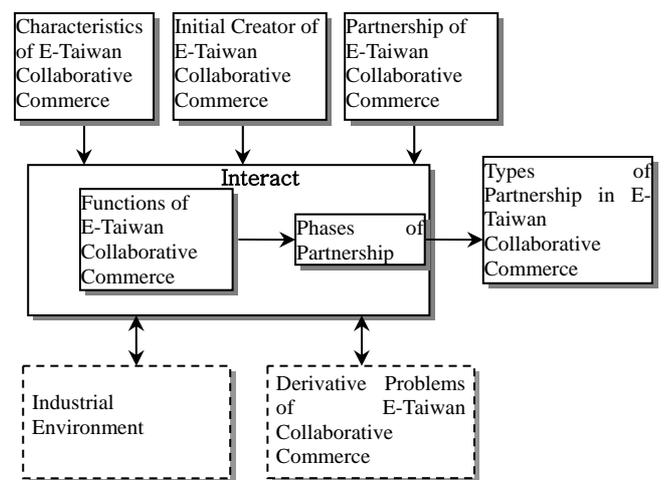

Figure 1. Research Model

Table 4. Crucial Influencing Factors of Partnership in E-Taiwan Collaborative Commerce

Phase	Selecting of Partners	Developing of partnership	Maintenance of partnership	
Factor	credibility	ability of improving transaction quality	information transparency of capability of information integration	
		information sharing	ability of improving for transaction quality	
		ability of communication	information sharing of ability of communication	
		exceptional management	exceptional management of trust	
		security	e-business capability of standards setting	

V. Conclusion

The research findings have been shown the influencing factors are not the same in three phases of partnership in E-Taiwan Collaborative Commerce. These factors are dispersed in different dimensions as Figure 1. The research findings imply to manage a Collaborative Commerce must have different strategies to select, develop, and maintain participants. As to the prospective relationship style of partnership in E-Taiwan Collaborative Commerce, experts involved in the questionnaire survey suggest partnership maintaining is better for Plan A and Plan C; partnership maintaining or integration of value chain are two possible forms for Plan B; Arm's length, partnership maintaining or integration of value chain are three possible forms for Plan D and Plan E.

Due the scope of E-Taiwan Collaborative Commerce, small size of purposive sampling is the limitations of this research. Also path analysis is being applied to find the

relationship among these dimensions for providing administrators of Collaborative Commerce some detailed information for controlling and decision makings.

Abstract: Business to customer (B2C) e-business has opened many new opportunities for businesses. In response to studies that underscore the importance of maintaining strong and learning relationship between the organization and customer, many have turned to customer relationship management (CRM) to manage their interactions with their customers and other external entities. Although IT enables CRM, other organizational factors, such as organizational absorptive capacity's effect on innovativeness, may have greater impact on its ability to continually satisfy the business' customer needs and expectations. However, IT may be a critical element to both absorptive capacity and innovation. This study examines the relationship between IT diffusion, organizational absorptive capacity and innovation, and proposes a research model. A clearer understanding of these relationships will provide businesses a means to appropriately direct their investments in IT and absorptive capacity.

Keywords: Customer relationship management, absorptive capacity, information technology diffusion.

I. Introduction

In recent years, businesses have begun transitioning to e-business models and consequently engaging in customer relationship management (CRM). Information technology (IT)-enabled e-business has opened many new opportunities for business organizations, yet reaping the rewards of these opportunities has required them to adopt more advanced IT-enabled means. In contrast to their traditional markets and business models (i.e., brick and mortar business models), many businesses are finding themselves immersed in highly competitive, consumer driven global markets conducted over the Internet, and competing against virtual alliances, organizations that collectively work together in either horizontally or vertically integrated partnerships that are facilitated by IT. Continual advances in IT have fueled this drive in competitiveness to new heights, and in cases such as the airline industry [13], have changed the way business is conducted. Thus, IT has not only changed the competitive landscape, but it also requires businesses to seek innovative

IT-based solutions to better leverage themselves.

On the consumer side, the market potential is enormous. For 2008, Jupiter Research forecasts that half of the US population will purchase their goods and services online through the Internet (versus 30 percent in 2004) and the estimated spending per buyer will average \$780 (versus \$585 in 2004); this translates to \$117 billion in sales. In contrast, Forrester Research predicted that online retail volume for 2004 would reach \$100 billion. Yet, profiting from electronic marketplaces will require businesses to become highly knowledgeable of their environments and customers. Thus, competitive threats and market opportunities are driving businesses to intelligently innovative applications of IT to ensure their longevity and survival. Market demands and expectations make IT a necessary resource to effectively compete, especially in global electronic marketplaces.

Business to customer (B2C) e-business poses several new challenges to businesses. The shift from mass marketed to micro-segmented, tailored products and services has forced businesses to establish and build closer learning relationships with their customers. As a result, many have turned to customer relationship management (CRM) to manage their relationships and interactions to gain greater insights into their (customers') needs and expectations [35]. However, their success with CRM lies in their ability to continually innovate to meet changing market conditions and customer needs, and gain competitive advantages through products and services that cannot be easily duplicated, imitated or substituted [29], [44]. This implies that businesses must be capable of not only learning from the entities of their external environment (i.e., customers, suppliers and other sources of information), but also to be able to leverage and exploit their organizational knowledge to innovate. Thus, conceptually, CRM's success hinges on how well the business *absorbs* pertinent information about its customers and applies the knowledge it has gained toward developing products and services that closely fit their needs and expectations. An organization's absorptive capacity, the ability to recognize and assimilate information and apply its cumulative knowledge toward a profitable gain [11], defines this ability.

Yet, the ability to innovate may not sufficiently meet the demands of highly competitive markets. The *speed* at which electronic markets operate becomes the underlying concern.

A common definition describes CRM as a process that utilizes technology to capture, analyze and disseminate current and prospective customer data to develop deeper and more insightful relationships, and identify and more precisely target products and services to specifically match their customers' needs [30], [35]. Thus, IT assumes a critical role in CRM performance since it may boost the business' abilities and subsequent productivity (*speed*). However, Grover et al. [19] cite inconsistencies in the results of studies that have examined the effects of IT investment on productivity do not lend an overwhelming endorsement to the relationship between IT investments and productivity (i.e., IT investments increase productivity) and suggest the presence of an intervening variable, perceived process change. Their study suggests that perceived process change's mediating effect on the relationship between IT investments and productivity (i.e., requires process change) is stronger and more consistent than its moderating effect (i.e., enables process change). This indicates that IT must be coupled with other organizational changes for it to have a desired effect on productivity. They recommend further studies to explore the relationship. Therefore, *to what degree does IT contribute to an organization's CRM performance in terms of its absorptive capacity and innovative output (i.e., products and services)? Do greater investments in IT lead to higher levels of organizational absorptive capacity and innovative output?*

The purpose of this paper is to propose a model of IT diffusion's effects on an organization's absorptive capacity and innovation, and examine the relationship between them in the context of CRM performance. IT diffusion refers to the acceptance and adoption of new IT solutions implemented for purposes of gaining competitive advantage. Given that the primary purpose of implementing CRM is to gain unprecedented competitive advantages and all businesses strategically position themselves differently, all businesses will apply CRM differently to produce different results (i.e., product and service differentiation). However, its performance as measured in organizational and customer relationship benefits should reflect the *return* on its investment, the number of successful (i.e., profitable) innovations over the amount of knowledge collected. This study proposes that greater investments in IT as captured through IT diffusion will not only increase organizational absorptive capacity, but will also allow the business to reap greater benefits from CRM and provide more tailored innovative products and services to their customers. Thus, IT influences the effects of organizational absorptive capacity and CRM performance. Absorptive capacity will be examined in terms of its ability to leverage and exploit organizational resources in contributing to CRM success. Understanding these relationships will provide businesses a means to direct their investments in IT and absorptive capacity.

II. CRM, Innovation and Absorptive Capacity

CRM is commonly recognized as an information system to assist the customer retention process or a methodology that extensively employs information technology (IT), particularly database and Internet technologies, to enhance the effectiveness of relationship marketing practices. It allows an organization to listen to its customers and customize its products and services to meet their personal needs [29], [30], [35], [44]. In consumer-driven markets where switching frequently occurs, successful businesses must be able to act quickly to seize opportunities through well-developed processes, maintain a wealth of information on their customers that is readily accessible, accurate and current, and leverage and exploit their knowledge and resources to sustain their competitive edge. CRM represents an IT-enabled system designed to meet these requirements. Experience suggests that a well-designed and implemented CRM will help ensure the longevity of a customer-business relationship, and enable the business to thrive in a consumer-driven market through such means as loyalty and (high) switching costs.

Often referred to as one-to-one marketing and relationship marketing, CRM allows organizations to individually focus on their customers rather than mass-marketing their products and services to broadly defined market segments [30]. It places emphasis on retaining existing customers [29] through such means as loyalty [26] since the greatest leverage comes from investments in retention rather than the generation of new customers [44]. Winer [44] cites a 1999 McKinsey study that strongly suggests repeat customers can generate over twice the gross income as new customers. Similarly, Reichheld and Sasser [32] reported that a 5 percent increase in the customer retention rate can lead to increases of 35 to 95 percent in average customer lifetime value (i.e., net present value of a customer). A survey conducted of 300 business executives underscores the importance of maintaining good customer relationships. It revealed that a one-point increase in an organization's customer satisfaction index (based on annual surveys conducted by the University of Michigan, the American Society of Quality and Arthur Andersen) corresponded to an average \$240 million increase in market (equity) value [40]. Building loyalty among existing customers often leads to increases in repeat-purchase rates and usage frequency, and raises barriers of entry into the markets as it makes it difficult for new businesses to court customers of established competitors [37]. Furthermore, the cost of acquiring new customers may be five times greater than that of satisfying and retaining current customers [31]. The Boston Consulting Group estimated that it costs a business \$6.80 to market to an existing customer via the web versus \$34 to acquire a new customer (via the web) [20]. Yet, building a long-term relationship involves more than innovating new products and services to meet the customer's needs. It also means delivering quality and value [21]. Given these rewards, it behooves most businesses to carefully plan, develop and invest in their CRM systems. Thus, the investment in relationship management can yield enormous and continuous returns; small increases to the number of repeat customers

frequently equate to large increases in profitability. Much of this success can be attributed to advances in IT that have allowed businesses to collect, retain and analyze customer data, gain greater insights into their customers' behavioral patterns, and innovate.

Effective investments in CRM and continual innovations increase customer switching costs through added value and trust [45]. Added value comes from the business' understanding of its customers' needs and targeting them through customization, one-to-one interactions, relevant promotions and information, and rewards and incentives. Each of these increases value since they may not be readily obtainable from other businesses. For the customer to receive the same benefits elsewhere, he/she would need to build another relationship. However, this would require the customer to entrust his/her personal information with an entity he/she may know little of. Consequently, the time involved with developing a new relationship will depend upon the pace at which the organization gains the trust of the customer. Furthermore, the customer must make investments in time and effort to convey his/her needs and personal information to the new organization. Therefore, the customer incurs several costs with switching. If the business maintains a healthy relationship (i.e., loyalty) and continually satisfies its customers' needs (i.e., does not provide the customer with reasons for shopping elsewhere), the cost remains high to the customer. Thus, continual innovation becomes a key factor in keeping switching costs high.

Innovation reflects the business' ability to understand its customers' needs, and leverage and exploit its knowledge into products and services. Thus, innovation can be used as a measure of CRM performance and is essential to CRM success. A general definition of innovation presents it as the development and successful implementation of new and creative ideas [3], [15], [42]. It includes processes involved with the generation (i.e., search and discovery) and acceptance of new ideas, processes, products or services [17], [18], [23], [41]. Innovations characteristically yield new techniques that are most likely superior to the ones they succeed [17], and lead to the achievement of higher levels of performance [22]. Hence, they embody improvements. However, the propensity towards adopting the innovation lies in the perceived benefits that exceed those of alternatives [4] and the added value perceived through adoption [36].

Organizational innovation depends on the collective creativity of employees and three basic environmental components: the motivation to innovate (i.e., competitive orientation as manifested in the organization's vision and mission), availability of resources, and innovation management skills (i.e., management support and skills that nurture creativity) [3]. In the absence of these components, innovations will lag. An underlying motive is the perception of capitalizing on unexploited technological and economic opportunities, and involves uncertainties (and consequently risks) in search activities and outcomes [17], [24]. Thus, economic gain or reward often accompanies innovation with

risks. Yet, the success of innovating products and services requires critical investments in the accumulation of knowledge [23], [24]. For this matter, Kanter [24] characterizes innovation as being knowledge-intensive, and dependent on how well an organization configured its knowledge to create new knowledge [43]. As a resource to innovation, IT advances information discovery and knowledge management, and thereby reduces risks.

Although IT serves as an underlying (i.e., necessary) condition, it may not be sufficient to ensure CRM success. IT will facilitate CRM success, but as in the case of other IT-enabled systems, the presence of organizational elements and factors that will benefit from IT will affect CRM performance. Since a fundamental objective of CRM is to translate the individualism of its customers to an array of differentiated product and service offerings, a business must rely upon innovative product and service discoveries that are developed through both the exploitation and exploration of information. This implies that an essential success factor of CRM lies in organizational knowledge and the organization's ability to leverage and exploit it. Prior studies [8], [11], [22] suggest that an organization's ability to link its knowledge to its innovations depends upon its capacity to innovate, the ability to successfully adopt or implement new ideas, processes or products. Similarly, Cohen and Levinthal [11] contend that innovations are products of an organization's absorptive capacity, its ability to recognize and assimilate new information, and apply the ensuing knowledge to commercial ends.

Zahra and George [47] define absorptive capacity as "a set of organizational routines and processes by which firms acquire, assimilate, transform and exploit knowledge to produce a dynamic organizational capability" (p. 186). The four capabilities interact and build upon one another to create a dynamic capability that leads to other organizational capabilities, such as marketing and production. The organizational change it (dynamic capability) produces is often strategic in nature. Yet, absorptive capacity largely depends on precursory learning (within the organization) and the dissemination and integration of subsequent knowledge [11]. As more knowledge is accumulated, the organization's absorptive capacity grows as its ability to recognize and assimilate information expands. Greater frequencies of learning reinforce prior knowledge and increase the organization's capacity to retain new knowledge, which in turn yields the application of knowledge to new scenarios [9]. A mechanism (i.e., process) to disseminate and share this knowledge becomes critical to developing innovative competitive advantages [27]. Because absorptive capacity will vary from organization to organization, product and service innovation success will vary accordingly, and depend on the knowledge it leverages and exploits.

This study posits that businesses with greater absorptive capacity will not only be more innovative, but will also more accurately meet and satisfy their customer needs. As a result, CRM will better position them competitively. Therefore, differences in CRM performance may be attributed to

differences in absorptive capacity. However, the IT an organization adopts may critically influence its absorptive capacity or its innovativeness.

III. Diffusion of IT and CRM Performance

The diffusion of IT in an organization concerns the extent to which it is adopted (i.e., accepted), and assumes the introduction of an innovative use of IT [7]. Because IT enables CRM, its diffusion may determine the extent to which a business can compete. Based upon innovation diffusion theory, the acceptance of new IT (innovation) hinges on the assessments and adoption of potential adopters who subsequently determine the adoption behavior in others [34]. Individuals regarded as potential adopters engage in information seeking behaviors to overcome a perceived uncertainty. Upon examining an innovation they view as a possible solution, they form an attitude toward it which eventually leads to a decision to adopt (accept) and implement the innovation or reject it. Given the relationship between innovation characteristics and innovation adoption, five key perceptions will influence an adopter's decision to accept IT: compatibility (i.e., perceived consistency with existing values, needs and past experiences), relative advantage (i.e., perceived advantage or improvement over the former method or technology), complexity (i.e., perceived difficulty to understand and use), trialability (i.e., degree to which it may be experimented with on a limited basis), and observability (i.e., degree to which the results of adoption are visible to others) [34]. The perceptions of compatibility and complexity are consistent with Bandura's [5] self-efficacy beliefs (i.e., behavior modification) and Davis' [16] perceived ease of use while relative advantage lends support to Ajzen's [2] outcome beliefs and Davis' perceived usefulness constructs. Trialability and observability provide the opportunity for potential adopters to expose and demonstrate IT-use to encourage others. They will communicate through the organization's formal and informal social system their information to others who they influence. The study of Agarwal and Prasad [1] implies that the perceptions of early adopters (in contrast to non-early adopters) will have a greater impact on adoption. Therefore, carefully planning an adoption strategy will greatly enhance IT's successful adoption [12].

In their study of the effects of absorptive capacity on IT use, Boynton et al. [8] suggest that IT management climate strongly influences an organization's absorptive capacity. They define IT management climate as management's attitudes and perceptions of IT's role in the organization, and are reflected in its planning orientation, vision and control structures. Bannister [6] further states that IT leadership contributes to forming the IT management climate. As they apply to IT diffusion, IT leadership and management climate create an atmosphere and culture that promote and facilitate the introduction and adoption of IT, and the dissemination of information throughout the organization, all crucial to diffusion. Thus, their studies establish the positive

relationship between IT diffusion and absorptive capacity as IT diffusion supports higher levels of knowledge development and intelligence gathering. Other factors that influence the adoption of IT include organization culture, knowledge sharing and learning [24], [25], [46], norms and opinion leaders [34].

The diffusion and deployment of IT will be unique to each organization due to its characteristics, particularly its accumulated knowledge [7], [28]. The interpretation of information entering the organization is contingent upon the organization's ability to recognize and link new information to its stored knowledge. Its current technology base (and the knowledge of that technology base) initially influences its perceptions and determines whether an innovative technology is deemed appropriate and useful. Furthermore, an organization's absorptive capacity may promote IT use (i.e., the greater the absorptive capacity, the greater the IT use) [8]. Once assimilated, IT's adoption and use depend upon the focus of the organization's knowledge. Applying the technology to non-complementary applications (i.e., applications that do not converge on a common body of knowledge) rarely occurs due in part to the organization's bounded rationality; organizations will adopt solutions that fit within the scope of their knowledge [28], [33], [38]. Additionally, an organization's interpretation of efficiency directs its emphases on different aspects of knowledge and how it applies its knowledge. An organization's means for converting inputs to desired outputs (based upon its interpretation of efficiency) determines its capacity to plan, coordinate, control and monitor the diffusion of IT [28]. Therefore, the content of IT in CRM will differ among organizations. Largely, it depends on the extent to which diffusion (i.e., adoption) has occurred, as determined by their focus and knowledge. This suggests that IT will facilitate absorptive capacity since IT will influence the development of absorptive capacity as it (IT) focuses the organization's intellectual resources toward achieving higher levels of performance (i.e., researching and developing innovative products and services) in specific areas of CRM. Hence, IT diffusion plays an important role in determining the extent to which new knowledge can be *absorbed* into the organization. The underlying goal is to create an environment of continual innovation.

IV. Proposed Model of IT and CRM Performance

A business' absorptive capacity plays a critical role in determining its CRM performance. The information the business learns from its customers and about pertinent market conditions will become part of its knowledge (through assimilation), which will eventually drive the innovation of products and services that directly target its individual customer's needs. To sustain its competitive position, its knowledge must also incorporate a sense of perceived benefits and added value over alternative offerings,

and featured qualities that cannot be easily duplicated, imitated or substituted. Continual innovation to meet these requirements and others imposed by changing market conditions requires continuous learning and knowledge accumulation. As more knowledge is amassed, the business' power to accumulate further knowledge and more precisely direct its innovative activities becomes greater. In this study, CRM performance will be based on the business' innovation output, and success can be tied to the organization's ability to leverage and exploit its knowledge with IT providing the means (for leveraging and exploiting it). As in the case of Cohen and Levinthal [11] and Stock et al. [39], the number of products and services produced through CRM can therefore reflect the organization's absorptive capacity. In the absence of organizational absorptive capacity, IT alone will be incapable of supporting CRM.

The proposed model of this study embodies the dynamic capabilities of absorptive capacity and their interrelationships [47]. In examining the relationship between IT diffusion and CRM performance (i.e., IT's contribution to CRM performance), this study proposes that organizational absorptive capacity mediates (i.e., require process change) the effects of IT diffusion on innovation. A mediating effect suggests that IT diffusion enhances the effects of organizational absorptive capacity on innovation (Figure 1), similar to the study of Boynton et al. [8] on the effects of IT management climate on absorptive capacity, and the ensuing effects of absorptive capacity on IT use. For IT diffusion to have an impact on innovation, IT-enabled process changes in absorptive capacity must occur among its capabilities. This may include devising new ways in which opportunities are recognized, information is acquired, assimilated and transformed, and knowledge is exploited. As a result, the effects of IT may amplify or enhance the effects of organizational absorptive capacity on innovation. Greater levels of IT investments within limits [39] may lead to higher levels of absorptive capacity and consequently a greater number of successful innovations (i.e., successful CRM performance) if process changes occurring in absorptive capacity take advantage of the investments.

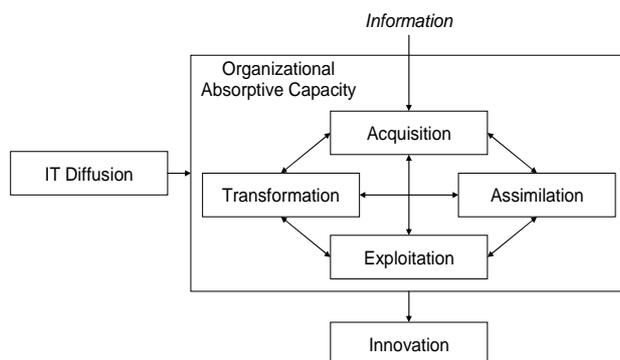

Figure 1. Proposed model with IT diffusion's mediated effect on innovation

Because IT enables CRM, its (CRM's) success hinges on how well the business has adopted innovative applications of

IT to maintain its IT sophistication throughout the organization. In dynamic global markets, changes can occur quickly and suddenly due to advances in IT. As new technologies become available, businesses must learn their benefits and examine ways in which their adoption can provide a distinct competitive advantage. If these advantages become apparent and supportive of the business strategy, the adoption of the technology must quickly be disseminated throughout the organization's work processes and activities. However, these advantages are often only short-term. As the technology becomes readily available, its mass adoption throughout an industry overcomes the advantages. Thus, the search for new technologies continues and IT diffusion becomes critical to a business' long-term profitability. Currently, innovations in network infrastructure, client-server computing and business intelligence application are leading IT factors in CRM development [10] that will benefit a business with their timely adoption. To ensure the quick adoption, the organization must have in place channels or an organization structure (i.e., social network) conducive to diffusion.

In CRM, the discovery of knowledge is a major component to its success. The business must focus on increasing customer satisfaction and loyalty through the information it acquires through its one-to-one relationships with customers and learns of market trends and other environmental factors that will impact future customer needs and expectations. IT can be used to quickly access information, retain volumes of data for future analysis, assess markets and transform the information it gains (i.e., data analysis) into knowledge. In electronic marketplaces, the speed and sophistication of knowledge discovery is a critical element. Absorptive capacity represents the learning and knowledge building component of CRM and relies upon IT for the discovery of new and retention of existing knowledge. Thus, IT diffusion leads to the introduction and adoption of new tools or processes that will benefit the *absorption* of new knowledge, leverage and exploit the organization's knowledge, and consequently seize opportunities and provide a competitive advantage. Prior studies have shown IT development supports higher levels of knowledge development and intelligence gathering [6], [8]. Hence, IT enables absorptive capacity.

Proposition 1. *IT diffusion will have a positive effect on organizational absorptive capacity.*

The purpose of building absorptive capacity is to leverage and exploit the organization's knowledge towards a commercial end [11]. It involves the business identifying its customers' buying behaviors and habits with granularity, integrating this information into an existing body of knowledge, discovering new knowledge from the information it has gained and applying its knowledge to innovate products and services that more precisely meet its customers' needs, preferences and expectations, thereby increasing their switch costs through quality and value not readily obtainable elsewhere, and providing at least a

perception of superiority or achieving a higher performance level. These innovations should possess a uniqueness that competitors cannot easily overcome and find difficult to imitate, duplicate and substitute the product or service to gain a competitive advantage. Internally, innovations may include improved processes or methods for customizing or delivering the products or services. Given these characteristics, innovativeness is knowledge-intensive. By continually applying what it learns from its customers, the business will ensure the longevity and benefits of their relationship. Thus, the greater the resources that are committed to developing absorptive capacity, the greater the capacity of the organization to innovate and reap greater benefits from CRM (i.e., improved operating performance, customer retention, loyalty and satisfaction, repeat transactions, market share and opportunities, etc.); absorptive capacity enables innovation.

Proposition 2. *Organizational absorptive capacity will have a positive effect on innovation.*

Prior studies indicate that IT has no direct effect on productivity [8] or CRM impact [14]. Instead, another factor will mediate its effect. A mediating effect occurs when variations in the independent variable account for variations in the mediator (i.e., intervening variable), variations in the mediator account for variations in the dependent variable, and when controlled the independent variable has no effect on the dependent variable. Hence, IT's effect on innovation must be mediated by an intervening variable; this study proposes absorptive capacity. Although IT diffusion opens opportunities for the expansion of innovations, IT by itself cannot be directly linked to innovativeness since it represents only a means (tool) for discovery. Yet, the development and expansion of knowledge in the form of absorptive capacity benefits from IT diffusion (i.e., proposition 1). In turn, increases in an organization's absorption capacity will lead to higher levels of innovations (i.e., proposition 2). The research model presented in this study proposes that innovations will benefit from IT diffusion if it targets knowledge development (i.e., absorptive capacity), a key element to innovations. If absorptive capacity is a mediator, IT diffusion will not have a direct effect on innovation, as suggested by prior studies. In this study, innovations reflect CRM performance as they are a result of CRM use in leveraging the organization's knowledge.

Proposition 3. *Organizational absorptive capacity will mediate the effects of IT diffusion on innovation.*

The purpose of the proposed model is to examine the roles IT and absorptive capacity play in the innovations aspect of CRM performance. In the ever-changing global electronic marketplace, a business' ability to continually innovate will contribute to its longevity through customer satisfaction and loyalty.

V. Practical Business Implications

In the past years, businesses have increasingly invested in CRM. Yet, according to the Meta Group, several implementations have either failed to go live (25 percent) or fallen short in meeting expectations (59 percent). AMR Research indicates only 16 percent are considered complete successes. This is in spite of the \$10.8 billion it estimates American businesses have invested in CRM software and services during 2004, a \$1 billion increase over the previous year. Although many of the failed endeavors have been traced to business change and adoption imposed by the new system, Forrester Research suggests successful CRM implementation have focused on delivering customer experiences.

Understanding the needs, preferences and expectations of customers with the goal of retaining them in long-term relationships is paramount to CRM. The competitive edge goes to the business that cannot only acquire the essential information containing customer buying habits and preferences but can profitably leverage and exploit the ensuing knowledge in a very timely manner. This suggests three implications to practice: IT should facilitate communications between the business and its customers and within the organization, businesses need to focus their investments in absorptive capacity on long-term innovative discoveries, and diffusion plays importantly to ensure the timely adoption of IT that will benefit the previous two implications.

Meaningful interactive communication is vital to building relationships in relationship marketing (RM) and CRM. It enhances the customer's experience by providing the business with information that will be used to target customer satisfaction and the customer with products and services that reflect his/her preferences. The particular value and benefits the customer derives from these offerings increases his/her switching cost through increased satisfaction, thereby raising uncertainties with patronizing another business. The more effective and efficient the means for fostering or facilitating the communication between the business and customer is, the greater the impact the communications will have on the business' absorptive capacity development. Communication within the organization and between the business and its partners (i.e., suppliers, distributors, etc.) ensures the business will benefit from its knowledge, alerts the business to shifts in its markets and helps expand its organizational knowledge. IT provides the means for delivering knowledge as a shared resource through a technical infrastructure and communication networks.

Because the development of absorptive capacity embodies a continuous learning process, investments in it should focus on the long-term discoveries of innovations. To maintain its long-term relationships with its customers, the business must continuously seek new products and services that they can recognize and associate with value and benefits. These innovative offerings will result from established learning relationships that feed an accumulated body of

knowledge. Innovations also involve new processes, such as the delivery of information, or products and services, that improve and enhance the customers' experiences. IT provides the means to quickly recognize new opportunities, accumulate and disseminate knowledge, and maintain the learning relationships.

Lastly, the diffusion of IT supports the business' CRM endeavors in communications and absorptive capacity. Competitive market forces play a major role in the adoption of IT, particularly those which provide a distinct competitive advantage. Enhancements to communication come with the adoptions of newer technologies, such as wireless devices that support mobile commerce (m-commerce) or ubiquitous commerce (u-commerce), and web technologies. Advances in IT have made data repository capacities in the terabytes common and data warehouses the focal points of business intelligence. The medium on which data are transported now supports transmission speeds in the gigabytes. Together these have opened new possibilities to enhance the customer experience (e.g., on-demand streaming video, personalized and customized products and services, etc.) and the diffusion of IT has become more crucial to the business' ability to leverage and exploit its knowledge to effectively compete in global electronic marketplaces. Because e-business requires the business and its partners to work as one to project a single image, an organizational structure and channels to ensure the rate and degree to which IT becomes embedded in processes and activities are important.

VI. Summary

The movement toward B2C e-business opens many new challenges to business organizations. Competing in highly competitive and consumer-driven markets has shifted business emphases from mass marketed to micro-segmented, tailored products and services that target the specific needs of customers. As a result, many businesses have turned to CRM to establish closer learning relationships with their customers and gain a greater understanding of serving them in hopes of building their loyalty and increasing their switching costs. However, CRM performance must be gauged by the business' ability to continually innovate products and services while remaining competitive. An organization's absorptive capacity becomes a critical element as it assimilates customer information (along with other information) and further leverages and exploits the organization's knowledge. Organizational absorptive capacity in turn forms the basis for innovations. Rapid changes and unexpected shifts in market expectations place additional demands on CRM to innovate quickly. Thus, the adoption of innovative IT may help in leveraging the organization's absorptive capacity. However, the effects of IT diffusion on absorptive capacity and innovation are uncertain. This study proposes the development of a model to further examine their relationships.

Abstract: Successful e-commerce portal organizations focus intensely on customers. They try to consider every bit of information that flows from the customer to their system as an input for analyzing and identifying their needs precisely and catering to them. Being mostly 'click and mortar' or completely e-enabled, they have a lot of operational flexibility to address customer requirements in a more personalized and customized way than their brick-and-mortar counterparts with more operational rigidity and resource constraints.

Managing diverse range of channels is a challenge because of exponential and sometimes disruptive growth of diverse technologies that are used for supporting high-volume e-commerce operations. Customers are bouncing between phone, email and the web with greater fluidity than ever and therefore, fragmented, 'stove-pipe' communications, in such situations, can create problems as they lose out the holistic view on the basic nature of the problems and customer priorities. Therefore, the use of a common knowledge base across all channels is a dire necessity for an e-commerce portal, especially the ones which do not have a 'brick-and-mortar' back-end. The customer-support knowledge network as proposed in this paper addresses these issues. Using Self Organizing Maps(SOM), the network becomes incrementally self learning representing various groups of communication instances at any point of time. The advantages include the integration of all communication elements and an assimilation of all the customer communication issues into a reusable form of self-learning network. It adds an immense value for a customer-focused e-commerce company for identification of generic issues, better understanding of customer concerns and priorities and designing products/ services/ promotions accordingly, to ensure an overall better success of business.

Keywords: Self Organizing Maps(SOM), Customer Relationship Management (CRM), E-Commerce, Knowledge Network.

I. Introduction

I.1 Importance of Effective Customer Communication-Based Knowledge

Successful e-commerce organizations treat customers as the only way of their survival as well as gaining competitive advantage. They focus intensely on customers, creating customer profiles, designing promotions and offers focusing onto particular customer segments and online communities. They try to consider every bit of information that flows from the customer to their system as an input for analyzing and identifying their needs precisely and catering to them. Being mostly 'click and mortar' or completely e-enabled, they have a lot of operational flexibility to address customer requirements in a more personalized and customized way than their brick-and-mortar counterparts with more operational rigidity and resource constraints. Big e-commerce portal companies like Yahoo and Amazon.com invest heavily in systems like CRM (Customer Relationship Management), processes and often in capturing inputs also to improve their products and provide better services. They focus on retaining customer loyalty as well as on attracting new customers. In Roffey Park research (2004), high performance has been shown to be strongly correlated to customer-focused purposes. Internally also, a significant high proportion of employees in HPOs think that their organization is highly customer-centric or even customer-driven. So, ignoring customer needs can be completely detrimental to sustainable growth of any organization. The most effective vision for change is customer focus. [3].

To achieve customer focus, one of the crucial and valuable sources for any company is the customer communication. It is all the more important for e-commerce portals which often do not have any backend brick-and-mortar interface for handling customer communication, and thereby consequently have to manage a diverse range of communication channels for customer interfacing. Most of the e-commerce or e-business portal companies have a lot of ways to gather customer feedback, e.g. through online chatting with a support-resource, or through e-mails or form-based interfaces on the net, because it gives the customer the flexibility to communicate in an asynchronous

domain (which is not the case with the telephone calls) and also gives them a platform to communicate in writing which is a more convenient way as perceived by people for putting the problems or thoughts in a more structured fashion. Also it reduces the anomalies in understanding as everything is in writing, and it also helps the customer or the company to keep a track of the communication that has taken place for example in terms of a series of request-response mails. Even in case of e-commerce-based companies which completely rely on digital medias for customer interfacing, customers communicate in a variety of ways. These are usually mentioned and supported as the communication channels between the customer and the company in the company website, e.g. the contact email_ids, the phone numbers or online forms. So, consequently, the customers call. They send email. They visit web sites and use the self-service portal facilities or chat services or online complaint register forms etc. Managing each of these communications channels as effectively as possible is a real challenge. It has now become even more critical to manage these channels collectively, because, with the exponential and sometimes disruptive growth of diverse technologies that are used for supporting high-volume e-commerce operations, customers are bouncing between phone, email and the web with greater fluidity than ever. They send emails about problems that they have already discussed by phone, and then visit the web site to double-check the information they received on the phone. Fragmented communications, in such situations, can create problems. The portal's service representatives get blindsided by calls from frustrated customers. They repeatedly answer redundant questions, as they do not have any unified or holistic view of all the communication instances of the same customer on a same issue. Neither can they easily add new knowledge items to the web site or the portal's back-end knowledge resources. Worst of all, e-commerce companies with "stovepipe" communications channels e.g. isolated calls, email and web self-service systems can not adequately understand or address customers' top service issues, because they lose out the holistic view on the basic nature of the problems and customer priorities. Use of a common knowledge base across all channels is therefore a dire necessity for an e-commerce portal, especially the ones which do not have a 'brick-and-mortar' back-end equipped with actual people or real human faces to interface with the customers. The business impact of this unified approach is substantial. A unified knowledge network for managing customer responses can deliver competitively superior service at dramatically reduced cost, because each channel becomes more efficient and, over time, more and more customer interactions are driven to the least expensive and most scalable channel that is the web. This also provides companies with clearer insights into their customers' top concerns. These insights are enormously helpful for improving customer care, driving the development of successful products, promotion schemes, special offers focusing on particular customer segments and services, and formulating high-impact marketing strategies.

I.2 The Customer-Support Knowledge Resources

When an e-commerce portal handles customer interfacing in a stove-piped situation:

- The phone channel is managed by a call center platform.
- The email channel is managed with an email management system.
- The web channel is managed with a content management system.
- Chat, if provided at all, is managed by a chat system.

All these systems, when disconnected, on heterogeneous platforms without any integration, communication or sharing, create information/ communication islands of their own without any connecting road-maps. So, naturally, the portal company tries to manage each of these communications channels as effectively as possible. But it has now become critical to manage these channels collectively. That is primarily because customers are bouncing between phone, email and the web with greater fluidity. Any interaction with a customer on one channel is completely divorced from any other interaction with that same customer on any other channel, because the interactions do not flow down to any common knowledge repository. When customer service representatives (CSRs) are on the phone with a customer, they have no idea what that customer's emails looked like. The information that a customer gets in an email may not exactly match the information on the company's web site. Each channel is isolated from the others—to the detriment of both the company and its customers. Subsequently, the problems that companies and their customers experience every day because of stovepipe communications channels are exemplified in situations as described below:

- The "Didn't you see my email?" syndrome

A customer with a problem takes the time to carefully describe that problem in an email message and then calls for a follow-up. The support person taking the call has no clue of the original email exchange. So instead of just asking a follow-up question, the customer has to explain the whole situation all over again. The customer gets annoyed, the CSR spends an unproductive time.

- The endless repetitive calls syndrome

Companies with conventional "stovepipe" customer communication channels have great difficulty developing effective self-service content for their web sites. When the support representatives encounter a new support issue, they have no fast and easy way to *capture* that issue and *publish* it as a knowledge item on the web. So instead of answering questions only once on the phone and then having them answered automatically in the future with relevant online knowledge items, "stovepipe" communication channels answer the same questions over and over.

The overall negative business impact of these problems can be that inconsistent information can be provided by each channel and customers are more frequently annoyed,

angered and confused. "Stovepipe" channels also deprive companies of insight into the issues that most concern their customers. It is difficult to get that insight if the company can not get a holistic view of customer interactions i.e. they can not look at communications activity across all of the customer service communications channels.

I. 3 Customer Communication Elements

Customer communications with an e-commerce portal can be broadly classified into following categories based on the purposes of communication:

- Enquiries e.g. on new products/ services/ schemes
- Feedback.
- Complaint
- Support

There are also the various ways customers communicate to the organizations using technology/ media combinations at different levels of complexities. From Figure 1, it can be derived that the customer input/ feedback sources are not only varied in terms of their use of various channels or media, or their degree of structured-ness and unstructured-ness, but also in terms of the underlying technologies like the communication domains, which also encompasses the network elements, the server technologies, data repositories like warehouses or operational RDBMS.

Using all possible combinations of these varieties, capturing customer knowledge from these combinatorial resources in a unified form is a daunting task. The ideal situation in this case would be as shown in Figure 2:

This is precisely the solution that we are proposing in this paper. Towards this end, we have first developed a generic process model, explained in the next sections, based on SOM for dynamically gathering communication inputs from all channels and then converting them into a knowledge network based on the unsupervised learning mode of the neural networks.

I. 4 Existing Tools and Techniques to Capture Customer Communication

Generally, in the context of capturing knowledge or discovering reusable patterns from customer inputs, data mining, pattern recognition techniques have been abundantly used. Data warehousing and on-line analytical processing (OLAP) have typically been used to solve data extraction, transformation, data cleaning, storage, and mining issues. Regarding handling of natural-language based unstructured information sources; previous efforts have used document-based technologies and supported document-level functions such as full text search, document classification, and so on. Business practitioners have developed automated tools to support better understanding and processing of information. Researchers have also developed advanced analysis and visualization techniques to summarize and present vast amount of information. [4] Despite recent Improvements in analysis capability [4], there is still a long way to go to assist qualitative analysis effectively. Most tools that claim to do

analysis simply provide different views of collection of information {e.g.. comparison between different products or companies}.Lin [8] identified various display formats for handling multi-dimensional data e.g. hierarchical displays-an effective information access tool for browsing, network displays, scatter displays [10]. There are other methods for document representation and visualization also which primarily concerns the task of getting insight into information obtained from one or more documents [12]. Most processes of document visualization involve three stages i.e. document analysis, algorithms, and visualization [10]. Web content mining treats a web document as a vector of weights of key terms [1]. He et al. [5] proposed an unsupervised clustering method that was shown to identify relevant topics effectively. The clustering method employed a graph-partitioning method based on a normalized cut criterion. This method we are using in this paper to extract knowledge from customer communication resources.

II. Creation of a Knowledge Web Using Customer Communication Elements

As explained in Figure 1 regarding various elements in customer communication, there is a need for integrating the knowledge captured from these communication resources. Customers sending mails or leaving voice messages are generating valuable knowledge assets. Voice recordings can be converted into text documents. Now, treating these text messages (source being emails/ form based text inputs/ voice messages converted) as unstructured documents, we can use co-occurrence analysis to find the similarities and then consequently the dissimilarities between the messages/ text contents. For this paper, herein after, we are using messages as the unit of customer communication and thereby are referring to any of the communication elements as messages. Messages which are very similar in terms of their contents i.e. many of the identified key-terms (i.e. Terms excluding the general terms like pro-nouns, prepositions, conjunctions etc.)are same, can be clubbed up together to form a cluster. Dissimilar message/ text bodies can be created as other clusters. These clusters can then form a network using hierarchical and partitional clustering method to form a graph which we are mentioning in this paper as a Knowledge Web based on customer communications.

II. 1 Self Organizing Maps

In this paper, we are proposing a generic model for developing a knowledge network to integrate various customer interaction/ communication elements. This network is developed using SOM(Self Organizing Maps) proposed by Kohonen[6].

If we treat team the customer communication resources broadly as textual(which most of them are, as is apparent from their description above in Figure 2, there are various classification schemes applicable to them. Most popular text-data classification techniques include clustering. There

are two main clustering methods: statistical and neural network approach. In the serial statistical approach, automatic text-data classification involves two processes: 1) a text representation structure, 2) a method to determine similarity between such text data. Once the class identification is done, the hierarchical clustering of text data can be done divisively or agglomerative. In divisive clustering, one cluster is further broken down into smaller segments, whereas in agglomerative clustering, a gluing operation based on the similarity between clusters takes place to form groups. There is also a method of conceptual clustering. [11]. Algorithms for clustering involve co-occurrence analysis for similarity measurements, discovering conjunctive features and clumping relationships based on most frequently occurring data, and then a pairwise comparison.

The neural network approach is a connectionist approach. Algorithms in neural networks are mainly parallel where multiple connections among the nodes allow independent, parallel, and consequently faster comparisons. These techniques are also of two types: supervised and unsupervised. In the supervised mode, a training data set is first presented in the training phase, based on which the network calculates the input weights, compares it with the desired output weights for a particular input, then derives the weights and minimizes errors incrementally. In unsupervised method, an input vector is given to the network. Through various network learning rules, these input vectors are analyzed for their statistical or similarity properties, and the network consequently dynamically adjusts the weights of each node forming in the graphical representation of the cluster. SOM is an unsupervised learning method for the neural networks. This is based on the associative properties concept of human brain functioning. The network contains layers like the input layer and the mapping layer in the form of a 2-D grid. The output layer can be thought of as a distribution layer. SOM has been applied successfully in many research efforts concerning document classification. Kohonen[6] applied this model for finding out logical similarities between words. Lin et al [7] used it for information retrieval. Orwig[9] and Chen [2] used it as SSOM or Scalable SOM to classify electronic brainstorming outputs.

We intend to use SOM developing a knowledge network with inputs from various customer communication resources as shown in Figure 2. These resources are to be extracted from heterogeneous sources i.e. mail servers, chat servers, IVR(Interactive Voice Response) systems, web-based forms, self-service portals etc. and then can be given as inputs to the knowledge network creation module. SOM appears to be a best candidate for choice in this context primarily because:

- Neural network methods being able to work in parallel can be much faster, provided adequate hardware resources are there, to handle complex, and voluminous text data resources, which is the typical case in the context of this paper, i.e. IS development projects.

- SOM in particular is an unsupervised learning method, so this can effectively self-enhance itself and keep the temporal consistency and integrity of communication elements i.e. can self-enhance based on the latest customer inputs

III. The Generic Model for Integrated Customer Communication-Based Knowledge Network Creation

This model takes all heterogeneous inputs from various sources as the inputs to the SOM module, as shown in Figure 3 below.

We explain this model with an example as below. Suppose a customer has bought a high-value electronic gadget from an e-commerce portal. The gadget has been installed but is not functioning properly. So, the customer has to communicate about this with the portal company. Suppose he/she makes the communication as follows:

- He/ she first tries the self-service facilities that provides information on trouble-shooting of that particular gadget. But, the customer does not succeed in solving the problem following the instructions or information that were given in the self-service portal.
- So, he/she calls up the portal's help-desk. An IVR complaint recording is done. The complaint_ID gets auto-generated by the IVR back-end and is given to the customer through the IVR system.
- The customer is worried because it is a brand-new high-value item. So he again calls for a follow-up. This time he chooses to speak to a service rep. He gives the IVR-given complaint-ID to the service rep.
- The service rep checks up on the status of the complaint handling process and gets back to the customer saying that it would be better if the customer could send a detailed e-mail on what is precisely the problem, as the voice recorded message is short and not fully explanatory.
- The customer sends a long e-mail explaining the whole problem in detail including his/her experience in trying to fix it by himself/herself using the self-service portal, and then giving reference of the same complaint-ID.
- The problem is sorted out next day when a mechanic visits, equipped with the necessary parts and tools.

Now, this sequence of communication has the following elements:

- A self-service session: can be identified by a transaction_ID on the log-file records of the portal.
- An IVR interaction and a voice-recorded message: identifiable with a complaint_ID
- A telephonic interaction with a service rep: identified and referred with the same complaint_ID
- An e-mail with the complaint_ID and referring to the transaction with the self-service portal.

According to the generic model, the unsupervised SOM-

based knowledge network module would take these inputs in an integrated fashion as follows:

- The network would receive messages from
 - the IVR back-end database,
 - the call recording
 - converted into digital contents using voice analyzer software,
 - e-mail messages from the e-mail server
 - transaction log-files from the self-service portal server
- The network will create the first level of clusters:
 - In the example case, first by locating the corresponding transaction_ID and associating it with the complaint_ID
 - Then by grouping the entire sequence of communication as:

CommunicationInstance[i] {Complaint_ID, [elements of communication]}

Otherwise, this primary clustering can be also based on:

- Customer_IDs e.g. for new product/ service queries/ promotions
- Query_IDs etc., depending on the purpose of communication which is explained in section 2
- This level of cluster would give an integrated view of all communication elements for a particular sequence or communication instance.
- Now, these communication instances will be fed into the SOM module for creation of a reusable customer communication knowledge network, the steps being depicted below:

- Collate all elements, say $\sum_{i=1}^N [E_i \dots E_j]$ from N communication instances, over a time t
- group them by automatic parsing for a reference information i.e.
 - Class_reference numbers for complaint classes in the Complaint_IDs
 - Error/ exception no.s
 - Transaction IDs
- Create an input vector of N keywords for each group, e.g.:

GroupInstance1[reference index(Complaint_Class/TxnID), string_of_terms_used (nouns(a..n), verbs(a..n), qualifiers(a..n),)]
- Input an initial group vector e.g. GroupInstance1 to the SOM module
- Initialize the input nodes, output nodes and connection weights: Represent each string as input vectors as shown above. Create a 2-D grid based on the N input vector elements and M output nodes.
- Input all the GroupInstance vectors for all the groups and the grid gets created by dynamically adjusting the weights to the input nodes based on the input vector string terms
- Compute distance between all nodes e.g. D_j between the input and each output node j as follows:

$$D_i = \sum_{i=0}^{N-1} (x_i(t) - w_{ij}(t))^2$$

where $x_i(t)$ is the input to node I at time t and $w_{ij}(t)$ is the weight from input I to output node j at time t.

- select winning node j^* (i.r. the node with the minimum distance) and update weights to node j^* and its neighbors based on reducing distances.
- Label the regions in the map identifying the typical group features.
- Go to step 1

The SOM network that is formed this way will become a self learning incremental knowledge network representing various groups of communication instances at any point of time t.

IV. Conclusion

There are two main advantages of this customer-support knowledge network for an e-commerce portal:

1. With the primary clustering, all the communication elements regarding one sequence or one problem are integrated. So, the problem of stove-piped communication is resolved.
2. With the knowledge network, all the customer communication issues are assimilated into the self-learning network in a reusable form, which again would add immense value for a customer-focused e-commerce company, for identification of generic issues, better understanding of customer concerns and priorities and designing products/ services/ promotions accordingly, to ensure an overall better success of business.

There are various possibilities of extending the premises of this paper like creating a knowledge network of support teams themselves and/or the support aspects of an organization.

Abstract: The Internet has introduced major changes in the way companies conduct business. Practically, rising numbers of customers are using the Internet for Electronic Commerce (EC). In the respect of customer relationship, Business-to-Consumer (B2C) EC provides ongoing information, service, and support that have changed the approaches of communication and interaction with customers. The nature of online customer behavior in the EC transaction is therefore different from the one in a traditional retailing channel. This research focuses on the online customer behavior through examining the relationship between the behavior intention and the online behavior itself. Based on the Theory of Planned Behavior (TPB), a base model of Online Customer Loyalty is developed. The research also proposes an alternative model in which Satisfaction is adopted as a mediated variable. Four hundred and twenty-three questionnaires are collected for the empirical experiment. The method of Structural Equation Modeling (SEM) is used to evaluate the measurement and structural models. The result indicates that TPB can be used to explain the behavior of Online Customer Loyalty. The structure relationship between Behavior Intention and Online Customer Loyalty is significant. The three constructs influencing Behavior Intention including Attitude toward Behavior, Subjective Norm and Perceived Behavioral Control also have indirectly positive effects on the behavior of Online Customer Loyalty. The two competing models are compared. Both models are acceptable when judged by the criteria of goodness-of-fit measures. However, the alternative model has a higher explained proportion of variance in Online Customer Loyalty.

Keywords: Customer Relationship Management (CRM), Electronic Commerce(EC), Theory of Planned Behavior (TPB), Structural Equation Modeling (SEM).

I. Introduction

The Internet has been applied in different kinds of commercial activities, among which Electronic Commerce (EC) is the one best providing a close contact between customers and business owners. The commercial competition is thus extended from physical market to online marketplace [37]. Consumers can use the Internet to watch all kinds of digital catalogues and multimedia product information. Through the more convenient product searching

function and virtual shopping feeling, B2C EC model is becoming more acceptable to customers. B2C websites can not only provide the introduction of products and the company, but also the real-time information. The website design emphasizes on the personalization and interactive nature, and the function providing customers with online order and payment has also been added to it.

Along with the vigorous development of EC, many businesses from the traditional market have begun to involve in the virtual electronic market; however, there are discrepancies of certain degree existing between the consumer behaviors of these two markets. Further, the shopping environment is facing a competitive situation even much keener than ever due to the rising trend of the Consumer to Consumer (C2C) personal online sales. Thus, understanding the behavior model of online customers to develop a most advantageous managing model is the key factor leading to the success in today's customer-oriented relationship management.

Based on the Theory of Planned Behavior (TPB), this research investigates the purchasing behavior model of online customers from the viewpoint of user behavior. Since loyalty is a crucial factor dominating consumers' real purchasing behaviors [37] and the main profit source of electronic retail websites is loyal customers [25, 40], the research mainly examines the online customers' loyal behaviors. In addition to verifying if TBP appropriate for the discussed online purchasing behavior, the research also proposes an alternative model in which Satisfaction of Online Customers is adopted as a mediated variable in order to analyze its effect on the base model and to compare the two competing models.

II. Literature Review

II.1 Internet Use

To the business owners, setting up their websites on the Internet can provide them with the advantages of lowering the expenses and expanding the managing scope to the global market. Through websites, they offer their products and services to online customers, meanwhile the customers can browse the merchandise and decide if they want purchase the products or request for services [19]. E-retailing can be viewed as an application of the electronic feature of the Internet to play as a medium for marketing route and dissemination, performing as an integrated EC model for product sales and service offers.

Angelide [5] argues that e-retailing is the business offering merchandise and service to online customers

through the interactive process between both sides of the commerce. O'Connor and O'Keefe [34] pointed out the importance of the interactive model in the marketing process, indicating that it not only provides the opportunity for customers and business owners to interact before the transaction, but most important is the follow-up interactions in the transaction process and after the transaction. Scansaroli [38] found that comparing to traditional shopping, consumers can save more time, effort and money and obtain merchandise of more diversity through using search engines and browsing major websites online.

Some researchers have investigated website uses, for example, Liang & Lai [27] derived the website design functions from customer-oriented viewpoint; Sterenson et al. [41] explored the browsing attitude of the website users; Eroglu et al. [16] studied the atmosphere and quality created by retail websites.

II. 2 Customer Loyalty

Loyalty is a crucial factor which dominates the customers' purchasing behavior and represents their behavior tendency toward the merchandise or service [39]. Griffin [18] suggests that loyalty includes the following behaviors or attitudes of customers: frequently repeated purchasing, willing to use all kinds of products or serial services the company provides, praising the company and advertising it, and refusing the promotion activities of other companies. Lee, Kim and Moon [25] proposed that the value and profit of websites comes from the number of loyal customers. Srinivasan et al. [40] pointed out two main factors for evaluating online loyalty: customers' passing on and price tolerance. When the online loyalty increases, the price tolerance is higher, and the customers are more willing to recommend the company to others.

II. 3 Customer Satisfaction

Satisfaction is the customers' overall evaluation towards the merchandise or service before and after their actual purchasing behavior occurs. The evaluation content is mainly a comprehensive examination of the product/service quality, the acquired value, the performance and expenses. Howard & Sheth [20] defined satisfaction as the customers' assessment and cognitive status by comparing the expenses they paid and the rewards they obtained. Kotler [23] defined satisfaction as a kind of after-purchasing evaluation of the product quality based on what they expected before purchasing the product. Oliver [35] claimed that satisfaction is the mental expectation customers have of the products before the purchasing behavior occurs. If the product quality is not as good as the customers expected, this discrepancy will cause a sense of uncertainty, which affect the satisfaction degree of customers.

III. Theory of Planned Behavior

TPB is an expansion modified theory proposed by Ajzen [2]

based on Fishbein and Ajzen's [17] Theory of Reasoned Action (TRA), which has better explanation capacity on the actual behavior.

TRA predicts and explains the relationship between an individual's attitude and behavior based on the hypothesis that a behavior occurs due to the volitional control of each individual. According to TRA, one's will decides his actual behavior, and actual behavior is represented by behavior intention, which is affected by attitude toward behavior and subjective norm. Yet each individual's will control is affected by several internal and external factors, most behaviors have the uncertainty of certain degree. Thus, when investigating non-will factors affecting behaviors (such as opportunity, environmental resources, cooperation from others, and so on), the explanation capacity of TRA will decrease, and cannot offer reasonable explanations [3].

Ajzen [2] therefore expanded TRA to TPB, which has one more construct added - perceived behavioral control, control ability toward the opportunity and resource when a person adopts his behavior. This construct can enforce the prediction ability of behavior, while the other three constructs are affected by the external variables. The overall structure of TPB can be depicted in figure 1.

Behavior Intention is the intentional degree of certain behavior a person acts, which can reflect his own will. Through understanding the intention of a person's behavior, the possibility of this behavior being actually performed can be observed. Because the behavior intention and the actual behavior have an extremely close relationship, the intentional degree will determine the possibility of such behavior. Thus, by measuring such a latent component like behavior intention, the reason of adopting the real behavior can be derived. It is hypothesized in TPB that the attitude toward behavior, subjective norm, and perceived behavioral control are independent to each other, and can affect the actual behavior directly through behavior intention.

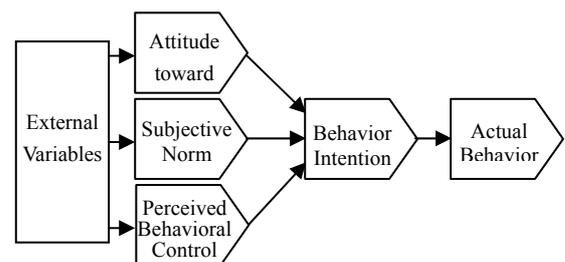

FIG 1. Overall Structure of TPB [2]

Attitude toward Behavior is the goodness or badness a person feels about a behavior or the positive or negative judgment after performing such behavior. The attitude is not the behavior itself, but both have high consistency with each other. If a person can act following his own free will, his attitude shall be highly consistent with his behavior [29].

Subjective Norm stands for the impact and stress from the social groups around a person when he decides to act

certain behavior. The stress from these surrounding social groups (such as parents and friends) is mainly caused by the thought that this person considers them as his important others and cares about their agreement of his behavior. Ajzen and Fishbein [1] thought that if the influence of the attitude toward behavior is larger than the social stress, the attitude will decide the intention of behavior, and vice versa.

Perceived Behavioral Control is defined as simplicity degree that a person tries to perform certain behavior. The control may be dominated by the past training, experience and the current obstacles. If a person has more chances, resources and performing capabilities, and believes there are fewer obstacles, then the degree of Perceived Behavioral Control is higher, and the control cognition is stronger. Hence, the influence of this perceived behavioral control tends to be more obvious.

TPB is based on the hypothesis that the behavior intention will become more obvious when the attitude toward the behavior tends to be more positive, the stress from the surrounding social groups is stronger, and the degree of the presumed control abilities is larger. Mathieson [32] adopted TPB to explain the behaviors of students using the trial balance and found out that the three major components of this theory (the Attitude toward Behavior, the Subjective Norm and the Perceived Behavioral Control) could explain the Behavior Intention properly. Talor & Todd [42] used TPB to study the cognitive and psychological factors which affect the use of information, and they proposed a behavior model for the use of Information Technology to analyze the service behavior of the computer center in business school. The result indicated that TPB could effectively explain the use of information.

IV. Research Model

TPB is adopted in this research to explain the loyalty of online customers. The research model includes five constructs: LOYalty of online customers (LOY), behavior INTention (INT) of online customers, ATTitude toward behavior (ATT) of online customers, SUBjective norm (SUB) of online customers and PERceived behavioral control (PER) of online customers; the definitions of constructs is listed in Table 1.

IV.1 Loyalty of Online Customers

According to Griffin's definition of loyalty [18], this research proposes the following four dimensions of LOY: "Continued Sales" is when customers having the same purchasing demand, they are willing to come back to use the same online transaction service; "Extended Consumption" is when customers having the other purchasing demand, the request from customers for further related online transaction services; "Resistance against a competitor's discount offers" can be viewed as when other retailing channels offer promotion discounts or decent services, customers will not take the offers and stay with online transaction services they originally used; and "recommendation of the product or

service to others" is the enthusiastic recommendation way of customer behaving about the use of online transaction services.

IV.2 Behavior Intention of Online Customers

INT is defined as the intentional degree of certain behavior a person acts for purchasing online, which can reflect his own will. In the operational level, this research proposes the intentional degree of collecting and requesting product or service information through the Internet can reflect customers' will for further purchasing merchandise or service online. The operational items for INT include searching for products information [12, 43] and new products information [40] through the Internet, using the information or searching services provided by retailing websites [12, 28, 30, 43], and responses from retailing websites to the requests of customer problems [28, 42].

TABLE 1. Construct Definitions

Construct	Definition
LOY	The loyal degree of online customers when a customer purchases merchandise or service on the Internet, including the following four dimensions: continued sales, extended consumption, resistance against a competitor's discount offers, and recommendation of the product or service to others.
INT	The intentional degree of certain behavior a person acts for purchasing online, which can reflect his own will.
ATT	The goodness or badness a person feels about the behavior of online purchasing or the positive or negative judgment after performing such behavior.
SUB	The impact and stress from the social groups around a person when he comes to a decision to perform online purchasing behavior.
PER	Simplicity degree that a person tries to perform online purchasing behavior.

IV.3 Attitude toward Behavior of Online Customers

The research defines ATT as the goodness or badness a person feels about the behavior of online purchasing or the positive or negative judgment after performing such behavior. In the operational level, this research refers to the related literatures for most feelings the online customers experience and develops the following items: ease of use [28, 29, 31], personal customization [15, 31, 44], convenience [12], autonomy [12], interference [12], privacy [31, 38], and security [12, 17, 44].

IV.4 Subjective Norm of Online Customers

The research defines SUB as the impact and stress from the social groups around a person when he comes to a decision to perform online purchasing behavior. In the operational level, this research refers to related literatures [28, 32] and develops the following items of SUB: some information to promote the convenience of online purchasing through newspapers and media; the advertisement and the marketplaces business owners provide on the Internet; and the purchasing experiences, recommendations and consulting of the relatives and friends.

IV. 5 Perceived Behavioral Control of Online Customers

The research defines PER as the simplicity degree that a person tries to perform online purchasing behavior. Past training, experiences and current obstacles may influence PER. In the operational level, this research refers to related literatures [14, 30, 44] and develops the following items of PER: the accumulating experience of using the Internet by time and frequency; the familiar degree of using the Internet; the ability to gather enough product and service information, to make purchasing decisions, and to judge the safety of websites.

The overall research framework is shown in Figure 2. The research hypotheses are as follows:

- H1: Behavior intention has positive effect on loyalty of online customers.
- H2: Attitude toward behavior has positive effect on behavior intention of online customers.
- H3: Subjective norm has positive effect on behavior intention of online customers.
- H4: Perceived behavioral control has positive effect on behavior intention of online customers.

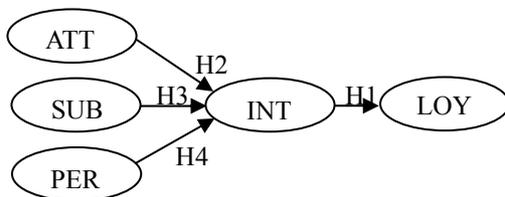

FIG 2. Overall Research Framework

V. Research Model

V. 1 The Research Process

The survey method is used to collect the empirical data. A questionnaire is developed and a five-point scale is applied to the measurement of total 45 questionnaire items. In order to effectively represent the constructs in the research model, this study adopts certain procedures to ensure that the measurement can achieve the expected quality. In respect of the content validity, this study refers to the viewpoints of the TPB theory and relevant EC papers to develop questionnaire items. In respect of the face validity, this study invited ten users with Internet shopping experiences to discuss the questionnaire wording in order to ensure that the person can

understand all the questionnaire items. Furthermore, thirty-five graduate students in the areas of business and information management participated in the pre-test. Thirty-five valid samples are obtained and analyzed by the tool SPSS 10.0 for Windows. The initial reliability analysis and exploratory factor analysis are conducted to check the reliability of questionnaire items and the appropriateness of their factor structure.

The Structural Equation Modeling (SEM) method is adopted and the software LISREL 8.71 is used to conduct the SEM analysis. This study first evaluates measurement models by the Confirmatory Factor Analysis (CFA) method. The structure model is then examined to test the hypothetical relationships. This study also proposes an alternative model with the construct Satisfaction of Online Customers as a mediator. Multiple goodness-of-fit indexes are compared between the two competing models.

V. 2 The Data Collection

In addition to one hundred and fifty samples distributed via the Internet, three hundred questionnaires are distributed to college students (including undergraduate and graduate), staffs and faculties with Internet shopping experiences from a university in northern Taiwan. Out of the total 450 questionnaires distributed, 423 valid samples are collected after deducting the samples with more than three items not answered. The effective response rate is 94%. The correlation matrix for all constructs is shown in Table 2, in which SAT (SATisfaction of online customers) is a mediated variable proposed in the alternative model. The descriptive statistics of respondents' characteristics are shown in Table .The operational definition of SAT and the details of the alternative model are further described in section 5.4.

TABLE 2. Correlation Matrix

	LOY	INT	ATT	SUB	PER	SAT
LOY	1.00					
INT	0.60	1.00				
ATT	0.41	0.68	1.00			
SUB	0.40	0.66	0.65	1.00		
PER	0.40	0.67	0.73	0.51	1.00	
SAT	0.63	0.73	0.50	0.48	0.49	1.00

V. 3 The Data Analysis

The measurement model

Through the CFA method, this study basically examines the following two subjects: (1) whether the factor loading estimates are significant, that is, the t-values should be greater than 1.96 at the significant level of 0.05; (2) whether the measurement models are good of fit. The overall fit of the model to the data can be evaluated by goodness-of-fit measures. The goodness of fit of the whole model may be judged by means of the following measures:

- Chi-square (χ^2)
- Comparative Fit index (CFI) [9]
- Normed Fit Index (NFI) and Non-Normed FI (NNFI) [7]
- Root Mean Square Error of Approximation (RMSEA) [10]
- Standardized Root Mean square Residual (SRMR)

According to Joreskog and Sorbom [23], if the model is correct and the sample size is sufficiently large, the χ^2 test may be used for testing whether the model fits the data well. Instead, χ^2 may be regarded as a goodness-of-fit measure in the sense that the degrees of freedom (df) is provided to judge whether χ^2 is large or small. Large χ^2 values correspond to bad fit and small χ^2 values to good fit. The criteria of goodness-of-fit measures are as follows: χ^2/df is suggested to be smaller than 2 for good of fit [11] and 3 for acceptable fit [13]; CFI greater than 0.95 for good of fit [8]; NFI, NNFI greater than 0.9 for good of fit [21]; SRMR smaller than 0.08 for good of fit [21]; and RMSEA smaller than 0.05 for good of fit and 0.08 for acceptable fit [33].

This study deletes SAT4, SAT9, ATT8, SUB5, SUB7, and PER2 which are suggested by the standardized residuals output to have large negative/positive residuals between variables. For model modification, LISREL8 provides modification indices (MI) which indicate an improvement in fit measured by a reduction in χ^2 . It is recommended only when relaxing a parameter makes sense from a substantive point of view [23]. This study follows the principle of unidimensionality in developing index and scale [6] and deletes PER3 which is suggested by MI to have multidimensional factor loadings.

The Maximum Likelihood (ML) results of loading estimates and goodness-of-fit measures are shown in Table 4 and Table 5. The values of the factor loading between all latent variables and their first observable variable are fixed to 1 for the purpose of standardization. All t-values for loading estimates are greater than 1.96. χ^2 of the two measurement models are 340.83 with 116 degrees of freedom ($\chi^2/df=2.9381$, $p<0.0000$) and 378.66 with 132 degrees of freedom ($\chi^2/df=2.8686$, $p<0.0000$) respectively. And other goodness-of-fit measures indicate that the measurement models are acceptable (CFI>0.95; NFI, NNFI >0.9; RMSEA<0.08; and SRMR<0.08).

The reliability

The reliability statistics are shown in Table 6. The values of Cronbach's α are all above the 0.7 level and thus satisfy the reliability requirement.

The structure model

As the statistics for the base model shown in Table 9, χ^2 of the structure model is 905.50 with 343 degrees of freedom ($\chi^2/df=2.6399$, $p<0.0000$). Other goodness-of-fit measures are as follows: CFI=0.96, NFI=0.94, NNFI=0.96, RMSEA=0.062, and SRMR=0.072. The statistics indicate that the structure model is acceptable.

The structure model with standardized solutions is shown in Figure 3. All path coefficients are significant indicating that the hypothesized relationships H1~H4 are supported. Square Multiple Correlations (SMC) for the structural equations are also reported. SMC for the structural equations indicate the explained proportion of variance in the endogenous variables accounted for by the variables in the structural equations [23]. The effect results of the path analysis are shown in Table 7. The test results of hypothesis are shown in Table 8.

V. 4 Alternative Model Comparison

Furthermore, this study proposes an alternative model with a mediated variable SATisfaction of online customers (SAT) added into the base model. SAT concerns a customer view of online transaction quality. A shared expression of satisfaction includes the consumer's perceived expectations [36]. SAT is therefore coupled with the consumer's prior intention about the online quality and very possible to influence the subsequent behavior.

TABLE 6. Coefficient of Reliability

Construct	α
LOY	0.8143
INT	0.7554
ATT	0.7653
SUB	0.7626
PER	0.7672
SAT	0.7251

	PER	-	0.39	3.85***	0.39
LOY	INT	-	0.67	9.24***	0.67
	ATT	0.13	-	2.16*	0.13
	SUB	0.26	-	4.93***	0.26
	PER	0.26	-	3.66***	0.26

* $p<0.05$, ** $p<0.01$, *** $p<0.001$

TABLE 8. Test of Hypotheses

Hypothesis	t value	Decision
H1	9.24***	Accepted
H2	2.16*	Accepted
H3	4.93***	Accepted
H4	3.66***	Accepted

*p<0.05, **p<0.01, ***p<0.001

This study defines the concept of SAT as a perceived level of electronic transaction quality resulting when a customer purchases merchandise and receives services on the Internet. This study also proposes that SAT has components such as product satisfaction with price [12, 30, 43], time and energy consumed [12, 30, 43], and quality of product from Internet shopping [28]; and service satisfaction with service items [30, 31], order and transaction processing [12, 28, 30, 43, 44] and services after sales [24, 28, 35, 42].

As shown in Figure 4, SAT is proposed to influence LOY and to be influenced by INT. The two added research hypotheses are as follows:

- H5: Behavior intention has positively effect on satisfaction of online customers.
- H6: Satisfaction has positively effect on loyalty of online customers.

In Figure 4, all path coefficients are significant indicating that the hypothesized relationships H1~H6 are supported. The SMC of LOY is 0.44 for the alternative model greater than 0.36 for the base model. This indicates that the alternative model has higher explained proportion of variance in the endogenous variable “online customer loyalty”.

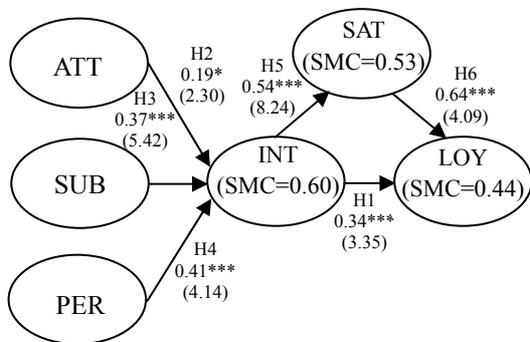

FIG 4. Alternative Model with Parameter Estimates

The results of model comparison are shown in Table 9. χ^2/df is 2.45168 for the alternative model smaller than 2.63994 for the base model. This indicates that the alternative model has a smaller χ^2 value corresponding to better fit after considering the degrees of freedom. And the comparison for other goodness-of-fit measures is as the follows:

- The CFI-values are the same.
- Although NFI is 0.93 for the alternative model smaller than 0.94 for the base model, the NNFI values are even indicating that the fits for the two

models are the same after considering the degrees of freedom.

- RMSEA is 0.059 for the alternative model slightly smaller than 0.062 for the base model. This indicates that the alternative model fit the data a little better.
- SRMR is 0.071 for the alternative model a little smaller than 0.072 for the base model. This indicates that the alternative model is with a slightly smaller error.
- ECVI [10], AIC and CAIC [4] are indexes indicating the level of model parsimony, especially useful for comparing competing models. The smaller the three indexes, the more parsimonious the model is. The ECVI, AIC, and CAIC values for the base model smaller than the ones for the alternative model. This indicates that the base model is more parsimonious.

TABLE 9. Model Comparison

Fit measure	Base model	Alternative model
χ^2	905.50	1350.88
df	343	551
χ^2/df	2.63994	2.45168
CFI	0.96	0.96
NFI	0.94	0.93
NNFI	0.96	0.96
RMSEA	0.062	0.059
SRMR	0.072	0.071
ECVI	2.44	3.58
AIC	1031.5	1508.88
CAIC	1349.49	1907.62

In summary, both the base model and the alternative model are acceptable when judged by the criteria of goodness-of-fit measures. The alternative model fits the data slightly better by having smaller χ^2/df , RMSEA, and SRMR. The alternative model also has higher explained proportion of variance in LOY than the base model. However, the base model is more parsimonious.

VI. Discussion and Conclusion

Internet, one of the fastest growing media, was developed for facilitating the supply of all kinds of products and service. It attracts millions of people to participate the online activities everyday through the friendly explorer interfaces. In addition to providing electronic information and integrated functions, the next stage of company websites is to provide electronic transaction service including online order and payment mechanisms [22]. It's essential for website owners to have knowledge of the behavior of online customers. How to attract more people to visit and shop on the website, and continue to become a loyal customer is extremely of importance.

The study develops a research model of loyalty for online customers based on TPB. Some results are found after

the SEM analysis:

- TPB can be used to explain the loyal behavior of online customers.
- Behavior intention directly influences the actual loyal behavior of online customers. This result indicates that if we want to keep an individual continuing to purchase online, it's practical to increase the intensity of his/her behavior intention.
- Attitude toward behavior is the largest effect factor for behavior intention of online customers. The second effect factor is subjective norm. And the last one is perceived behavioral control. The result indicates that the factors which influence the intention in sequence are: the positive feeling and evaluations the users have toward the online behavior, the reference opinions from surrounding people, and the final is the capability and resource of the users to use the Internet.
- In the alternative model, behavior intention indirectly influences loyalty of online customers through the mediated variable satisfaction. The SMC of loyalty for the alternative model is 44% exceed 36% for the base model. The result displays that the alternative model has a great explanatory power on loyalty of online customers.

The research limit of this research is that the data were not randomly selected. Most samples are collected from the college/graduate students. Although the online users are in reality younger and have higher academic background [26, 28], the results still cannot be generalized. In addition, the universities in Taiwan have provided overall environment for the Internet use and basic courses of computer information are opened in many departments. Hence, the samples collected in this research may cause a lower estimation of the influence of Perceived Behavioral Control of online customers.

The future research can expand to various influential models, and continue discussing these influential factors that involve in users' adoption of online behavior. In the SEM analysis, the comparison of competing models can help to measure and evaluate these influential factors and their effects. Besides, this research expects to examine competing models such as moderated models and multi-group models, in order to establish a better research model for explaining the online behaviors.

Abstract: Since it is a well known fact that the cost to attract a new customer is approximately 5~10 times more than the cost of keeping existing clients for the enterprise, it is a very crucial issue for the business to focus on the need of customer relationship management. Therefore, e-CRM (electronic CRM) is widely accepted recently and the adopting rate in certain organization is up to 49% annually.

In this study, a systematic multi-case study in Taiwan is performed for the B2B manufacturing industry and B2C service business in order to find the critical function and important issues for e-CRM in those businesses. In addition, the efficiency factors for e-CRM are analyzed since the roles of the clients in B2C and B2B are different, i.e., the organizational and personal behavior is compared.

The preliminary results show e-CRM in Taiwan has been successfully improving the service for B2B and B2C and promoting closer relationship for both the sellers and buyers. The target of new customer acquiring is also improved effectively.

Keywords: e-CRM, Multi-Case study, manufacturing, service business.

I. Introduction

Customer Relationship Management (CRM) has changed dramatically throughout its dynamic transformation from a conceptual framework to a core business function. CRM isn't just the domain of gurus or a software package anymore. To succeed in managing customers, managers must address e-CRM as part of their core operations. E-CRM is not just customer service, self-service web applications, sales force automation tools or the analysis of customers' purchasing behaviors on the internet. E-CRM is all of these initiatives working together to enable an organization to more effectively respond to its customers' needs and to market to them on a one-to-one basis.

II. Literature Review

CRM has long been hailed as a way for companies to find, influence, and retain customers. CRM solutions have evolved to go beyond simple contact and sales management

application to now link sales, marketing and customer support operations into a single, cohesive platform. E-CRM concept provides the ability to capture, integrate, and distribute data gained at the organization's Web site throughout the enterprise.

A company's continued success comes from two groups: new customers and repeat customers. Since it always costs more to attract new customers than to retain current customers, customer retention is more critical than customer attraction. The key to customer retention is customer satisfaction [1].

E-CRM expands the traditional CRM techniques by integrating technologies of new electronic channels, such as Web, wireless, and voice technologies, and combines them with e-business applications into the overall enterprise CRM strategy [2]. In other words, what the traditional CRM delivers can be considered only a fraction of an e-CRM solution.

E-CRM applications have the power to create an enormous amount of value by allowing companies to collect, organize, and disseminate a wealth of customer information. The e-CRM concept is designed to understand who the customers are and the products that are of interest to them—only then is it possible to provide them with the products and services they want. A more sound approach is to install a comprehensive software platform of the following five applications that together enable the e-CRM business process.

Essentially, this model shows how a firm can develop and manage customer relationships to enhance competitiveness and create a strategic advantage. It is also a powerful tool for building stronger and more loyal customer relationships [3].

III. The Outcomes of Implementation

Enterprises should change their managerial approaches and business process. They can not only simplify the transaction and customer service process, but also provide customers with more considerate customized services which can make differences from others, enhance customer loyalty, decrease the steps of sales, and reduce the sale cost. The well outcomes after introducing e-CRM of the four selected case companies are arranged as follows:

Advantech <http://www.advantech.com/>

Advantech is an enterprise which has the most successful

e-business website for his automated products in the world. 80% of incomes until 2001 are from his electronic business operation. The beneficial results after implementing e-CRM are as follows:

1. Raise customer loyalty and profits
2. Reduce the cycle time of new products and serve the target customers in the most economical way.
3. Steeply decrease the transaction cost, service cost and service time.
4. Own a stable e-Business platform
5. Customer classification and the detailed information of the top 15 customers will be independently further analyzed
6. Automated pricing process and the order can be integrated with ERP system
7. Enhance the productivity of service engineering department
8. Organizational learning
9. Reduce 22% of sales and marketing cost

Arima <http://www.arima.com.tw/>

Arima used to be the government-chosen enterprise for setting a model of applied development planning, the planning period was from July 1 of 2002 to the end of 2003, the implementation performance are as follows:

1. Raise the service quality and satisfaction of customers
2. Always know the repair condition and remain the repair records
3. The transparency of inventory volumes is helpful to reduce global inventory and make it more elastic in control. The delivery speed and quality are also quite raised.
4. Improve and simplify the inside operation process of enterprises. Consolidate the accounting management and auditing.
5. Quick information acquirement can help managers have the ability of quick response, information transparency, and know the latest situation in real time.
6. Participate the supply chain of electronic business hosted by Arima to make suppliers, transporters commonly take part in this supply chain and their relationship tighter with global market.
7. Follow the standard of Rosettanet, and make suppliers and transporters do not need to introduce other operation systems due to different operation and information standards.
8. Provide Arima with the information from HUB, to make both of them have more time and information to prepare materials.
9. Base on the document of forwarder RN 3B3/3B18 and the real-time information exchange of merchandise delivery tracing, the related operation staffs in Arima can easily understand the shipment status.
10. Arima provides different solution policies in the aspect of B2B, and reduces the introduction cost of related projects through the standardization of specification.

Fareastone <http://www.fetnet.net/>

The benefits that e-CRM brought in the case companies, Fareastone, are illustrated as follows:

1. Decrease the cost of business operation
2. Implement the marketing affairs and raise service quality
3. Raise the satisfaction of customers
4. Adjust the structure of staffs
5. Trend and fashion, and the image improvement of enterprise

DaimlerChrysler Taiwan <http://www.mercedes-benz.com.tw/>

DaimlerChrysler Taiwan used to be suffered from low efficiency of car repair, bad management of part inventory, and unclear information of customers. However, the customers of DaimlerChrysler Taiwan currently are able to acquire information they need in three minutes through e-CRM. It totally improves the dilemma which always takes 3-5 days for data mining and other analysis by IT staffs. The system DaimlerChrysler Taiwan set up basically owns four critical dimensions of performance:

1. Become a kind of assistant tool for marketing
2. Understand consumers and self product.
3. Performance analysis of repair factory
4. Part inventory control

IV. Synthesized Benefits and Analysis

The conceptual structure of e-CRM is at least composed of the following five concepts: application of information integration, application of customer analysis, application of sales promotion management, application of real-time decision making, and application of individualized messages etc. The e-CRM system of the research case in the paper is just constructed from the above five concepts, and then do customization for each enterprise base on their requirements.

According to the above four cases, the five success factors and four advantages of e-CRM can be arranged:

Some CRM research firms report that nearly 70 percent of CRM implementations fail to deliver measurable benefits. In contrast, IBM research has found that companies that focus on and prioritize critical activities actually increase the likelihood of CRM success by more than 70 percent—flipping the ratios.

The five success factors or keys to doing e-CRM right are:

- Realize your e-CRM value case for change.
- Identify and prioritize your e-CRM value propositions.
- Design your new e-CRM operational blueprint.
- Construct your transformational multi-generational roadmap and implement your solutions.
- Build support for your e-CRM efforts and stay on track through sponsorship, governance, and change management.

And the four advantages of e-CRM are shown as follows:

Efficiency

Efficiency comes from the correct and rapid operation process without any waste. For example: The traditional manual process is replaced with automation, and the accomplishment of information rationalization. In the above ways, enterprises can increase their margin of profit and reduce cost.

Benefit

Benefit comes from the better or the more simple operation process. For example: the more income growth brought by new software application, mixed sales, telephone service center, interactive sales tool, customer collaboration, product tuning tools, and other sales methods without any participation of salesmen, are all the empirical benefit-oriented application

Cost saving

DaimlerChrysler Taiwan made use of e-CRM to effectively lower the inventory; Advantech also used it to reduce 22% of sales and marketing cost, Arima made his product deployment and the check-up of electronic orders in streamline shape. Undoubtedly, e-CRM does not only makes the sales process smooth and improved, but also shorten the delivery cycle time from the initial ordering to the final shipment.

Invisible benefit

The individual behaviors and organizational behaviors about the introduction of e-CRM are quite different. In the organizational behavior aspect of B2B, the relationship between the upstream and the downstream industries becomes more solidified due to owning the same information communication platform of e-CRM system. Besides order taking, the communication interaction among systems and the information transparency go one step further. Invisibly the industries built a higher entering barrier from other industries. For instance, Arima applied the standard of Rosettanet to make its suppliers and transporters not necessary to introduce other operation systems. Moreover, organizations emphasize the coordination and the convenience of system use between the upstream and the downstream industries. In the individual behavior aspect of B2C, customers tend to pay more attention to their feeling. The pleasure shopping atmosphere can be helpful to customer return. Mehrabian indicated that three key emotional variables that may determine behavior are pleasure, dominance, and arousal [4]. However, in other researches, It is also illustrated that while convenience and control are at the top of consumers' lists of benefits from online shopping [5][6], enjoyment of the shopping experience may also be an important determinant of customer loyalty [7].

It is easily understood that four case companies used different kinds of methods to do their e-CRM, like the sales promotion messaging of cell phone in Fareastone,

DaimlerChrysler Taiwan made the utilization of information integration of front-end (client) to manager the inventory, Advantech used e-CRM to enormously extend his customer service time and take advantage of its application on information integration to allow the customers to inquire their RMA returned purchases from internet, which reduce lots of complaints of customers and delay of returned purchases.

In other words, the case companies transformed their conventional static and single-way customer services of CRM limited in the factors of time and space, to the real-time and two-way customer services of e-CRM without any limitation of time or space. They also hope to introduce more functions in e-CRM system so as to enhance their competency. In the future, the height of business intelligence decides the success or failure in markets. If enterprises can make use of e-CRM to make a recheck up for its business process, it is believed that enterprises are able to increase the benefit of its investment and create more competitive edges.

V. Conclusions and Future Works

E-CRM is the edge tool that can help enterprise to raise its competitive advantage in electronic business. To make conclusions for the research, the business added value of the investment in e-CRM can be found as follows:

- (1) Raise the satisfaction of customers
- (2) Reduce cost
- (3) The information transparency can improve the managerial ability of inventory control
- (4) Improve the relationship between collaboration partners and customers
- (5) Heighten the entering barrier
- (6) Improve the image of enterprise

Taiwanese manufacturing industries and service industries currently obtain lots of benefit and advantage after introducing e-CRM, especially in the aspects of raising the satisfaction of customers and increase the proportion of market holding. In the future, if some advanced technologies such as MVPN and Push mail receiving, can enhance the mobility of staffs to achieve the goal of enterprise mobilization easier; the use of RFID can trace the staffs, movement of merchandises, the volume of inventory, and position vehicles, to further improve managerial performance or the Location Based Service. It helps enterprises to know all kinds of information well in this moving process so that the business efficiency can be increased..., all the above can be more beneficial to the introduction performance of e-CRM. Moreover, the selection of the industries in the paper is limited in the Taiwanese manufacturing and service industries, In the future, more different kinds of industries in Taiwan or the same kinds of industries in other foreign countries can be other research issues, and then it is believed that more enlightenment from those related researches can be found.

email: batanov@cs.ait.ac.th

Abstract: In the knowledge economy, Intellectual Capital (IC) has been reported as the new measure for enterprise values, intangible assets and economic performances. Customer Relationship Management (CRM) has also been recognized as a new paradigm of business services. However, the knowledge about IC and customer services in Thailand is very limited according to the very few studies reported up to now. In order to overcome these difficulties, the Web based Intelligent System for SME has been developed to provide knowledge and serve as an intelligent system for measuring the Intellectual Capital and CRM for SMEs in Thailand. The performance of this Web-based system has been evaluated by 10 Thai SMEs. Results revealed that participants in the evaluation are satisfied with the system and they are willing to use it in the near future.

Keywords: Web Intelligence, Web Based Information Technology, Intelligent Systems, Intellectual Capital, CRM, SME.

I. Introduction

Intellectual Capital (IC) plays an important role for the innovation and competitive advantage in the new era of knowledge society. IC is a driver or catalyst of organisational growth. This catalyst is a significant resource for any company as it has a major and considerable impact on its performance. Due to the limited number of research on IC in Southeast Asia, the understanding of IC measurement and management is a substantial problem for many enterprises in this region. Our preliminary analysis of CRM readiness in SME [9] shows that this is also true for most of Thai SME.

In order to compete successfully in the highly competitive local and global market, CRM is a significant factor for all companies including small, medium and large enterprises. It is commonly accepted that companies spend five times more money to acquire a new customer than to keep an old one for purchasing a new product [8]. CRM is a proven approach for increasing the competitiveness. It is a business strategy providing complete combination of business functions for contacting the customers such as marketing, sales, customer service and field support via assembling of people, process, and technology. CRM is based on coordination of all business processes that deal

with customers. Further, it involves the collection, collation, and interpretation of customer data to attract and keep customers through business process in order to create long-lasting, customer centric and mutually beneficial relationships [5], [7].

To provide more knowledge and understanding of IC, its management, and measuring the effect of CRM, a systematic study on the necessity of building information system for Thai SME has been conducted by a joint team from Kasetsart University and Asian Institute of Technology in Bangkok. The basic result of that study was the created framework for development and deployment of a prototype of SME Web-based Intelligent System (SWIS).

This paper is divided into four sections. Section two describes the most recent studies on IC and the proposed IC measurement model. Section three justifies the methodology used for developing the system. Section four summarizes the results from the prototype system evaluation. The last section includes some discussions and draws the conclusions.

II. Literature Review

In Bontis (1999) four performance measurement systems including human resource accounting (HRA), economic value added (EVA), Balanced Score Card (BSC), and Intellectual Capital (IC) are proposed. The HRA aims to quantify the economic value of people to the organizations and also provide input to managerial and financial decisions. There are three types of HRA models: cost models, HR value models and monetary emphasis models. HRA models estimate human capital in financial terms and are applied in organizations where human capital plays important role in organizational value. However, all models are subjective and suffer of lack of reliability. EVA is an overall performance measurement which bundles capital budgeting, financial planning, goal setting, performance measuring, shareholder communication and incentive compensation. This model emphasizes on measuring financial indicators while none of intangible resources are evaluated. Balanced Score Card (BSC) is a multi-dimensional measurement system proposed by Kaplan and Norton (1996). This system assesses both financial and non-financial factors including customer perspectives, internal process, and these factors are linked in a logical system. BSC is different from traditional measurement systems since it adds non-financial factors. Therefore BSC neglects the hidden values of employees and pays attention to the importance of knowledge management as significant drive

of the economic success and sustainability of the organization [2].

Intellectual Capital (IC) is introduced in the beginning of 90s and became well known by Skandia - the largest insurance company in Sweden. Recently, a significant amount of studies have been oriented to and focused on intangibles, knowledge management, and IC measurement by both researchers and practitioners. There are some substantial IC measurement models proposed in those studies. The most famous IC definition has been suggested by Edvinsson (1997) which states that “The Intellectual Capital of a firm is its possession of the knowledge, applied experience, organizational technology, customer relationships and professional skill that provides it with a competitive edge in the market”. The Skandia Model extensively refers to IC measurement and includes both financial and non-financial factors just like BSC. In this model IC is comprised of human capital and structural capital. Human capital includes knowledge, know-how, skills and personnel expertise. Structural Capital is a composite element that includes organizational capital and customer capital. Organizational capital consists of innovation capital (intellectual property and intangible assets) and process capital (databases and information systems). Customer capital is the external capital which includes the organizational relationships with external actors including customers, suppliers, partners and/or other stakeholders. Skandia model measures the company intangible assets and extends the traditional financial model measuring the real value of the company. More specifically, Skandia model includes customer capital, which plays an important role in creating company’s value. Furthermore, this model consists of organizational and process factors, which have not been included in traditional models. However, this model lacks of some indicators for customer relationship management.

Engstrom et al. (2003) conducted a case study of the intellectual capital evaluation for a hotel chain in Scandinavia. The ICAP methodology and multiple source data were used to investigate the knowledge and data produced by an intellectual capital evaluation, and explored the potential relationship between intellectual capital and business performance. The ICAP methodology was analysed together with financial indicators including (a) ability to generate sales and control expenses; (b) revenue per available room; (c) occupancy percent; (d) room profit; (e) food sold profit; and (f) personnel cost. However this measurement model is specific for the hotel industry. Moreover, there are still unanswered questions about the proposed model including (1) reflection on the operationalized constructs; (2) the model represents the essential of intellectual capital; and (3) the truthfulness of the model.

Srivihok and Intrapairote (2004) have proposed the IC measurement model specifically for SME which includes three clusters: human capital, structural capital and relational capital. This model is originated from Skandia model. Relational capital in this model consists of customer capital

and actors including partners, government actors and suppliers. Customer relationship indicators are added to make the model more practical for SME.

II. 2 The IC Measurement Model

The IC measurement model used in our development is derived from Srivihok and Intrapairote (2004). The model includes three clusters: human capital, structural capital and relational capital. The new IC model is adjusted for the Thai SME and presented in Figure 1.

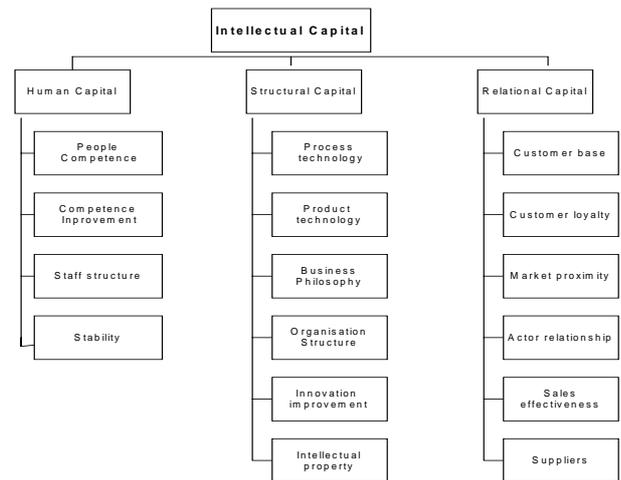

Figure 1. Intellectual Capital measurement model

Human capital refers to the employee knowledge of a firm and capacity to generate this knowledge. The value has been created by employees through using their skills, applying their knowledge and initiating innovative ideas. The utilization of employee knowledge and skills are performed if the employees are willing to do so. Thus, the human capital management should be concerned about knowledge management of employees including maintenance of knowledge base, encouragement, innovation and motivation of employees to transform their tacit knowledge to explicit knowledge [11]. There is also a direct cause effect relationship between knowledge *reuse* and *invention* of new knowledge. Then knowledge is turned into value by commercialization which is called *exploitation*. The summary of the above two factors (knowledge *reuse* and *invention*) multiply by exploitation is *innovation* [4]. In addition, human capital is the fundamental knowledge to generate the other two Intellectual Capital components. The human capital does not belong to a company but it is “hired” by the company for a period of time. This capital will be removed when staff resigns or is retired from the company. Human capital includes people competence, competence improvement, staff structure, and stability (as shown in Table 1 in Appendix 1).

Structural capital is a composite item which is mainly organizational capital. It comprises information and communication systems, management systems, patents and everything that systemizes knowledge of the company and makes it internal and explicit. This capital consists of seven

main indicators: business philosophy, organization structure, intellectual property, research and development (R&D), process technology, product technology and IT penetration per total investment [e.g. key word and directory search engine, EDI (Electronic Data Interchange), and database]. The structural capital belongs to and still remains within an organization even though employees have resigned. Structural capital includes process technology/ IT penetration, product technology, business philosophy, organization structure, improvement of innovation, and intellectual property (as shown in Table 2 in Appendix 1).

Relational capital refers to external relations with customers, suppliers, partners, networks, and regulators. Customer relationship is the value resided in the marketing networks and relationships that a company develops by doing their business. The quality of the relationships, the ability to keep present customers and creating new customers are key factors for the success of a company. The relational capital is classified into customer base, customer loyalty, market proximity, actor relationship, sales effectiveness, and supplier base (as shown in Table 3 in Appendix 1).

III. Conceptual Design of SME Web-based Intelligent System (SWIS)

SWIS is designed for Thai SMEs and consists of four main modules: (1) Navigation, (2) Library, (3) Intelligent System, and (4) Support System. In Navigation, new user starts with registering its personal information to the system, logging in to and out from the system. Library module consists of the following sub-modules: Intellectual Capital, Knowledge Management, Customer Relationship Management, SME and generals. Both Thai and English-translated documents in the library are selected from text books, academic magazines, journals and knowledge portals. The Intelligent System module includes Intellectual Capital and CRM questionnaires for SME to evaluate. Then, the systems will give advice related to the data which have been put in and may suggest documents to be read respectively. The Support System module provides information for SMEs about using facilities in the system such as web board, Help and FAQ and also more specific information such as SME Laws and Regulations, Strategic Planning, Management and Software. The design of SWIS is depicted in Figure 2.

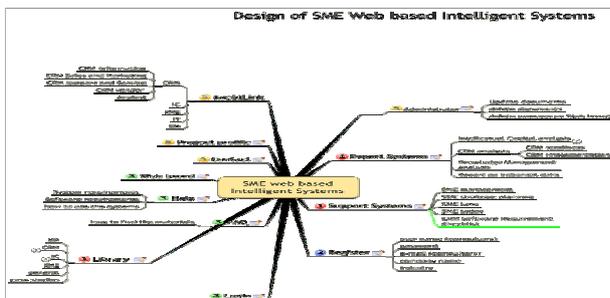

Figure 2. Design of SME Web-based Intelligent System (SWIS).

III. 1 Architecture of SWIS

The system consists of user interface, access control, analyzer agent, and knowledge base (Figure 3). Users get access to the system via the web based interface. The analyzer agent is responsible for analysing and extracting the users' information for each category such as Intellectual Capital or CRM by using provided input data, and it is referenced with the provided knowledge base. Advice messages, documents, activities and support actions are prepared. Authoring interface is updated by administrator. Knowledge base includes documents for SME, guides for SMEs in doing business, rules, Intellectual Capital management and information technology management in organisations, principles and procedures in CRM. The advised message and answers are sent back to users by passing access control and user interface.

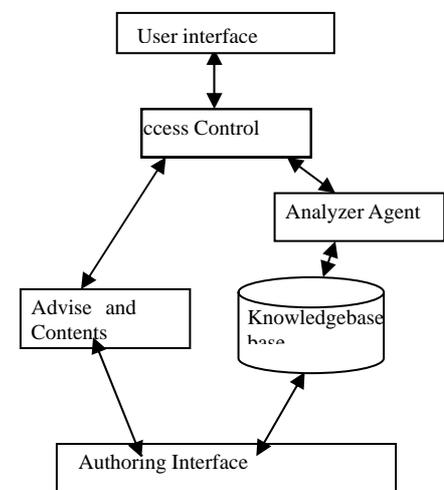

Figure 3. SWIS architecture

III. 2 Prototyping of SWIS

The front page of the system is depicted in Figure 4. In the system, SME can evaluate the company Intellectual Capital (IC) by putting company information in the model (as shown in Figure 5). The system analyses and compares data with benchmark values for IC. The items are reported if their values are higher, or lower than benchmarks. If they are lower, the system suggests related IC materials for SME to be read. These materials can be retrieved from SWIS. Results from IC model measurement are depicted in Figure 6.

Figure 4. SWIS home page (<http://smexpert.kasetsart.org/>)

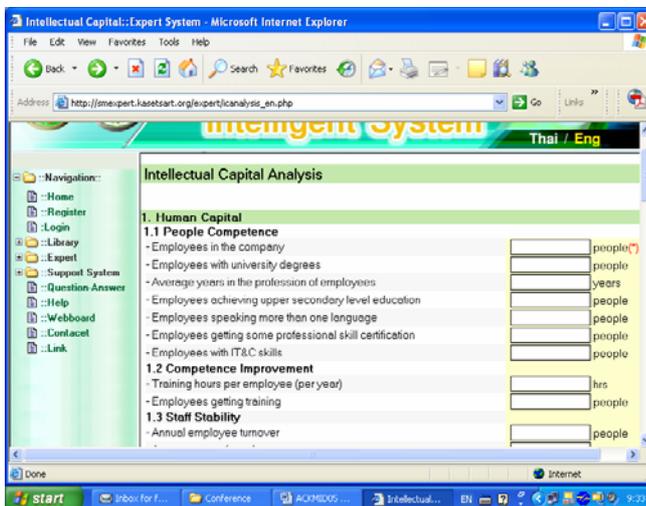

Figure 5. Intellectual Capital Analysis model

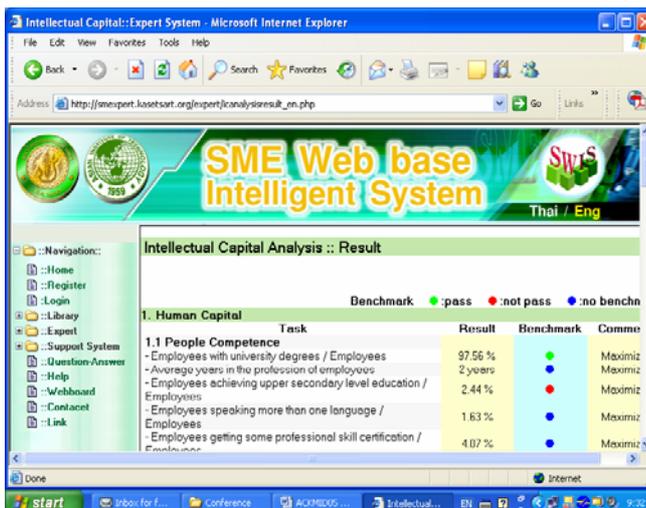

Figure 6. Results of Intellectual Capital Measurement.

III. 4 CRM Evaluation

SMEs can evaluate their organisation readiness for CRM implementation by using CRM readiness module (Figure 7). Then the system will give advice or suggest activities to be performed according to organisational characteristics (Figure 8).

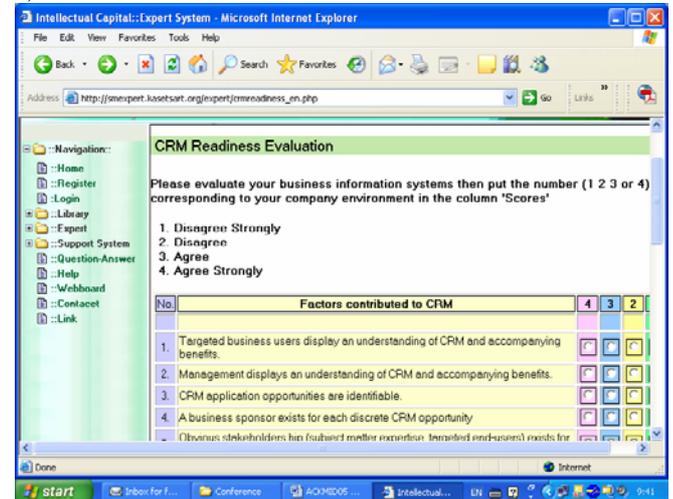

Figure 7. CRM readiness module for SME evaluation.

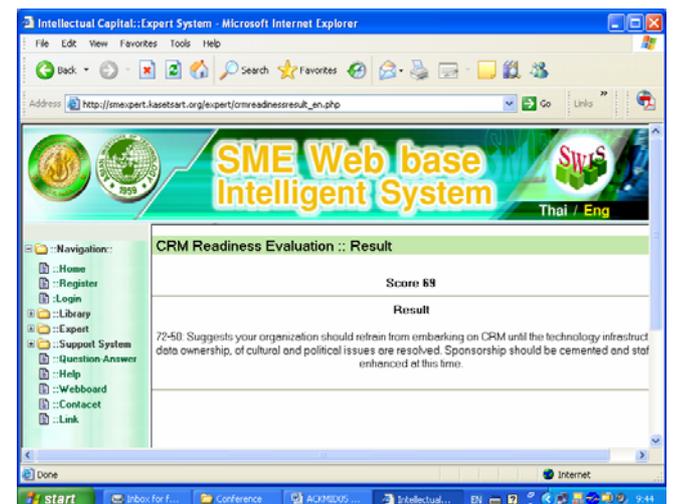

Figure 8. Results from CRM readiness evaluation.

IV. System Evaluation

The system evaluation was designed to be an exploratory, cross sectional, statistical, and based on survey. For the purpose of evaluation we investigated ten Thai SMEs from various industry types. Participants were provided with survey questionnaires. Each questionnaire is divided in two parts: Section 1 is on organisational characteristic (presented in Appendix 2) and Section 2 is system performance evaluation.

IV. 1 Organisational Characteristics

Participants from ten Thai SMEs have been selected to evaluate the systems. Their profiles are illustrated in Table 1.

Three SMEs are in IT services, two are software houses, and the rest are in printing, media production, education, construction and import. Majority of them have 10-100 employees. The registered capitals are between 5 and 300 million Baht. Most companies are relatively young with 5-10 years of services. There are two companies approved for applying ISO9000 for quality assurance. Majority of the respondents are managers who do the administrative work in the organisations.

IV. 2 System Performance Evaluation

The model has been evaluated using the evaluation questionnaires (Appendix 2). Participants evaluate the four main criteria: system performance, user interface, design and presentation, and perceive usefulness. The evaluation score ranges from 1 to 5 on Likert scale. If participants are very satisfied with the model, they will give the score of 5. On the other hand, they will give the score of 1 if it requires some improvements. The feedback information from the ten cases is illustrated in Table 2.

The evaluation scores range from 72% to 90.4%, which implies that the participants are satisfied with this system. All participants accept the system and are willing to access the system in the future. However, some revealed that the model should be simplified to match better with SMEs in various fields.

V. Conclusions

Competing in the knowledgebase society requires that organizations get the maximum benefits from their human capital (employees), structural capital (organizational structure and information systems) and relational capital (relationship with customers and actors). It is difficult to manage these capitals since the measurement tools are not widely introduced and understood. The literature review shows that a very little work has been carried out on the study of IC measurements in Thailand. To overcome this deficiency, the paper introduced a measurement tool for evaluating intangible assets in the company. This measurement model includes three clusters: human capital, structural capital and relational capital. The qualitative measuring indicators are developed to the respective content. SME Web-based Intelligent System (SWIS) has been developed and described in this paper. It provides various measurement modules including IC, CRM implementation

and KM implementation. It also includes knowledge base of IC, CRM, KM and SME management. The system itself contains valuable information that gives each organisation an opportunity to effectively work with and improve the intellectual capital and CRM. Working with this system is useful for strategic planning and for improving business performance.

Application of Business Intelligence Techniques in China Telecom

Li Haigang

School Of Management, Shanghai Jiao Tong University, P.R. China, 200052
hglihg@yahoo.com.cn

Abstract: In this paper, we have developed a data warehouse and an OLAP(on-line analytical processing) based framework that has been used for customer profiling and comparison. The system architecture for OLAP and data warehouse based calling behavior profiling and multilevel multidimensional pattern analysis is introduced. First, the method how customer profiles can be represented as data cubes is described, then, the architecture of a profiling engine is presented, finally, the process of using the engine to compute profiles and calling patterns is discussed and an application case of China telecom is studied.

I. Introduction

In the last decade, China's telecom industry has made great progress. The reopening of market and the lifted ban of government monopoly changed its whole situation and brought it development and innovation of great significance. Nowadays its scope of business has become increasingly extensive, and more and more services are becoming available. On the other hand, the development of basic institution doesn't match the increasing demand. And the expense on 3G has been heavy burden to the telecom industry. Then they turn to some basic aspects, such as lowering the operation cost and maintaining the service of their current customers.

Though to support the commercial operations, telecom companies have spent plenty of money and energy installing automatic systems, the real problems are always more complicated than the systems. For instance, they do not know who their customers are and who may be interested in their new service. But in fact, they are not able to tell which customer are those who can bring them more profit, or which kind of service is more profitable, or which province should be paid more attention.

With the deepening of informization in China, especially the popularization of the data analytical software, the data accumulation of the users has come to a certain scale. But most of the users just do some simple or partial enquiry dealing with the data. In some sense, data may be burden rather than resource to them. For the business intelligence applications can do the analysis and mining of large volumes of transaction data to support business managers in making informed decisions, the situation can be improved.

II. Relative Concepts

As a technology of transforming the information of a company to useful resource as well as knowledge, business intelligence gathers, manages and analyzes large amounts of data on a company's customers, products, services, operations, suppliers, and partners and all the transactions between them. Business intelligence applications require the analysis and mining of large volumes of transaction data to support business managers in making informed decisions. Typically, these applications involve extracting data from operational databases, transforming the data, and loading it into data warehouses. The data in the warehouse is then input to a variety of reporting, querying, on-line analytical processing (OLAP) and data mining tools, which generate patterns, rule, or models used by business managers for making decisions. These decisions are then fed back in the form of business actions such as product recommendations or fraud alerts (see Fig. 1).

The overall architecture of an OLAP system comprises a hierarchy of basically three data models: the physical model, the logical model and the presentation model. The central logical cube model defines the concept of a cube and its corresponding operations. The physical model deals with how the cubes are stored or indexed for efficient access. The presentation model is concerned with grouping several logical cubes, defined as parts of one (or more) underlying cube(s), in one presentation entity. The mapping between these levels ensures independence and this is achieved through the use of the intermediate logical model.

III. Application of Crm Based on Olap in Telecom

III.1 Overview

In a telecommunication network, hundreds of millions of call detail records are generated daily. Business intelligence applications such as fraud detection and churn analysis require the collection and mining of these records on a continuous basis. An important component of many of these applications is customer profiling, which aims to extract patterns of behavior from a collection of transaction records, and the comparison of such patterns. In telecommunication applications, for instance, a customer's calling behavior is represented by the composition and periodic appearance of the callees (the persons called); time-windows (when calls are made); and duration (how long calls last). Through e-commerce applications, a customer's shopping behavior could be represented by ads viewed, products selected, products bought, time-windows, price, etc. The techniques for customer profiling and comparison are very similar. Nowadays, Business Intelligence has attracted more and

more people's attention. In Europe and US, it even has been an essential equipment of the personal computer. And BI is believed to play a more and more important roll in our life in the future.

Since the similarity of customer behavior can be represented from different angles, they compare calling patterns derived from customer calling behavior profiles, rather than comparing profiles directly. For example, some calling patterns might be similar in terms of the volume (total number or duration) of calls to a set of callees, others

might be similar in terms of the time windows when these calls were made. Their objective, therefore, is to enable the comparison of calling patterns along multiple dimensions and at multiple levels of the dimension hierarchies. This type of multidimensional, multi-level pattern extraction and comparison is facilitated through the use of OLAP. Like many existing efforts, they take advantage of OLAP technology for analyzing data maintained in data-warehouses. In particular, they perform large-scale data mining on an OLAP based computation platform.

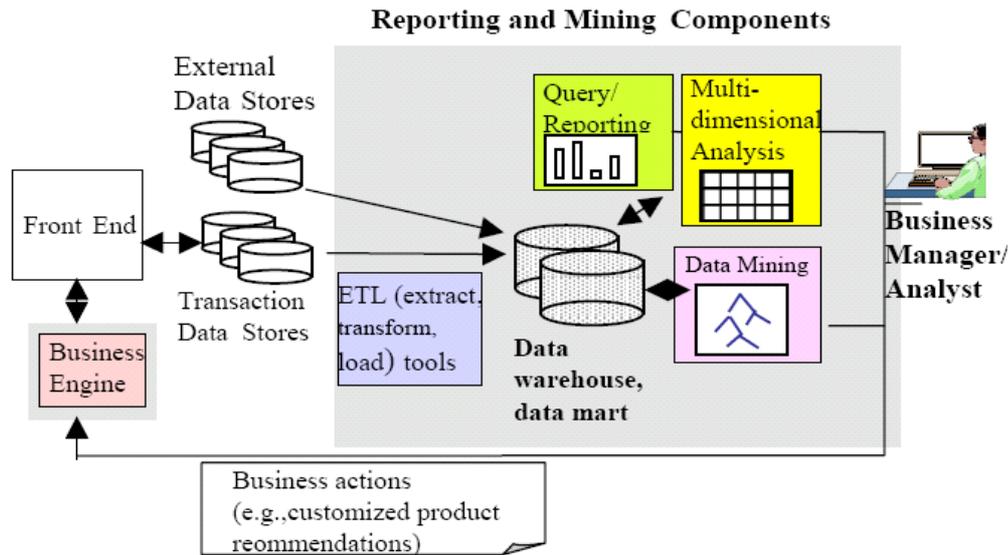

Fig. 1: A typical architecture for business intelligence

III.2 The Construction of the MASA System

Application of information technology today in the telecom industry can be concluded like this: first, the prevalent instrument and software used nowadays cannot meet with the increasingly highly required service quality, and then, 0.2 billion telecom customers in China promise a profitable market, third, along with China's entering in the WTO, the telecom industry in China will confront strong competitors from all over the world. A chance but a challenge for state-owned telecom companies arises. In general, the telecom industry will burgeon in the near future and this could bring both opportunities and challenges.

ABC Mobile Communications (AMCC) has fully adopted the advanced business intelligence solutions provided by Informix, which aid it constructed the mobile communication market and consumer conduct analysis system (MASA). The development and application of MASA finds its origin from the urgent needs required by company's operation, which contains data mining (DM) analysis on historic data, kinds of report forms showing the status quo, dependable information when making a decision, and the support to operation system and net maintenance, etc. According to the demand of the enterprise, the data

warehouse in AMCC is the data-analyzing warehouse based on calling records. It contains list of VIP, assaying customers' credits (namely the Fraud Inspection), the calling stream, analyzing efficiency of the selling channels, assessing the effect of market competition and measures used in operation, etc.

In the process of operating the system, we construct the data warehouse that is independent from the payment recording system. The memory cells of data warehouse use the dynamic server options for advanced decision support system, the extraction and load of data adopt the loading system that is especially devised for applications of the data warehouse, data analytical and information visiting part use OLAP which is based on web techniques as well as multiple stratum client/server structure, meanwhile it can be shown directly through the combination with map information system. The system structure can be seen like fig. 2. First, AMCC does market segmentation by synthesizing and analyzing the different business behavior of consumers, and make relative product and consumption section to conduct cross-sale. Second, it Segments consumer and adjusts consumer structure and make marketing strategy by synthesizing and analyzing the accumulative total consume and payment behavior of consumers. Third, it can know information of sales channel and control the sales channel. Finally, the company uses the system to adjust the net

according to net operation analysis result. Fig. 3 shows the business development analysis result of AMCC.

Fig. 3 the business development analysis

Fig.4 analysis of customer cluster

Fig.4 shows the analysis result of customer cluster.

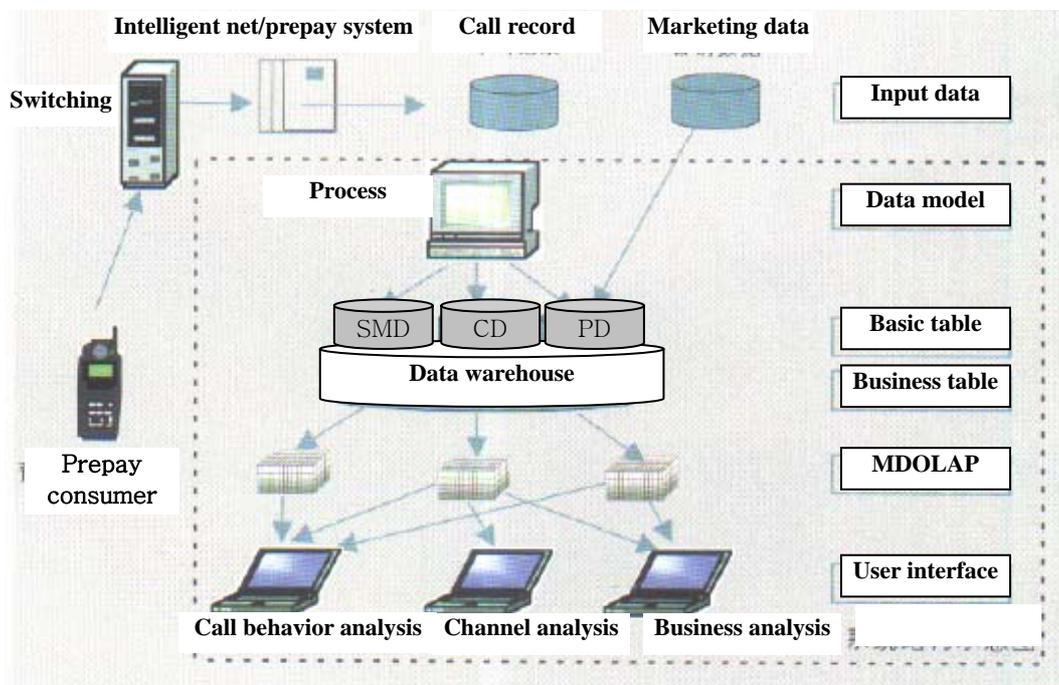

Fig. 2 MASA structure of BI system for prepay
SMD: small message data, CD: calling data, PD: payment data

III. 3 Profiling Engine

To create and update customer behavior profiles, hundreds of millions of call records must be processed every day. The profiling engine is built on top of an Oracle-8 based data-warehouse and Oracle Express, an OLAP server. Customer behavior profiles and other reference data are persistently stored in the warehouse and handled in the OLAP multidimensional database (MDB) as data cubes. The profiling engine architecture and flow of data is shown in Figure 6. From the calling profile cubes, individual customer

based, multilevel and multidimensional calling patterns are derived. The similarity of calling patterns belonging to different customers, or belonging to the same customer but for different profiling periods, can then be computed. The profiling engine can be used by a fraud detection application to generate alarms when suspicious events are detected (e.g., a call exceeds some threshold, an abnormal calling pattern occurs; or a pattern similar to a known fraudulent one occurs). An investigator can then examine the case database to determine whether a fraud indeed occurred.

III. 4 Calling Pattern Cubes

A calling pattern cube is associated with a single customer for representing the individual calling behavior of that customer. Multiple calling pattern cubes may be generated to represent a customer's calling behavior from different aspects. They may be based on volumes or probability distributions; and they may be materialized (defined as variables) or not (defined as formulas). In our design, probability-based calling pattern cubes are derived from volume-based ones.

A volume based calling pattern summarizes a customer's calling behavior by counting the number of calls of different duration in different time-bins. Represented as cubes, they are commonly dimensioned by time, duration and dow (day of week), and in addition, for those related to outgoing calls, dimensioned by callee, and for those related to incoming calls, dimensioned by caller. Their cell values (measures) represent the number of calls. For example, a calling pattern might express that there were 300 short calls, 100 medium calls, and 50 long calls in the mornings of the profiling period, from one specific phone number to another. A probability distribution based calling pattern represents a customer's calling behavior with probability distributions. For example, a calling pattern from one phone number to another might express that 70% of the calls in the morning were short, 20% were medium, 10% was long. Cubes representing different probability measures can be derived from a profile cube or a volume-based pattern cube. For efficiency as well as consistency, it is only necessary to store profile cubes persistently in the data warehouse. Calling patterns, either based on volume or probability, can be

derived on the fly (at analysis time) using the OLAP engine for computation. This shows the simplicity, and yet the power, of OLAP for customer profiling.

IV. Conclusion

Telecommunication prepay satisfies the benefits of operation company and user. For operation company, prepay can avoid much debt from consumer, as for consumer, prepay is the best choice for those low consumption and low credit. In our approach, the OLAP engine actually serves as a scalable computation engine. From a performance point of view, it supports indexed caching, reduces database access dramatically and extends main memory based reasoning. From a functionality point of view, it allows us to deliver powerful solutions for profiling, pattern generation, analysis and comparison, in a simple and flexible way. We have developed the multi-dimension and multilevel cube similarity comparison formalism for comparing customers calling patterns in terms of cube manipulation.

An Initial Design of a Website Snapshot Management System

David Chao
College of Business
San Francisco State University
San Francisco, CA 94132
E-mail: dchao@sfsu.edu

Abstract: A website snapshot is the state of a web site at a specific point in time. It supports applications that require historical data. Most website snapshots are created by making a copy of the website. These date-time stamped physical snapshots are unable to satisfy users' need for snapshots of different snapshot times. This research proposes a scheme that is able to create website snapshots that meet any snapshot time requirements by recording changes to a website in a log. For web pages producing dynamic content from a database, this scheme will allow the pages to access a database snapshot at the website snapshot time.

I. Introduction

A website snapshot is the state of a web site at a specific point in time. It supports applications that require historical data and preserves website content for future reference. In practice, some website snapshots are created to answer questions about website content at the snapshot time for audit and compliance purposes [5]. Some are created due to government policies for preserving government-supported Web content [3]. Some are created in an attempt to preserve the web content as an archive of civilization for future generations to study. Creating and preserving web site snapshots have been ongoing undertakings of many web projects. An example is the Internet Archive which uses web crawler to collect all open access web pages since 1966. Its Wayback Machine lets users view snapshots of Web sites as they appeared at various points in the past [2]. Some are created for research and analyses that use snapshots to study certain trends in the study subject. Website snapshots enable researchers to analyze data with new tools that haven't existed before [2].

In addition to providing historical data, website snapshots are also used in web server's cache engines. The goal is to save bandwidth and improve download time by delivering data from the cache that otherwise would make repeated trips across the Internet. Similarly, popular internet search engines such as Google also create a cache of website snapshots in order to speed up searching [11]. Website snapshots can also be used as a backup of the operating website.

Website snapshots may exist in many forms. They may be accessible online as a server-side resource, downloaded to a user's machine, or created on a disk for offline access. A

typical way of creating a server-side website snapshot is using a program that copies files from the Web server to a computer at an archive. The snapshot may contain all the files at the site or a subset. Snapshots are taken periodically, so that the archive has a sequence of snapshots for each site [9]. A client-side website snapshot can be created by using a website downloading software; an example is Web Site Downloader [11]. This type of software lets users download an entire website, or a selective part of it, for offline viewing.

Although the process of creating a website snapshot is simple, it may still face some practical problems [1]. The state of a website changes whenever a change occurs to the website. Most website snapshots created today exist physically as a date-time stamped copy of the website. A major problem with the physical snapshot is that it only represents the website's state at one specific time. It is unable to satisfy a user's request for a snapshot of a different time. Dynamic web pages pose another problem because they use server-side and/or client-side script code to create dynamic content. These pages may also retrieve information stored in databases. Thus, retrieving the page alone may not yield the desirable result.

This research proposes an initial design for a website snapshot management system. The system is able to: (1) generate a website snapshot with any snapshot time specified by a user, (2) generate a website snapshot only when requested, and (3) provide database snapshot that is consistent with the website snapshot time to create dynamic content. The system is designed to manage the website snapshots of only one website.

II. Tracking Changes to Website State

II.1 The Needs for Tracking Changes

A web site is a system of integrated web documents where each document is identified by a URL. Therefore, the state of a website represents the state of all web documents of the website, and it changes whenever the website changes its content by inserting a new document, deleting an existing document, modifying a current document, relocating a document to a new directory, or reorganizing its directory structure.

A website as currently published is the result of past changes; it represents the current state of the website. Tracking all changes to a website to its current state enables a website to rollback its current state to any state in the past. In so doing, many non-current documents need to be kept; these include deleted documents and old versions of a

modified document. All old versions of a web document are its snapshots at various times in the past. The URL of a current document may also go through many changes due to a renaming or relocating of the document.

Figure 1 summarizes the effects of web site reorganization and change to a document on its URL. When a web site reorganizes its directory structure, all affected documents will have a new URL. Similarly, when a web document is renamed or relocated to another directory, it will have a new URL as well. When a document is modified, its URL will not change and the old version before the modification becomes the document's snapshot between the previous and the current modification. In order to retrieve the snapshot the old version is archived. A deleted document is archived as well for later retrieval.

Web site actions	Effects on current and historical links
Adding a new document	Adds a new URL to current links
Modifying a document	No change to URL; the old document becomes a snapshot and is archived
Deleting a document	Deletes a current link; adds a historical link and document is archived
Renaming a document	Adds a new URL to current links; the old URL becomes historical link
Relocating a document	Adds a new URL to current links; the old URL becomes historical link
Reorganization	Adds all affected documents' URLs to current links; all affected documents' old URLs become historical

Figure 1: Effects of web site reorganization and web document changes.

Together, the URLs invalidated by a web site due to reorganization, document removal, renaming, or relocation, plus the links to document snapshots are a web site's *historical links*. From this perspective, a website consists of two parts: links to current documents and links to historical documents..

II. 2 Factors Affecting Website State

A website state captures not only the code that defines the web documents but also the presentation of the web documents as a results of running the code [2]. Thus, factors affecting the rendering of web documents will affect website state. These factors include:

a. Web document code: This includes the code that creates web page's static and dynamic contents including server-side and/or client-side scripts. Frequently, code creating dynamic content is stored separately in a different file as in the case of Server-Side-Include, Code-Behind

technologies, and XML document style sheet.

b. The state of internal resources it references: Internal resources are files managed by a web site and are available in creating the web site's contents. Typical examples of internal resources referenced by a web document that affect its rendering are style sheets, files embedded by a Server-Site include directive, image files, script files, and databases. These internal resources may create dynamic contents that change every time the document is opened, and they are subject to change that consequently changes the web document's rendering. Many of these files are *internal supporting files* that are created for supporting a web document and are not for publishing individually.

c. The state of external resources it references: External resources are files not managed by the web site but can be referenced in creating the web site's contents. A web document may reference external style sheets, components, web services, or databases. These external resources are also subject to change.

d. Web site host environment variables: Script code may reference a host's system variables in creating dynamic content. A typical example is using the system clock to get the current date and time. A web document that displays the current date and time is always in a new state.

e. Web technologies implemented on the server-side as well as on the client-side: A web page is often created by using many technologies and may reference documents that are created by a different set of technologies. The complete rendering of a web document requires that all technologies, client-side and server-side, are properly implemented.

The first three factors affect the consistency of the data of a web document and are called *consistency* factors. The last two factors are *environment* factors. Figure 2 shows the relation between a web document and factors affecting its rendition. Note that a web page may be a composite document of several tightly-coupled documents, such as style sheets and code-behind files.

Based on the consistency factors' effects, three levels of a web document's snapshot can be defined. (1) Level 1 snapshot: A web document snapshot is the state of web document code at snapshot time. Creating a level 1 snapshot enables a web site to trace the changes to the web document code over time. (2) Level 2 snapshot: A level 2 snapshot is a level 1 snapshot with the additional requirement that all the internal resources it references are at least level 1 snapshot at the same snapshot time. These internal resources can be categorized into two groups: database and non-database files. For a database file to be a level 1 snapshot, it must be consistent with the state of the database at the snapshot time. (3) Level 3 snapshot: A level 3 snapshot is a level 2 snapshot with the additional requirement that all the external resources it references are at least level 2 snapshots at the snapshot time.

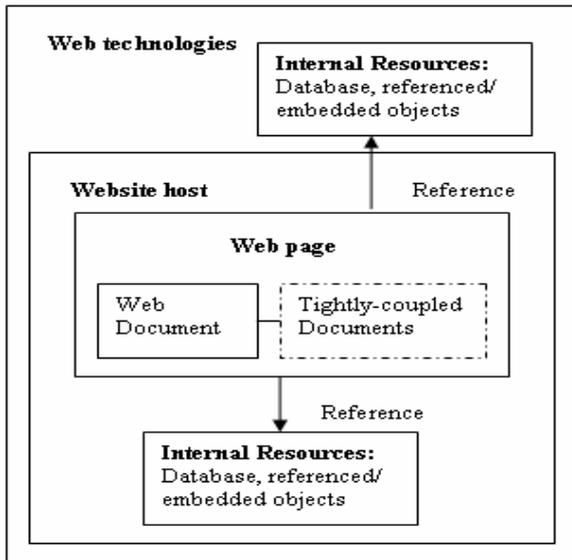

Figure 2: Relations between a web page and factors affecting its rendition.

The two environment factors will improve the consistency of a web document snapshot if they are enforced; that is, the host variables are reset to snapshot time and web technologies implemented are compatible with the technologies at the snapshot time. Four levels of consistency improvement are defined depending on whether the environment factors are enforced: (1) Plus 0: If both environment factors are not enforced. (2) Plus 1: If the host variables are reset to the snapshot time. (3) Plus 2: If web technologies are compatible with the technologies at the snapshot time. (4) Plus 4: If both factors are enforced.

		Consistency factor		
		Level 1	Level 2	Level 3
Environment factor	Plus 0	Level 1 + 0	Level 2 + 0	Level 3 + 0
	Plus 1	Level 1 + 1	Level 2 + 1	Level 3 + 1
	Plus 2	Level 1 + 2	Level 2 + 2	Level 3 + 2
	Plus 3	Level 1 + 3	Level 2 + 3	Level 3 + 3

Table 1: Levels of website snapshot

Table 1 summarizes all possible levels of snapshot states. The level 1 and level 2 snapshots are related to files that are managed by the website and changes to these files can be recorded by the website; hence, they are relatively easy to achieve. The level 3 snapshots involve resources that are not managed by the web site and it's difficult, if not impossible, for the web site to keep track of changes to these resources. This research develops a web document snapshot management system to deliver web documents' level 1 and level 2 snapshots.

III. Initial Design of Website Snapshot Management System

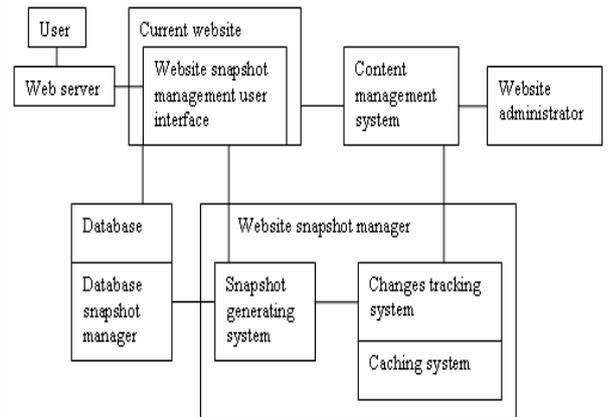

Figure 3: Components of a website snapshot management system.

This system consists of two modules: Database Snapshot Manager for maintaining database snapshots and Website Snapshot Manager for maintaining web document snapshots. Figure 3 shows the major components of this system in a typical website environment. This system assumes that the website administrator uses a content management system in maintaining the website. Changes to the website as discussed in the previous section are passed from the content management system to the Website Snapshot Manager.

The Website Snapshot Manager contains 3 components: (1) Changes Tracking System: This system uses a log to record all website changes including insertions, deletions, modifications of web documents, and changes to web document's URL. (2) Caching System: This system is responsible for storing deleted documents and old versions of current web documents. (3) Website Snapshot Generating System: This system generates a website snapshot based on a user's requirement for snapshot time.

The objective of the Database Snapshot Manager is to provide a database snapshot at any snapshot time requested by users. This requires recording all updates in a log. The log uses time stamp to record update times and uses flags to indicate deletions and insertions where a modification is treated as the deletion of the old version followed by an insertion of the new version. With such an update log available, rolling back the current database using updates with time stamp later than the snapshot time can generate a snapshot at any snapshot time. Database snapshot management and related materialized view management have been the topics of much research [3][4] [8] [9].

The current website contains a user-accessible module of snapshot management user interface. This interface lets users submit a request for a website snapshot. This request translates to a command: Create Website Snapshot As Of *snapshot time*.

IV. Summary

Website snapshots have been used in many applications. Most website snapshots are created by making a copy of the websites. These date-time stamped physical snapshots are unable to satisfy users' need for snapshots of different snapshot times. This research proposes a scheme that is able to create website snapshots that meet any snapshot time requirements by recording changes to a website in a log. For web pages producing dynamic content from database, this scheme will allow the pages to access database snapshots at the website snapshot time.

SAP-leerstool Extended Enterprise Infrastructures

Abstract: Nowadays, companies want to share information. When doing so, many issues have to be taken care of, and many options are available for most of these issues. Realizing B2Bi is a very complex task. It is the aim of this paper to make it possible to oversee the complexity of information sharing in a B2B context by structuring the issues that have to be taken care of in a new framework: the DA (Data Aspects) – framework; and by relating this framework to the existing FADEE framework.

Keywords: Data Warehousing and Data Mining

I. Intro: Structuring the Problem Space

Rather than *owning* information, *sharing* information is nowadays often said to be an important source of competitive advantages. Sharing data is, however, not an easy task. Many different issues have to be dealt with, and the many decisions that are taken should fit together, and should fit the requirements of the business.

This paper reports on our research-in-progress (updates will be posted at www.frankgoethals.tk – publications). The research is meant to overcome one of the frustrations one may get by reading through literature on B2B (Business-to-Business) data exchanges: such papers are typically very *fragmentary* without positioning the niche they cover within the entire field of data-exchange related issues. Moreover, while the discussions are often fragmentary, they are not *'normalized'*. With this we mean that concepts are used which seem to possess a number of properties in the mind of the authors, but which are not defined explicitly. These concepts can be looked at from different points of view, and by not presenting those viewpoints, or by highlighting only one, the concept remains obscure for the reader. For example, terms like an 'extended enterprise wide datawarehouse' are very obscure. Does this mean all the data is stored geographically in a location that is central and which can be accessed by all parties? Or does every party have a replication of all data? Or is the warehouse actually only a database with meta-data through which the scattered databases are connected? Can one request data from the datawarehouse, or should one subscribe at the warehouse to get the information the datawarehouse publishes? Is the 'central database' (whatever that means) located on the premises of one of the partners, or on a third party's webfarm? Is one of the parties the 'owner' of the database,

or are all parties owner of a part of the database, or... Many questions and answers are thus hidden under such a title.

When looking at the data side of the B2Bi story alone, many issues can be identified that should be taken care of. In this paper we try to bring all these issues together in a simple framework.

In order to identify what are the data-related issues that should be dealt with in B2Bi in general, investigating a single in-depth case study was considered inappropriate. After all, choices and options become better visible if one case is contrasted with another one. Therefore, we decided to draw up the framework on the basis of a study of many cases that were published (also by others), as well as on papers that do not present specific cases but relevant constructs (e-business standards and the like). After some time of working bottom-up (i.e., starting from practices and trying to put them in a structure), we noticed the topics fitted in the often discussed classification of Zachman [17]. Zachman states that different (normalized) views are possible on some entity. Following Zachman, a discussion of an entity has to include the following six questions in order to be complete: what, how, where, who, when and why¹. Consequently, if one wants to find out how to deal with data, it is actually logical to stumble across these six questions. In what follows we handle the six questions as six boxes in which we can put data-related issues. As such, the six boxes function as a simple placeholder, a framework. We call this the DA (Data Aspects) – framework.

Figure 1: The DA (Data Aspects) framework

Knowing the six questions, we were able not only to work bottom-up, but also top-down. That is, while topics identified in literature nicely fitted with the six questions, the six questions helped us identifying issues that were not visible in literature. We could formulate questions such as 'who wants the data?', 'where is the data?', 'how will the data be moved from point A to point B?', etc.²

By working in both directions we believe we have covered a good part of the ground. Above that, the

¹ While in his ISA framework the entity under consideration is typically an entire enterprise, we consider 'data' to be the entity.

² We note that one may also apply the six questions to the meta-level. For example, in stead of discussing 'who needs what data' and 'how he will get the data', one may investigate 'who should define who needs what data' and 'how he should define that'. For now, however, we do not look at this meta-level.

framework is well-structured so that at any moment new topics (if any would have been overlooked) could be added without repercussions for the existing framework (i.e., the six boxes will stand the test of time).

In the following section we present the data-related issues in the framework. While space limitations make it impossible to deal with the issues in detail, we discuss some options that are available in each box. After that, we bring a short case study from the health care industry, covering a number of different aspects.

The DA-framework enables people to easily pinpoint the data-related topics that have to be (or are being) dealt with in B2Bi. While the framework is a nice contribution because of this enablement, it does not show how to actually *deal* with the issues. Classifying the issues might create the impression that setting up B2B data exchanges is simple. Indeed, the classification gives people a clear view of what B2Bi entails. Still, dealing with the issues (and their interdependencies) is a complex task in which many people are involved. This is shown in the final section of the paper where we relate the issues in the boxes to the FADEE-framework (the Framework for the Architectural Development of the Extended Enterprise, see e.g. [8]).

II. The Design Variables to Play With

In what follows, we discuss the different issues that should be dealt with. The issues are grouped in six subsections showing the HOW, WHERE, WHO, WHAT, WHEN and WHY aspects respectively of the data sharing.

II.1 How

One has a large choice with respect to the medium that is to be used to exchange the data. Knowledge may for example be transmitted visually (e.g., with pictures and models), orally (e.g., telephone conversation), or written (e.g., a facsimile, a letter, e-mail), or by a combination of these (e.g., through video-conferencing). A further discussion of all the options is not the goal of this research. In practice, however, choosing the medium is very important because a decision with respect to the medium has stringent consequences for options in the other boxes in the framework. Indeed, for choosing a medium, one will have to keep the other questions (mentioned in the following sections) in consideration: where the data is stored, who is involved, what kind of data it is, etc.

II.2 Where

With respect to the where dimension two questions have to be assessed: where is the data located?, and what is the structure of the network?.

Network structure

Two nodes will always exist when information has to be shared: the location(s) of the data before transmission, and the location(s) of the data after transmission. Beside these nodes, other (intermediate) nodes may also be involved; for

example because they will store the information that is transmitted (temporarily or permanently).

One has to investigate which relevant nodes do exist, and whether new nodes should be added, and where they should be added. Each node may be located on the premises of the parties, or at some other location (e.g., a webfarm, external to the business relationship). The location of the nodes, of course, has consequences for the communication medium (see HOW) that can be used. We note that, in general, the communication medium also has some topology. This topology is, however, transparent. For example, when using the telephone or the Internet many switches are included in the network. For realizing data transmissions the presence of these switches is transparent. They can be seen as infrastructure.

Data location

Companies that want to share data may agree to create a replication of the data. This replication may be located outside their company or not. The replication-dimension should be seen as a continuum, from 'no replication', over 'thin replication' to 'fat replication'. Besides the data itself, data about the data can be stored too: meta-data about where the data can be found.

Data replication should be considered for all the nodes in the network. If an intermediate node is used, the node may store copies of (some of) the data. The node may then be a thin or a fat centralized datawarehouse. In case the node does not possess replications of the data itself, it can use meta-data to function as an information broker. The information broker can then act like a buffer for changes in relationships between companies. In case the counterparty in some process changes, the sending/requesting system does not need to be aware of this change: the information broker keeps track of such changes, and makes sure valid data (i.e., data from the right party) is transmitted to the right party. This is done on the basis of the meta-data the broker can investigate.

II.3 Who

The 'who question' pertains to the parties that are involved in the information exchange, and the roles they may play. Again, several issues come to the front: Who is involved? Who initiates the information exchange? and Who is authorized to ask/send/get data?

Needy/Sender/Intermediary

In every data exchange, at least two parties are involved: a party that wants to get the data (who we call 'the needy'), and a party that has to transmit the data (called 'the sender'). Besides these two parties, intermediaries may be involved in the information exchange. An intermediary may be owned by the organization of the needy, by the organization of the sender, by a third party, and by any combination of these. With 'ownership' we refer to the party who can make the

decision³ as to how the intermediary should take part in the information exchange. By including an intermediary in the exchange, a many-to-many exchange infrastructure can be set up, rather than a point-to-point infrastructure.

Push/Pull

A party can get data via a pull model or a push model.

- The pull model implies that the data is requested by one party, and the other party replies (Request/Reply).
- In the push model, the data is transmitted by the data sender automatically because the sender knows the other party is interested in the data (Publish/Subscribe). This model fits an 'event-driven' way of working (as is advocated in business practices such as Supply Chain Event Management, but also in systems development methodologies such as MERODE).

Irrespective of which model is used, we refer to the party that wants to get the data as 'the needy', and to the party that has to transmit the data as 'the sender'.

We note that if we assume that subscription in the push model cannot only be done by the information needy (but also by the information sender), the push model also allows for sending orders for example (as if the supplier of the product is subscribed for getting the order).

As stated, besides the primary needy and sender also intermediaries may be involved. The interaction between needy and intermediary, and between intermediary and sender may happen through different models. The needy may use the push or the pull model in his interaction with the intermediary, and irrespective of this choice, the intermediary may use the push or the pull model in order to get the required data in his system.

If we now consider the Where-question again, one can see that in case of the Request/Reply model, the needy can choose to make the data he received persistent or not. Irrespective of whether he did so, meta-data can be useful to find out where to request the (updates of, and additional, detailed) information. In case of the Publish/Subscribe model, meta-data is only useful for subscription purposes. Once subscribed, the meta-data is no longer useful for the subscriber, as any information that comes available will be transmitted to him. Not storing the information means the data is lost for the receiver (if the parties stick to the push model).

Choosing to replicate the data at some other location should not be done without thinking about the intermediary's ownership that is created this way. A party may actually lose the ownership over the data if a replication is stored at a location outside the company walls. This may particularly be the case if the intermediary where the replication is stored is owned by another party.

³ Please note that the term 'makes the decision' is narrower than 'control'. One party may influence another party in making decisions, and another party may influence the execution of the decisions. Control is therefore often shared by many organizations. This, however, depends on the decision making process that is used, and thus varies from case to case.

Authorization and authentication

A needy may not accept data coming from just any sender. Authorization and authentication⁴ can be needed here. Authorization and authentication are, however, also going to play a big part when turning the picture upside-down: By looking at the needy from the point of view of the sender, it is clear the sender does not want to give his data to just any party. A needy needs to be authorized data access. Every message exchange between parties can be accepted or rejected. In the Publish-Subscribe model, if one party subscribes (be it the needy or the sender), this subscription has to be accepted by the other party. Given the fact that a subscription is considered valid by both parties, publishing data is authorized as well (authentication may still be needed). In the Request/Reply model, the sender has to assess (after authentication) whether the needy is authorized to get the information. Given the fact that the needy-system has asked the sender-system for the information, the sender is authorized by the needy to send a reply message (authentication may still be needed).

It should be noticed that giving deliberate access to one party may result in giving implicit access to many parties. This may for example be the case if the systems of the counterparty are not well secured. The idea arises that a network is only as secure as its weakest link. From the case study research done by Dynes et al. [3] at five partnering companies, it seems that managers believe that their firm's internal networks "are not at additional risk as a result of using the information infrastructure to integrate their supply chains" [3, p2]. It seemed that the firms in the study did not put big security requirements on their suppliers, although one of the firms posed it would start having requirements in the near future. This company actually believed that having a high level of information security was not merely a 'qualifier' (to be allowed to play the game), but a competitive advantage.

Still, in [4] (where Dynes presents the findings of a roundtable with a number of business leaders and academics) it is stated that in general companies are auditing the information security status of potential partners. One difficulty with such assessments is that they slow down the partnering. Besides that, it should be noticed that security is not just something that the IT department has to take care of. Employees in all parts of the organizations need to be educated (in relationship to their roles) about their responsibilities with respect to security.

Besides the unwillingly sharing of data by the new information possessor, there may also be a problem of the needy willingly sharing the data with other parties. 'Privacy' is a topic that is often mentioned in the context of partnering companies. In general, information privacy concerns the fact that individuals require that information about themselves should generally not be available to others, and that, where

⁴ Authentication has to do with determining who a user or a system is, whereas authorization is about stipulating who is allowed to access which resources [DP15].

data is possessed by another party, the individual should be able to control the data and its use to a considerable extent [2]. If a customer gives personal information to a specific company, this does not mean the customer would agree to give this information to the partners of this company. Moreover, the partners should handle the data with care, fully respecting the agreement the source organization has with its customer (although this partner may not have a direct relationship with the customer). Interestingly, privacy regulations seem to differ widely across countries [4].

As a side note, we notice that data access management requires the storage of data for authorization and authentication purposes, and that – just like for all other data – many questions have to be answered about the storage and the transmission of the access information (e.g., the information can be stored centrally or not, can be replicated or not, can be accessed directly or not, etc., see below). Based on access information, needy and senders can be further divided into categories, based on their specific permissions to create, read, update, or delete the data (see e.g., [5, and 10] for a discussion on this).

II. 4 What

When exchanging data with another party, one has to make choices on a number of properties of the data itself. These properties, and the associated different options, are discussed below. First, however, we shortly have to mention a property that all data exchanges are likely to have: the data exchanged is a so-called ‘Boundary Object’; an object that links two fields which are divided by a boundary.

Boundary objects

Levina and Vaast [11] identified two basic requirements for an object to be a boundary object. First, the artefact has to acquire a local usefulness. That is, agents in each field must use and make sense of the artefact in the context of their field. Secondly, the artefact needs a common identity. To make this possible, a joint field (which serves to bridge the separate fields) must be established within which agents jointly recognize and value the artefact.

Levina and Vaast found that organizations rely on boundary spanners to establish the local usefulness and a common identity of boundary objects. The boundary spanners (1) reflect on objects from each field and on their utility within the context of the joint field, and (2) they create new artefacts and try to establish their new identity within the joint field. Then (3) they try to establish the local usefulness of these artefacts.

What (type of) information is being shared

Companies that pursue B2Bi can do this in various practices. On the one extreme, standard practices may be automated. The transmission of purchase orders may for example be automated (with no people being involved in the B2B practice). At the other extreme, the ICT systems may only be used as the start for a close collaboration: to find people in a partnering company who can help on some

practice. The information companies want to share in the latter case is typically tacit in nature, and is thus not present in computer systems. Therefore, they share other data to find out who has the necessary tacit knowledge.

In order to align the ICT with the business, one first needs to decide what *type* of data fits the *type* of the business. Only then it can be decided what data should appear in the system. This is also true in a B2B scenario. Companies have a relationship for some business reason. If this business reason is that the supplier sells some half-finished product at the cheapest rate, the data exchange will be limited to placing orders automatically. If the companies collaborate because their production processes are similar, and one can help the other out on improving its production process, the data exchange will concern the experiences, background, education, etc. of the personnel. Aligning the *type* of data with the *type* of business the companies are in, is what we call ‘high-level alignment’. Unfortunately there is no space to deal with this issue in detail. One may refer to Hansen, Nohria and Tierney [9], and to Birkinshaw and Sheehan [1] for studies within the frame of isolated enterprises (thus not B2Bi).

Batches or singles

Data that is needed by a user may be requested and transmitted as an exchange on its own. Alternatively, requests and/or replies may be grouped in batches.

Annotation

If the data is meant to be made persistent in another system, the job of storing the data usefully will be greatly facilitated if the data is annotated. That can be done by sending the data in an XML format that follows some (standardized) XML schema. To this purpose, the sender can try to push forward the degree of structuration, so as to transform unstructured data into semi-structured data.

The other way around, if the sender would not like the user to store the information, he can make things more complex to the user by not annotating the data, and sending highly unstructured documents. In this case, data that is highly structured at the sender’s site (e.g., prizes of products) may be transmitted in unstructured documents (e.g., highly graphical brochures).

As an example, a purchaser who is interested to buy products from a supplier may want to look into the supplier’s catalogue. The supplier does not want the purchaser to load the entire catalogue into his system (e.g., because the catalogue gets out-dated fast; because this would make it easy for the customer to compare prizes with competitors more easily, etc.). Still, it is important for the purchaser that when he selects the products in the catalogue, that the data on the order is made persistent in his ERP system. A solution to this problem was defined by SAP and Ariba. The Open Catalog Interface (OCI) or ‘punch-out’ solution offers a purchaser the possibility to see the catalogue via the web. The catalogue does not enter the ERP system of the purchaser. The purchaser can select the

products he wants to order in the web interface, and he can have a standard message sent to his ERP system so that the data on the desired products enters his own ERP system.

Standardization

The data may be represented in a standard or a proprietary format. For two companies to exchange data they need some agreement. This agreement may be established by a third party in neutral standards, or may be set up by the partners themselves. Of course, by choosing for a proprietary format, chances for including other parties in the data exchange later on are reduced.

We note that during the last years many standards have arisen on messages that may be exchanged between companies. While some of these standards can be used in any industry (i.e., it are 'horizontal standards'), others or tailored to a specific industry (so called 'vertical standards'). To a big extent, these standards try to bring a standard structure in the messages that are exchanged. This is pretty straightforward when dealing with common business messages such as orders and invoices (see cXML, UBL, and CBL). For files, such as patient records in the social sector, contracts in the context of legal arrangements, or curriculum vitae in the human resources, it also seems possible to find a structure. These unstructured documents can then be translated into semi-structured documents (see for example the HL7 standard, the Legal XML standard, and the HR-XML standard respectively). We note that this fact can give rise to new intermediaries in the data exchange process. For example, Oracle's iRecruitment module can be connected (through HR-XML) with providers of resume-parsing functionality or background checking functionality. If an applicant submits his resume (be it in Word, PDF, HTML, or some other format), the employer can forward this document to a 'resume parsing company' as an attachment to a HR-XML message. The resume parsing partner then unleashes his algorithms to get elements (such as address, professional experience, skills, et.) out of the unstructured document, and puts these elements in a structured HR-XML document. Information formatted in the HR-XML format may then be transmitted to a background checking partner for checking the correctness of the information in the resume (e.g., about the education). After that, the data can finally be sent to a company who is interested to hire someone with specific characteristics.

Existing or new data

The data that is being exchanged may be data that is already available at the site of the sender. However, sometimes the needy may be interested in new data. That is, he can demand/request the counterparty to create new data (e.g., new indicators for monitoring some process). Moreover, cooperating companies may start to manage data that only exists at the level of the collection of the companies, and not at the level of the individual companies. For example, if an airline company, a car rental company and a hotel chain together offer trips, each of them generally

only has information on its own sales. By putting the information together, data is available on how many customers booked an airplane seat as well as a hotel and a car. This data may then be linked to data on (individual/grouped) marketing campaigns for example to do data mining.

A side note on Web services

We note one can distinguish between 'parameter-based' Web services and 'message-centric' Web services. The first type of web services is *usually* linked with synchronous communication, realizing RPC (Remote Procedure Call)-style web services. The second type of web services is *often* related to 'asynchronous' communication [12]. The RPC-style web services may work well for some cases, but for other types of applications (e.g., when human interaction is involved at the partner side) they are less appropriate. Patil [13] states that using document-style web services has some benefits, as there are: (1) they facilitate the exchange of self-describing documents that have a business context instead of data structures that reflect application interfaces (i.e., they show the way businesses really interact with one another), and (2) they provide better insulation from changes to the underlying service because changing a few fields in a document does not break the contract between the two parties, as changing the application interface would. Consequently, the message-centric model can be used to realise a more loosely coupled integration [12].

II. 5 When

Synchronous/Asynchronous - Real-Time/Postponed

In case of the Request/Reply model, the needy may have to defer his activities until he gets a response from the information sender. This is the *synchronous* model of communication. In the *asynchronous* model, the information needy does not halt its execution. That is, in the synchronous model the sender is assumed to reply immediately, while in the asynchronous model he is not.

If the synchronous mode is desired, requests have to be dealt with in *real-time* (that is, they have to be transmitted in real-time, and be processed at the sender side in real-time). In case the asynchronous mode is chosen, requests can be dealt with in real-time or can be postponed. An intermediary may for example postpone the transmission because he wants to group all requests in a batch (see What?) before sending them to the sender. Therefore, replies may concern a single request, or a batch of requests. The real-time/postpone distinction can also be made in the Publish/Subscribe model: the data can be transmitted immediately as it comes available (an event is fired), or can be transmitted at regular time intervals irrespective of when the data came available.

II. 6 Why

In practice, the options discussed so far should be put together. Many different combinations are possible. However, not all combinations are appropriate for a given

situation. While the answers on the five questions presented so far should be chosen with attention for their interdependences, the sixth question is directional. That is, to a big extent the why-question gives direction on which options to choose in the other boxes of the framework⁵.

The why-question pertains to (1) why data is exchanged (which will not be dealt with here), and (2) why data is exchanged the way it is done.

As per the question why data exchanges happen in a specific way, a number of issues should be considered. Data is needed as the input for some task. Following Thompson [16], one would call this ‘serial interdependency’. Each party who executes a task may thus have requirements on the way the exchanges should happen. Thompson, however, also mentions another type of dependency: ‘reciprocal interdependency’. This refers to the case where A is dependent upon B for giving him some data, but B is also dependent upon A for giving him some data.

This results in the following viewpoints:

- The needy needs the data to execute some task. Therefore, he may have requirements pertaining to the availability of the data (see e.g. [3] for a case study on this), response time of the system, consistency and being up-to-date, ease of access vs. privacy and security, reliability, etc.
- The sender not only has to transmit the data, but also may have to create, read, update, and delete (CRUD) the data. Therefore, the sender may also have a number of requirements related to availability, reachability, ownership, etc.
- We note that an intermediary can function as a needy and as a sender. Therefore, he may have similar requirements. The requirements depend on the tasks the intermediary has to do. For example, in the health care industry one may want to run algorithms to find out about the state of the entire population in a country. This algorithm needs data that is actually dispersed over many health care institutions. If running such an algorithm would happen to be the key reason for getting into B2Bi, replication of the data to a central place may be desired.
- The reciprocal relationship is important because it may tie messages together. For example, if a customer asks A for the execution of some service, A may need the help of B. Imagine that A first sends information to B, B then requests additional information from A, A transmits this extra information, and B replies with a final answer. If the customer wants a response in real-time from A, this

has a consequence for the reciprocal relationship between A and B. The messages are tied together in a single process. A will require a real-time answer from B, and *therefore* B will require a real-time answer from A on his request for additional information.

Besides tying messages together, the fact that A is dependent upon B, and B is dependent upon A may have a consequence on the way companies deal with the interaction. No party has individual power over the other.

III. A Short Illustration

We will conclude this discussion with a short example from the health care industry (see [14, 15] amongst others). In the health care industry the idea has arisen to share information on patients among authorized institutions if a patient enters one of these organizations for help. Knowing the medical background of the patient can be very important. Because so many different institutions may have information on the patient, an institution needing information would need to contact all other institutions. One can hardly call this an efficient search. Therefore, in the Netherlands, a central point has been entered in the network where a needy can request for information. The central point itself does not have the data on the patients history. However, it has information on where information on some patient can be found. It got this information because it is subscribed with the different institutions who publish this information to the intermediary. In a similar set-up, the English central point *does* contain some of the information on the patients. That is, there is a thin replication in the English system, while there is no replication in the Dutch system.

As the Dutch central point does not possess the patient information itself, one might think the central point would answer the request by replying with the data about which institutions do have data on the patient. This is, however, not the case: the central point contacts these institutions (i.e., the single request from the requestor results in many requests from the intermediary) and groups the replies of the different institutions before transmitting the data to the needy.

Message exchanges between the different parties happen in the format described in the HL7-standard. Using a standard is important because it should be possible to flexibly change the parties that are involved in the whole set-up.

IV. Dealing with the Six Questions

The topics identified so far have been placed into six boxes. While these boxes give a nice categorization of the issues that have to be dealt with, actually doing so is not simple. This is because

- (1) many of the questions relate to both, the business and ICT side;
- (2) the answers to the questions should not only be

⁵ While decisions in the other boxes may have influence on each other, decisions in other boxes do not have consequences for the why-question. The strategy drives the choices that are made. The strategy can be driven a-priori by the many options that are available, but is not driven a-posteriori by the options that were chosen. Of course, strategies are dependent upon decisions made in the past, but a strategy that is adapted that way only takes effect in the next cycle (at time t+1) of making decisions on the other questions.

appropriate for a specific project, but should fit with the longer term strategy for these questions; and

(3) one company cannot answer the questions in isolation: answers that are formulated within an individual enterprise should fit with the way the Extended Enterprise (i.e., the collection of partnering companies) is conceived.

These three dimensions can be found in the FADEE framework we presented in [6, 7, 8] (see Figure 2).

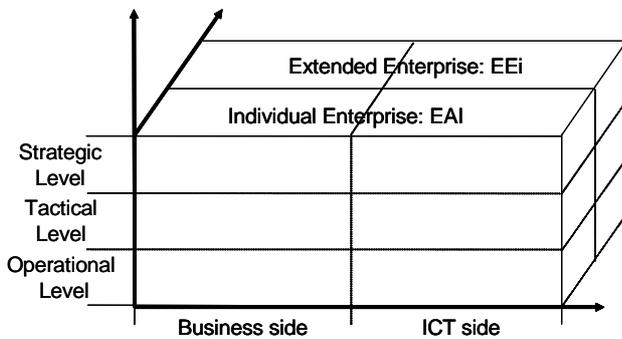

Figure 2: The three dimensions of the FADEE framework

At this point we do not want to deal in detail with the question how to bring the data-related questions into the FADEE. Rather, we give an example of the relevance of each of the dimensions.

(1) The concept of boundary objects is present at the business and at the ICT side. UBL, the Universal Business Language, for example is a standard for realizing B2Bi. As such, UBL defines seven business documents (such as ‘order’ and ‘invoice’), and gives accompanying XML-schema definitions. While the UBL schemas are meant to be exchanged between computer systems of different companies, the documents they represent should function as a boundary object between business people as well. Therefore, specifications have been developed for automatically rendering a classic visual of the content of the XML documents, for example as a .pdf document, meant for human usage.

(2) The fact that companies should have a strategy with respect to these questions can be shown with important issues such as replication. If the strategy of the Extended Enterprise is to leave data ownership in the hands of the original owners, data replication should be limited. In the case of the health care industry in the Netherlands for example it was stated that duplicating some of the information in the central hub could be good for performance reasons. However, duplicating the information would not have fitted the strategy, which states that the individual organizations who create the information should remain the owners of this information (also making it possible to hide information at some future point in time for example).

(3) The Extended Enterprise and the companies that are part of it should be aligned. If the Extended Enterprise believes that it should be possible for other companies to easily enter the network, an individual enterprise should not

try to forge its proprietary data formats upon the other parties. Standard data formats are then the way to go.

In fact, while the concepts presented above may seem very simple at the start they become more complex when looking at them in detail. For example, what is a needy and what is a sender? Is this an entire organization? A person? A department? An ICT system? In fact, the concepts needy and sender are not fully defined until one reveals about which cell of the FADEE framework he is talking. At the strategic level, one deals with entire organizations. At the ICT side one talks about systems, not people. Etcetera. Another example would be the concept of reciprocal dependencies. While there may be a reciprocal dependency between two companies, there may be no obvious reciprocal dependency between individuals of these companies (e.g., because the needy and senders from each company belong to different departments).

V. Conclusions

In this paper, we looked at the Extended Enterprise from a data-point-of-view. First, we organized data-related issues in the simple DA (Data Aspects)-framework. While space limitations made it impossible to deal with the six cells in detail, the paper gives a nice overview of the issues that should be dealt with if companies want to share information. A full account of the complexity of dealing with the issues is made when the issues are placed in the FADEE framework.

We believe that – for practitioners – the B2Bi exercise becomes more intelligible by structuring the problem domain in categories that fit with common sense. For researchers, the framework is interesting because it offers a structure to compare different cases and to investigate why some option was chosen in a specific case.

As we stated, this paper presents research-in-progress. Our future research will result in a more complete account of the DA framework. Also, we will broaden the discussion so as to draw up a TA-framework (similar to the DA framework) covering the Task Aspects. These TA issues will then be positioned together with the DA issues in the FADEE framework.

Biographies

Frank Goethals completed his Master studies in economics (option informatics), at the K.U.Leuven, Belgium, in 2001. He is presently researching for a PhD under the theme of 'Extended Enterprise Infrastructures'. This research is conducted at the K.U.Leuven under the guidance of

professor J. Vandenbulcke, and is financed by SAP Belgium. Frank has a strong interest in Web services technology and Enterprise Architecture, and is investigating how supply chain partners could integrate their systems efficiently and effectively

Jacques A. Vandenbulcke is professor at the Department of Applied Economic Sciences of the Catholic University of Leuven, Belgium. His main research interests are in Database management, Data modelling, and Business Information Systems. He is co-ordinator of the Leuven Institute for Research on Information Systems (LIRIS) and holder of the SAP-chair on 'Extended enterprise ICT-infrastructures'. He is president of 'Studiecentrum voor Automatische Informatieverwerking (SAI)', the largest society for computer professionals in Belgium, and co-founder and vice-president of the 'Production and Inventory Control Society (PICS)' in Belgium.

Wilfried Lemahieu holds a Ph. D. from the Department of Applied Economic Sciences of the Katholieke Universiteit Leuven, Belgium (1999). At present, he is associate professor at the Management Informatics research group of this department. His teaching includes Database Management, Data Storage Architectures and Management Informatics. His research interests comprise distributed object architectures and web services, object-relational and object-oriented database systems and hypermedia systems.

Monique Snoeck obtained her Ph.D. in May 1995 from The Department of Computer Science of the Katholieke Universiteit Leuven with a thesis that lays the formal foundations of the object-oriented business modelling method MERODE. Since then she has done further research in the area of formal methods for object-oriented conceptual modelling. She now is Associate Professor with the Management Information Systems Group of the Department of Applied Economic Sciences at the Katholieke Universiteit Leuven in Belgium. She has been involved in several industrial conceptual modelling projects. Her research interests are object oriented conceptual modelling, software architecture and software quality.

Designing And Implementing An Online WebGIS-Based Decision Support System

Lihua Zhao*, Hongwei Lu **, YouSheng Yu***

** School of Marketing, The University of New South Wales, Sydney, Australia,

*** Zhongbing Geo-Informatics Engineering Co. Ltd, Beijing, China

Abstract: This paper focuses on providing a market analysis solution through designing and implementing an online decision-support system (DSS) for businesses decision makers in Tobacco industry in China. The procedure makes use of data, information and software from Web based Geographical Information Systems (GIS) to generate online analysis, mapping and visualisation systems. These procedures are integrated and synchronised with market analysis techniques and customer relationship management (CRM) systems.

By integrating these two techniques, a webGIS-based tobacco market information system is presented to demonstrate the significance of WebGIS in market analysis field. Specifically, to meet the needs of market practitioners (retailer, distributor and industry authority) in understanding the current market and sales performance, the system is designed and mainly consisted of four functional components: Communication and administration, Current market analysis, CRM (Client Relationship Management) and Sales/customer analysis, and Operational issues. From the system design and system usage perspectives, the illustration on the system architecture and the process of marketing information transmission reveals the benefits raised from this E-commerce tool to both the system users and service provider in marketing analysis. Based on this, the fusion of technology enhancement and marketing strategy in business process are called for and discussed.

Keywords: Decision Support & Group Systems, WebGIS, Market Analysis.

I. Background and Current Development of WebGIS In E-commerce

I.1 E-commerce Role in Business and Marketing

So far, Internet is becoming a global common platform where organizations and business people communicate with each other to carry out various commercial actives and to provide vale-added services [4].

With the variety applications of e-commerce in business, Feeny [3] summarizes the role of e-commerce into three perspectives: E-operations, E-marketing and E-service (see Table 1). As he says, "For traditional bricks and- mortar companies, components of e-operations and e-marketing are likely to represent immediate opportunities with real economic benefits. The e-service strategy creates a strategic

intent that will influence the evolution of the other two strategies". He predicts that e-services will be the focus of firms' business strategies in the future and the source of great potential profit; according to him, "E-services represent the ultimate aspiration of the Information Age, with their electronic orchestration of offerings that span the breadth and lifespan of a customer/client's needs within a chosen and defined market space".

Table 1. The Role of E-commerce

E-opportunity	Component
E-Operations	<ul style="list-style-type: none"> • Automation of administration processes • Supply chain reconfiguration and integration • Re-engineering of primary infrastructure • Intensified competitive procurement • Increased parenting value
E-Marketing	<ul style="list-style-type: none"> • Enhanced selling process • Enhanced customer/client usage experience • Enhanced customer/client buying experience
E-Services	<ul style="list-style-type: none"> • Understanding of customer/client needs • Provision of customer/client service • Knowledge of all relevant providers • Negotiation of customer/client requirements • Construction of customer/client options

(Source: Feeny, 2001)[3]

Today, e-commerce provides ready access to a vast array of information resources and facilitates the gathering of valuable knowledge and competitive intelligence. As the network of Internet users expands, marketers are increasingly turning to the Web for market research information needed for decision making [2, 13], for example, market surveys, "virtual shopping" experiments for testing new product concepts, customer satisfaction measurements, etc.

Based on internet technology, more and more techniques from the other disciplined have been integrated for e-commerce activities, for example, data-mining techniques

have been applied to Web sites for providing timely trend analysis and customer/client profiling information that is valuable in making effective marketing- mix decisions [7]. Applying GIS technology in e-commerce is another example of providing market intelligence by focusing on spatial context.

I. 2 WebGIS-based E-commerce Application

A Geographical Information System (GIS) is a digital mapping and spatial analysis system capable of assembling, storing, manipulating and displaying geographically referenced information. It helps users understand spatial relationships, enhances decision-making and solves problems more quickly [5, 10]. A Web GIS platform provides a powerful online data process and display system. The swift development Marketing Information System (MIS) or Decision Support System (DSS) enables it now becoming an important part of business life [12]. The power of a WebGIS in business decision support areas could be its ability to manage spatial data from a number of sources, to display spatial data online dynamically, and provide spatial analysis modelling and decision support scenarios.

Specifically, GIS is capable of integrating retailers' internally-generated databases (eg. CRMs) with database produced by 'external' sources using spatial proximity, GIS helps to analyse and visualise these data effectively, therefore, enhance communication and provide knowledge to decision makers for their decision making. The use of WebGIS technology to enable or facilitate the delivery of information services online has the potential to benefit both the system users and service providers alike. These benefits could be seen from the above three perspectives in Table 1. Although the significance of GIS in business world has been identified by more and more researchers and practitioners in marketing [1, 6, 14], there is not enough attention has been drawn on the application of WebGIS on marketing research, especially, from both academic and managerial perspective to explore the significance of WebGIS application in marketing analysis perspective.

Based on this, the purpose of this paper is to explore the designing and implementing the hierarchical structures and the analytical process of this WebGIS based tobacco marketing analysis system, and then further elaborate benefits of such WebGIS based E-commerce system can be made to the business world. Considering the information needs from different users, firstly and broadly, the structure design of this WebGIS-based system is illustrated in Section 2. Then, the process of information transmission in using this online MIS is explored in Section 3. Specifically, the detailed information on the functionality of the system is demonstrated in Section 4. This leads to the discussion of the benefits fetched by this system and the consideration of the future research in Section 5.

II. The Architecture and Structure of WebGIS-Based Market Analysis System

II. 1 Tobacco Industry in China & Information Need

In China, over the last decade, tobacco has perennially been the largest contributor to China's tax coffers by industry [8]. In 2003 alone, tobacco taxes nationwide totaled approximately US \$29 billion [15]. The production, marketing, and distribution of tobacco have remained under the watchful control of China's State Tobacco Monopoly Bureau [8], by considering the tobacco risk-reduction to the public health (for instance the license control in each geographical area and different type of retailers/clients). Specifically, in this information era, the role of government authority in tobacco industry has been gradually transferred to a service provider in the industry to enhance the tobacco-control and improve the efficiency of tobacco distribution and marketing.

Considering the government authority as the service provider for this market analysis system, the key users will include the Tobacco industry clients (i.e. tobacco retailers, and distributors) and industry authority itself. As the system involves the users in different geographical areas, and different levels in the administration system, thus different information are needed by different system users, which is shown in Table 2.

Table 2. Information Needed by the Different Users

System user	Information needed
Retailer	<ul style="list-style-type: none"> • Current sales of tobaccos • Spatial distribution of sales within the local area • Market share • Brand sales • Sub-category sales • Sales change • Customer (group) behaviour • Market potential in each area
Distributor	<ul style="list-style-type: none"> • As the above • The performance of covered retailer • The change of performance of covered retailer • The network of local retailers distribution • The efficient way to keep inventory and deliver tobacco to the retailers.
Industry authority	<ul style="list-style-type: none"> • As above information within industry in the context of country/regional wide • The cost and efficiency of running tobacco business • The cost and efficiency of doing market analysis

As shown in table 2, this market analysis system should

be designed not only to help the clients of industry authority (retailers/distributor) understand the geographical distribution and the behaviour of customer (i.e. the individual end-user/consumer of tobacco), but also help industry authority auditing the sales, marketing and behaviour of its clients. Consequently the system will help to improve both industry economic efficiency and public health awareness, and protect the industry from international/national threats of smoking restrictions and supporting the industry position [11].

II. 2 The Structure Design of WebGIS-based Market Analysis System

The WebGIS-based market analysis system developed provides both users and decision-makers with a flexible, problem-solving online environment with a geographic foundation. From the perspectives of the industry authority/information provider and the clients, the accurate updated data is a common fundamental issue. In order to track the market trend and collect sales-related data on a regularly (daily) base, the whole system is designed into three interrelated layers: user layer, application layer, and service layer, which is shown in Figure 1.

In computing network design, user layer is described as a client, and the other two layers within the network, which are used to store the comprehensive databases and ran more complicated applications, are described as servers.

User layer

As it is shown in Figure 1, the main tasks of the system users (retail outlets or decision makers in different level) include:

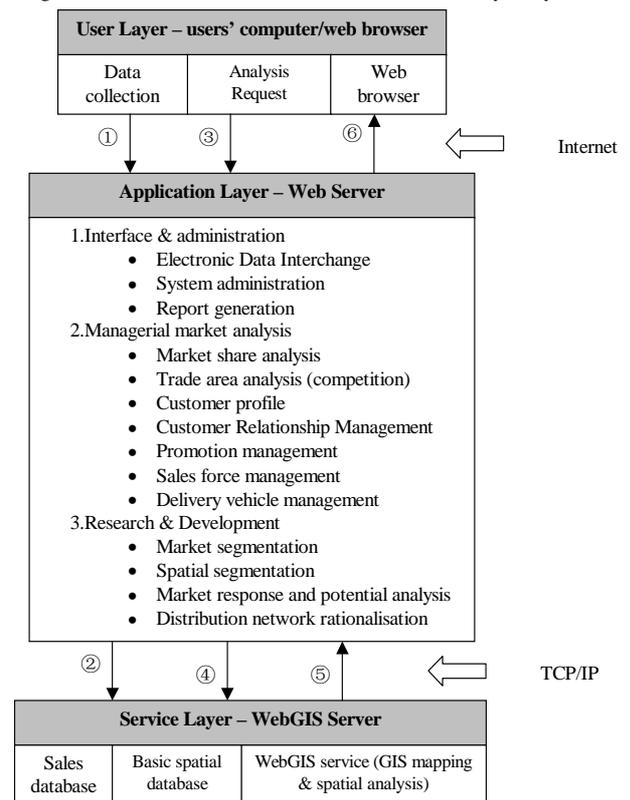

- 1) Data collection - to update their sales related data on a regular base.
- 2) Request sending - send the requests to the server about various market analyses for examining the current market performance, evaluating the market potential of a certain customer group or a target area.
- 3) Web browser - to receive and display the result of analysis from the server.

Considering the main duties of users are to provide the detail sales information, send request for the market analysis and receive the analysis results to/from a stand-alone server rather than running a comprehensive and sophisticated marketing analysis in a single computer. As the main duties at user level are simplified to the basic level, the requirements are minimised in terms of the hardware computing power and technical skill required to a user in data collection, marketing analysis and computer usage.

Application layer

To meet the variety needs from the different users, application layer is designed to provide a comprehensive marketing managerial and research analysis module.

Figure 1. The Structure of WebGIS-based Market Analysis System

(After: Lembo, 2004)

Internet is the connection link between the requests from client-side (user layer) and the result analysis provided from service-side (this application layer). The web interface & system administration tool links system user to various analytical and managerial analyses. This standardized interface and system administration tool facilitates the automation of administration processes, reduces the cost on learning and training the use of the system, and minimise expenses on maintaining and providing technical support of using the system.

As the major analysis and administration functions are pushed back, the requirement to the computing hardware, system design is quite high, since this is application-running station of interface & administration, managerial market analysis and research & development.

Service layer

The service layer consists of two key components: relational database system and WebGIS module. This relational database system stores and provides geo-referenced datasets requested by the applications in the application layer. The requested spatial analysis and geographical mapping tasks will be fulfilled by GIS module.

Specifically, relational database includes CRM (sales database) and the basic spatial database. Sales database will be updated on a regular base by the users of the system. And

basic spatial database is a pre-build database set, which contains all the relevant information about the whole study areas.

Within this relational database system, not only the comprehensive geo-referenced datasets are kept, but also, the spatial relationships among these geo-referenced datasets are stored and structured, therefore, geo-referenced information could be retrieved, aggregated, calculated based on the request from the users.

As this market analysis system is set on a spatial base, thus spatial analysis and geographical mapping will be requested by almost all the analysis. And the results of each analysis can be reported by geographical mapping. In addition, as GIS and spatial database need to work together closely, thus, this relational database system and GIS module are developed together. TCP/IP, a special language, is used to link this layer with the other (i.e. application layer)

III. The Information Process in WebGIS-Based Tobacco Market Analysis System

The above structure design provides efficient information flow, and generates useful market analysis knowledge and intelligence to be used by various users and decision makers.

Step ①: Data collecting, data entry, and data coding (E-operation)

Currently, aided by bar-code reader, the sales data on daily base could be captured and stored easily. For instance, roughly, there is 16 million sales of tobacco in Hainan province, i.e. 50 thousand sales in daily based records, which is shown in the sales scanner data records. Based on this imported scanner data, the system will automatically assort the data into pre-set standardized format for the next step analysis.

On a regular base, the users of the system within broad geographical areas update their sales data from their own computer. This update information is passed through Internet to the Web server. The electronic data interface (EDI) structures the updated information from the users in a broad geographical area in an identical format. This standardized and atomised E-operation in data entry and coding method will improve the efficiency of data collection, entry, and coding within whole industry/system.

Step ②: Sales data updating (E-operation)

Then this structured sales information is passed on to the central sales database via TCP/IP automatically.

Step ③: Analysis request sending (E-operation, E-service and E-marketing)

Based on different purposes, the analysis request is sent out from user to the web server (computer(s) in belonging to application layer). For instance, as a member of user group, user can request to update the user profile via *system administration* module.

The general marketing analysis tools can be requested by the users. As there are series inter-related analyses within web server, users can customize their request for their specific purpose and just pay for the use of their customized analysis. Consequently, reduce the cost of users and improve the efficiency of the system performance, since only the requested analyses are run on the system.

Based on result from general marketing analysis tools, the more sophisticated and specific researches can be conducted via the interactive communication between system user and this marketing analysis system. This research and strategy development module includes market and spatial segmentation, market response, retail network rationalisation and budget optimisation.

Within this application layer, it is noted the *CRM* and *delivery vehicle management* module are incorporated, thus, based on the result of customer profile, the target market will be revealed and determined. And the spatial differentiation in terms of demand can be identified. Accordingly, the promotion management can directly send out promotion letters/advertisement to the target market. And the *delivery vehicle management* can automatically coordinate the distribution schedule based on the principle of minimizing the total distribution cost by considering both the travel path distance, traffic flow and the labour cost etc. Thus, in this layer, all the functions of E-commerce, which are listed in Table 1, could be found in this system, i.e. E-operation, E-marketing and E-services.

Step ④ data communicating and result generation request

Because, the sales database and relevant spatial database are requested and incorporated during these analysis and exploration processes, the data communication occurs all the time. And at the end of analysis and exploration, the result generation request is always sent out to WebGIS server for a more vivid analytical output.

Step ⑤ GIS mapping & output exporting

Within this WebGIS server, firstly, sales database is updated and geocoded as a routine updating process. Then, the sales database will be incorporated into the Basic spatial database for spatial analysis and mapping. The detailed trading area market analysis could be found in Appendix A. The significant features of GIS module could be found not only in market share analysis, spatial segmentation, but also in distribution network rationalisation. At the end of these analyses, geographical maps will be created *within* WebGIS server. Then these maps (only the image itself) will be exported application layer, i.e. Web server.

Step ⑥ result browsing

The output image exported from WebGIS server will be packaged into a customized format in Application Layer according to the request from user and *System*

administration tools. Eventually, this formulated output will be displayed by the Internet browser in user's side.

IV. The Functional Components of the WebGIS-Based Marketing Analysis System

To meet the requirement of different users in understanding current market performance, customer behaviour, and working out the solution for daily business practice (e.g. tobacco delivery). This WebGIS-based marketing analysis system is consisted of four major functional components (shown in Table 3): A) Communication and administration, B) Current market analysis, C) CRM and Sales/customer analysis, D) Operation & Decision Support Issues.

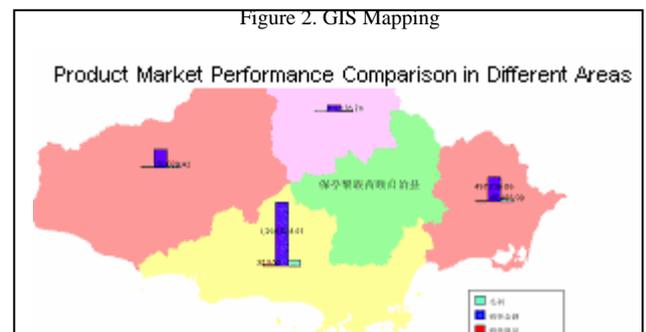

A. Communication & administration

In this module, administration means the market information is periodically collected from the retail outlets, and provides system management mechanism as well. For example, as the users of system, they are authorised to logon the system to acquire the marketing information they need. However, by categorizing the user into different groups and allowing them to access information they want at different content levels, Thus, not only this mechanism can reduce the cost of system user, but also improve the speed of whole system operation. 'Information user group management' function can easily match customer identity with the customized information will be offered.

With this WebGIS-based system, not only the system could incorporate and integrate the data from different sources by GIS Database functions, but also geographical mapping improve the communication efficiency and effectiveness by putting the intensive marketing information into easy to understand map format. With maps, the enormous and complicated marketing analysis and spatial modelling results can be vividly presented, the presentation can help system users and/or decision-makers easily link or integrate their considerable influencing factors (eg, experiences, consciousness) and the complicated analysis results together. Thus, maps have the potential to integrate the human intelligence with the Internet-based powerful computing capacity to achieve the communication and analysis efficiency and effectiveness. For instance, in Figure 2, while the colour base map shows the level of total sales in each area, the three bar chart figure in each area indicated the level of detail sales performance, i.e. sales profit, total quantity sales, total sales amount. This map output can help users/decision makers to understand sales performance in different regions by simply glancing.

Table 3. Functional component of the WebGIS-based MIS

Functional module	Function -classification
A. Administration & Communication	<ul style="list-style-type: none"> • System administration • System tool • Information user group management • Information management • Information collection and assortment • Internal management
B. Current market analysis	<ul style="list-style-type: none"> • Total sales • By the class of quality • By sub-category • By produce origin • By functional specification • By brand • Sales spatial distribution pattern
C. CRM & Sales/customer analysis	<ul style="list-style-type: none"> • CRM • Performance analysis • Customer value evaluation • Customer audit system
D. Operational / Decision support issues	<ul style="list-style-type: none"> • Logistic management • Area-based optimisation • retail outlet rationalization

B. Current market analysis

As the intensive marketing information is organised in GIS-based relational database, thus, a variety combination of marketing analysis can be offered by the system to meet the needs of different users under the different conditions, which is shown in Table 3.

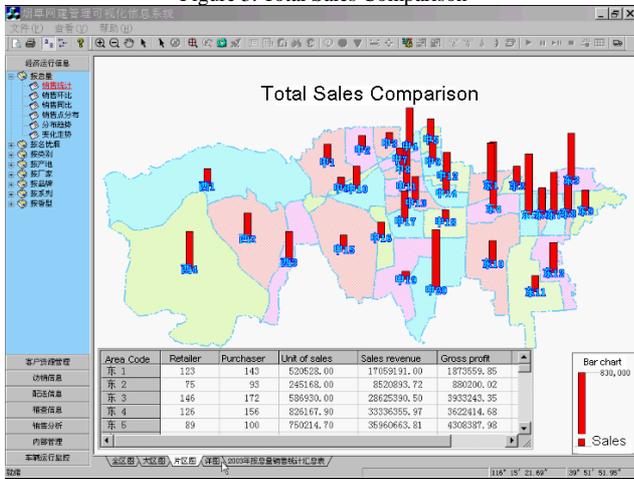

By compacting and integrating the various market analysis and knowledge discovery module on customer study, market segmentation, spatial segmentation, 'if-then' multi-criteria scenario exercise, and optimisation/operation research into the analytical system, it could provide the chance of mass-customisation, i.e. the user can select and pay for the analysis based on their needs and preference. Also, it is noted, this standardized managerial market analysis and research & development module not only can provide the valuable information on current sales pattern, demand distribution, market pattern in a standard format within various time and spatial context, but also it could

improve the comparability of sales and market in different places and time frames. In addition, this standardized analytical module makes it easier and cheaper to update the entire analytical system and functions without big changes in user-side. Consequently, reduce the overall cost of market analysis within the whole user group or industry.

C. CRM & Sales/customer analysis

This GIS-based CRM system can go beyond the functionality provided by general CRM system, i.e. the performance, value and preference of each customer. In addition, the CRM system links customer with geography. Thus, the system user could get additional information of the spatial distribution and spatial location of the high value/potential areas/clients and the comparison of the market performance could be revealed, which is shown in Figure 3.

Figure 3. Total Sales Comparison

Not only the sales statistics across a broad geographical area could be displayed in a single map, but also the performance of each individual retail outlet could be linked and examined, which is shown in Figure 4. This can facilitate the target market planning in the organization.

Figure 4. Link to Individual Retail Outlet

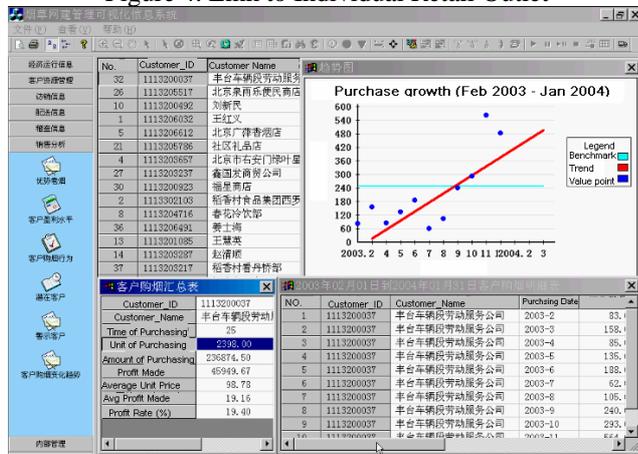

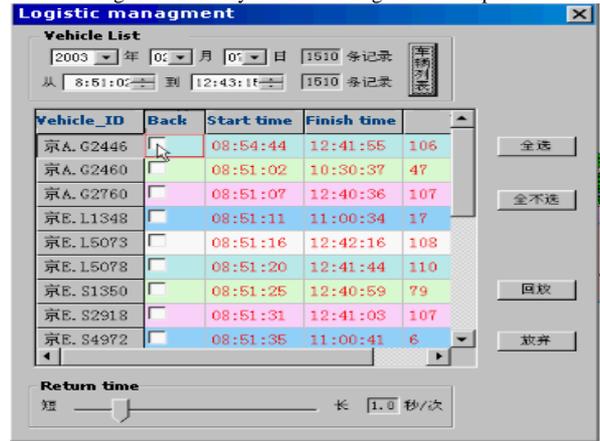

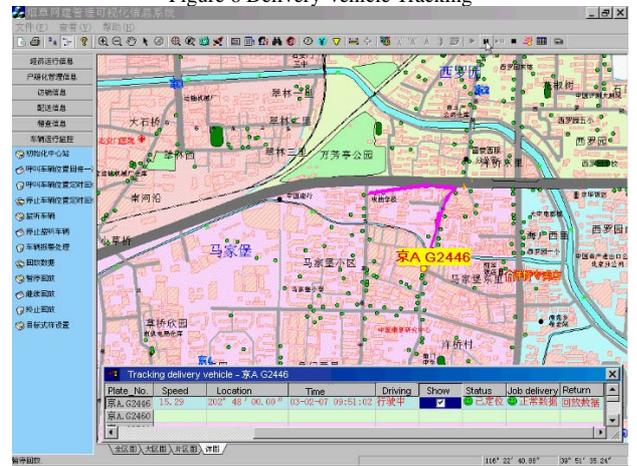

Figure 5 Delivery Vehicle Management Component

D. Operation and Decision Support Issues

Different from the general MIS, this GIS-based DSS provide a special facility in spatial analysis. Thus, it enables the decision-makers conduct the operational planning on *delivery vehicle management, area-based optimisation, and retail outlet rationalization*. For example, based on spatial analysis results, that is shown in Figure 5, the real-time delivery vehicle tracking function provides decision makers a practical tool to coordinate the members in the distribution channel, accordingly, improve the delivery efficiency by incorporating the local traffic information, which is shown in Figure 6.

Figure 6 Delivery Vehicle Tracking

As it is mentioned above, to meet the needs of the system users in different levels, the Internet-based technology provides significant advantages. These advantages could be perceived clearly by examining on the architectures of this WebGIS-based DSS.

V. Discussion

V. 1 Benefits Raised from WebGIS-Based System Design

By fulfilling the role of E-commerce (E-operating, E-marketing and E-service), which is shown in the above illustration, it is shown that this WebGIS-based tobacco market analysis system can help in improving the market analysis functionality, reducing the cost, enhancing the operational efficiency, and increasing the adaptability of the system:

1) *Improving the functionality*, as it is shown above, by developing the applications into a few different modules, more functionalities are provided, thus it could match the different demand of marketing analysis. Within this open system (to every user in a broad geography areas, and decision-makers in different levels and departments), the horizontal and vertical integration of available datasets make the prediction accuracy improved. Thus, the marketing analysis and exploration will be conducted based on longitudinal data rather than cross-section data, and a spatial continuous area rather than limited spatial points. In addition, not only the sales-related dataset is incorporated, but also, the geo-referenced data is intensively used. Accordingly, the information provided by this system represents the spatial-temporal dynamics, i.e. close to the spatial reality, which lead to more accurate result for market analysis. More importantly, the system is available online and maintains an open and fair market place to member in this industry. In addition, as the GIS-based exploratory researching modules are incorporated, the multi-criteria based 'if-then' scenario exercise will help the users simulate the spatial reality. These will contribute the improvement on the quality of marketing analysis and prediction.

2) *Reducing the cost*, by modelling the process and analytical modules into a hierarchy structure, linking the computers and analysis together via Internet, this system reduces the workload on each single computer. This structured design reduces the technical and skill requirements on user side and it makes the marketing practitioners feel easier with market spatial analysis. Also, as the users only pay for the customized services (analysis) and need not to run it on their machines, thus it reduces the cost for the users. In addition, the standardised and automated process of data collection, transaction and analysis extremely reduce the cost and effort put in by comparing the conventional approaches. From the users' perspective, the customized functions and analyses provide the chance to minimum their budget on the service.

3) *Enhancing the operational efficiency*: The analytical system interoperation and working efficiency for administrating and communicating are improved by a series of standardized and automated process and approaches. By organising the marketing analysis into different modules, it facilitates the users to choose and customized the modules they want and the order to do the analysis. Thus, in one hand this flexibility will lead to the budget saving, on the other hand, this flexibility could increase the customer participation and remove the customer resistance to adopt the service. By pushing the analysis layer and database layer backwards, it standardises the content format and database

manipulation process and market analysis. Thus, this structure makes it easier to transform the whole system into the new operating system, database management system and networking structure, i.e. improving the compatibility.

4) *Improving relationship* between the system users (decision-makers in different levels) and *the adaptability*, by working under online open environment, the sales-related figures and analyses could be updated automatically in the same format and/or under the request of the users, this will reduce and remove the suspicion and misunderstanding, increase trust. As the analytical module is removed from user layer, it reduced the knowledge and skill requirement level of using the specific software and makes the marketing analysis job easier. And the visualization of GIS increase the level of interesting and reduce the complexity.

V. 2 Future – the fusion of marketing practice and technology transformation

1) *Technology → service: WebGIS, Customer-based decision support system & service*

WebGIS can help integrate the spatial information and bridge human analytical skills with their machine-processability. As it is shown above, the architecture of WebGIS-based DSS provides the possibility to solve the technique-oriented problems, i.e. the appropriate GIS services (both spatial information and analysis) could be requested from and delivered to the users who have different GIS skills to match their needs.

Currently, Internet accelerates the integration of information in both horizontal (spatial) and vertical (temporal) dimensions. The extensive information extends decision-makers' scope in one hand, in the other hand the overload and under-utilized data confuse and frustrate decision-makers' motivation and interest. However, the mechanism of WebGIS provides customized decision support system based the client-server structure, 'if-then' scenario spatial analysis and vividly computer mapping. Thus, it (WebGIS) turns this desktop-based software or system (i.e. GIS) into a Web-based service. During this process, the emerging/new role of marketing could be seen. Therefore, in this field (WebGIS in marketing), the critical thing goes beyond the functionality of WebGIS could provide. Also, when, what and how to provide these information/solution to the decision-makers in different level become the other important thing. And this directly relates to the marketing strategy on subscription of system usage.

2) *Service → technology: The role of service provider and its marketing strategy*

When market analysis is taken as a service, the standardization of spatial data used, the system tool for spatial analysis in an open GIS environment is requested. As the standardization can significantly improve the inter-operationality, it will improve the efficiency from the whole system perspective. As WebGIS is turning this market analysis system into a service, then the concept of

coordination in terms of the relationship within client-server and the net of computers will become a critical issue. Then from a technology perspective, if the client-side strategy should be adopted or the server-side strategy should be adopted will become the other issue in this field. With client-side strategy, the enhancement in client-side infrastructure will be improvement, thus it can speed up data manipulation and the interaction between user and system. However, the requirement of the users' computing/GIS skill will be very high. On the other side, if the server-side strategy is adopted, the requirement of users' skill will be reduced, while the requirement of the server-side will be highlighted.

In sum, the swift development of information technology (e.g. Internet) has bought the revolution in marketing; on the contrary, the shift of marketing's role in the new technology environment accelerates the evolution of information technology. From both technology and marketing perspective, how can we utilize the available techniques, resource and marketing strategies to improve the business practice is becoming a hot topic in both academic and practice field.

Abstract: Data warehouses contain data consolidated from several operational databases and provide the historical, and summarized data which is more appropriate for analysis than detail, individual records. Fast response time is essential for on-line decision support. A bitmap index could reach this goal in read-mostly environments. For the data with high cardinality in data warehouses, a bitmap index consists of a lot of bitmap vectors, and the size of the bitmap index could be much larger than the capacity of the disk. The WAH strategy has been presented to solve the storage overhead. However, when the bit density and clustering factor of 1's increase, the bit strings of the WAH strategy become less compressible. Therefore, in this paper, we propose the FZ strategy which compresses each bitmap vector to reduce the size of the storage space and provide efficient bitwise operations without decompressing these bitmap vectors. From our performance simulation, the FZ strategy could reduce the storage space more than the WAH strategy.

Keywords: bitmap index, compress, data warehouse, OLAP, storage.

I. Introduction

The *Data Warehouse* (DW) is a subject-oriented, integrated, time-variant, and non-volatile collection of data in support of management's decision-making process. In other words, a DW is large, special-purpose database that contains data integrated from a number of independent sources, supporting clients who wish to analyze the data for trends and anomalies. The process of analysis is usually performed with queries that aggregate, filter, and group the data in a variety of ways. OLAP is designed to provide aggregate information that can be used to analyze the contents of databases and data warehouses. Because the queries are often complex and the warehouse database is often very large, processing the queries quickly is a critical issue in the warehousing environment.

The read-mostly environment of data warehousing makes it possible to use more complex indexes to speed up queries than in situations where concurrent updates are present [19]. Bitmap indexing has been touted as a promising strategy for processing complex adhoc queries in read-mostly environments, like those of decision support

systems. Most of the major commercial database systems now support some form of a bitmap index. A significant advantage of bitmap indices is that complex logical selection operations can be performed very quickly, by performing bitwise AND, OR, and NOT operations.

Data warehouses are essential for modern business to support the decision making. For various applications in data warehouses, where most of the attributes have high cardinality, the classical bitmap index produces one bitmap for each distinct value of the attribute being indexed [4] [5] [6] [8] [11] [13] [14] [15] [16] [17] [18] [19]. The size of the indices could be much larger than the size of the dataset. The main advantage for using a compressed bitmap index is to reduce the space requirement. However, the bitmaps from the bitmap indices are often very sparse; that is, they contain mostly zero bits. Moreover, most of the generic compression algorithms do not support fast bitwise logical operations, the compressed bitmap indices are usually slower in processing queries than their uncompressed counterparts. To increase the efficiency of query processing, a number of specialized compression algorithms have been developed [1][7][12][17][18][21][22]. The Byte-aligned Bitmap Code (BBC) is an example of such a strategy [1]. This strategy permits efficient operations without decompression, thereby reducing both the disk space requirement and the memory requirement for performing operations. Another specialized compression strategy called the Word-Aligned Hybrid run-length code (WAH) [21] is an efficient strategy that significantly outperforms BBC.

The WAH strategy [21] has been presented to solve the storage overhead. The main advantage of the WAH strategy is that compressed indexes are much smaller than the uncompressed ones and the average processing time is about the same [22]. However, when the bit density and clustering factor of 1's increase, the bit strings of the WAH strategy become less compressible. Therefore, we propose the Filtering-Out-Zeros (FZ) strategy to compress each bitmap vector to reduce the size of the storage space. The basic idea of the FZ strategy is to remove some continuous 0's in the bitmap vector, since there often exist large amount of 0's in the bitmap vector. For the bitmap vector with 128 bits (as shown in Figure 1-(a)), after compression, our FZ strategy stores only 40 bits (as shown in Figure 1-(b)), as compared to 96 bits in WAH strategy (as shown in Figure 1-(c)), where the length of the basic unit for compressing in FZ strategy is eight bits and that in WAH strategy is a word (= 32 bits).

run-length encoding and the literal strategy. There are two types of words in WAH: *literal* words and *fill* words. WAH uses the most significant bit of a word to distinguish between a literal word (0) and a fill word (1). This choice allows one to easily distinguish a literal word from a fill word without explicitly extracting the bit. The lower bits of a literal word contain the bit values from the bitmap. The second most significant bit of a fill word is the fill bit and the lower bits store the fill length. WAH imposes the word-alignment requirement on the fills, it requires that all fill lengths be integer multiples of the number of bits in a literal word. The word-alignment ensures that logical operation functions only need to access words not bytes or bits.

Figure 3 shows a WAH bit vector representing 128 bits. In this example, each computer word contains 32 bits. Each literal word stores 31 bits from the bitmap and each fill word represents a fill with a multiple of 31 bits. If the machine has 64-bit words, each literal word would store 63 bits from the bitmap and each fill would have a multiple of 63 bits. The second line in Figure 3 shows how the bitmap is divided into 31-bit groups and the third line shows the hexadecimal representation of the groups. The last line shows the values of the WAH words. The first three words are normal words, two literal words and one fill word. The fill word 80000002 indicates a 0-fill of two-word long (containing 62 consecutive zero bits). Note that the fill word stores the fill length as two rather than 62. In other word, we represent the fill length by multiples of the literal word size. The fourth word is the active word that store the last few bits that can not be stored in a normal word, and another word (not shown) is needed to stores the number of useful bits in the active word. Each WAH word (last row) represents a multiple of 31 bits from the bit sequence, except the last word that represents the four leftover bits.

128 bits	1, 20*0, 3*1, 79*0, 25*1			
31-bit groups	1, 20*0, 3*1, 7*0	62 * 0	10 *0, 21 *1	4 *1
Group in hex	40000380	00000000	00000000	001FFFFF 0000000F
WAH (hex)	40000380	80000002	001FFFFF	0000000F

Figure 3: A WAH bitmap vector

III. The Filtering-Out-Zeros (FZ) Strategy

A bitmap index consists of a set of bitmap vectors and the size of the bitmap index could be much larger than that of the disk. This is especially true for scientific databases where most of the attributes have high cardinality. The WAH strategy [21] has been presented to solve the storage overhead. The main advantage of the WAH strategy is that compressed indexes are much smaller than the uncompressed ones and the average processing time is about the same [22]. However, when the bit density and clustering factor of 1's increase, the bit strings of the WAH strategy become less compressible. Take Table 1 as an example, we observe an interesting property that there are magnificent continuous zeros in the bitmap index. If we can filter out the

consecutive 0's and only record the rest of bits, the storage space of the bitmap index could be reduced.

Table 1: An example of the range-based bitmap index

raw data	14, 16, 10, 17, 9, 16, 10, 12, 15, 21, 22, 12, 19, 15, 14, 19
$Range < 12$ Bitmap Vector 1	0 0 1 0 1 0 1 0 0 0 0 0 0 0 0 0
$12 \leq Range < 15$ Bitmap Vector 2	1 0 0 0 0 0 0 1 0 0 0 1 0 0 1 0
$15 \leq Range < 18$ Bitmap Vector 3	0 1 0 1 0 1 0 0 1 0 0 0 0 1 0 0
$18 \leq Range$ Bitmap Vector 4	0 0 0 0 0 0 0 0 0 1 1 0 1 0 0 1

To reduce the storage space of the bitmap index, we present the Filtering-out-Zeros (FZ) strategy. We take bitmap vector 4 in Table 1 as an example to illustrate the FZ strategy. First, we divide the total 16 bits into 2 bit strings, i.e., [00000000 01101001], and the length of each bit string is 8. Next, the first bit string includes only consecutive 0's, and the second one includes 1's. Therefore, we record the first bit string by 0, and the second one by 1, i.e., the first two bits in [01 01101001]. We still record the whole bits of the second bit string, [01101001], i.e., the last eight bits in [01 01101001]. Finally, the original bitmap vector 4 [00000000 01101001] has been stored as [01 01101001] after the process of the FZ strategy. In this example, the FZ strategy reduces the storage cost from 16 bits to 10 bits.

Let's take another example shown in Table 2 to describe the FZ procedure in Figure 4. The variables used in the FZ strategy is shown in Table 3. In Table 2, the bitmap vector of raw data contains 48 bits, and every 8 bits among these 48 bits construct a bit string. Therefore, there are $w=n/BL=48/8=6$ bit strings, where n is the number of the bits in each bitmap vector and BL is the length of the bit string. We use an array $NZflag$ to record whether the bit string includes only consecutive 0's or not. The first, third, and 4th bit strings include only consecutive 0's in this example, and the first, third, and 4th bits of array $NZflag$ are set to 0. The rest of bits of array $NZflag$ are set to 1. The array $NZflag$ is [010011] as shown in Table 2. According to $NZflag$, we know which bit string includes some 1's. Then, we use another array $NZString$ to record the whole bits of the bit strings that include 1's. In Table 2, array $NZString$ records 3 bit strings that are composed of 0's and 1's.

Table 2: An example of the FZ strategy

raw data	00000000 10000000 00000000 00000000 11110000 10101000
NZflag	010011
NZString	10000000 11110000 10101000

```

Procedure FZ(n, BL);
begin
  w :=  $\lceil n/BL \rceil$ ;
  let n bits be [a1, ..., an];
  set the non-zero-flag array NZflag to zero;
  for i := 1 to n do
    begin
      if (ai = 1) then
        begin
          j :=  $\lceil i/BL \rceil$ ;
          NZflag[j] := 1;
          put the jth part into the non-zero-string
          NZString;
          i := BL * j;
        end;
      end;
    end;
  end;

```

Figure 4: The *FZ* procedureTable 3: Variables used in the *FZ*, *FZ_Retrieve*, *FZ_AND*, and *FZ_OR* procedures

Variable	Description
<i>n</i>	The number of records
<i>BL</i>	The length of each bit string
<i>w</i>	The number of bit strings
<i>NZflag</i>	The array that records whether the bit string includes only consecutive 0's or not
<i>NZString</i>	The array that records the whole bits when the bit string includes 1's
<i>a</i> _{<i>i</i>}	The <i>i</i> th bit of a bitmap vector
<i>temp</i>	The array that records the bit string
<i>finalNZflag</i>	The array that records the result of <i>NZflag</i>
<i>finalNZString</i>	The array that records the result of <i>NZString</i>

```

Procedure FZ_Retrieve(n, BL, NZflag, NZString);
begin
  for i := 1 to  $\lceil n/BL \rceil$  do
    begin
      j := 0;
      if (NZflag[i] = 1) then
        begin
          j := j + 1;
          for k :=  $8 * (j - 1)$  to  $(8 * j - 1)$  do
            begin
              if (NZString[k] = 1) then
                retrieve the  $(8 * (i - 1) + k)$ th data
                of records;
              end;
            end;
          end;
        end;
    end;
  end;

```

Figure 5: The *FZ_Retrieve* procedureTable 4: An example of the *FZ_Retrieve* strategy

raw data	00000001 00000000 00001000
	00000000 00000000 10100000
NZflag	101001
NZString	00000001 00001000 10100000

Figure 5 states how to retrieve data from the compressed bitmap index. For example, shown in Table 4, there are 4 1's in the bitmap vector of raw data. After the process of the *FZ* strategy, the resulting arrays, *NZflag* and *NZString*, are shown in Table 4. Array *NZString* records those 4 1's. We use the array *NZflag* to calculate the position of 1's. The formula is $8*(i-1)+k$, where *i* is the position of the *i*th bit string that contains 1's, and *k* is the *k*th 1's in this bit string. Therefore, the positions of the 4 bits are 8 ($=0*8+8$), 21 ($=2*8+5$), 41 ($=5*8+1$), and 43 ($=5*8+3$), respectively. According to the calculation, we directly retrieve the 8th, 21th, 41th, and 43th records, respectively.

A significant advantage of bitmap indices is that complex bitwise operations can be performed very quickly, such as bitwise AND, OR, and NOT operations. Therefore, we explain the bitwise operations, including *FZ_Retrieve*, *FZ_AND*, and *FZ_OR*, on bitmap vectors which are stored after the process of the *FZ* strategy.

Figure 6 illustrates how to perform an *FZ_AND* operation on those two compressed bitmap vectors. The variables used in *FZ_AND* operation are shown in Table 3, and the *FZ_AND* procedure is shown in

Figure 7. The bitmap vector in Table 2 is recorded by *NZflag1* and *NZString1*, and the bit vector in Table 4 is recorded by *NZflag2* and *NZString2*. First, we get the *finalNZflag*=[000001] by *NZflag1*=[010011] AND *NZflag2*=[101001], as shown in the left part of Figure 6-(a). Next, according to the position of 1's in *finalNZflag*, we retrieve the corresponding bit strings *temp1* and *temp2* in *NZString1* and *NZString2*, respectively, and add *temp3* into *finalNZString*, where *temp3* = *temp1* AND *temp2*. Since the 6th bit of *finalNZflag* in Figure 6-(a) is 1, we retrieve the bit string related to the 6th bit in *NZString1* from *NZString1*, [10101000], to *temp1*, and that in *NZString2* from *NZString2*, [10100000], to *temp2*, as shown in Figure 6-(b). After getting *temp1* and *temp2*, we perform an AND operation on them, i.e., *temp3* = [10101000] AND [10100000] = [10100000], as shown in Figure 6-(c), and add the bit string [10100000] into *finalNZString*, as shown in Figure 6-(d). After the process of the *FZ_AND* operation, we have *finalNZString* equal to [10100000], as shown in Figure 6-(d).

This strategy provides efficient bitwise operations without decompression, which reduces both the requirement of the disk space and the memory space for performing bitwise operations. In this example, we perform 4 ($=6+8$) bitwise AND operations on them, where *finalNZflag* includes 6 bits, and *finalNZString* includes 8 bits. If we do not use the compressed bitmap vectors, we need to retrieve

$48 * 2 = 96$ bits and perform 48 bitwise AND operations.

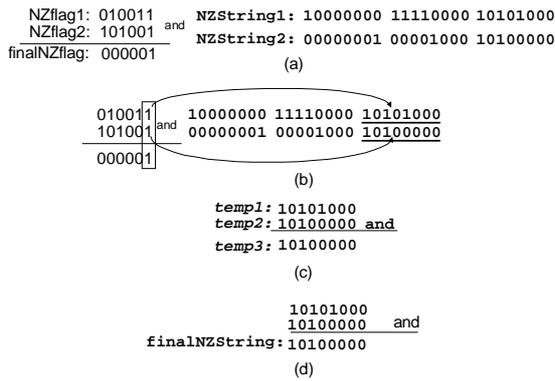

Figure 6: A bitwise FZ_AND operation on two compressed bitmap vectors by the FZ strategy: (a) the result of *finalNZflag*; (b) the bit string related to the bit in *NZString1* and *NZString2* from *NZflag1* and *NZflag2*; (c) *temp3* = *temp1* AND *temp2*; (d) the result of *finalNZString*.

```

Procedure FZ_AND(n,BL);
begin
  finalNZflag := NZflag1 AND NZflag2;
  w := ⌈n/BL⌉;
  for i := 1 to w do
    begin
      if (NZflag1[i] = 1) then j := j + 1;
      if (NZflag2[i] = 1) then k := k + 1;
      if (finalNZflag[i] = 1) then
        begin
          for p := BL * (j - 1) to (BL * j - 1) do
            add NZString1[p] into temp1;
          for q := BL * (k - 1) to (BL * k - 1) do
            add NZString2[q] into temp2;
          end;
          temp3 := temp1 AND temp2;
          add temp3 into finalNZString;
        end;
    end;
end;
  
```

Figure 7: The FZ_AND procedure

Figure 8 illustrates how to perform a bitwise FZ_OR operation on those two bitmap vectors. We take the same two bitmap vectors, as shown in Figure 6, to perform the FZ_OR operation. The variables used in the FZ_OR operation are shown in Table 3, and the FZ_OR procedure is shown in Figure 9. First, we get *finalNZflag*=[111011] by *NZflag1*=[010011] OR *NZflag2*=[101001], as shown in the left part of Figure 8-(a). Next, according to the position of 1's in *finalNZflag*, the first, second, third, 5th, and 6th bits, we retrieve the corresponding bit strings. There are three cases according to *NZflag1* and *NZflag2*. In Case 1, the first bit of *NZflag1* is 0 and the first bit of *NZflag2* is 1. We retrieve the bit string [00000001] related to the first bit in *NZString2* from *NZString2*, as shown in Figure 8-(b), and add the bit string into *finalNZString*, as shown in the first 8-bit string of Figure 8-(f). In Case 2, the second bit of *NZflag1* is 1 and the second bit of *NZflag2* is 0. In this case, we retrieve the bit string [10000000] related to the second bit in *NZString1* from *NZString1*, as shown in Figure 8-(b), and add the bit string into *finalNZString*, as shown in the second 8-bit string of Figure 8-(f). In Case 3, the sixth bit of *NZflag1* is 1 and the sixth bit of *NZflag2* is also 1, we retrieve the bit string

temp1 (= [10101000]) related to the bit in *NZflag1* from *NZString1*, and the bit string *temp2* (= [10100000]) related to the bit in *NZflag2* from *NZString2*, as shown in Figure 8-(d). We finally add *temp3* into *finalNZString*, where *temp3* = *temp1* OR *temp2*, as shown in Figure 8-(e). After eight iterations, the result *finalNZString* is shown in Figure 8-(f).

In this example, we retrieve $6 * 8 = 48$ bits, and perform 14 ($= 6 + 8$) bitwise OR operations, where *finalNZflag* includes 6 bits, and *finalNZString* includes 8 bits in Case 3. If we do not use the compressed bitmap vectors, we need to retrieve $48 * 2 = 96$ bits, and perform 48 bitwise OR operations.

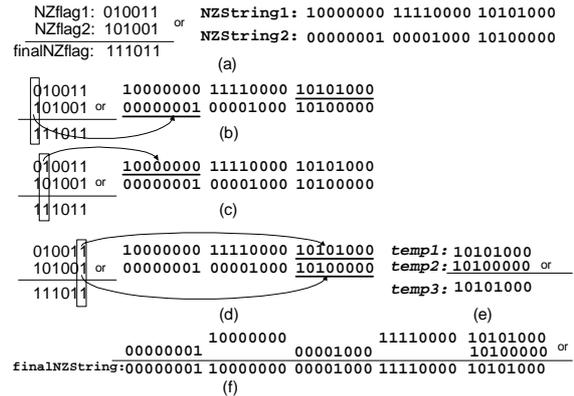

Figure 8: A bitwise FZ_OR operation on two compressed bitmap vectors by the FZ strategy: (a) the result of *finalNZflag*; (b) the bit string in Case 1 is retrieved; (c) the bit string in Case 2 is retrieved; (d) the bit strings in Case 3 are retrieved; (e) *temp3* = *temp1* OR *temp2*; (f) the result of *finalNZString*.

```

Procedure FZ_OR(n,BL);
begin
  finalNZflag := NZflag1 OR NZflag2;
  w := ⌈n/BL⌉;
  for i := 1 to w do
    begin
      if (NZflag1[i] = 1) then j := j + 1;
      if (NZflag2[i] = 1) then k := k + 1;
      /* Case 1 */
      if (NZflag1[i] = 0 and NZflag2[i] = 1)
        then
          begin
            for q :=  $8 * (k - 1)$  to ( $8 * k - 1$ ) do
              add NZString2[q] into finalNZString;
            end;
          /* Case 2 */
          if (NZflag1[i] = 1 and NZflag2[i] = 0)
            then
              begin
                for p :=  $8 * (j - 1)$  to ( $8 * j - 1$ ) do
                  add NZString1[p] into finalNZString;
                end;
              /* Case 3 */
              if (NZflag1[i] = 1 and NZflag2[i] = 1)
                then
                  begin
                    for p :=  $8 * (j - 1)$  to ( $8 * j - 1$ ) do
                      add NZString1[p] into temp1;
                    for q :=  $8 * (k - 1)$  to ( $8 * k - 1$ ) do
                      add NZString2[q] into temp2;
                    temp3 := temp1 OR temp2;
                    add temp3 into finalNZString;
                  end;
                end;
              end;
            end;
          end;
    end;
end;
  
```

Figure 9: The FZ_OR procedure

IV. Performance Study

The parameters used in the performance model for the FZ strategy is shown in Table 5. Basically, we generated num bits, 1's or 0's, as the bitmap vector and this bit string is controlled by two parameters, the bit density and the clustering factor [21]. The performance measure in evaluating those strategies is the length, Len , of the bit sting after it is compressed. We plotted the average length of each bit string from experiments, and conducted 1000 experiments for each average value. The experiments were run on a Pentium 4 1.6 GHz, 256 MB of main memory, and running jdk 1.4.2 and Windows XP.

For the simulation results, the number of bit string, num , is bounded by 20000. In the figures to be presented as follows, the curves corresponding to the WAH and FZ strategies by changing different parameters are labeled as WAH and FZ, respectively. In Figure 10, Figure 11, and Figure 12, we compare the length of the bit string after it is compressed.

Table 5: Parameters used in the WAH and FZ strategies

Parameter	Description
num	The number of bits in the bit string
d	The fraction of bits of 1's
cf	The upper bound of the range of 1's

Figure 10 shows the length of bit strings for different $num=10000, 12000, 14000, 16000, 18000, 20000$. Each data point in this figure represents the average length of bitmap vectors with the same bit density ($= 0.01$) and the same clustering factor ($=1$). The resulting lengths constructed from both the WAH and FZ strategies increase when num increases. However, the length of the bit string compressed by the WAH strategy is 2 times larger than that compressed by the FZ strategy.

Figure 11 shows the length of bit strings for different values of density $d=1/500, 1/200, 1/100, 1/50, 1/20$, where $num=10000$ and $cf=1$. As the bit density increases form $1/500$ to $1/20$, the bit strings become less compressible and it takes more space to represent them after the compression. Moreover, the FZ strategy is more suitable for the case with the high density.

Figure 12 shows the length of bit strings for different clustering factors $cf=0.2, 0.4, 0.6, 0.8, 1$, where $num=10000$ and $d = 0.01$. The clustering factor, cf , is the fraction of the upper bound of the range of 1's. For example, when $cf=0.2$, the bits of 1's only exist from the first to 2000^{th} bits in the bit string with 10000 bits. In other words, the bits of 1's are highly concentrated. As cf increases from 0.2 to 1, the bit string of the WAH strategy becomes less compressible and that of the FZ strategy still could be compressed well.

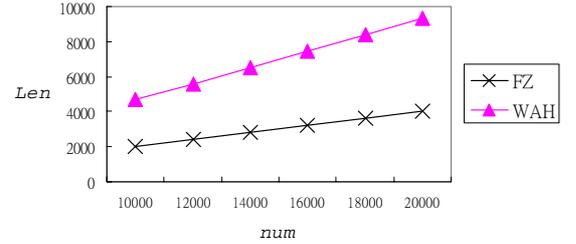

Figure 10: A comparison of the Len for the WAH and FZ strategies by using different numbers of bits in a string (num)

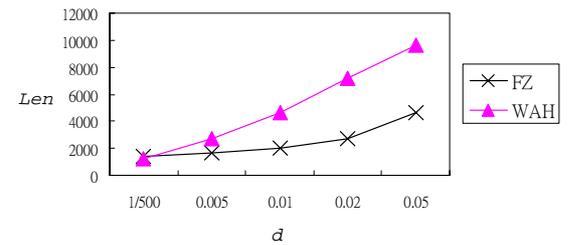

Figure 11: A comparison of the Len for the WAH and FZ strategies by using different values of density (d)

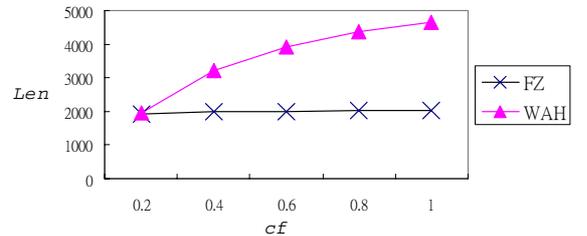

Figure 12: A comparison of the Len for the WAH and FZ strategies by using different clustering factors (cf)

V. Conclusion

To reduce the storage of the bitmap index, in this paper, we have proposed the FZ strategy which compress the bitmap vector by filtering out many zeros. We have studied the performance of our FZ strategy, and have compared it with the WAH strategy by simulation. From the simulation results, we have shown that the FZ strategy can reduce the storage cost more than the WAH strategy.

Abstract: One of the widely used methods for product recommendation in Internet shopping malls is matching product features against customers' profiles. In this method, it is very important to choose suitable set of features for recommendation efficiency and performance, which has, however, not been rigorously researched so far. In this paper, we build a data set collected from a virtual Internet shopping experiment and adapt and apply feature reduction techniques from pattern matching and information retrieval fields to the data to analyze recommendation performance. The analysis shows that the application of SVD (Singular Value Decomposition) can be the best among the applied methods for recommendation performance.

Keywords: Intelligent agent and data mining technologies in e-services; product recommendation; content based filtering; singular value decomposition.

I. Introduction

There have been a large number of studies for recommendation of products to promote cross-selling or up-selling in Internet shopping malls. The studies can be broadly classified into two types: collaborative filtering methods that use similarity of ratings for products among shoppers, and content-based filtering methods that utilize features or attributes of products and users [2, 3, 7, 10, 15, 16]. Although collaborative filtering methods have been proved to be successful in many studies, it is often very difficult or expensive to collect the ratings, and moreover, when rating data is sparse, recommendation results are usually impaired severely [9, 14, 18]. For these reasons, because it is easier to collect purchase data and associated product features, content-based filtering methods can be a practically better choice for many real world recommendation problems.

In content-based filtering methods, product attributes and user characteristics, often called features, are collected and analyzed with recommendation models such as statistics methods and artificial intelligence models. The features may comprise of various values such as demographic data or user-specified preferences, but in general, for the practical difficulty of collecting data in Internet shopping malls, many methods suggested in previous studies use characteristics of products that shoppers have purchased or shown interests in the past [13, 17].

Although the product characteristics are comparatively

easier to acquire, there are often too a large number of available features. For example, in the cases of book or movie recommendation, there can be a large number of keyword features of the products from their themes, genres, and text-based description of the products. These features may directly affect the choice of shoppers, and thus, are often used as key features of recommendation, especially for cultural and content-focused products. This problem may lead to inefficiency or ineffectiveness of recommendation. In terms of efficiency, inaccurate or irrelevant keywords may require huge system memory or lead to increased processing time; in terms of effectiveness, there can be often inaccurate or irrelevant words that may damage the recommendation quality. Consequently, it has been recognized to be very important to extract a more meaningful subset of features that can contribute better to recommendation performance [1, 5, 8].

In this study, we utilized a data set that was constructed from a virtual shopping experiment in an Internet book shopping mall in Korea to find out how feature reduction techniques that have been widely used in pattern matching or information retrieval can be applied to the recommendation problem. We used a Korean lexical analyzer to extract features and use the features to construct user and product profiles. The Term Frequency (TF), Inverse Document Frequency (IDF), TFIDF, mutual information, and Singular Value Decomposition (SVD) methods were chosen and adapted for the experiment.

The remaining part of the paper is organized as follows. In the second section, we provide a brief review of feature selection methods from other disciplines. In the third section, we explain the experiment procedure and present the results of the analysis. The fourth section concludes with discussion and further research issues.

II. Review of Related Research

II.1 Feature Extraction from Product Description

The studies on feature selection has been mainly the focus of pattern matching, machine learning, or text categorization research [1, 5, 8]. The studies have mainly focused on investigating what types of features affect learning performance more. However, there have been not many studies that have applied those methods to product recommendation in Internet shopping malls. Similar methods for feature reduction used for classification problems are often not directly applicable for recommendation.

In order to extract keyword-based features from product

description, the tools and methods developed in the information retrieval field can be well utilized. In general, sentences and phrases of product description include many words that are not suitable to be used as features such as articles, conjunctions, or pronouns. After filtering out unsuitable words, it is needed to extract the stem of the chosen words to make the keywords compatible with other variations of the same stem. For example, after stemming, two words 'processing' and 'processes' will have the same stem 'process'. These processes are usually performed using lexical analyzer software programs, and as the result, vector profiles of features such as $\langle w_1, w_2, w_3, \dots \rangle$ are generated for each product and shopper, where each w_i represents the relative importance of a keyword feature in the profile. Thus, we may compare vectors of users and products to calculate the similarity between them, which can be easily used for recommendation. Two most widely used similarity measures are linear correlation and cosine value between two vectors.

II. 2 Vector Space Model

Vector space model[12] is also widely used in the information retrieval field for representing documents and queries. Documents and queries are modeled as vectors of keywords where the keywords have different weights according to their relative importance in documents and queries. Table 1 shows an example vector for a document and a query. If we assume that there are only three keywords such as $\langle \text{information, management, computer} \rangle$, the document and query can be represented with 3 dimensional vectors such as $\langle 0.3, 0.7, 0.1 \rangle$ and $\langle 0.5, 0, 0.8 \rangle$ respectively. Each number in the vectors shows the relative importance of the keywords in the example. We may then calculate the similarity between the two vectors using the cosine measure that will be close to 1 if the two are very similar to each other and 0 if they are very different from each other.

Table 1. Example of vector space representation

Keyword	Document	Query
Information	0.3	0.5
Management	0.7	0
Computer	0.1	0.8

II. 3 TFIDF

We have seen examples of weights in the vector representation in table 1. There can be numerous ways of calculating weights but the most widely used weighting scheme in the information retrieval field is TFIDF [12]. TFIDF combines TF (Term Frequency) and IDF (Inverse Document Frequency), where TF is the simple number of occurrence of a keyword in a given document or query, and IDF is the discriminative power of a given keyword in a given set of corpus. For example, a keyword that appears in most documents in a corpus will have a very low value of IDF, while a keyword that appears in only a small number of

documents will have a very high value. As a result, because TFIDF is the product of the two, it considers both the frequency of a keyword within a given document or query and its discriminative power in a given corpus. Formally, TF, IDF, and TFIDF are defined as follows:

$$TF(t, d) = \frac{Occ(t, d)}{MaxOcc(d)} \quad (1)$$

where $Occ(t, d)$ is the number of occurrence of the word t in the document d , and $MaxOcc(d)$ is the number of occurrence of a word that appeared most in d .

$$IDF(t) = \frac{N}{N(t)} \quad (2)$$

where N is the number of entire documents in a given corpus and $N(t)$ is the number of documents that contains the word t .

Accordingly, TFIDF can be calculated as follows:

$$TFIDF(t, d) = \frac{Occ(t, d)}{MaxOcc(d)} \cdot \frac{N}{N(t)} \quad (3)$$

II. 4 Mutual Information

Mutual information was first introduced in Shannon's information theory and is used to represent the amount of information that two probability events provide to each other [1, 9]. That is, $MI(a, b)$, mutual information for events a and b , is bigger if the occurrence of an event gives higher information on the occurrence of the other. This value is symmetric for both events, thus, if a and b are more associated probabilistically, they produce higher mutual information value.

In product recommendation, we can use mutual information to estimate how strongly a feature is associated with a user and recommend products with features of higher mutual information value. A mutual information for two events a and b can be calculated as follows:

$$MI(a, b) = \log_2 \frac{P(ab)}{P(a)P(b)} \quad (4)$$

where $P(a)$ is the probability of a 's occurrence, $P(b)$ is the probability of b 's occurrence, and $P(ab)$ is the joint probability of a and b occurring together.

II. 5 Singular Value Decomposition (SVD)

SVD is one of the matrix decomposition methods in Linear algebra. The basic idea of this method is based on the fact that a small subset of singular values generated by the decomposition can be a good approximation of the entire original matrix. The decomposition gives us two matrices of orthogonal vectors and a diagonal matrix with singular values as diagonal elements. The number of non-zero diagonal elements equals or is smaller than the dimension of the original matrix. It has been shown that reduced matrices

with smaller dimensions and hence smaller singular values may well produce a matrix which is very close to the original matrix in many research problems. For example, it is often used to compress a large image file or reduce the number of keywords for indexing documents in huge document management systems. In particular, in the information retrieval field, it has been found that the dimension reduction leads to the finding of *latent meaning* in documents, which have been proved to be successful for document indexing and retrieval. The use of SVD in information retrieval is also called Latent Semantic Indexing (LSI) for the reason. The most significant implication of using SVD is that using a smaller dimension in information retrieval may lead to enhanced retrieval performance, contrary to intuition, because SVD helps utilize the latent meaning structure in documents [6, 11].

Figure 1 shows how a matrix can be decomposed using SVD. The original matrix is transformed into a product of the matrices U, D, and V, where U and V are each orthogonal matrices and D is a diagonal matrix where the diagonal elements are called *singular values* of the decomposition. It follows that the singular value σ_i gets smaller as i increases, which means that the earlier singular values have greater influence if we reassemble the original matrix by multiplying the three matrices with only a subset of the singular values.

$$A = UDV^T$$

Figure 1. Illustration of singular vector decomposition

III. Experiment and Analysis

III.1 Data Collection

Data for the experiment and analysis were collected through two activities. First, a virtual shopping experience was performed where 140 examinees browsed freely through a real Internet book shopping mall in Korea and put items they wanted to buy into virtual shopping carts provided by the mall and the result was recorded for each examinee. Table 2 shows the basic statistics of the experiment. Second, they were presented with 32 books as shown in table 3 and were asked to rate the books with scores ranging from 1 to 5, 5 meaning most preferred and 1 meaning least preferred. The 32 books for this experiment were chosen from the 16 categories shown in table 3. We chose only recently published books at the time of the experiment and placed a gap of 1 month between the two experiments to avoid any overlap between the books purchased in the virtual shopping and the 32 books for rating, which was successful. The books collected by the virtual shopping experiment are used

to develop user profiles and the 32 books with ratings are used for evaluating the performance of recommendation using different feature reduction methods.

Table 2. Virtual shopping experiment

Average books purchased	10.93
Standard deviation	7.01
The largest number of books purchased among all the examinees	50
The smallest number of books purchased among all the examinees	2

Table 3. 16 categories from which 32 books were chosen for examinees' rating

Computer/Internet	Management/Economics	Foreign languages	Children
Hobby/health	Comics/Animation	Novel	Poem
Humanity	Essays	Classics	Social science
Science	History	Art	Magazines

Each record collected for the books contains ISBN or ISSN that uniquely identifies a book, as well as title, and description of books.

III.2 Extraction of Features

For the content-based filtering experiments, first, keywords were extracted from the books of the two experiments. Table 4 shows basic statistics of the extracted keywords.

Table 4. Basic statistics of extracted keywords

	Average no. of keywords	Standard deviation	Maximum no. of keywords among all examinees	Minimum no. of keywords among all examinees
Per each user	551.2	238.8	1374	64
Per each of the 32 books for recommendation	150.1	132.5	721	15

Among all the keywords extracted, only 3034 keywords that appear at least once in both experiments were chosen because the other words cannot contribute to recommendation at all. The frequency of keywords shows an exponential distribution as shown in figure 2. This shows that there are keywords that appear too frequently or too rarely, which in both cases may not be effective for recommendation, and which justifies the attempts to reduce the number of keywords.

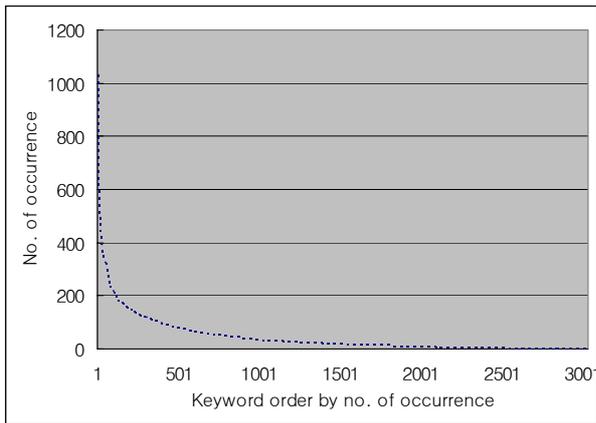

Figure 2. X axis represent each of the 3034 keywords that were ordered by their frequency of appearance. Y axis shows actual frequency of appearance.

On the other hand, figure 3 shows the histogram of keywords according to the frequency of occurrence. This graph roughly shows that a large portion of keywords appear in less than 5 documents and almost all keywords appear in less than 100 documents.

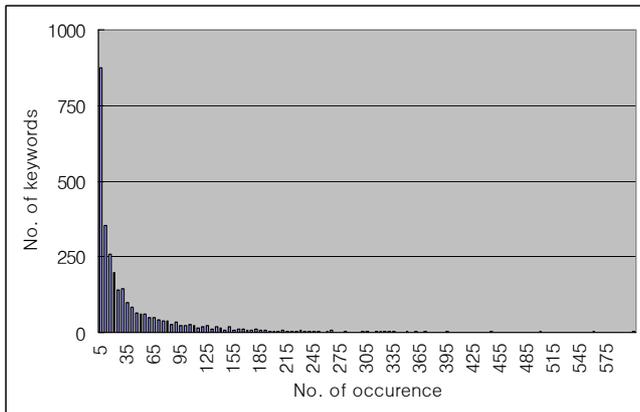

Figure 3. X axis shows the number of occurrences (frequency). Y axis shows the number of keywords for a corresponding frequency on the X axis

III. 3 Recommendation Experiments

With the data collected through the aforementioned methods, 5 recommendation experiments were performed using different ways of feature reduction: TF, IDF, TFIDF, MI (Mutual Information), and SVD. In each of the experiment, we measured the recommendation performance increasing the number of features or dimensions from 1. In using TF, IDF, TFIDF, and MI methods, considering that the average number of keywords in the recommended books is 150, the number of features or keywords was increased up to 200. With the SVD method, since the original matrix is of size 140 by 3034 with only 140 singular values, the experiment was performed using dimensions ranging from 1 to 140. For TF, IDF, TFIDF, and SVD methods, the cosine measure was used for similarity calculation. In the MI method, since we have *information value* for each feature instead of a vector profile, the amount of information measured in bits was used for similarity calculation.

Table 5. Summary of each experiment

Method	Range of features or dimensions	Similarity measure used
TF	1~200	Cosine
IDF	1~200	Cosine
TFIDF	1~200	Cosine
MI	1~200	Amount of information
SVD	1~140	Cosine

(1) Feature reduction using TF

The TF method is the simplest one among the five methods, where we chose those keywords first that appear more in each user profile. We increased the number of keywords for recommendation from 1 to 200.

(2) IDF

With the IDF method, we chose those words first that have higher discriminative power, or higher IDF value. For the calculation of IDF values, we treated all the books purchased by users in the virtual shopping experiment as a corpus.

(3) TFIDF

With this method, the words with higher TFIDF value were chosen first.

(4) MI

Using the MI method, we use the amount of information of each keyword of each user’s profile, where the information represents the strength of association between the keyword and the user. For example, if a keyword w is highly associated with a user, the user will purchase many books containing the keyword, and conversely, the books purchased by the user should contain many occurrences of w . Suppose that $P(B)$ represents the portion of the books purchased by a specific user among the entire set of books exposed to the user, and $P(w)$ the portion of books containing the word w , and $P(Bw)$ the probability of the intersection of the two. Then the MI value can be calculated as:

$$MI(B, w) = \log_2 \frac{P(Bw)}{P(B)P(w)} \tag{5}$$

However, we cannot know the size of the entire books exposed, and hence, we cannot precisely measure $P(B)$, $P(w)$, and $P(Bw)$ but should approximate them. First, when the sample size is large enough, we can replace $P(w)$ with $P'(w)$

where $P(w) \approx \frac{N'(w)}{N} = P'(w)$, N is the total number of books found in the virtual shopping experiment, and $N'(w)$ is the number of books that contain w .

Second, suppose $N(U)$ is the number of all the books in

the shopping mall which can be possible exposed to users, and $N(B)$ is the the number of books a user has purchased after being exposed to all the books. Since we may not assume that the user has been exposed to all the books, we use an approximation $N'(B)$ which should be a subset of $N(B)$: $N'(B) \approx \frac{N(B)}{k}$, where $k > 1$ is an unknown real number. Upon the same assumption, the size of $N(Bw)$, which is the size of the intersection between B and W , can be approximated in a similar way: $N'(Bw) \approx \frac{N(Bw)}{k}$. Thus, finally, we can approximate the MI value of a specific keyword for a specific user using only observable values as follows:

$$\begin{aligned} MI(B, w) &= \log_2 \frac{P(Bw)}{P(B)P(w)} \approx \log_2 \frac{\frac{N'(Bw)}{N(U)}}{\frac{N'(B)}{N(U)} \frac{P'(w)}{N(U)}} \quad (6) \\ &= \log_2 \frac{kN'(Bw)}{kN'(B) \frac{N'(w)}{N}} = \log_2 \frac{N \cdot N'(Bw)}{N'(B)N'(w)} \end{aligned}$$

After each MI value for each keyword feature had been calculated, we chose the keywords with higher MI values first for the recommendation test.

(5) SVD

The matrix that utilizes SVD has the size of $\langle \text{No. of keywords} \times \text{no. of examinees} \rangle$. Thus, we have a matrix of size 3034×140 , which was decomposed into U, S, and V as shown in figure 4. Each column vector in the original matrix that corresponds to a single user was composed with TFIDF-based weight values.

$$\begin{array}{ccc|ccc|ccc|ccc} a_{11} & a_{12} & a_{1n} & u_{11} & u_{12} & u_{1m} & \sigma_1 & 0 & 0 & v_{11} & v_{21} & v_{n1} \\ a_{21} & a_{22} & a_{2n} & u_{21} & u_{22} & u_{2m} & 0 & \sigma_2 & & v_{12} & v_{22} & v_{n2} \\ & & & & & & & & & & & \\ a_{m1} & a_{m2} & a_{mn} & u_{m1} & u_{m2} & u_{mm} & 0 & & \sigma_n & v_{1n} & v_{2n} & v_{nn} \\ & & & & & & 0 & & 0 & & & \end{array}$$

3034 X 140 3034 X m m X m m X 140

Figure 4. SVD decomposition of the user profile matrix (U, S, and V')

Figure 5 shows the 140 singular values that were gained as the result of the decomposition. We can also note that there are a small number of large singular values that may contribute highly to the original matrix.

In order to use the decomposed matrices for recommendation, we apply the following formula to calculate the similarity between user i and a particular book. Assuming that the book is represented as a vector X_q , the following vector is treated as a row of V: $V_q = X_q'US^{-1}$. And then, for the similarity calculation, cosine distance between V_q and V_i for user i is calculated[4].

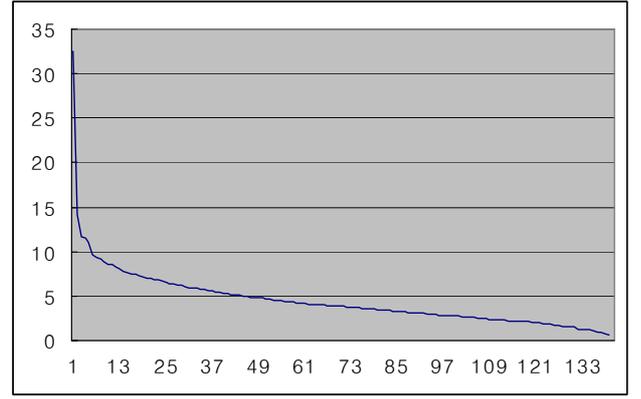

Figure 5. 140 singular values in a descending order

III. 4 Analysis of the Result

Figure 6 shows the result of recommendation experiment with X axis representing the number of features or number of dimensions used for recommendations, and Y axis representing the recommendation performance. In the experiment, 3 books with the highest similarity values were recommended to each user and the average rating of the 3 books by each user was used as a measure of performance.

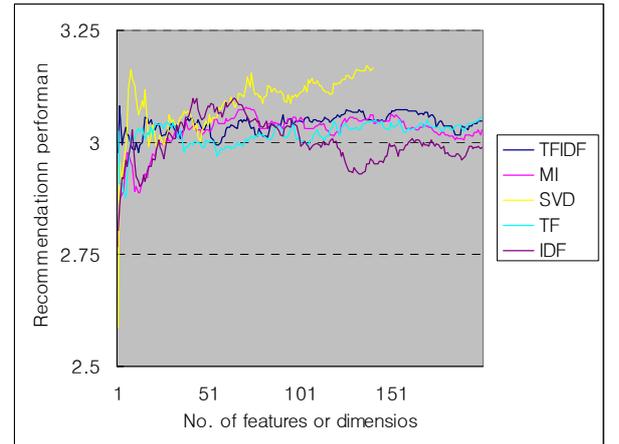

Figure 6. Number of features or dimensions and the recommendation performance

The result in figure 6 can be summarized as follows. First, on the whole, the recommendation using SVD shows better performance than other methods, while there is no different among the performances of the other methods. In TFIDF and TF methods, the results using only a small number of features are not much weaker than the results using much more features. With some variations, it is also observed that the use of additional keywords is not contributing much to increase in the overall recommendation performance. SVD method shows an interesting result where the performance is at its maximum when only 9 dimensions were used for recommendation, while the recommendation performance gradually reaches the same level as the number of dimensions approaches 140. This result is in accordance with the prediction of many studies that have shown that the

dimension reduction of SVD can utilize latent semantics in the data, which may better reflect the nature of data than using the entire set of dimensions.

However, there are a couple of aspects in this result that require more attention. First, although the experiment shows that using SVD may improve the overall recommendation performance, it is not clear how many dimensions should be used in general. For example, in figure 6, when there are approximately 50 features, it is outperforming the SVD method using 50 dimensions. Second, the concept of number of dimension is not exactly the same as the number of features. When using features in other methods than SVD for recommendation, the amount of information the recommendation system should manage is $\langle \text{Number of features} \times \text{Number of users} \rangle$. In the case of SVD, the amount of information required is $\{ \langle \text{Number of features} \times \text{Number of dimension} \rangle + \langle \text{Number of users} \times \text{Number of dimension} \rangle \}$, which is larger than the other methods. This amount is still proportionate to the number of dimensions, and in terms of computational capacity, may not give much burden to recommendation systems. However, when the amount of information is also of great concern, it may be required to consider both aspects when choosing a feature reduction method.

IV. Conclusion and Further Research

In content-based filtering, the number of features has been one of the critical problems in terms of both recommendation efficiency and effectiveness. The contribution of this paper can be summarized as follows. First, we applied feature reduction methods from other disciplines with adaptation to the content-based recommendation problem. Second, we showed that, among the methods, SVD method can present the best recommendation performance with much smaller number of feature dimensions. Further research issues are as follows. First, in the current research, it has not been clearly shown how many features are required in general for various recommendation problems. Second, in order to generalize the findings of this research, experiments using other sets of data from different settings can be required.

Abstract: In the recent years, each industry has to face the situation of making the decisions from global markets, especially the industries within lower technicality. These industries earn money hardly in the perfectly competitive markets. Sometimes, decision makers have to decide how to allot orders in the different factories because of distinctive requests from individual consumer. It is necessary to find a way to help managers with making a decision and allotting orders effectively.

The purpose of this study tries to develop a decision support system (DSS) to help the managers and decision makers of a real garment industry in Taiwan to decide order allocation, and we used genetic algorithm (GA) for analysis tools and results would be showed by visual graphs to assist managers in decision making. By decision support systems, managers and decision makers might decide order allocation quickly and save the costs.

Finally, the decision support system results in a visional frame within lowest cost, and managers decide order allocation with effectiveness by graphs. With this information, decision makers might make different decisions in unlike situations for dissimilar goals. The system had developed to be used easily and suitable to the garment industries and other similar manufacturing industries.

Keywords: global industry, garment industry, DSS, GA.

I. Introduction

It's very important to make a suitable decision within effectiveness for industries, especially in the global industries. In the past approaches, many scholars and senior decision makers always make decisions by their brains with professional experiences and some information including balance sheets and etc. And they respected to get competitive advantageous positions if decisions could fulfill demands of consumers [1-4]. By this traditional method to make decisions has become more difficult and inefficient in recent years because sciences and information technology grow up fast causing influencing factors excess and complex. Many enterprises have to make efforts on the global logistics management (GLM) for raising their competitive capability, but there are still some problems to be solved.

In generally, benefits of consumers from a competitive market are limited. It is harder to obtain extra profits than to reduce costs. The proprietors of global industries always try to find a way to reduce cost without high interests. Some scholars proposed that using resources around the whole world properly could decrease costs [5]. Taking the garment industry in Taiwan for example, it has lower entry barriers and a new competition enters easily with advanced technology so if the global garment industry want to move manufacturing factories from Taiwan to other countries, it is easier than other industries. To find cheaper labors is necessary for garment industry. This is why many global industry move factories to developing country to get some resources [6].

Fig. 1 The global sketch of a real famous garment corporation in Taiwan

As Figure 1 shows, country of origin, main markets, and manufacturing factories are in the different geographical locations, even in the different countries. The data presented in Figure 1 was collected from a real global garment corporation in Taiwan and triangles represent sales offices, the rhombuses represent factories producing fabrics, the circles represent for factories producing garments, and the squares stand for places of providing raw material for garment.

Global resources bring the chance to reduce costs and cause some problems. To transport goods by freighters often takes long time. In global competitive markets, the most

important job is to satisfy with customers including productions and delivery date. Reducing delivery time and quickly responses would let industry get lower costs [7]. Thus, many decision makers always try to make a decision for allotting orders with effect to different manufacturing factories, and the decision must conform to minimum cost. In traditional method, making a decision for order allocations wastes time and often be impacted by decision makers' and managers' personal experiences. There are lots of influencing factors affecting a decision making. If decision makers made a wrong choice, the final result causes additional costs. "Decision Support System, DSS" was developed for assisting decision makers and senior managers to make a correct decision for corporation goals, and it also solve the problems with uncertain and blurred elements [8]. With electronic technology, DSS could process complex and a great quality of factors. Thus, DSS [9, 10] would be a important role in the modern garment industry.

In this study, we tried to develop a global decision support system for a real garment corporation in Taiwan. The senior managers in the corporation try many ways to conduct electronic systems into business strategies, especially in decision making. They respect that could get a helper to make a decision within the goal of lowest cost. Because of lowest cost, we let "Genetic Algorithm, GA" [11-19] be a analytic tool for the decision support system. After executing the system, the results would be presented by Gantt charts and lists, and decision makers and managers could make decisions effectively by charts and lists.

The rest of this paper is introduced as follows. Section 2 depicts slightly overviews of "Genetic Algorithm" and "Decision Support System". The approach of this study is described in Section 3. Section 4 would describe the experimental results. Finally, conclusions are presented by summarizing the findings in Sections 5.

II. Genetic Algorithm (GA) and Decision Support System (DSS)

II.1 Genetic Algorithm (GA)

Genetic Algorithm (GA) was developed by Holland. GA is usually used to find the best solution or process complex problems by the different ways with the rules as imitating organisms' evolution. It is just like a learning cycle and it is always executing until satisfying the goals of decision makers need. After each round of checking results, the better result would replace the bad one within conditions made by senior managers. The processing of GA is presented as Figure 2 shows as following.

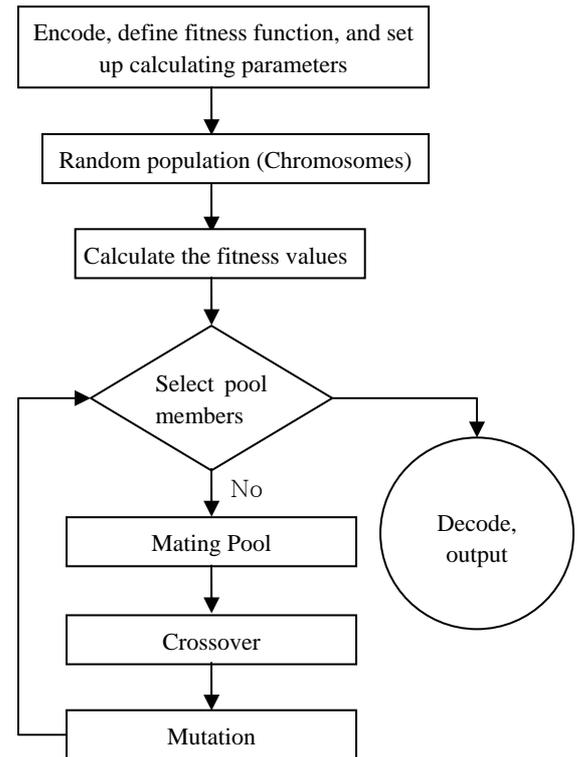

Fig. 2 The flowchart of GA

GA has applied to lots of fields, such as system intrusion detection [20], production scheduling [21], and others [22]. Maybe the subjects are different, but it confirmed GA could process complex data.

The characteristics of GA different from traditional algorithms were defined as following [23].

1) GA is more suitable for solving some complex problems because it uses encoding string to calculate, and it won't be limited by some real condition of parameters.

2) GA is a better tool to find a global optimization than other algorithms because GA is used to calculate from many of points to find the best solution.

3) While calculating, it is necessary to add some extra numeric to find the best solution. The final result is impacted easily by additional values. GA calculates with information created by previous generations.

4) GA suits different kinds of problems because it randomizes chromosomes for copulations and mutations.

In some studies, GA could execute varied phenotypes in multi-processing units so it would handle a large number of data [24].

II.2 Decision Support System (DSS)

The concept of DSS was presented by Scott Morton [25] and the system was called "Management Decision Systems". The main characteristic of systems is to assist decision makers to use data and models to solve unstructured

problems by interactive decision systems. As figure 3 shows, there are three principal elements within DSS, including Data base Management Software (DBMS), Model Base Management Software (MBMS), and Dialog Generation and Management Software (DGMS) [8].

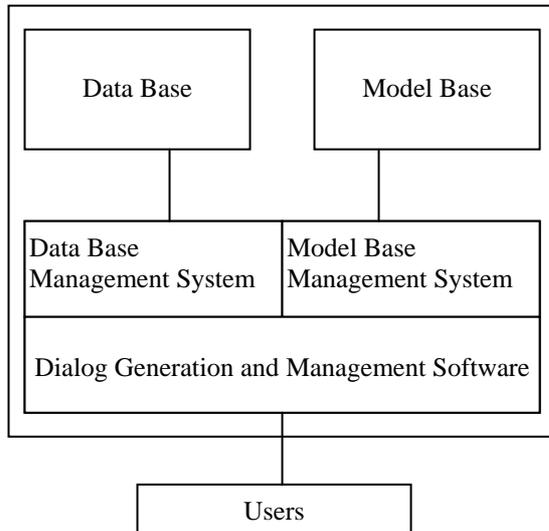

Fig. 3 The structure of GA [8]

The purpose of DSS is not to do decisions for senior managers or decision makers. It always creates some information by tables and lists to assist senior managers to make a correct decision. It also helps decision makers to settle the semi-structured and unstructured problems [26, 27]. DSS can calculate by different formulas and fit it to the real situations with electronic systems because the conditions of global industries always change.

III. Approach

III.1 Influencing Factors of the Decision

There are about some important influencing of a order allocation decision, including competitive strategies of business, global competitive environments, tariff duties and quotas, elements of consumers, elements of politics from each country, capacity, delivery time, costs, technology of manufacturing factories, and elements of factories' operations.

Each kind of industry has own goal of strategy, for example lowest cost, and the goal also impacts the final decision. The final decision would influence some decisions of partners from supply chain. Quotas could impact deeply on global garment industry from each country, especially in Taiwan. Since 2005, World Trade Organization (WTO) had announced canceling quotas measure of the whole world. The policy has exchanged import and export of garment industry.

In global garment industry, to satisfy demands of consumers and deliver goods on time are two major factors to enhance competitive capabilities. If senior managers wants to get lowest, there are some factors had to be solved, including order allocation. To shorten delivery time could

reduce correlative costs.

III.2 The Structure of DSS

After interviewing with senior managers from a real global garment corporation, we synthesize the documents and factors provided by managers. We built a model with these factors and the model is presented as figure 4 as following.

As we have said above, there are many complex elements that could influence our decisions and every element also could influence one another. Therefore, we select the strategies by gradation.

In the first stage, this is a very broad field of making decisions. This stage is aimed at the goals of the organization and competitive strategies. Senior managers have to consider more and extensive factors such as the competitive strategy of the organization, global competition and internal constraints and select the supply chain strategy. In this stage, it pertains to long-term decisions. On the contrary, as short-term decisions, we regard as static.

There are different features and technology such as factors of customers between each factory. In the second stage, we consider some factors including production technology, factors of customers, quote and rewards, and regional demand to weed unsuitable factories artificially. Through the influence of these factors, we select some suitable factories. In this way, we could reduce complication of computation.

After second stage, we select parts of the factories because of some factors, but it may lead to the high cost. In the third stage, we balanced the capacity. Therefore, we select the factories with capacity surplus and less utilization ratio to balance the capacity and find the suitable factories effectively.

In the fourth stage, we take cost minimum as the goal to select the most applicable factory. Therefore, we draw on systematized tools like Gantt chart to simulate the strategies and find the most applicable factory. Also, it assists senior managers or decision makers in making decisions.

In line with the rules of how an organization works and consulting some excellent documents, we come up as figure 4 showing.

III.3 Encoding and Calculating

Before beginning to calculate by using GA, we have to define and encode some elements. In this study, each order was presented by each gene and denoted the number for each order as A, B, C, and etc. The fitness function combined by "Cost Based Measure, CBM" and "Due-date Related Measure, DRM" can be presented as

$$F = \sum_{i=1}^n [w_1 CBM(i) + w_2 DRM(i)] \quad (1)$$

and w_1 is the weight of CBM and w_2 is the weight of DRM.

Both of w_1 and w_2 are binary.

$$CBM(i) = M_i + T_i + L_i \quad (2)$$

where

M_i is the raw material cost of i_{th} order.

T_i is the transportation cost of i_{th} order.

L_i is the labor cost of i_{th} order.

If the goods deliver late, the additional cost can be expressed as

$$DRM(i) = \max[(C_i - D_i), 0] * Q_i * U_i * \mu \quad (3)$$

where

C_i is finish time of i_{th} order.

D_i is expected delivery date of i_{th} order.

Q_i is the amount of garments of i_{th} order.

U_i is the price of each garment of i_{th} order.

μ is the punitive factor behind time.

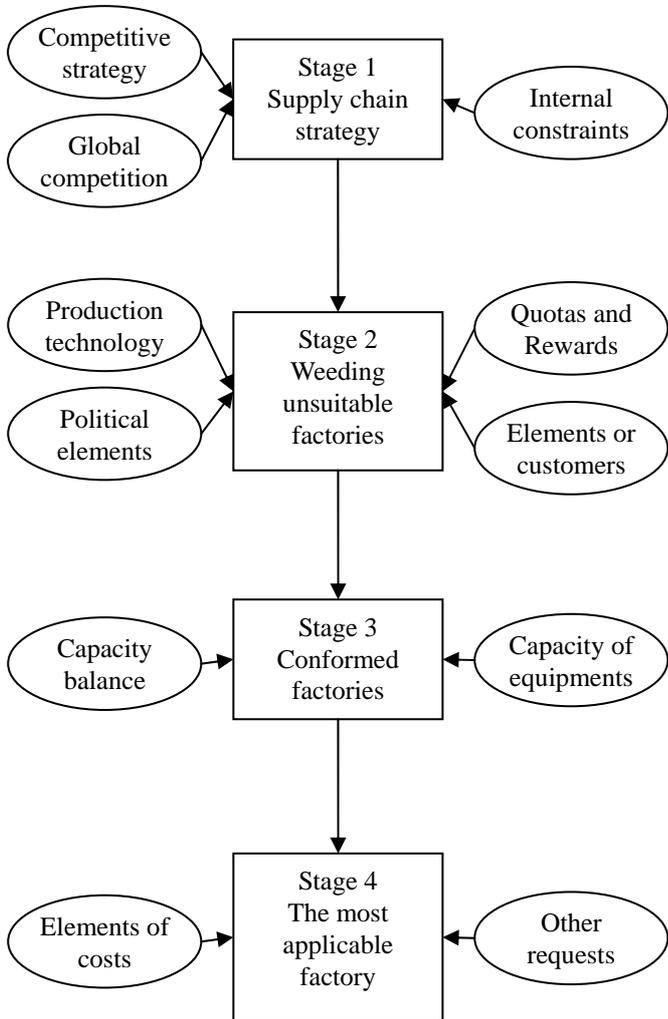

Fig. 4 The processing of DSS

IV. Experimental Result

In this study, we used Microsoft Visual C++ to develop the global decision support system and the operation system was Windows XP. We used GA to be a analytic tool, population size was 100, crossover rate was 0.8, mutation rate was 0.05, and generation was 100. Because of complex types of real data, we wanted to present the status of data as true as possible, and then, we encoded in enumerating was employed rather than in binary. We used two-point crossover and two-point mutation to find the final solution.

The system always executes based on “lowest cost” and it also provides two goals for decision makers, including “the highest capacity utilization rate” and “the highest on-time delivery rate. If a factory can not fulfill with requirements of orders, there is a red vertical line shown up and warn the decision makers.

Fig. 5 The initial frame of global garment DSS

This system provides “semi-manual” and “semi-automatic” methods to executive for decision makers. As figure 6 shows, if there are some orders important, decision makers could put them into the schedule. After scheduling by decision makers, the system would arrange remainder orders. The red line in left of figure 5 means the final time when fulfilling contracts, and the green line means time to start manufacturing.

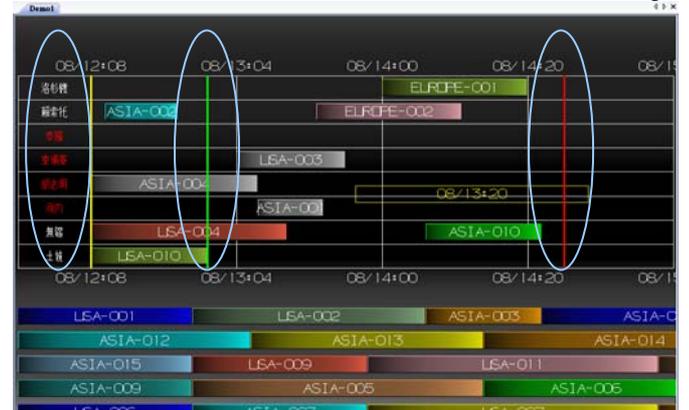

Fig. 6 Scheduling by semi-automatic

Maybe there are some importers who don't want goods manufactured in some countries. When we chose one tag as figure 6 shows, the order called "LEA-002", the system would show out suitable countries for requests of consumers within white words.

Fig. 7 The frame of global garment DSS after scheduling

When users had decided some important orders, they could arrange surplus orders into fit factories automatically. As figure 7 shows, users could press "Agent" and the system would schedule the orders. This system also provides a function that when users press the right button on the mouse, we can check information of data including costs, numbers of orders, kinds of goods, information of consumers, and etc. As figure 8 shows, information would present as a list. Decision makers or senior managers could compare information and make a manufacturing decision correctly and quickly.

Fig. 8 Information of a order

V. Conclusion

We had built a global decision support system for decision makers from a real global garment corporation, and the system could assist decision makers and senior managers to make a decision of order allocation within effectiveness. And this system always executes based on lowest cost.

The global DSS contains three major elements, including input databases and parameters, the analytical tools, and the presentation mechanism. The input data was collected by Enterprise Resource Planning (ERP) systems of a real garment corporation. Because there are too many factors with making a decision, we used genetic algorithms (GA) to be a analytical tool. GA is a useful tool to solve the problems within complex factors.

In the end, tables and Gantt charts could be reference materials for making decision by decision makers. The system is developed to be easy and quick to use. And it is also suitable to the global garment industry for order allocation. In the future, we could join more factors, for example, extra flight brings lots of additional cost. With more factors, the system could simulate a real situation of global garment industry. However, each algorithm has own-self defects. If we can't accept too many inaccuracies, we maybe focus on using improving algorithms for analyzing tools in the future.

Abstract: The data mining approach of rough set theory is being adopted to study the multi-index question of supplier's evaluation and determination in order to reveal the determining rules hidden in the historical evaluative data. After introducing some basic notions of rough set theory, this paper uses a sample to tell the steps of the deducing process in detail, and figures out some satisfying rules of supplier's determination and weights of various attribute's indexes which have been compared to other methods after the calculation. All of these illustrate the method of rough set theory can be used in the area of supplier's selection and solve them with great efficiency.

Keywords: Decision Support, Group Systems

I. Introduction

The supplier's determination is the core of the whole acquisition system, and it can be considered as the most important step in the acquisition process. It has been a time-consuming question for each administrative sector to determine an appropriate supplier. Nowadays, various approaches are adopted to solve the problem of suppliers determination and decide on the quantity of the stocking goods from a selected supplier. The common methods include description, experience and optimization method etc. The descriptive and experimental methods describe the feature of the supplier or set up the weights of determination indexes to undertake the evaluation, the typical methodologies are the plus-weight element analysis method, layer-analysis method and so on[1][2]. As the weights of the determination indexes are set up on the basis of the determiner's experience, the evaluative result is somewhat subjective unavoidably. The optimization method is used to determine who is the supplier of paying the less, and suiting to the special requirement on the basis of the product quality and the consignment of time. Eventually, the factors such as linear, non-linear design, dynamic planning and objective planning are often involved, so the evaluative process is much more complicated. Further more, the determinative process may not be continuous and complete because the historical evaluative data of suppliers are not covered in the method. Rough set theory is a mathematic tool to deal with the incomplete and uncertain problems, to analyze and

dispose efficiently the imperfect information, to uncover the hidden knowledge and reveal its potential rule based on the people's cognition of acquired data[3].

The rest of this paper is organized as follows. Section 2 briefly describes the basic notions of rough set theory. Section 3 provides a case on suppliers' determination and tells the applications that rough set theory can be used in such problems. Concluding remarks and directions for further research are given in section 4.

II. Basic Notions Of Rough Set

II.1. Positive, Negative And Boundary Region

Let U be a non-empty finite set, called universe, and R be an equivalence relation. The pair $K = (U, R)$ is referred to as knowledge base and conceptually, represents our knowledge about the universe. The equivalence relation represents a classification of the domain objects into disjoint classes of objects, which are indistinguishable in terms of available information about them. In other words, these classes represent the basic properties of the universe that can be expressed by the knowledge represented by the relation R , and so they are referred to as elementary categories.

Any subset $X \subseteq U$ of the universe will be called a concept in U . Some concepts can be exactly defined in the approximation space K , whereas other ones cannot be defined. A subset X is an exact set or definable in K , if X is the union of some elementary categories, otherwise, X is a rough set or un-definable. A rough set can be defined approximately by the employment of two exact sets, called lower and upper approximations. The lower approximation, denoted as $R_-(X)$, is the set of all elements of domain objects U , which can be certainty classified as elements of a concept X in the knowledge R . The upper approximation, denoted as $R(X)$, is the set of elements of U that can be possibly classified as elements of X using knowledge R . According to these basic concepts, universe can be divided into three disjoint regions, called positive, negative and boundary regions and defined as follows:

$$POS_R(X) = R_-(X) \quad (1)$$

$$NEG_R(X) = U - R(X) \quad (2)$$

$$BND_R(X) = R(X) - R_-(X) \quad (3)$$

The positive region $POS_R(X)$ has the same interpretation as lower approximation. The negative region $NEG_R(X)$ is the collection of objects that can be determined without ambiguity, employing knowledge R , that they do not belong to the set X , that is, they belong to the complement of X . The boundary region $BND_R(X)$ is the un-decidable area of universe, i.e. none of the objects belonging to the borderline area can be classified with certainty into a set X or its complement ($-X$), at least using knowledge R .

II.2. Reduction, Core And Attribute's Significance

The rough set framework is especially suitable to the determination of attribute-value relationships in attribute-value systems. Information systems are formal models of attribute-value systems[4].

Rough set is defined as an information system as a pair $S=(U,A)$, where U is a non-empty, finite set called the universe, and A is a non-empty, finite set of attributes. Also we can describe S in detail that it contains four subsets, $S=\{U, A, V, f\}$, A contains two subsets C and D , that's mean $A=C \cup D$, where D is a distinguished attribute called the decision attribute, elements of set C , are referred to as condition attributes. V is the set of values of A , called the domain of A , and f is the function that can be defined as: $\forall a \in A, x \in U, f(x, a) \in V$. We can call such information system a decision table, it represents a classification of the domain of interest. The decision attribute establishes a partition of the universe in disjoint classes. We are interested in identifying every class according to values of condition attributes.

An equivalence relation, called indiscernibility relation, is associated with every subset of attributes $B \subseteq A$. This relation is defined as:

$$IND(B) = \{(x, y) \in U \times U : \forall a \in B, a(x) = a(y)\} \quad (4)$$

During the application of rough set theory, we must emphasize two definitions: Reduction and Core. Reduction means deleting the redundant attributes and values of the decision table. In order to reduce the complexity and gain a better result, a parallel arithmetic should be used. So the definition of core is being put forward. Core consists of indispensability attributes, and it can be deduced by the significance of attributes. Suppose r is a equivalence relation of R, G and R are two sets, if $POS(R-\{r\})(G) = POSR(G)$, then we say r can be reduced, or can not be reduced. If any element of R can not be reduced, then we call R is independent. Suppose $H \subseteq R$ and H is an independent set, if $POSH(G) = POSR(G)$, then H is the G reduction of R . The intersection of all relations that can not be eliminated in set R call the core of R , noted $Core(R)$.

Suppose C, D are subsets of A , then the dependency of knowledge D to Knowledge C can be described as: $\tau = \gamma(C, D) = \text{Card}(\text{PosCD}) / \text{Card}(U)$. Card is the radix of set A , and PosCD is the positive region of knowledge D to C . At the foundation of dependence, the significance of an attribute can be described as the changes happening to the

classification of the set after the attribute eliminated from the condition attributes. i.e.

$$\text{Sig}(C_i) = \frac{\gamma(C, D) - \gamma(C - \{C_i\}, D)}{\gamma(C, D)} \quad (5)$$

In formula 5, i is the number of condition attribute, the significance of an attribute describes the effect which takes in the whole decision table and influences to the decision result.

In the rough set framework, the simplifying process of a decision table includes two fundamental tasks. On the one hand, reduction of attributes consists of eliminating redundant or irrelevant attributes, without losing any essential classification information. On the other hand, reduction of attribute values is related to the elimination of the maximum number of condition attribute values, maintaining the classificatory power. Thus, if we obtain a reduced table, it is known as the decision algorithm. Each row of the table represents a decision rule.

Perceived value is a difficult concept in that it is hard to define and measure (Zeithaml, 1988; McDougall and Levesque, 2000). Broadly defined, perceived value is the results or benefits customers receive in relation to the total costs. In other words, it is the difference between perceived benefits and costs (McDougall and Levesque, 2000).

According to Zeithaml (1988), customer-perceived value is the consumer's overall assessment of the utility of a product based on a perception of what is received and what is given. This can vary between people but also from occasion to occasion for the same person (Zeithaml, 1988). Caruana et al. (2000) state; "value is seen to be more individualistic and personal than quality and involves both a give and get component" (p. 1339). Ravald and Grönroos (1996) suggest that customer-perceived value has to be related to different personal values, needs and preferences. In addition, they state, that the financial resources of the consumer must be taken into account.

III. A Case On Supplier's Determination

III.1. Initial Data of Suppliers

This section demonstrates the application of rough set theory on supplier's determination through a case. The integrated indexes of evaluating suppliers during the actual procurement activities are: Product Quality(PQ)、Purchase Cost(PC)、Service Quality(SQ)、Fulfillment Of Contract(FOC) etc[5]. Before the step of knowledge discovering through rough set theory from the suppliers' history operation data, we must organize the data in a proper order.

Suppose we have the history data table (Table1) of ten suppliers, in order to reduce the complexity of our exemplification in the case, we classify the four indexes that influence the determination of suppliers into two conditions:

Table1. Suppliers' History Date Table

NO	PQ	PC	SQ	FOC	SL
1	Good	High	Good	Bad	Medium
2	Good	Low	Good	Bad	Important
3	Bad	Low	Bad	Bad	Subordinate
4	Bad	High	Good	Bad	Subordinate
5	Bad	Low	Good	Bad	Medium
6	Good	Low	Good	Good	Important
7	Good	Low	Bad	Good	Important
8	Good	High	Bad	Bad	Subordinate
9	Good	High	Good	Good	Subordinate
10	Bad	Low	Good	Good	Medium

Table2. Suppliers' History Date Table after Dispersing

NO	a	b	c	d	e
1	1	0	1	0	1
2	1	1	1	0	2
3	0	1	0	0	0
4	0	0	1	0	0
5	0	1	1	0	1
6	1	1	1	1	2
7	1	1	0	1	2
8	1	0	0	0	0
9	0	0	1	1	0
10	0	1	1	1	1

Good, Bad or High, Low and Suppliers Level(SL) into: important, medium and subordinate. Universe $U=\{1,2,3,4,5,6,7,8,9,10\}$, Condition attribute set $C=\{ \text{Product Quality, Purchase Cost, Service Quality, Fulfillment Of Contract} \} = \{ \text{PQ, PC, SQ, FOC} \}$, Decision attribute set $D=\{ \text{Suppliers Level} \} = \{ \text{SL} \}$.

Here, we use number 1 represents Good condition or low cost, while 0 represents Bad condition or high cost in the value of condition attributes. In decision attributes value, 2 represents the supplier is Important, 1 represents Medium and 0 represents Subordinate. After dispersing the data, we use a, b, c and d representing the condition attribute PQ, PC, SQ and FOC, while e representing the decision attribute SL. After these works, we get Table2.

III.2. Application on Rules mining

Form Table1, we know that each row represents a supplier while a column represents an evaluating index to the supplier. These indexes are called attributes in the table and classified into condition attributes and decision attributes. In order to form the simplest decision one, we can reduce the table through the reduction theory of rough set. Then, the decision rules about the selection of suppliers can be deduced from the simplest table. All the rules can guide

the decision makers to choose a good supplier from competition ones.

The detailed steps of mining rules are as followings:

(1) Describe the attribute values of history data in a standard mode and reduce the redundant attributes.

(2) Make reduction to the value of decision rule and make out the core of each rule.

(3) Select the effective decision rule to form the reduced decision table.

Now, we use the method of attribute's significance to reduce the redundant attributes of condition table in step(1) above.

$$U/\text{Ind}(a)=\{(1,2,6,7,8)(3,4,5,9,10)\},$$

$$U/\text{Ind}(b)=\{(1,4,8,9)(2,3,5,6,7,10)\},$$

$$U/\text{Ind}(c)=\{(1,2,4,5,6,9,10)(3,7,8)\},$$

$$U/\text{Ind}(d)=\{(1,2,3,4,5,8)(6,7,9,10)\},$$

$$U/\text{Ind}(a,b,c,d)=\{(1)(2)(3)(4)(5)(6)(7)(8)(9)(10)\},$$

$$U/\text{Ind}(e)=\{(1,5,10)(2,6,7)(3,4,8,9)\},$$

$$\text{PosC}(D)=\{1,2,3,4,5,6,7,8,9,10\},$$

$$\gamma_C(D)=|\text{PosC}(D)|/|U|=10/10=1.$$

After reducing attribute a:

$$U/\text{Ind}(b,c,d)=\{(1)(2,6)(3)(4,9)(5,10)(7)(8)\},$$

$$\text{PosC-(a)}(D)=\{3,7,8,9\},$$

This time, the dependence of attribute a is:

$$\gamma_{C-(a)}(D)=4/10=0.4.$$

Following the same principle above, the dependence of other attributes are:

$$\begin{aligned} \gamma_{C-(b)}(D) &= 4/10=0.4, \\ \gamma_{C-(c)}(D) &= 6/10=0.6, \\ \gamma_{C-(d)}(D) &= 10/10=1. \end{aligned}$$

From the attributes' dependence we know that the classification ability does not change after deleting attribute d, so attribute d is redundant in this decision table. Then deleting attribute d and unite line 1 and 2, line 3 and 8, 7 and 10, we get a new decision table Table3.

Table3. Decision Table after Attribute Redundant

NO	a	b	c	e
1	1	0	1	1
2,6	1	1	1	2
3	0	1	0	0
4,9	0	0	1	0
5,10	0	1	1	1
7	1	1	0	2
8	1	0	0	0

The second step of the deduce process is value reduction to table 3 and achievement of the cores of all rules. First, let us look at rule 1 of Tab.3:

$$\begin{aligned} \text{Set } F &= \{[1]a, [1]b, [1]c\} \\ &= \{(1,2,6,7,8), (1,4,8,9), (1,2,4,5,6,9,10)\}. \end{aligned}$$

$$\text{Decision Category } [1]e = \{1,5,10\} .$$

$$\text{Here, } a(1)=1, b(1)=0, c(1)=1, e(1)=1.$$

$$[1]a \cap [1]b = \{1,8\} , \{1,8\} \not\subset [1]e ;$$

$$[1]a \cap [1]c = \{1,2,6\} , \{1,2,6\} \not\subset [1]e ;$$

$$[1]b \cap [1]c = \{1,4,9\} , \{1,4,9\} \not\subset [1]e .$$

So, we make out the core of decision rule 1, the core is: $a(1)=1, b(1)=0, c(1)=1$.

In the same method, we can get the cores of other decision rules:

$$\text{Core of rule 2 and 6 is: } a(2)=1, b(2)=1 ;$$

$$\text{Core of rule 3 is: } a(3)=0, c(3)=0;$$

$$\text{Core of rule 4 and 9 is: } b(4)=0, c(4)=1;$$

$$\text{Core of rule 5 and 10 is: } a(5)=0, b(5)=1, c(5)=1;$$

$$\text{Core of rule 7 is: } a(7)=1, b(7)=1;$$

$$\text{Core of rule 8 is: } b(8)=0, c(8)=0.$$

At last, we get the decision Table4 after the value reduction.

Table4. Decision Table after Value Reduction

NO	a	b	c	e
1	1	0	1	1
2,6	1	1	—	2
3	0	—	0	0
4,9	—	0	1	0
5,10	0	1	1	1
7	1	1	—	2
8	—	0	0	0

At last, we get the rules about suppliers' determination from Table4, these are:

(1) If supplier's product quality and service quality are good, though the cost of purchase is high, we can consider the supplier as a medium one during selection;

(2) If supplier's product quality is good and the cost is low, even we don't know the other indexes of the supplier, we can consider it as an important one;

(3) If the supplier's quality of product and service are bad, even we don't know the other indexes of the supplier, we can consider it as a subordinate one;

(4) Need not consider supplier's product quality, if the cost is high, though the service quality is good, we also consider it as a subordinate one;

(5) If the supplier's product quality is bad, while the cost and service are satisfying, we can consider it as a medium one during selection;

(6) Need not consider supplier's product quality, if the cost and service are not satisfying, then we can consider it as a subordinate one.

III.3. Application on Weights Ascertaining

Besides the rules we got in section 3.2, we can also make out the weights of the evaluating indexes of these suppliers from the following steps.

(1) According to formula (5), make out all the significances $\text{Sig}(C_i) (i=1,2, \dots, n)$ of every attributes in set $C = \{C_1, C_2, \dots, C_n\}$.

(2) Treat $\text{Sig}(C_i)$ we got in step(1) with formula (6) and consider the result P_i as the objective weight of every condition attribute C_i .

$$P_i = \text{Sig}(C_i) / \sum_{i=1}^n \text{Sig}(C_i) \quad (6)$$

(3) Experts give the subjective weights $Q_i(i=1,2, \dots, n)$ of all attributes of set $C=\{C_1, C_2, \dots, C_n\}$ and the subjective

weights must fulfill the condition of $\sum_{i=1}^n Q_i = 1$.

(4) Decision makers choose the proper experiential factor “a” and make out the integrated weights of attributes C_i based on formula (7).

$$I = \alpha Q + (1 - \alpha)P \quad (0 \leq \alpha \leq 1) \quad (7)$$

The first step is to make out the significances of all attributes, so the significances of suppliers’ evaluating indexes a、b、c and d are:

$$\text{Sig}(a) = (\text{Pos}C(D) - \text{Pos}C(a)(D)) / \text{Pos}C(D) = (1 - 0.4) / 1 = 0.6,$$

$$\text{Sig}(b) = (\text{Pos}C(D) - \text{Pos}C(b)(D)) / \text{Pos}C(D) = (1 - 0.4) / 1 = 0.6,$$

$$\text{Sig}(c) = (\text{Pos}C(D) - \text{Pos}C(c)(D)) / \text{Pos}C(D) = (1 - 0.6) / 1 = 0.4,$$

$$\text{Sig}(d) = (\text{Pos}C(D) - \text{Pos}C(d)(D)) / \text{Pos}C(D) = (1 - 1) / 1 = 0.$$

According to formula (6), we can get:

$$\text{Sig}(a)' = 0.6 / (0.6 + 0.6 + 0.4 + 0) = 0.375,$$

$$\text{Sig}(b)' = 0.6 / (0.6 + 0.6 + 0.4 + 0) = 0.375,$$

$$\text{Sig}(c)' = 0.4 / (0.6 + 0.6 + 0.4 + 0) = 0.25,$$

$$\text{Sig}(d)' = 0 / (0.6 + 0.6 + 0.4 + 0) = 0.$$

After getting the objective weights P_i , we should combine them with experiential ones Q_i . Here, suppose experts’ weights of condition attributes $C = \{a, b, c, d\}$ are 0.3、0.4、0.2 and 0.1, decision makers attach much more importance to experts knowledge, so we choose the experiential factor to 0.8, then, according to formula (7), these integrated weights are:

$$I(a) = 0.8 \times 0.3 + (1 - 0.8) \times 0.375 = 0.315,$$

$$I(b) = 0.8 \times 0.4 + (1 - 0.8) \times 0.375 = 0.395,$$

$$I(c) = 0.8 \times 0.2 + (1 - 0.8) \times 0.25 = 0.21,$$

$$I(d) = 0.8 \times 0.1 + (1 - 0.8) \times 0 = 0.08.$$

From the Formulas above we know that the weights of ascertaining indexes a、b、c、d are: 0.315、0.395、0.21、0.08. So, decision makers emphasize “ Cost” most during their procurement, the followings are “ Product Quality”、 “Service Quality” and “Fulfillment Of Contract”.

Table5. Attributes’ weights from different methods

Meth \ Attrib	a	b	c	d
Delphi	0.300	0.400	0.200	0.100
Statistic	0.375	0.375	0.250	0
Duality comparison	0.333	0.333	0.250	0.084
Rough Set	0.315	0.395	0.210	0.080

Table5 compares weights of attributes deduced from different methods. Comparing with other methods (Delphi or Statistic Method), we can see that the weights deduced from method rough set are much more accorded with the principle of ascertaining weights (the principle of combining subjective attitudes of decision makers with objective condition). This method considers both the suggestions of experts and the influences of objective statistics, avoiding the shortcoming of emphasizing particularly on one side in ancient methods. Decision makers can choose proper experiential factor to modify the proportion of subjective and subjective significances according to the background of application, this way, we can get more rational indexes’ weights of evaluating suppliers.

IV. Conclusions

From the case have presented above, we can draw the conclusions about the application of rough set theory on the selection of suppliers as follows:

(1) From the sight of objectivity of supplier’s determination, the application of rough set, can make out the weights of decision indexes objectively and reflect the weights of them, avoiding the condition of establishing the weights subjectively in other evaluating approaches. Further more, with the increase of experiment data, the rules we deduce will press close to the real world, so the approach of rough set can increase the objectivity and reality of the determination.

(2) From the sight of continuity of supplier’s determination, the application of rough set, can take good advantage of the supplier’s history evaluating data and analyze the experimental knowledge of former determination, finding the potential rules in supplier’s selection. So, the classification model established through rough set has good continuity.

(3) From the sight of data mining, the decision table in rough set approach is similar with the relation table in relation database, so the application of rough set is good at practicability and reliability[6]. In addition, rough set

approach can analyze suppliers' historical data in advance and delete the redundant attributes, so it improves the efficiency of determination and reduces the faulty rate.

An Approach to Integrate Heterogeneous Data Sources

Chaiyaporn Chirathamjaree

School of Computer and Information Science, Edith Cowan University, Perth, 6050, Australia
c.chirathamjaree@ecu.edu.au

Abstract: To gain a competitive advantage, it is extremely important for executives to be able to obtain one unique view of information, normally scattered across disparate data sources, in an accurate and timely manner. To interoperate data sources which differ structurally and semantically, particular problems occur, for example, problems of changing schema in data sources will affect the integrated schema. In this paper, conflicts between heterogeneous systems are investigated and existing approaches to integration are reviewed. This research introduces a new mediated approach employing the Mediated Data Integration Mediator (MeD-Int), and wrapping techniques as the main components for the integration of databases and legacy systems. The MeDInt mediator acts as an intermediate medium transforming queries to subqueries, integrating result data and resolving conflicts. Wrappers then transform sub-queries to specific local queries so that each local system is able to understand the queries. This framework is currently being developed to make the integration process more widely accessible by using standard tools. A prototype is implemented to demonstrate the model.

Keywords: Decision Support & Group Systems Conflict Resolution, Heterogeneous Databases, Integration, Legacy Systems, Mediation, Wrappers.

I. Introduction

The information required for decision making by executives in organizations is normally scattered across disparate data sources including databases and legacy systems. To gain a competitive advantage, it is extremely important for executives to be able to obtain one unique view of information in an accurate and timely manner. To do this, it is necessary to interoperate multiple data sources, which differ structurally and semantically. In the process of interoperating any two or more database systems, there are critical problems that need to be solved, for instance, some databases are designed from different models, objects which have the same meaning in different databases might have different names, and objects which have the same meaning in different systems might be measured by different units. Furthermore, there are identity conflicts, representation conflicts, scope conflicts, etc [1; 2; 4; 8; 9]. Although several researchers have studied the conflicts and integration of heterogeneous database systems [1; 9; 11; 13; 14; 17], there is still no common methodology for resolving conflicts and integrating such databases. Particularly, few studies have

focused on the integration of databases and legacy systems. In legacy systems, the semantics are hidden and hard to determine. In fact, some legacy systems store data to flat files, which are completely different in schematic design from database management systems (DBMSs).

Another significant issue is that almost all research on database integration presents pre-integration approaches using global schema techniques, which require complete integration. All local views are mapped by one global view. This method is convenient for users but it does not operate in the real-time manner because the global view must be created before query processing. As a result when only one object of a local system is modified, it affects the global schema requiring huge changes [4]. Furthermore, schema and semantic conflicts must be solved in the process of the global schema creation. The more data sources involved, the more difficult such conflicts are to be solved. This research focuses on the database and legacy integrating solution that avoids using the global schema pre-integration approach.

The Mediated Data Integration (MeDInt) Mediator is introduced in an attempt to overcome the above difficulties. It has been developed by focusing on providing a solution to interoperate heterogeneous data sources by transforming both the queries and the data transparently. Furthermore, this approach does not only solve schema and semantic heterogeneities, but also conflicts from different query languages and data models, namely data model heterogeneity.

II. Related Works

II.1 Conflicts and Resolution

Information from different sources can not be presented to users if it has not passed the process of conflict resolution. In terms of database integration, conflicts are differences of relevant data between component local database systems. The taxonomy of conflicts in this paper is divided into Schema conflicts and Semantic conflicts.

Schema conflicts are discrepancies in the structures or models of heterogeneous database management systems. Naming conflicts [8], Structural conflicts [4; 8; 9], and Identity conflicts fall into this conflict category. Naming conflicts are the synonyms or homonyms of objects in local systems. Structural conflicts are the different uses of data models to represent the same object. Identity conflicts occur when the different attributes, as a key, are used to access the same meaning information.

Semantic conflicts are discrepancies in the meaning of related data among heterogeneous systems such as Naming

conflicts, Representation conflicts [3; 4], Scaling conflicts [2], Granularity conflicts, Precision conflicts [1], Missing data, Scope conflicts, and Computational conflicts [2]. Naming conflicts are able to occur in data itself as well as in the structure of data. Representation conflicts or Format heterogeneities are the different uses of formats or data types to represent the same meaning objects. The different units of measurement generate Scaling conflicts.

From a survey of the literature, several methods to resolve conflicts have been found. In the case of Naming conflicts, a catalog [7], tables [4], or meta-data repository [1] can be used for maintaining these correspondences. An Object Exchange model [12] is able to transform semantics into simple structures that are powerful enough to represent complex information by using meaningful tags or labels. Kim [7] suggests three ways to resolve different representations of equivalent data: static lookup tables, arithmetic expressions, and mappings. In addition, a formulae has been suggested by Holowczak & Li [4] for converting values in one system to correspond with units in another system. They also introduce Superclasses to encapsulate each component database to create their relationships. Differences in attribute naming are solved by aliases [1; 4]. By using benefits of functions, Hongjun [5] proposes a data mining approach to discover data value conversion rules. Furthermore, independent views can be constructed to solve Structural conflicts. A view neither depends on any specific names nor on changes when schemas are modified [9].

II. 2 Integration Approaches

Numerous integration approaches have been introduced throughout the last twenty years to bring about the interoperability among heterogeneous systems. Missier, Rusinkiewicz, & Jin [10] categorise heterogeneity resolution methodologies into four main broad approaches: Translation, Integrated, Decentralised, and Broker based.

Translation approach needs highly specialised translation for each pair of local database systems. Therefore, the number of translators grows up exponentially especially when local systems increase. The development of these ad hoc programs is expensive in terms of both time and money.

In Tight-coupling approach or fully integrated approach, individual schema from multiple data sources is merged by one or more schemas. If only one schema is prepared, it is called a global schema approach. Otherwise, it is called a federated database approach. The global schema approach allows access of multiple data sources by providing the conceptual global schema as a logically centralised database [6]. Multiple local schemas are consolidated to create the global schema. Users are able to use one database language to query the global schema without understanding any local schemas. Generally, problems of heterogeneity must be resolved in the process of creating the global schema. A major difficulty is the process of creating global schema which thoroughly understands the differences between the independently-designed heterogeneous local schemas, and homogenises such differences [7]. This approach is more

difficult when the number of databases increases. Another approach, the federated database, also allows users to query more than one federated schema without knowledge of local data sources. This approach still requires complete pre-integration. The federated schema must be developed before issuing any queries, so any changes in local schemas would affect the federated schema.

Loose-coupling approach [2] or decentralized approach has been introduced in an attempt to resolve the problems arising from tight-coupling approaches by discarding either pre- or partial-integrated global schema. This approach allows users to query local database systems directly without any global schemas by placing the integration responsibility on users. Multi-database manipulation languages, which are capable of managing semantic conflicts through their specification, are provided as query language tools that are able to communicate with the local databases. Users can see all the local schemas and create their own logical export schema from selected schemas relevant to the information they need [3]. However, it requires users to have semantic understanding and to be able to resolve conflicts in creating their schema, which will be numerous with large numbers of data sources. In Broker-based approach, the crucial part is the conflict detector module using shared ontologies, but the process of doing those ontologies is not completely automated.

The limitations of the above integration approaches have led integration technologies towards a new variety of solutions. Various theories have been applied to solve integration problems such as the object-oriented model, knowledge base [11; 14; 16], ontology [13], and modeling [4].

III. THE Medint MEDIATOR

The research has introduced a heterogeneous database integration model incorporating a mediator and wrappers as intermediate layers between the application and data sources. The mediator, MeDInt (Figure 1), serves as an information integrator, between the application and wrappers. Generally, mediators are responsible for retrieving information from data sources, for transforming received data into a common representation, and for integrating the homogenised data [15]. In this model, the MeDInt Mediator acts as an interchangeable agent and facilitator for wrappers and clients. It consists of six components working together transparently to facilitate clients and data sources to achieve the following tasks:

- transforming and decomposing the submitted query into subqueries and then distribute them to associated wrappers;
- providing both schematic and semantic knowledge which is critical for query transformation and conflict resolutions;
- resolving conflicts; and
- consolidating query results.

All the functions above are served by six components (Figure 2), which are the Registering Processor (RP), the Query Transformation Agent (QTA), the Mediated MetaData

(MMD), the Conflict Resolution Agent (CRA), the Consolidation Processor (CP) and the Rendering Agent (RA).

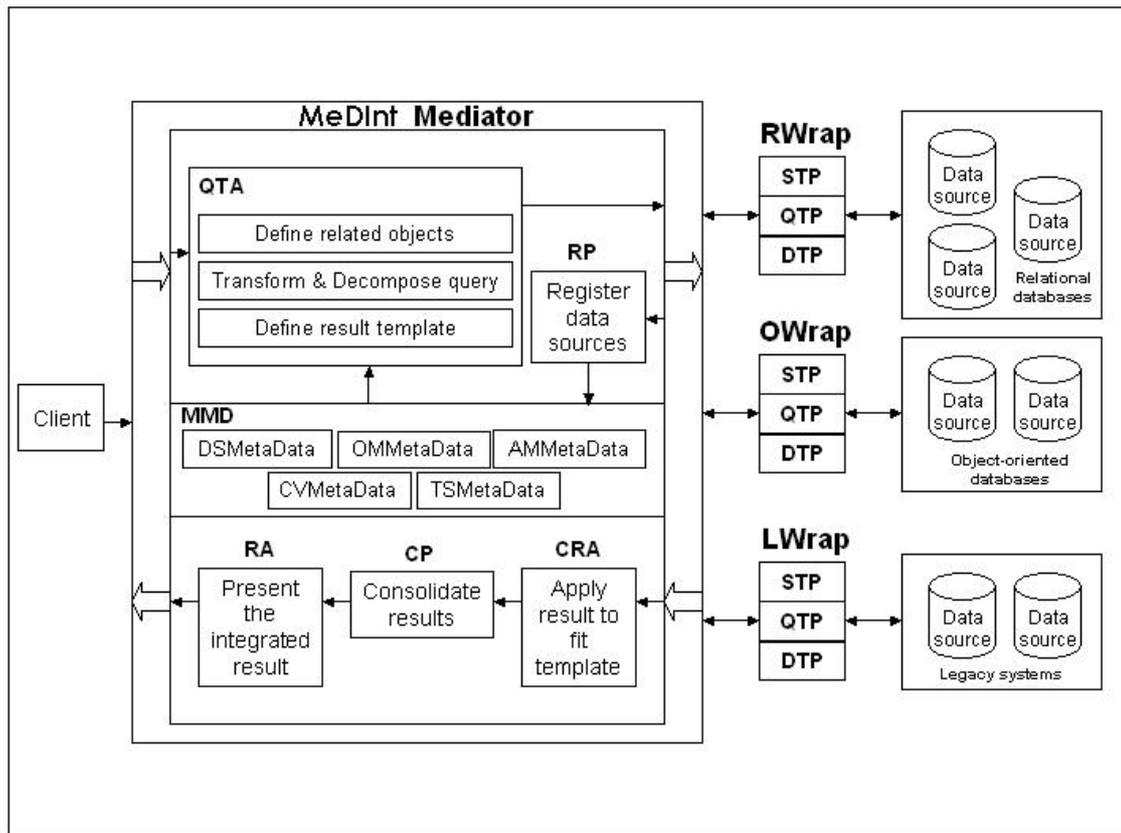

Figure 1. The MeDInt mediator

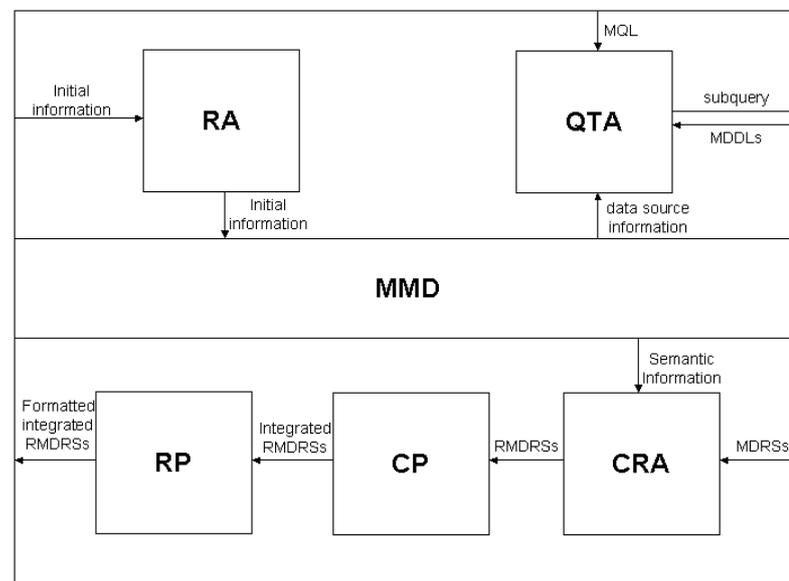

Figure 2. The six components of the MeDInt mediator

IV. MeDInt Processes

When a new data source is added to the integration system, it is registered to the Mediated MetaData (MMD). Data source information, for example, assigned name, location, type, description, and constraints relating to its structure and semantics are collected into the Data Source Metadata (DSMetaData), a category of MMD. A query from a user to retrieve the information from heterogeneous data sources is sent to the MeDInt Mediator instead of directly to the data sources. The required objects are determined and a request is submitted to the wrapper to get the related object schema definitions. The submitted query from the user is transformed to a specific query language appropriate to the database management system of the data source. A template for the results is created from the results obtained from multiple data sources. This method does not try to resolve conflicts directly which would be more difficult and complicated.

After getting a response data back from data sources, a component of a wrapper translates the query results into the Mediated Data Representation Structure (MDRS). The conflict resolution is done by applying all MDRSs to fit into the structure of the predefined template. The resultant MDRSs that are structurally equivalent are then integrated and consolidated. Finally the integrated result is sent to the user.

This approach overcomes the weakness inherent in other approaches that require the physical or logical integration of component schemas. Only the query result from each source, according to the result template, will be integrated instead. The template will be created from the submitted query. The resultant data from each data source will be applied to fit to the template which is the means by which the heterogeneities are resolved.

V. Wrapper Architecture

Wrappers are designed to handle data model heterogeneities arising from many different types of data sources. This includes the ability to deal with different schema definitions, different query languages, and different data representation structures. One novel feature of the approach is an attempt to reduce the amount of middleware modification when a data source is added, removed or modified. The approach is to map the foregoing objects to the Mediated Data Model (MDM), which is the common data model used in this research. The MDM, a way of facilitating the dealing of data model heterogeneities, consists of the Mediated Data Definition Language (MDDL), the Mediated Query Language (MQL), and the Mediated Data Representation Structure (MDRS).

A wrapper implementation is required for each different data model of a new data source. For m data sources comprising n different data models (where $n \leq m$) to be

integrated, this will only require n wrappers. This is much more favourable compared with the traditional translation approach in which $m*(m-1)$ translators are required. The computational efficiency is even more pronounced for higher values of m (for $n > 1$).

Figure 3 shows the area of responsibility of wrappers in relation to that of data sources. In this approach, objects and attributes are handled by the file/database management system of each data source. The data model heterogeneities are resolved and handled by wrappers.

Since the relational data model, the object data model and legacy text files are widely used in the real world, three wrappers are developed: an RWrap for the relational data model, an OWrap for the object-oriented data model, and an LWrap for legacy text files. Inside each wrapper (Figure 4), there are three algorithms serving as a Schema Translation Processor (STP), a Query Translation Processor (QTP) and a Data Translation Processor (DTP).

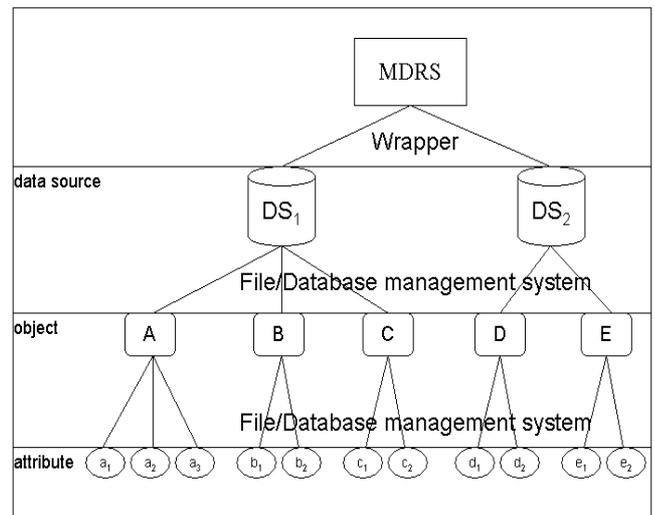

Figure 3. Data source and wrapper responsibility

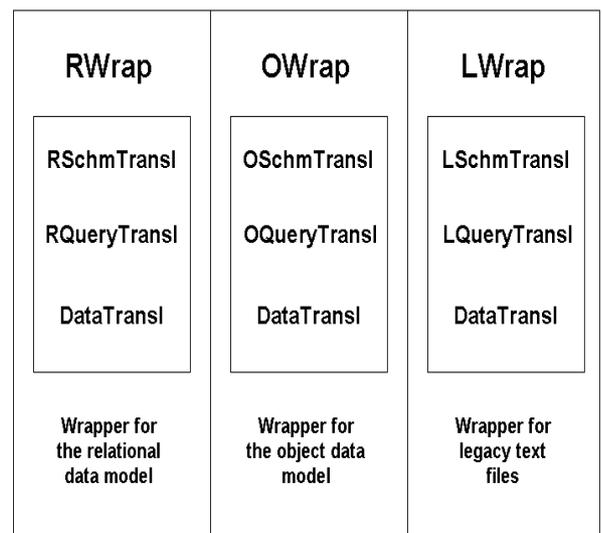

Figure 4. Three different wrappers

An STP translates schemas from the data source into the Mediated Data Definition Language (MDDL). A QTP is responsible for translating the Mediated Query Language (MQL) subqueries to a specific query to be processed by each data source. A DTP gets the query result from each data source, and then translates this into the Mediated Data Representation Structure (MDRS) where each unit is a set of required object attributes or properties.

VI. Results and Discussion

A number of example problems of heterogeneities from a number of information systems that require integration have been tested. The objectives are to demonstrate the integration process using the MeDInt mediator and to evaluate its correctness.

Test problem 1 is a Hotel Reservation Information System which provides information for travel agencies.

The information systems of contacted hotels need to be interoperated. Heterogeneities have been found when integrating them. The 2nd test problem is a university information system which is composed of a relational system and an object-oriented system.

The proposed MedInt Architecture and MDM have been tested for functionalities and the outcomes look promising. Results (Table 1) indicate that the objectives in resolving conflicts both structurally and semantically have been achieved. From the table mentioned above, the following three categories of heterogeneities have been determined: Model, Schema, and Semantic. All of them have been solved as shown by the MedInt with the support of the MDM (the Mediated Data Model has been developed in this study specifically for describing and representing heterogeneous data both schematically and semantically) which is suitable for homogenising different data models, schemas and semantics of component data sources. Another feature of our proposed model is that it can be implemented in any languages. We have chosen XML as the implementation language in the prototype because it offers a number of advantages. XML is platform independent, provides self-described tags which are easy to understand. It is also suitable for describing schema and semantic of objects in a real world since XML is based on an object-oriented model.

VII. Conclusion and Future Works

The research proposes the MeDInt Mediator as the framework based on the mediated approach for the integration of heterogeneous data sources to solve conflicts occurring when interoperability is required. The paper presents a new approach for achieving the interoperability of multiple data sources logically integrated at the time the query is issued. The system is able to describe or represent heterogeneous data both schematically and semantically. No pre-integration is required before users can issue their queries. This avoids the problem of local schema evolution

which usually happens in dynamic systems. Further investigations are planned to cover the query performance issues. Another possible future work is to incorporate the write access through the updating of master data sources and the replication of data sources.

Abstract: As demands of data processing and computing power are increasing, existing information system architectures become insufficient. Some organizations try to figure out how to keep their systems work without purchasing new hardware and software. Therefore, a Web-services-based model which shares the resource over the network like a P2P network will be proposed to meet this requirement in this paper.

In addition, this paper also discusses some problems about security, motivation, flexibility, compatibility and workflow management for the traditional P2P power sharing models. Our new computing architecture - Computing Power Services (CPS) - will aim to address these problems. For the shortcomings about flexibility, compatibility and workflow management, CPS utilizes Web Services and Business Process Execution Language (BPEL) to overcome them. Because CPS is assumed to run in a reliable network where peers trust each other, the concerns about security and motivation will be negated.

In essence, CPS is a lightweight Web-Services-based P2P power sharing environment and suitable for executing computing works in batch in a reliable network.

I. Introduction

In the era of host computing, almost everything is done by mainframe computers. Processing in the mainframe often becomes a bottleneck in the information systems. Therefore, it forces enterprises to spend more money in upgrading mainframe system in order to keep up with increasing demands of computing power. Then, the client-server architecture is proposed to address such issue. The client-server architectures shift processing burden to the client computers. By workload sharing, client-server systems can maintain efficiency of the information systems while reducing the budget for computing resources.

Although client-server architectures have gained wide acceptance, increasing maintenance cost after system deployment push many companies to search for another ways to improve their processing power again without more investment in new hardware and software in a competitive market. In the meantime, some people try to think about how to use existing resource in the company such as idle computers or free storage space to reach the goal. This new approach is called peer-to-peer systems. It allows users to

make use of collective power in the network and benefit by lower costs and faster processing times.

Since P2P model is a system that allows users to share their resources with each other over the network, it is a matter to think about what kinds of computer resources can be shared. Thus, computer resources such as file system, network bandwidth and computing power are shared in some current P2P models. But there are some problems in existing P2P models, like lack of ability to customize computing tasks, workflow management etc.

To address these problems, this paper presents CPS - a lightweight Web-Services-based P2P power sharing environment which is suitable for executing computing works in batch in a reliable network. The architecture relies on BPEL to provide workflow management and on Oracle's BPEL Process Designer to provide a visual development environment. CPS also benefits from the characteristics of Web services, which are an open standard and loosely coupled.

II. Peer-To-Peer Model

The term "peer-to-peer" (P2P) refers to a class of systems and applications that collect distributed resources to perform a critical function in a decentralized manner. The resources could be computing power, data (storage and content), network bandwidth, and presence (computers, human, and other resources) [6]. Generally, there are three features in the P2P system: [1]

- A Computer can act as either client or server in the system.
- It allows users to make use of the collective power in the network
- A user benefits from lower costs and faster processing times in the system.

By employing P2P model, an organization can accumulate the existing resources to more powerful resources to satisfy increasing demands of processing power with economic expense. No matter how old the computer is, how narrow the bandwidth is and how less the storage is, many a little may make a mickle in the P2P network and it is what P2P model want to do.

There are two main categories of P2P system currently. One is file sharing (Napster) model and another is distributed computing (CPU power sharing) model [1].

File sharing model

According to [6], Content storage and exchange is one of the areas where P2P technology has been most successful. Distributed storage systems based on P2P technologies are taking advantage of the existing infrastructure to provide the features of file exchange, highly available safe storage, anonymity, and manageability.

Napster is the first P2P file sharing application that jump started the P2P area. Napster uses the centralized directory model to maintain a list of music files, where the files are added and removed as individual users connect and disconnect from the system. Users submit search requests based on keywords such as "title," "artist," etc. Napster has been quite popular. It has had more than forty million client downloads and has led to numerous variants of file-sharing applications [6]. Other famous model like E-Donkey, eMule and Bittorrent are also the examples of P2P file sharing systems.

Distributed computing

Another model of P2P system is distributed computing. This model tries to combine computing power to satisfy processing demands. It can shorten a long processing time without upgrading processing equipments. For example, in January 1999, a system with the help of several tens of thousands of Internet computers broke the RSA challenge [DES-III] in less than 24 hours using a distributed computing approach [3].

Distributed computing is often implemented in large-scale scientific researches. A famous one is SETI@home [5]. Up to October, 2005, this project has a consolidated power of about 40 TeraFLOPs/s (Thousands of Billions of floating point operation per second), collected from more than five million registered user machines [12].

In general, works which will be solved in a distributed computing system need to be split into small independent parts. Then, each part will be done by the specific software which is downloaded from central server and is run on participant computer. The results will be collected by a central server. Because the results are collected, the tasks are assigned by a central server and no direct communication occurs between participant computers (peers), someone argues that this architecture is not a purely P2P architecture [6].

III. Problems Analysis

Problems about distributed computing

Because distributed computing can integrate computing power over network to meet high processing demands such as large-scale scientific computing and process efficiently, it is suitable to process complex tasks. Nevertheless there are some problems which make small-scale organizations hard to pursue this architecture. These issues are discussed as follows.

- Security

Security in the distributed computing model is based on trust. Participants must completely trust the research organization before they download the programs because to allowing unknown programs running on your own computer is greatly exposed to security breaches. A malicious attacker may add or delete files on the computer, or connect to other computers and perform illegal operations by attacking vulnerability on the computer. It is very difficult to secure P2P applications against such misuse, but if the patrons of P2P project are famous like Intel and the University of Oxford sponsoring the Cancer Research Project in UD, reliance on safety of their computers will be enhanced.

- Motivation

Participants who take part in distributed computing only want to make some contribution to the world and do not ask any pay back. In many companies, there are thousands of idle computers on 5:00 PM between 9:00 AM. Why do we use them to process something? Someone argue that those equipments are exclusive assets for companies and it is not necessary to do something that is not beneficial to them. Similarly, general participants do not hope to join the projects with commercial purposes. To gain the participant's confidence and attract them to participate, some famous P2P systems like UD - a cancer research project - announce their research results do not belong to any commercial originations.

- Flexibility

In order to contribute, participants must download the specific program which is developed for that project and install it on their computers to donate CPU power. Once that program needs to be updated to do new research, the tightly-coupled relationship between participating program and central server would make it hard to update all the programs around the world efficiently. In addition, such kind of project can not let participants design their own tasks and execute them in the system. Although grid computing provide such service, a command-line but not a visual interface to use the service will make participants feel less friendly.

- Compatibility

Compatibility of participating programs across different platforms is another problem. Some participating programs, such as ones in UD project are only run on NT-compatible platforms. However, there are a large number of workstations that use Unix or other as operating systems. It will be a pity that those workstations can't join this project due to compatibility. Although some distributed computing systems like SETI@home solve this problem by developing different versions of the program for different platforms, it will increase the maintenance cost as many versions of the program must be developed and updated.

- Workflow Management

What most of Grid or P2P distributed computing middleware focuses on is performance, workload balance or

stability but hardly workflow management. With workflow management, a complicated job which is composed of many small tasks can be executed in parallel or sequentially. At present, it is not natively supported by most models.

Available Solutions

According to the issues mentioned above, the paper presents some available solutions or technologies to address these problems.

Asynchronous Web Services

Web Services is a software development solution based on Services Oriented Architecture (SOA) in Figure 1. A Web-services-based system can inherit the features of Web Services which are loosely coupled and open standard. If a computing system is implemented by Web Services, it will not only improve flexibility of software updates in the system because of loosely-coupled relationship between service consumer and provider but also be easily to communicate because of open standard.

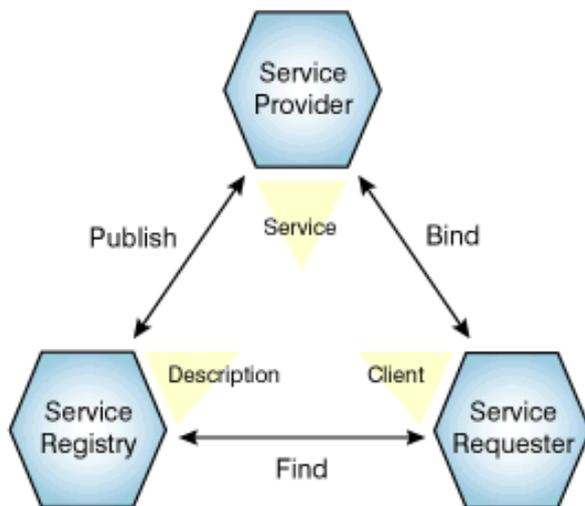

Figure 1 Architecture of Web Services [4]

Web Services is a message-based architecture and the interaction between services can be synchronous or asynchronous. In essence synchronous Web Services is not suitable for distributed computing system because it is hard to estimate the processing time in the system and it may cause timeout exception. Therefore, asynchronous Web Services [7,8,9] should be applied in the system to avoid over-time exception because it is usual to wait for response until tasks finished in distributed computing environment. The problem of flexibility will be addressed by using asynchronous Web Services to implement distributed computing system.

Business Process Execution Language (BPEL)

BPEL [9,13] is a de facto standard of Web Services composition and integrated by IBM and Microsoft from WSFL and XLANG. It has the characteristics such visual

development, workflow management, exception and transaction handling and compatibility with Web Services [2].

Based on the characteristics of Web Services, BPEL is suitable to solve the issues of a visual development environment and workflow management in distributed computing system. In addition, a complicated job can be tackled by Web services composition which BPEL aims to address and can be easily executed by BPEL engine.

Implementation in a trusty network

As discussed in last section, security in distributed computing system is based on trust. So, it will be easy for famous and large originations to sponsor P2P distributed computing project but not for small-scale and medium-scale companies. However, if we think from the perspective of an organization, how about using idle computers in the origination to process what the origination want to compute. In other words, it is implementation in a trusty network.

In this paper Trusty network is defined as a network where peers trust each other. No matter the intranet of an origination or computer network of the friends, it can be classified as trusty network if the peers in the network trust each other. Our lightweight distributed computing system is assumed to implement in a trusty network. Thus, the concerns about security and motivation can be negated.

IV. The Architecture of Computing Power Services

Based on the possible solutions in last section, this paper proposes the CPS architecture, which is a Web-services-based P2P architecture as shown in Figure 2. It provides users a platform to design the business processes and control workflow of the processes by using the visual characteristics of BPEL. The architecture is assumed to be implemented in the trusty network to execute the computation-intensive tasks by using the idle computing power in the enterprises.

The Model of Web-Services-Based Power Sharing

The key point of CPS is how to assign the jobs in distributed computing environment. Intuitively, the computing requester should search for the computing units and give them the tasks to do. If CPS is implemented so, each computing unit will need to publish a Web service as accessing point. It will mean an application server will be necessary to host a Web service.

However, such environment will be too complicated for users to provide computation and it will discourage users to participate the project. Hence, to comply with the concept of thin client and encourage users to provide their computing power, this paper makes the computing unit as service requester and the computing requester as service provider.

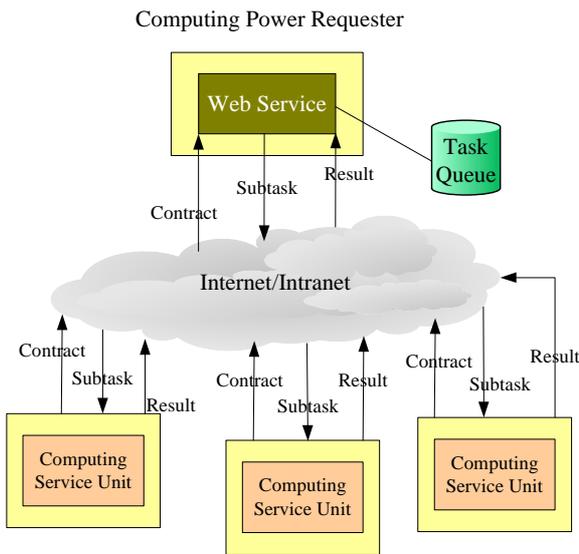

Figure 2 Architecture Diagram of CPS

The Roles of CPS Architecture

Because CPS bases on the architecture of Web services, it will inherit the characteristics of SOA which consists of 3 participants that are service requester, service provider and service broker. However, in order to make the program developed in CPS as thin as possible, 3 participating roles will be changed slightly to meet the requirement discussed in last section. The description of 3 roles will be explained in the following section.

● The role of Coordinator

The coordinator acts as a service broker to fairly mediate between the computing unit (service requester) and computing requester (service provider). Its main function is to maintain a list which records the URL and requirement of computing requester. This list will be created when the computing requester publishes its Web service in the coordinator. If computing unit asks for the subtasks through the coordinator, the coordinator will assign the URL of computing requester in the list to computing unit by round-robin mechanism. Afterward, the computing unit will use the specified URL to communicate with the computing requester directly.

In addition, the function of account and auditing management will be implemented at the end of coordinator. This role is corresponding to the role of UDDI in SOA.

● The role of Computing Power Requester

The requesters design their processes by a BPEL visual development environment. After designing, the requester will publish their requirement at the end of coordinator. If computing unit asks for the subtasks through the coordinator, the coordinator will assign the URL of computing requester in the list to computing unit by round-robin mechanism. Afterward, the computing unit will use the specified URL to communicate with the computing requester directly.

In addition, the function of account and auditing management will be implemented at the end of coordinator. This role is corresponding to the role of UDDI in SOA.

● The role of Computing Unit

This role is responsible for execute computation. It will inquire the coordinator to ask for the job when it is idle. After getting back the requester’s URL of Web services, it negotiates with the requester to download the task and required files for that task. Then, it starts to execute the task and respond the result to the requester when the task is finished. The whole procedure will continue until all tasks are done.

The interaction among roles and the operating procedures of CPS are described by Figure 3 below.

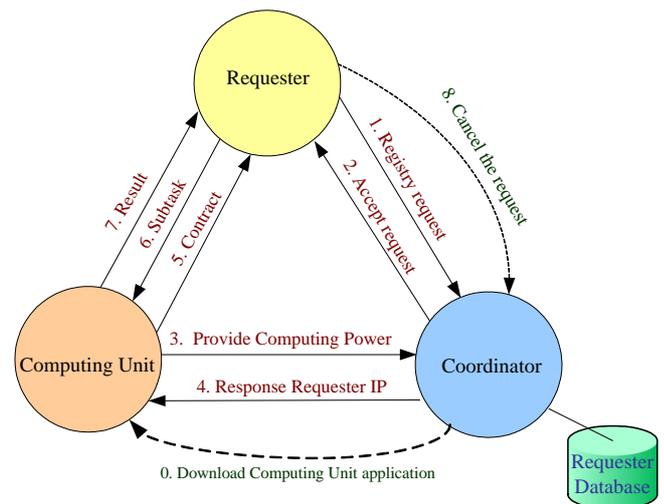

Figure 3 Operation Diagram of CPS

The System Architecture of CPS

The Figure 4 is the diagram of CPS architecture. By functionality, the architecture is divided into 5 layers, which are the User Layer, the Power Sharing Layer, the Communication Layer, the Contract Layer and the Discovery Layer.

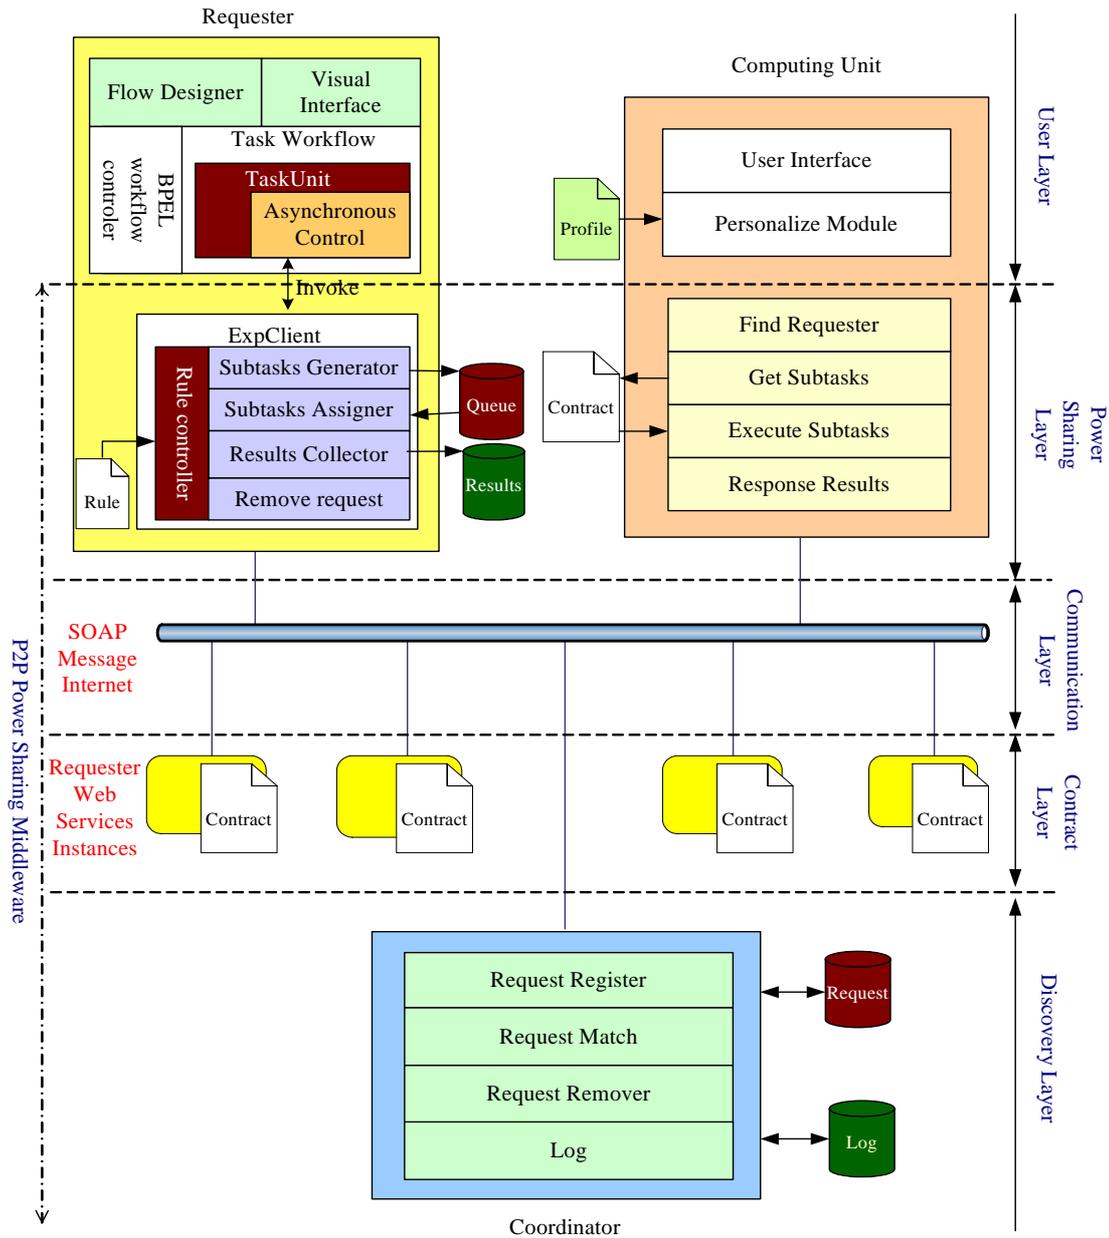

Figure 4 The Layer Diagram of CPS Architecture

P2P Power Sharing Middleware

Excluding the User Layer, the other 4 layers comprise the P2P Power Sharing middleware which is the core of CPS.

Because CPS is based on Web services, the middleware is also established by the protocols of Web services as the Figure 5 shows.

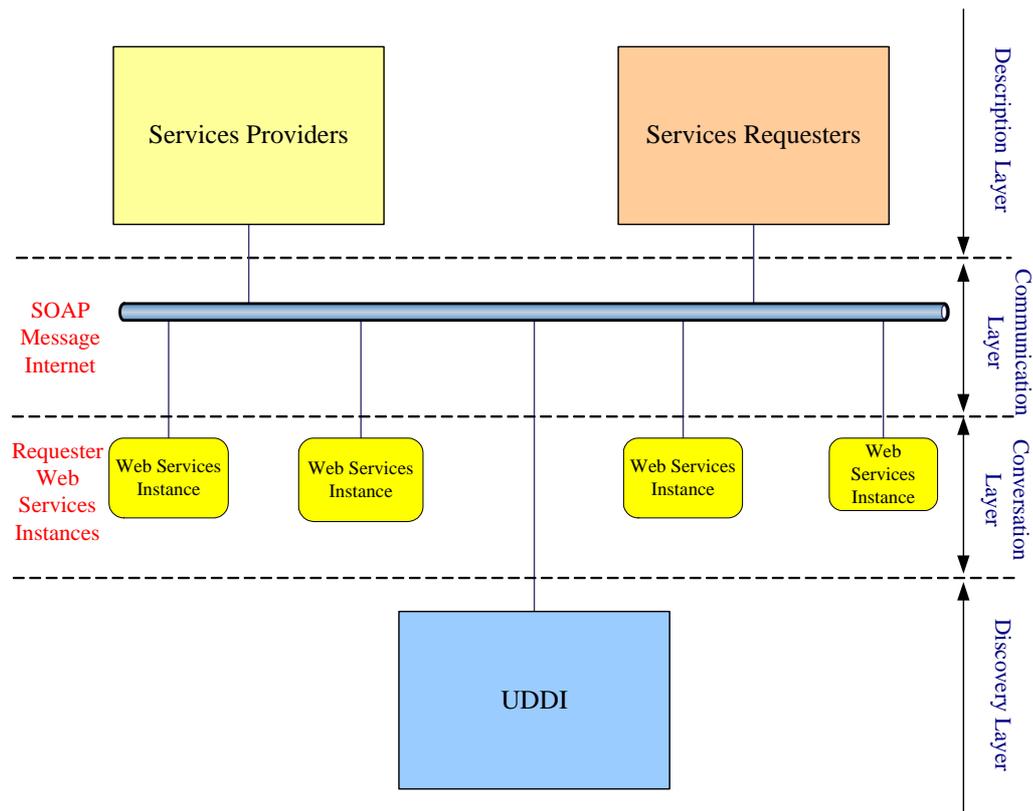

Figure 5 The Diagram of P2P Middleware in the CPS Architecture

- The User Layer

The users access the whole architecture in this layer. This layer will be implemented at the end of requester and computing unit. While, at the end of computing unit, it provides an interface to control the execution of the program, it will allow user to design the BPEL process at the end of the requester. Besides, it also provide GUI interface to facilitate the designing and managing the workflow of the process.

- The Power Sharing Layer

This layer corresponds to the Description Layer of Web services. It describes the interaction between the requester and the computing unit.

- The Communication Layer

This layer uses the communication mechanism of Web services, i.e. SOAP.

- The Contract Layer

The conversation between a computing unit and the requester will be defined by the contract in this layer.

- The Service Discovery Layer

The coordinator operates in this layer as a broker agent for the requester and computing unit. The coordinator will not involve the computing.

The Interaction between User Layer and P2P CPS Middleware

By using BPEL as a language to develop the process, CPS provides the environment of visual development and the capability of workflow management. However, BPEL doesn't support the distributed computing. Therefore, this paper develops a TaskUnit program which interacts with P2P CPS middleware to address this issue.

Actually, TaskUnit is a process developed by using BPEL. It can be viewed as the process of task dispatcher to provide the capability of distributing computing. It comprises of 2 modules. While One module is to invoke a ExpClient Web service, another module will asynchronous receives the result sending by P2P CPS middleware.

The Figure 6 describes the interaction between TaskUnit and P2P CPS middleware.

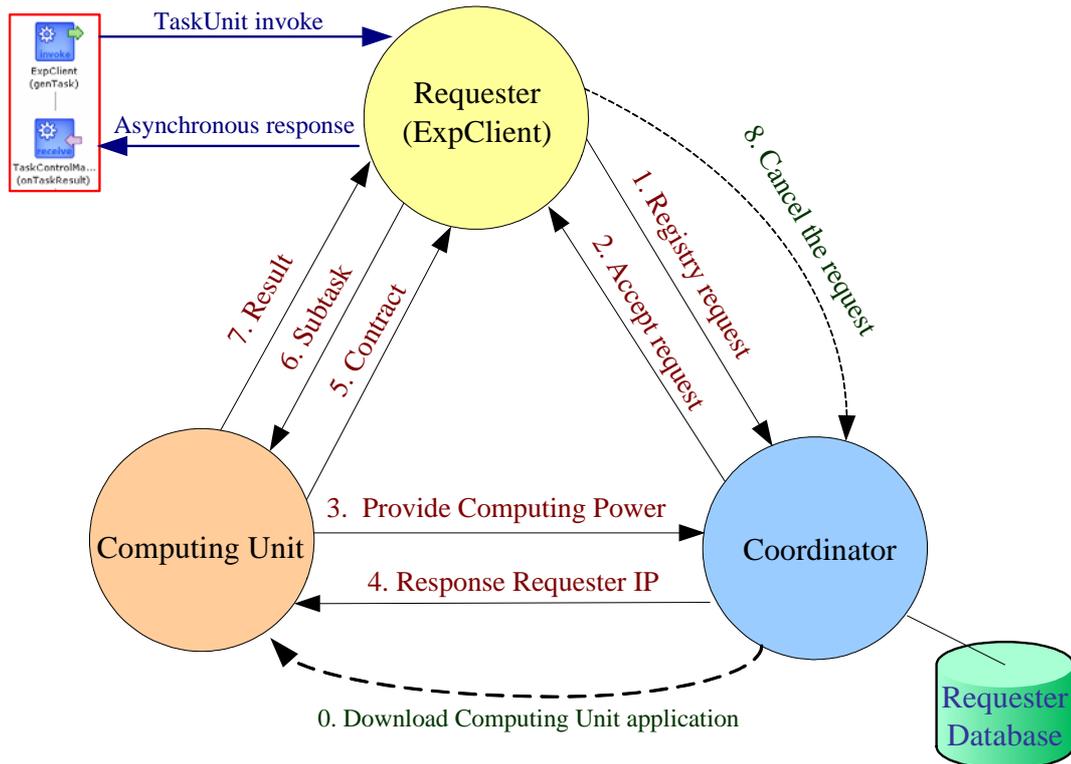

Figure 6 The Interaction Between TaskUnit and P2P Middleware

The Mechanism of Exception Handling

There are two possible exceptions when CPS operates. The one is that a user closes the program at the end of computing unit, the other is that the computing unit can not finish the task before time-out. To address both exceptions, CPS employs the mechanism of task reassigning after time-out and roll-back at the end of computing end.

The Assigning Rule at the End of Requester

The flowchart of assigning subtasks at the end of requester is indicated in Figure 7. In general, the mechanism of assigning subtasks will distribute the unassigned subtasks to the computing unit. If all subtasks are assigned, the requester will use the mechanism of reassigning subtasks to find the time-out tasks. The length of time-out timer will be defined in the assigning rules.

Although CPS can handle the breach of contracts by using the mechanism of reassigning subtasks, it will cost more resources to redo the tasks.

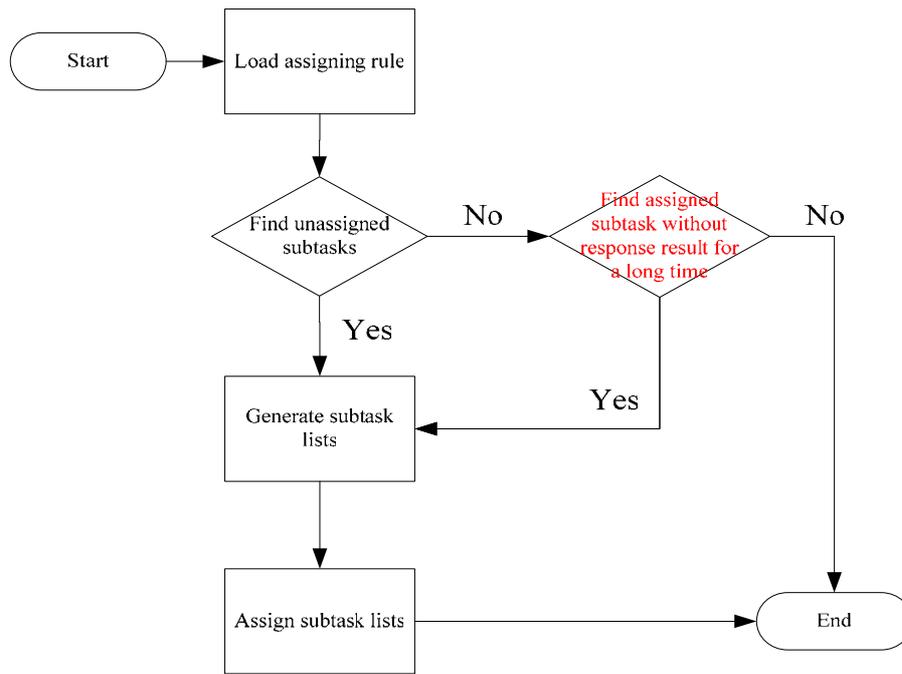

Figure 7 The Flow Chart of Assigning Subtasks at the End of Requester

The Roll-Back Mechanism at the End of Computing Unit

As Figure 8 depicts, the program at the end of Computing Unit will perform computation according to the contract. After finishing the subtask, it will reply the result to the requester, terminate the contract and remove results. If the program is abnormally terminated, the contract still exists at

the end of Computing Unit. Therefore, as soon as the program starts, it will verify existence of the contract. If it does, the program will remove the previous result and do computation again. Although this paper adopts the conservative way to roll back the computation, it guarantees finishing the contract.

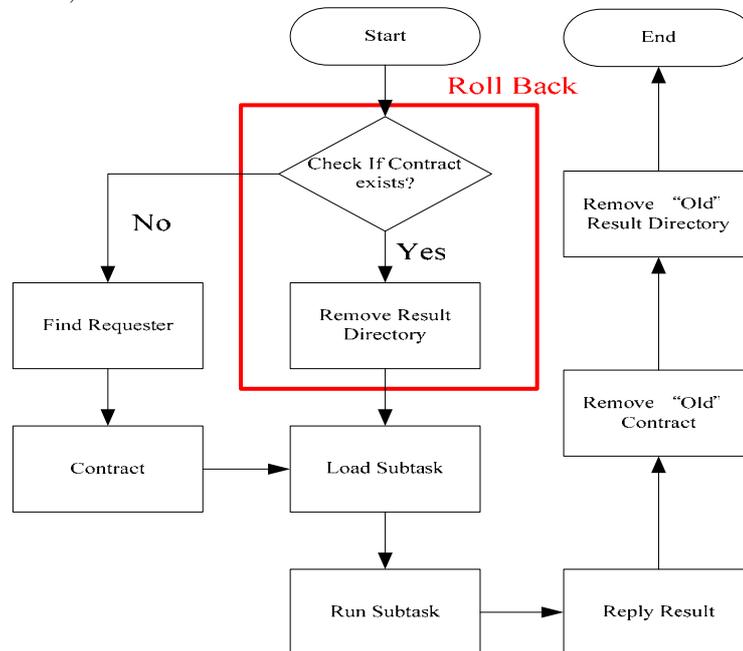

Figure 8 The Flow Chart of Executing Subtasks and Roll-back at the End of Computing Unit

V. Implementation and Result

System Implementation

As Figure 9 depicts, CPS is implemented in the trusted network to utilize the idle computing power. The coordinator publishes a Web service to provide the list of requiring

computing power as the access point of CPS. As for the requester, it uses Oracle Process Manager Server [11] to host BEPL engine and Oracle PM designer with Eclipse to provide GUI interface for designing and management. Meanwhile, a low-priority program is run at the end of the computing unit to execute the task from the requestor. The purpose to lower the priority of a program is to avoid impacting the routine work of the computing unit.

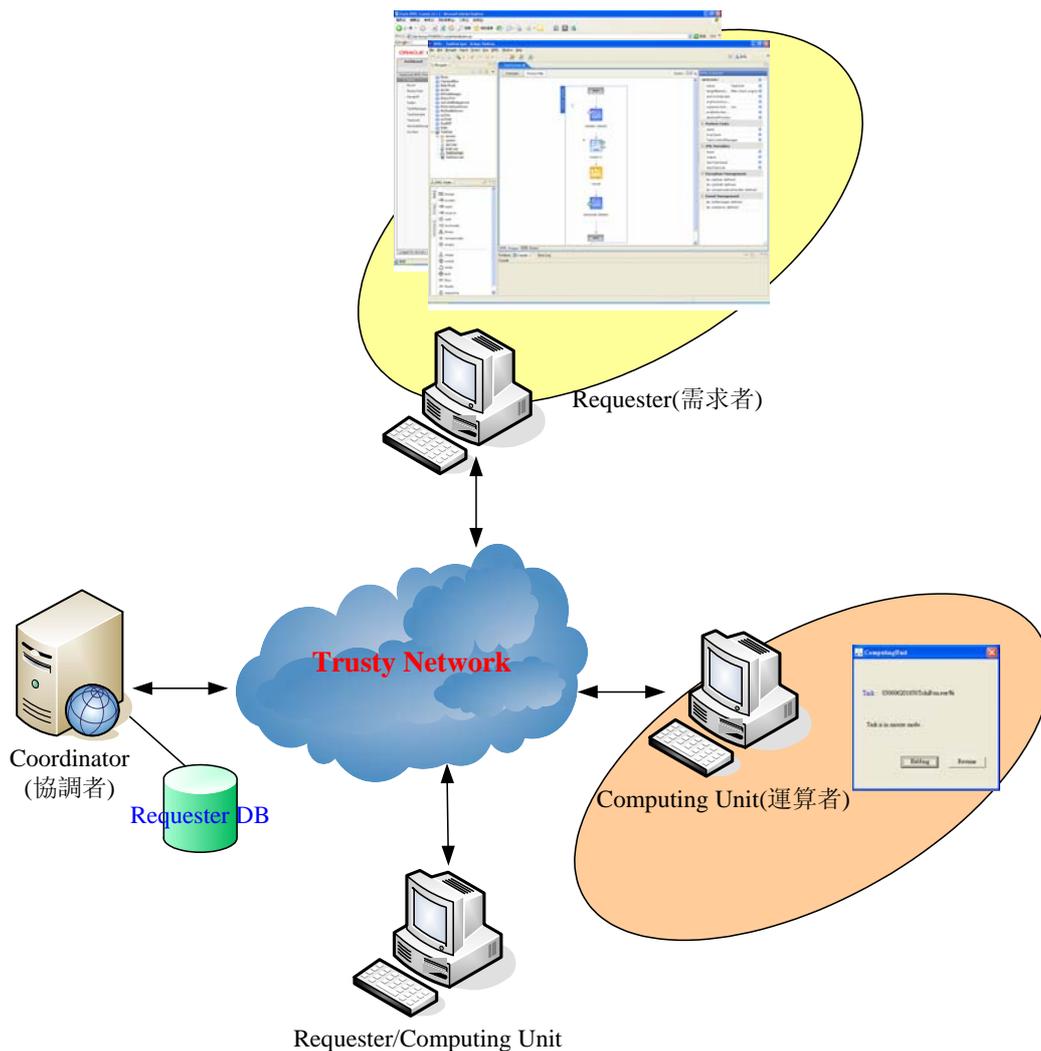

Figure 9 The Deployment Diagram of CPS

Result

To verify the architecture, a lab is arranged to test CPS on executing the program from [14]. This program will extract the watermark by using 76,177 files which will be grouped into several subtasks with a group having 100 filters. By using the similar computers at the end of computing unit, the

total computing time versus the number of computers involved to finish the lab is graphed in Figure 10.

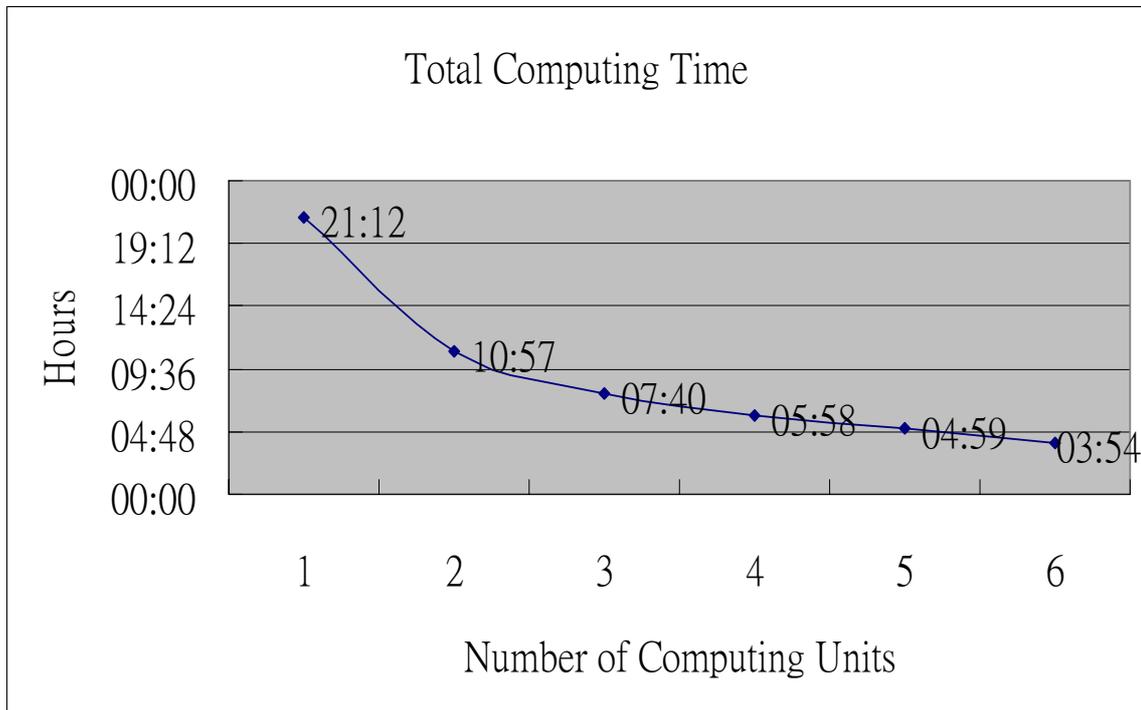

Figure 10 The Computing Time to Finish the Lab

According to [14], one computer will spend about 20 hours to finish the specified lab. If the number of filters is increased to 1,628,250 and each group consists of 500 filters, one computer will need 18 days to finish the lab. However, CPS will shorten the computing time to 2 days 14 hours 13 seconds to do the same lab. The deducting ratio is almost 1/9. As a result, CPS indeed helps executing a computation-intensive task.

VI. Conclusions

This paper presents the architecture of CPS which employs the protocols of Web services to address the flexibility issues of current P2P computing, uses BPEL to control the workflow of the process and provides a user-friendly environment to design the process. In addition, the architecture is assumed to perform in the trusted network to avoid the security issue.

Such a lightweight architecture is especially applicable to the batch programs which need intensive computing power and appropriate to the enterprises which can efficiently utilize their computing power after the office hours. Besides, it also provides a graphical designing and management environment to the enterprises.

Future Works

- Workflow Management

Currently, the mechanism of Roll-Back will redo the unfinished task when an exception occurs. The purpose to do so is to guarantee the contract is performed exactly. However, it will consume more resources to finish the same task. Therefore, how to efficiently continue the interrupted task will be a future work to address.

- Process Optimization

Although CPS shortens the computing time, is it an optimized solution? In Figure 11, there are 4 computing units A, B, C and D assigned to execute a process. Each colored block means the computing time needed to finish one subtask. If A and D ask the requester to assign a new subtasks at the same time when only 2 subtasks are left to finish, the requester will assign one subtask to A and D when the round-robin mechanism is used. Then, the total computing time will be depicted in Figure 11 (a). However, if the dynamic mechanism such as assigning the subtask according to the previous computing time, both subtasks should be assigned to D because it finishes the subtask faster. Then, the more optimized solution is concluded in Figure 11(b).

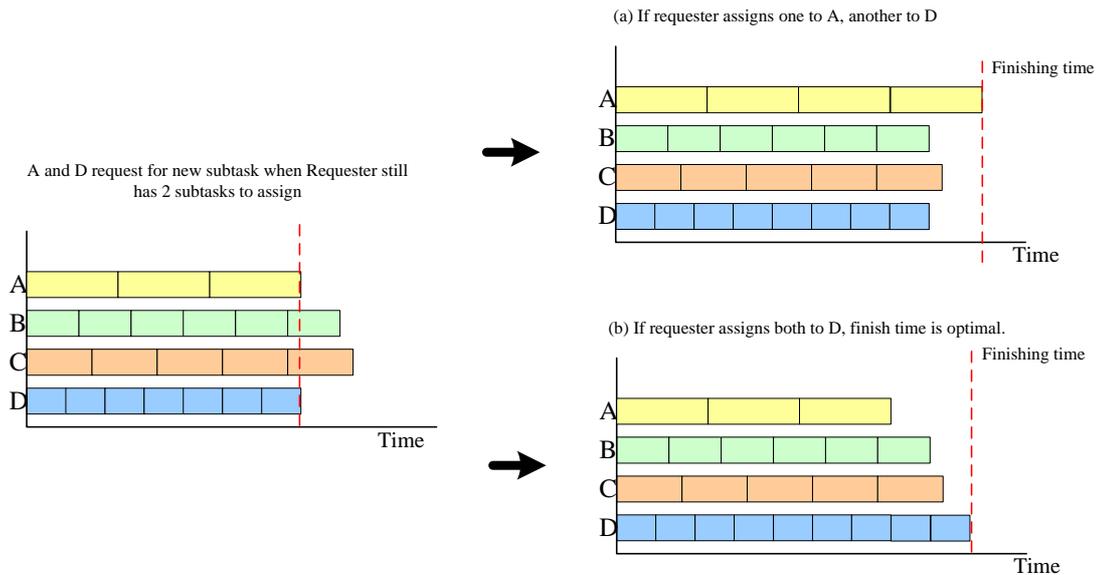

Figure 11 The Optimized Task Assignments of a Process

In addition, BPEL provide the capability to run the subtasks in parallel. Hence, the work to find the more optimized solution which finishes the parallel process is a topic deserved to research.

● BPEL Virtual Machine

In essence, BPEL could be though as programming language of the process. Therefore, BPEL virtual machine could be designed to execute the process. Doing so, the BPEL virtual machine will be downloaded to the computing unit and the subtask will be the fragment of BPEL document that could be executed in the virtual machine. Then, the issue of cross platform could be addressed.

Abstract: In this paper we study the bandwidth packing problem in the presence of priority classes. The bandwidth packing problem is defined as the selection and routing of messages from a given list of messages with prespecified requirements on demand for bandwidth. The messages have to satisfy delay constraints and have to be routed over a network with given topology so that the revenue generated from routing these messages is maximized. Messages to be routed are classified into two priority classes. An integer programming based formulation of this problem is proposed and a Lagrangean relaxation based methodology is described for solving this problem. Several numerical experiments are conducted using a number of problem parameters such as percentage of messages, ratio of messages of lower to higher priority, capacity of links and high quality solutions to the bandwidth packing problem are generated under the different situations.

Keywords: Optimization under uncertainty, Bandwidth, Heuristic, Lagrangean relaxation.

I. Introduction

Networks of today often suffer from congestion problems due to the tremendous increase in traffic in recent times as well as irrational allocation of bandwidth to support this increased traffic. One of the fundamental problems related to design of networks is determination of which messages to route among a given list of messages and determination of the routes to be used for delivering messages between communicating nodes so that the revenue generated from routing these messages is maximized. This is known as the bandwidth packing problem. The objective of this research is to use an optimization based approach for solving the bandwidth packing problem for messages belonging to multiple service classes. This will involve selection of a target group of messages from a list of messages with different delay requirements provided by the users, and determination of the best paths for routing these messages. Usually the topology of the network, the capacities of the links, the revenues to be generated by routing the messages, and the demand requirements of the messages are specified prior to the start of network design. The messages are listed in the form of a message table. In this table, the messages are prioritized based on the demand requirements. Since the

network capacity is usually insufficient to route all messages, a selected group of messages are routed during a given period of time. This is also known as the static bandwidth packing problem (as opposed to dynamic bandwidth packing where the demand requirements of the messages change over time) and is studied in this paper. Our goal in this paper is to find an appropriate message selection and routing scheme that provides an efficient resource allocation mechanism and maximizes the revenue generated from the usage of the network.

Various versions of the bandwidth packing problem have been studied in the literature. This includes research conducted by Amiri and Barkhi [1], Amiri et al. [2], Anderson et al. [3], Cox et al. [4], Laguna and Glover [5], Park et al. [6], Parker and Ryan [7], and Rolland et al. [8]. Most of these papers strive to maximize the revenue earned by routing the messages subject to some service related constraints. A notable exception is the paper by Amiri et al. [2] where the objective is to maximize revenue as well as minimize the delay cost associated with the use of the network. Various methods are used in these papers including tabu search [3,5], genetic algorithms [4], column generation [6,7], and Lagrangean relaxation [1,2,8]. However, the available research on bandwidth packing considers only a single message class. This assumption is not realistic as users may use the networks for running different applications. Some of these applications may be delay sensitive but others may be not. So it is more realistic to model the bandwidth packing problem in the presence of multiple priority classes. To the best of our knowledge, this is the first paper that addresses the priority bandwidth packing problem. As opposed to the existing literature this problem is considerably more difficult because exact analytical expressions for the average delay of the priority classes are difficult to obtain and this in turn complicates the formulation of the problem.

II. Problem Formulation

We introduce the following notation for developing an integer programming model for the priority bandwidth packing problem:

- N the set of nodes in the network
- E the set of undirected links (arcs) in the network
- M the set of messages
- M_1 the set of messages with lower priority
- M_2 the set of messages with higher priority
- $M = M_1 \cup M_2$

- $1/\mu_1$ average length of messages with lower priority
 $1/\mu_2$ average length of messages with higher priority
 d^{m_1} the demand for message $m_1 \in M_1$
 d^{m_2} the demand for message $m_2 \in M_2$
 r^m the revenue from message $m \in M$
 $O(m)$ the source node for message $m \in M$
 $D(m)$ the destination node for message $m \in M$
 Q_{ij} the capacity of link (i, j)
 δ_1 the upper limit on number of messages of lower

priority in the network

- δ_2 the upper limit on number of messages of higher

priority in the network

- $L_{ij}^{m_1}$ number of messages of lower priority on link (i, j)

- $L_{ij}^{m_2}$ number of messages of higher priority on link (i, j)

The decision variables are:

$$Y_m = \begin{cases} 1 & \text{if call } m \text{ is routed} \\ 0 & \text{otherwise} \end{cases}$$

$$X_{ij}^m = \begin{cases} 1 & \text{if call } m \text{ is routed through a path that uses link } (i, j) \\ 0 & \text{otherwise} \end{cases}$$

$$W_{ij}^m = \begin{cases} 1 & \text{if call } m \text{ is routed through a path that uses link } (i, j) \\ & \text{in the direction of } i \text{ to } j \\ 0 & \text{otherwise} \end{cases}$$

In order to obtain a mathematical formulation of the bandwidth packing problem we have to make several assumptions. These are listed below:

- The nodes have infinite buffers to store messages waiting for transmission
- Arrival process of messages entering the network follows a Poisson distribution
- Length of messages follows an exponential distribution
- Propagation delay in the links is negligible
- The average message length for each type of messages is used instead of using individual message lengths
- The link and message system is studied as a preemptive priority queue, i.e., the routing of lower priority of messages can be interrupted by higher priority messages

Based on the above assumptions, the telecommunication network is modeled as a network of M/M/1 queues. In this network, links are treated as servers with service rates proportional to the link capacities. The messages are treated as customers waiting to be routed at a particular node. If we measure delay in terms of messages, then the delay is defined as the total number of messages to be routed on a particular link. Since we want to limit the upper bound of delay, we can use a relaxed formulation of the delay in terms of maximum number of allowable messages on a link for priority 1 and priority 2 messages. We denote them by $L_{ij}^{m_1}$

and $L_{ij}^{m_2}$ respectively. The nature of the problem imposes certain restriction upon the characteristics of higher priority messages. Usually, they are shorter in length than low priority messages, i.e., $a = \mu_1 / \mu_2 \leq 1$. In addition, the higher priority messages generate more revenue while they are not as tolerant to queuing delay as the lower priority messages (i.e., $\delta_1 \leq \delta_2$) With the notations defined and queuing delay formulated, we can now model the bandwidth packing problem as follows:

Problem P

$$\text{Max } \sum_{m \in M_1, M_2} r_m Y_m \quad (1)$$

Subject to:

$$\sum_{j \in N} W_{ij}^m - \sum_{j \in N} W_{ji}^m = \begin{cases} Y^m & \text{if } i = O(m) \\ -Y^m & \text{if } i = D(m), i \in N \text{ and } m \in (M_1, M_2) \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

$$W_{ij}^m + W_{ji}^m \leq X_{ij}^m \quad \forall (i, j) \in E \text{ and } m \in (M_1, M_2) \quad (3)$$

$$\sum_{m_1 \in M_1} d^{m_1} X_{ij}^{m_1} + \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2} \leq Q_{ij} \quad \forall (i, j) \in E \quad (4)$$

$$\sum_{(i, j) \in E} L_{ij}^{m_1} \leq \frac{(Q_{ij} - \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2}) \sum_{m_1 \in M_1} d^{m_1} X_{ij}^{m_1} + a \sum_{m_1 \in M_1} d^{m_1} X_{ij}^{m_1} \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2}}{(Q_{ij} - \sum_{m_1 \in M_1} d^{m_1} X_{ij}^{m_1} - \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2})(Q_{ij} - \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2})} \quad (5)$$

$$\sum_{(i, j) \in E} L_{ij}^{m_2} \leq \sum_{(i, j) \in E} \frac{\sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2}}{(Q_{ij} - \sum_{m_2 \in M_2} d^{m_2} X_{ij}^{m_2})} \leq \delta_2 \quad (6)$$

$$Y^m \in (0, 1) \quad \forall m \in (M_1, M_2) \quad (7)$$

$$X_{ij}^m \in (0, 1) \quad \forall (i, j) \in E \text{ and } m \in (M_1, M_2) \quad (8)$$

$$W_{ij}^m \in (0, 1) \quad \forall (i, j) \in E \text{ and } m \in (M_1, M_2) \quad (9)$$

The objective function (1) represents the total revenue earned from the routing of messages. Constraint set (2) represents flow conservation equations, which define a route for each message represented by a communicating node pair. Constraint set (3) links together the X_{ij}^m and W_{ij}^m variables. Actually, the problem can be correctly formulated with either X_{ij}^m or W_{ij}^m variables only. The constraint set (3) is redundant but useful for Lagrangean relaxation. Constraint set (4) guarantees that total flow does not exceed link

capacities. Constraints (5) and (6) impose upper bound on the number of messages belonging to each priority class for each link. Constraint sets (7), (8) and (9) are the integrality constraints of the decision variables.

III. Solution Procedure

Problem P is a combinatorial optimization problem with non-linear constraints. It is known to be a NP-complete problem. So we propose a heuristic based on the Lagrangean relaxation by dualizing constraint set (3) using non-negative multipliers α_{ij}^m for all $(i, j) \in E$ and $m \in (M_1, M_2)$, then further dualizing constraints (5) and (6) using non-negative multipliers ψ_1 and ψ_2 . The resulting Lagrangean relaxation of Problem P is further simplified by decomposing it into several message sub-problems and link sub-problems. Each message sub-problem resulting from the Lagrangean relaxation can be solved by solving the shortest path problem from $O(m)$ to $D(m)$ using the non-negative multipliers α_{ij}^m as the cost of the links. If the revenue from the message is greater than the cost of the shortest path, then the message is routed through that path, otherwise, the message is not routed and we set $Y^m = 0$ and $W_{ij}^m = 0 \quad \forall (i, j) \in E$. On the other hand, for solving each link sub-problem we relax the integrality constraints and solve the continuous version of the problem using a greedy procedure. The solution obtained from solving each sub-problem is added up to give the upper bound of the optimal value of problem P. The feasible solution gives the lower bound of the maximization problem. The difference between the upper and the lower bound gives the gap in the solution and is a measure of how close the algorithm can approximate the optimal solution. The gap is usually calculated as a percentage gap. Like all relaxation procedures, the success of a tight lower bound depends heavily on the ability to generate good Lagrangean multipliers. In practice, the subgradient optimization method is used to obtain good values of the multipliers.

IV. Numerical Experimentation

In order to test the effectiveness of the solution procedure we conduct several numerical experiments. The experiments are conducted using networks where number of nodes is 10, 15, 20, and 25 respectively. The networks are generated in such a fashion that each node has a degree equal to 2, 3, or 4 with probability of 0.6, 0.3, and 0.1 respectively. The network is assumed to be made of OC4 links and has capacity of 192 Mbps. We perform some experiments using different values of link capacities as well. After the generation of the networks, we generate the message tables. The total number of messages in the message table is dependant on the number of nodes of the network and is

equal to $k*N*(N-1)$, where k is the percentage of messages whose value is controlled by the network designer. For the base case, k is assumed to be 0.6. Hence, for the 10-node case, the total number of messages generated is equal to 54. We perform some experiments when the value of k is changed from 0.4 to 0.8 in steps of 0.1. The message table lists two types of messages and indicates the origin and the destination node for each node belonging to each class. The ratio of the number of messages belonging to lower priority to the higher priority is taken to be 80:20 in the base case. We perform experiments when the ratio of messages is changed to 90:10, 70:30, 60:40, and 50:50 as well. The messages belonging to the higher priority class are more demanding and the demand is assumed to be uniformly distributed between 30 Mbps and 40 Mbps. On the other hand, for messages belonging to the lower priority class the demand is uniformly distributed between 5 Mbps and 10 Mbps.

The revenue generated from the routing of the two classes of messages are also assumed to be uniformly distributed between [10,25] and [30,50] for the lower and the higher priority class respectively. The upper bound on the number of higher and lower priority messages on each link is taken to be 800 and 400 respectively. In our experiments we obtain the feasible solution, the gap between the feasible solution and the Lagrangean solution, the maximum and average utilization of the links, and the number of higher and lower priority messages that are routed over the network.

In the first set of experiments, depicted in Table 1, the experiments are conducted for networks where number of nodes is 10, 15, 20, and 25. The networks have a link capacity of 192 Mbps. The ratio of higher priority to lower priority message is 80:20. The demand for higher priority message is U[30,40] Mbps and the demand for lower priority message is U[5,10] Mbps. For this experiment, the percentage of messages (k) is increased in steps of 0.1 from 0.4 to 0.8. As k is increased the number of messages in each network increases. For example, for the 25 node case, when $k=0.8$, the total number of messages is 270. Of these 96 messages belong to the higher priority class and 384 messages belong to the lower priority class. From Table 1, we can observe the following. The feasible solution increases with the increase in k across all networks. The percentage gap remains reasonably low for all cases except when $k=0.8$. In those cases, the average utilization of the links increases a lot and there is not enough bandwidth to route all messages. It is also to be noted that for all cases where gap is greater than 5% the maximum utilization reaches 100%, which implies that for such a choice of k , at least one bottleneck link is obtained for the network. Since the messages belonging to the higher priority class has preemptive priority over messages belonging to the lower priority class, the algorithm preferably routes higher priority messages. Hence, we note that for high values of k , greater number of lower priority messages is dropped compared to higher priority messages, though higher priority messages are more demand intensive.

Traffic ratio	Feasible solution	Percent. gap	Maximum utilization	Average utilization	Routed calls for priority 1	Total calls for priority 1	Routed calls for priority 2	Total calls for priority 2

50:50	9038.43	9.12	100	71.04	157	180	165	180

Table 2: Impact of ratio of low to high priority traffic

The impact of capacity of links on the generated solution is reported in Table 3. Our prior experiments assumed that all links in the network have a capacity equal to 192 Mbps which corresponds to an OC4 link. Next, we experimented with two more link capacities – 96 Mbps which represents OC2 links and 500 Mbps which represents OC9 links. Table 3 clearly shows that OC2 link is not suitable for our choice of problem parameters which are kept exactly same as the

earlier two experiments and with $k=0.6$ and ratio of low to high priority traffic fixed at 80:20. Our solution technique fails to generate high quality solutions for a link capacity of 96 Mbps and this leads to a large number of dropped messages. Between 192 Mbps and 500 Mbps it seems that the choice of OC9 links is overkill. When the link capacity is 500 Mbps, the average utilization remains less than 20%, which implies that a large amount of bandwidth is wasted.

V. Conclusion

In this paper we provide an integer programming based formulation for the bandwidth packing problem with two priority classes. Since the problem is NP-complete, we use a Lagrangean relaxation based heuristic for solving this problem. We solve it numerically using networks of different sizes. Several experiments are conducted to check the impact of percentage of messages, ratio of low to high priority traffic, and capacity of links on the solution and the algorithm is able to generate high quality solutions under different situations. The experiments show how various factors affect the generated revenue and the routing of messages.

Abstract: The new technological developments and business strategies hold considerable promise to eradicate market inefficiencies and unravel a new era of digital commerce. Micro-commoditization and micro-consumption are the two new economic forces in motion, in the world of e-Business. With the advent of electronic commerce there is a shift from the traditional Pay First-Consume Next model (PFCN) and Consume-First-Pay Next model (CFPN) to a Pay-As-You-Consume model (PAYC) configuration. Among the various genre of microproducts, digital microproducts, such as music, movies, news, information items, and video games have a huge industry.

The present work incorporates the concepts of micro-consumption, micro-commoditization and the PAYC model in a web-application named *On-Demand-Music*. The PAYC model enables automatic reduction of balance from the customer's bank account, making the payment process fast and easy. The application enables users to consume digital microproducts (here music) in small granules rather than buying huge bulk of music (e.g. buying an entire CD containing only one or few favorite song(s)).

The Software Development Life Cycle (SDLC) approach has been used to analyze, design, code and test the web-application. Developed using technologies such as Java Server Pages™ (JSP), MySql and various Java plug-ins, the application enables users to listen to their favorite song(s) or parts of chosen song directly from the server.

The usefulness of present work is that it makes the mode of payment easier and brings out the essence of micro-consumption, micro-commoditization and the PAYC model in *music* as an example of digital entertainment microproducts.

I. Introduction

Commerce on the Internet

Electronic Commerce (e-commerce) is a general concept covering any form of business transaction or information exchange executed using information and communication technologies. It takes place between companies, between companies and their customers, or between companies and

public administration.

Electronic Commerce includes electronic trading and goods, services and electronic materials.

Commerce on the Internet is becoming ever more pervasive, reorienting traditional business practices with new strategies and operations. The Internet continues to create new consumer markets that never existed before, new players that position themselves between consumers and producers for efficient market transactions, and new technologies and market drivers that are redefining the processes of production and consumption in a market economy.

Microproducts- The future of Digital Economy.

Micro-commoditization and micro-consumption are the two new economic forces in motion, in the world of e-Business. [2] The producer is said to offer micro-commoditized products, if it disaggregates a product or service into small components and delivers it to consumers in a sequential manner. On the other hand, micro-consumption is the ability of the users to consume such products, to satisfy their on-demand needs. Such products are termed as Microproducts. These new concepts are likely to revolutionize the business practices, in the digital entertainment industry.

Micro-consumption and micro-commoditization have originated from the interaction of newer technologies, evolving global market structures and will be able to change the very concepts of supply and demand, for the future markets. Micro-commoditization is definitely more advantageous both for the buyer and seller as compared to bundling based pricing mechanisms, where buyers only pay for what they use, scarce resources are directed towards higher-valued consumers, and the markets reacts quickly in response to changing demand and consumption patterns. Enhanced resource allocation, dynamic pricing that speedily responds to changing supply demand patterns and the very essence of customization and interactivity are better experienced by consumers in microproducts.

Terms and Definitions

- “Micro-commodity: The ability of a producer to disaggregate a commodity into components of consumption at lower levels of component granularity.
- Micro-consumption: The ability of a user to consume the components at lower granularity levels over time.
- Customization: The ability of the seller to offer a

large menu of fine grained components, enabling customers to tailor their usage according to specific requirements. The shift from SPSU to MPSU modes of consumption.

- **Interactivity:** The ability of multiple users to consume a component concurrently, to enhance interactivity. The shift from SPSU to SPMU modes of consumption.
- **Trade-level contraction:** The shift from the traditional PFCN and CFPN practices to a PAYC configuration.
- **The customization effect** is a consequence of micro-commoditization of digital goods. The customization effect enables the seller to tailor offerings that fit customer requirements, dynamically package them, and deliver a suite of high-level services from a core set of micro-commoditized products.
- **The interactivity effect** arises from simultaneous micro-consumption by multiple users of micro-commoditized seller offerings.

The **trade-level contraction effect** is a natural consequence of the customization and interactivity effects. Trade-level contraction due to customization and interactivity results in short-term and as-needed market trades with natural shifts from traditional PFCN and CFPN to PAYC configuration. Fig 1.2 shows the projected impacts of Trade-level contraction Effects.” [2].

One of the emerging Micro-Markets

The emerging Digital Entertainment Products

Entertainment products, such as music, movies, news and information items, and video games, are intrinsically digital in nature. Generally the industry follows the Pay-First-Consume-Next (PFCN) mode of payment with pricing strategies such as subscription or bundling.

For example, music is sold in albums, which are a collection of songs related to a band or single artist. But since these products are digital in nature, the mode of selling these would change in future. Consumer are no longer inclined to buy music in large bundles as CDs or DVDs, because most items in those chunks may not have much of a consumption utility and hence the willingness to pay decreases. So micro-commoditization is the call of the hour.

Some Insight

“Interpreted in this way, the New or Digital Economy is about dynamics, not static efficiency. It is more about new activities and products than about higher productivity. What is really new in the New Economy is the proliferation of the use of the Internet, a new level and form of connectivity among multiple heterogeneous ideas and actors, giving rise to a vast new range of combinations. There are some measurable effects on productivity and efficiency, but the more important long-run effects are beyond measurement.

“A motivation for the development of microproducts and micropayments stems from the need to assure product quality. A long term subscription of bundled digital products

may be sufficient to guarantee quality based on the reputation of the seller. However, reputation has to be developed after repeated purchases. If sellers know, on the other hand, that the market will end soon-or they are short-run players-it is profitable to cheat by selling low-quality products at high-quality price. Knowing this, would consumers be willing to buy a product from unknown sellers? This problem is magnified if buyers are required to commit for a long-term subscription or to pay for a large bundle of unknown quality. Instead, recent research in contract theory offers some positive evidence that short-term sales may indeed produce higher quality than subscription and bundling. Short-term sales (some involving only one page of information) will be based on micropayments.” [1]

“Microproducts are simply pure digital products that become technologically and economically possible because of the low costs of modifying and distributing digital products in general. They allow consumers to try out products before paying for a long-term subscription or a large bundle.”[4]

The web-application named *On-Demand-Music*.

As seen from above discussion, digital music is an example of digital microproducts. So the web-application was developed with the following features:-

1. The Web-Based application provides a database of music, so that users can listen to their favorite music as and when they like without having to download the song file.
2. It employs the Pas-As-You-Consume (PAYC) model, where there will be automatic reduction of balance from the customer’s bank account. So payment process will be fast and easy.
3. It enables the users to consume digital microproducts (here music), in small granules rather than buying huge bulk of music. (e.g. buying an entire CD containing only one or few favorite song(s))

II. The Sdlc Approach

The SDLC approach followed, simplified the analysis, design, coding and testing phase. So the application was developed, as a software project using the theories and principles of Software Engineering.

Purpose

The web-application provides a database of music, ubiquitously to Internet users and allows them to listen to it directly from the site rather than downloading the music file and then listening to it. It has many business advantages. Firstly, if a large number of users login, then the Website will earn very quickly. Secondly, it provides a database of music, so that users can listen to their favorite music, as and when the like and don’t have to buy music CDs or store music files in valuable hard-disk space. Lastly, the Pay-as-you-consume (PAYC) model is being employed here, where there will be automatically reduction of balance from the customers’ bank account. So the payment process is easy

and fast.

Scope

The application provides easy search and browse options to locate the songs which the user is willing to listen. It has connectivity with the bank's database to authenticate the users' credit card number and also to have the feature of e-payment where users' balance will automatically reduce.

The application also prompts a warning message when the user's balance goes to Rs.5 or less than Rs. 5. This feature ensures that no user can avail the service unless his/her balance in the bank is sufficient. The security aspect was given a lot of priority with lot of consideration done while coding.

General description

The product is perceived as a Web-site which will provide the netizens with unlimited music and will be played directly from the Web-site's server in the Web-browser. Any educated person with average knowledge of the Internet and basic computer skills can use the website.

Assumptions and Dependencies

- Users possess the basic know-how of computer and Internet usage.
- User understands simple English.
- The administrator of the web-application should be proficient in Java Server PagesTM, [3] Apache-Tomcat web-servers, and MySql- database server.

Use case Diagram

The figure below i.e. figure 1 shows the use case diagram and hence explains the way the user and administrator will interact with the web-application. It may be noted that, the use case diagram is more or less self explanatory. However, the user's and administrator's interactions with the web-application will be thoroughly dealt with, later. Also the <<extends>> feature has been used in the *Navigate/Search* use case with *search song* because another use case called *Browse category* is desirable in the web-application and should be added in the later stages.[see appendix].

III. Object Oriented Analysis

OOA consists of the partial static diagram (Figure 2), the Class responsibility collaboration (CRC) cards and the system sequence diagram. Such kind of analysis brings a thorough picture of the application to be developed. However, it is not necessary to discuss all these and present all these analysis in this paper.

Figure 2 show the partial static diagram of the web-application. In the diagram the *user* object initiates the *SearchASong* object, which is captured by the *WebApp* object. The *Playlist* is played by the *user*, which is updated by the *WebApp* and belongs to *AccountInfo*. The object *Bank* helps to determine *AccountInfo*. The various attributes of the

respective objects are shown below their names. Also the interaction of the objects are shown, where one object can interact with many objects.

IV. Object Oriented Design

Identification of the real classes is a very important job, before going forward in the design phase. From the partial static diagrams, a basic idea of what the classes will look like can be identified. The real classes are shown in Figure 3, in the next page. The classes are represented in the standard UML format, showing attribute and functions. For example, the class *Playlist* has No. of songs:int, Duration : double, rate : double as the attributes and play (song: Object): void as the only fuction.

Figure 4. shows the collaboration diagram of the web-application. Collaboration diagrams represent interactions between objects as a series of sequenced messages. Collaboration diagrams describe both the static structure and the dynamic behavior of a system. Various notes are show in the diagram, which are in fact self explanatory. This concludes the OOD and it is always advisable to go for coding only after completing the OOD. Also the OOD should be flexible to change later, as one follow a *spiral* model for software development life cycle.

V. Coding

The coding was done according to the analysis and design done previously. Although some new methodology and modifications were incorporated for convenience. It should be noted that, an object oriented language such as JAVATM was chosen to build the application as the analysis were done in the object oriented framework. JAVATM with Java Server PagesTM as the scripting language was used, which is easy to deploy, platform independent and robust. As the spiral model was followed, while coding the OOD part was modified, as and when felt convenient to improve the system performance and make the development easier.

VI. Testing

Various tests were performed to ensure that the web application was working fine and also to locate bugs.

Working of the search option

Various keywords were typed in the search text field and the results were observed. It was observed that if the keyword was the part of the song title or the album's name, then it all the results were displayed. Otherwise no result was displayed.

Reduction of balance from the bank account of the user

As the music was played simultaneously the site earnings should increase, the user's amount should increase and his

balance from the bank should decrease. This was tested and was found to be correct.

User authentication

Various wrong information like invalid credit card number, account number and invalid email address were entered. Javascript and sql commands were used to in the code to authenticate the user's information.

Working of the music player.

The player was tested with various play lists to see if it works in various situations.

Security

Security tests were made by logging off the user and trying to access the search.jsp page ,home.jsp page etc. With the use of sessions class of jsp the security was achieved where it will redirect the page to the login page if the user is not logged in.

VII. Conclusion

Summary

On-Demand-Music - the Web-application shows the application of micro-commoditization, micro-consumption and the PAYC Model. From this application a user only pays for what they consume and hence is the unique selling proposition of the service which they will avail. This web-application presents a business plan, which aims at delighting customers and also introduces to a market of on line digital media streaming, which is open without any major players. Hence that segment of the market is yet to be captured.

The web-application as developed with Java Server Pages™ and MySQL database server is compatible with all platforms as Java™ is platform independent. These technologies are latest and easy to deploy. Also the SDLC approach presents a clear picture of the various stages of analysis, design and development of the web-application as a software project. Also this web-application can be employed to generate raw data, and various data mining tools can be used to derive patterns and hence get to know what the customers wants.

Finally, this web-application as an example of digital entertainment products, shows a new business strategy which can be easily extended to other kinds of similar

products, such as, online newspapers, video streaming, online gaming etc. to name a few.

Scope for future work

On-Demand-Music – the Web-application being developed is just could be tested by the developer. Generally many new bugs appear when software is launched to be used by the users. So this web-application can be released as a beta version to know the bugs.

There are also a few things in the mp3 player which can be improved in future. The player doesn't have the seek option. Because of which consumers cannot drag to those part of the song which they want to listen directly.

There is only the search option to search the songs which the user wants to listen. But there is no browse category option. This is important because sometimes user doesn't know the exact keyword to search for a particular song or album. So after a few attempts and continuously getting no results, the user might get frustrated and leave the website.

Also to populate the database, the administrator should be proficient with MySQL server administration. But a separate Graphic User Environment or GUI can be developed specific to this web-application where it would be easier to manage the database as the database of songs will be huge if the application is launched for consumers.

Finally, there will be many legal and integration matters which will come as it is decided to launch this web-site. Matters like getting the rights from the producer of the music album, integrating the database connectivity with major credit card companies and banks etc. needs to be dealt with as they are few of the prime prerequisite before launching *On-Demand-Music* Web application.

Abstract: This paper aims at identifying the inside reasons of M&A(Merger and Acquisition) of online industry in China between international Internet giants and local companies and exploring the basis on which online industry can develop steadily and thus have a successful and sustainable business model. In the meanwhile, a case study will be made by analyzing the causes of the merger of Yahoo China into Alibaba from the perspectives of both parties. Then, this paper points out the possible effects of this merger on China's online industry. In the end, some conclusions will be made on how to build up core competence in online industry in a unique business circumstance in China.

US Internet giant Yahoo ended its six years of independent operations in China since August 2005 and joined forces with Chinese leading e-commerce company Alibaba.com. Yahoo China will transfer all operations in China including an Internet portal, e-mail services, instant messaging, Internet search services and its keyword services to Alibaba as well as paying US\$1 billion for a 40 per cent stake in Alibaba. This Merger is not only a single commercial buying case but also a symbol for creation of new revenue model in China. [2]

Keywords: Case Study in E-Business; M&A; Online Industry; China.

I. Characteristics of Online Business in China and Stages in M&A of Online Industry over the Past 5 Years

I.1 Characteristics of Online Business in China

With an online population of nearly 100 million, China's internet infrastructure is developing very fast, and China has surpassed Japan and become the second largest country in its Netizen number next to US [1]. However, due to its unique cultural and political environment, the development of online business in China seems to have had no breakthroughs since 2000 after the Dot-coms gradually lost their wizards. For example, because of the lack of credit system and strict regulations in China, the online business is

still at an early stage according to the turnover of online transactions.

However, the potential in online business in China can NOT be overlooked. According to a recent survey by IDC, the online population of China will surpass U.S. in 2010, and new killer applications including search engine, online games, instant messaging and internet phone calls will develop very fast in China due to its large scale of online population. Thus, a smart company can easily find the expanding potential in China and the cooperation between Yahoo and Alibaba is the best evidence showing the confidence in Chinese online business market.

I. 2 Stages in M&A of Online Industry over the Past Years

Looking back to the M&A cases in China in the past 7-8 years, it is not difficult to find that the merger and acquisition has experienced the following three stages:

● Stage 1(1998-2000)

Since it is the inception of development of online business in China, the business model was very simple at that time and the Internet portal dominated in online industry and the ad revenue is the main source of the income for most of the online companies. With the demonstration effect of the case that AOL.com merged Time-Warner, one of the characteristics of M&A at that time is that the merger occurred between an online company and a company dealing with traditional businesses, and the buyer in most cases was an online company especially an Internet portal.

● Stage 2(2001-2003)

After the Internet bubbles got broken in 2000, overnight wealth was no longer the dream of most online companies. They began to search for the business model that can be really materialized. During this period of time, the M&A was technology-oriented and online companies hope that they can earn money with the help of new technologies like search technology, instant messaging, online gaming, and so on. A good example is that Yahoo China acquired 3721 for US\$ 120 million with 3721 founder Zhou Hongyi becoming President of Yahoo China.

● Stage 3(2004-present)

In real operations, the international companies including Yahoo have no obvious advantages over the local competitors like Sohu, Sina and Netease. It is partially due to the fact that even a local company in China can easily copy the business model of a U.S. company let alone its advantages in knowing local factors well. For example, Yahoo China never won in its competition with its Chinese competitors in traditional businesses like e-mail services, online advertisement, etc. The merger between Yahoo China and Alibaba is a trial of cooperation other than a zero sum game.

II. Causes of Current M&A Between International Internet Giants and Chinese Companies

(1) Good Economic Outlook and Improvements in Internet Infrastructure in China

China's rapid growth in Internet users, rising disposable income, low Internet penetration, a huge population of mobile phone users and growing e-commerce has put the country front and center on the radar of most of the world's Internet companies. Western Internet businesses' eager to tap its growth has been expanding their investments.

(2) Cultural Differences and Complex Regulations on Internet Industry

As mentioned above, though China has the second largest online population in the world, the online transactions are still very limited due to its lack of credit system and its unique consumer behavior features. For example, online payment system is not easy to put into use because most consumers are unwilling to pay online and thus select a COD (Cash on Delivery) model. Another reason is that the Chinese Government has lots of regulations on Internet industry and are reluctant to let a foreign company control the country's top Internet portals and other kinds of Internet companies. Under these circumstances, it is the best way for the international Internet giants to get quick access to local market by forming strategic partnership instead of acquiring top Chinese portals directly.

(3) Getting Complementary Advantages for Both Parties

The international Internet giants and the local Chinese companies have their respective advantages and disadvantages. The international Internet giants have advantages in their capital assets, experience in going public on stock market and state-of-the-art technologies in Internet. While in the meantime, the local Chinese companies are better in their connections with governments at all levels, marketing channels and first-mover advantages as well as their inherent cultural similarities.

III. Case Study –The Strategic Partnership Between Yahoo! and Alibaba

III.1 Corporate Overview of Alibaba.com

Alibaba was founded in 1999 and is based in Hangzhou, eastern China. It has over 2,000 employees, 13 regional sales offices across China and other offices in Hong Kong, Silicon Valley, Europe, and Beijing. Alibaba.com is China's leading e-commerce company, operating the world's largest online marketplaces for both international and domestic trade, as well as China's most popular online payment system, AliPay. The Alibaba websites have more than 15 million registered users in 200 countries and territories. In 2004, over US\$4 billion in trade is estimated to have come from buyers and sellers connecting at Alibaba sites. [4]

III.2 Causes of Forming Strategic Partnership from the Perspective of Yahoo

(1) Yahoo has NOT been so successful in Mainland China

The US giant, which set up its Chinese operation in 1999, has been dogged by frequent personnel changes and twists in company strategies. Its first China general manager stayed at the post for only one year. Operations on the Chinese mainland were then overseen by executives in Hong Kong and Taiwan and the focus was still on online advertising which makes them face cooling ad revenue. Compared to other famous local Big Three portals, Yahoo's ad revenue in China in the year 2004 is very limited see Figure 1, amounting to only 50 million RMB Yuan. [5]

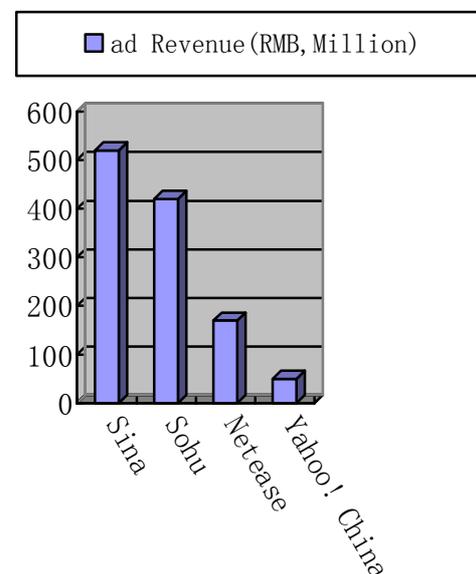

Figure 1. Ad Revenue Comparisons Between Yahoo! China and Big Three Local Portals

(2) Yahoo May Obtain Complementary Advantages from Alibaba

Since Alibaba is the most comprehensive website with its areas in e-commerce, business to business, customer to customer, payment system and an auction site, Yahoo may obtain the above-mentioned complementarities by forming strategic partnership with Alibaba very easily.

(3) Yahoo China Can Fulfill Its Strategic Shift from an Operator to an Investor

The merger of Yahoo China into Alibaba has made it become a local company instead of the branch of a U.S. company. The shift from an operator to an investor has greatly simplified its business in China.

III. 3 Causes of Forming Strategic Partnership from the Perspective of Alibaba

(1) Alibaba May Obtain Search Engine and E-mail Service Technology

As the biggest business-to-business website in the world, Alibaba is in urgent need of mature search technology and e-mail services for its 8 million customers all over the world. Yahoo's such expertise will greatly facilitate the searching efficiency for Alibaba customers.

(2) Removing the Obstacles for Alibaba to be Listed on the Stock Market

The business-to-business model that Alibaba adopted is no longer fresh to investors in international stock market. And Alibaba's auction site Taobao.com still lacks of enough revenue that can attract the investment from Wall Street. The partnership between Yahoo and Alibaba at least made Alibaba the most comprehensive website consisting of almost all the business models including BtoB, BtoC and CtoC. In addition, with an international Internet giant as its shareholders, it will win the Chinese company a worldwide reputation. [3]

IV. Effects of the Strategic Partnership Formed Between Yahoo! and Alibaba on China's Online Industry

IV. 1 Creating a New Revenue Model

The Internet industry has been plunged into slump since the overnight rich dream broke 1998 through 1999, and China is no exception. The real reason for that is that no good business model has been developed. Although Yahoo! is a successful net company in the U.S., however, its performance in China is not as good as expected. This can be seen from the following several criterion. First, its ad revenue is far less than the Big Three portals; Second, its traffic can only rank 6th in China, next to some "small" companies; Last, Yahoo! China is a company whose business has no apparent differentiation advantages. While in the same time, Alibaba is a young company compared to Yahoo!, but it is the largest B2B website in China, especially deemed as the largest horizontal e-marketplace for importers

and exporters the world over. In an industry where searching technology is most important of all, Alibaba finds the strength of Yahoo! China's search engine at first glance, especially Yahoo! China has very powerful technology in searching for keywords in Chinese, and this helps a lot for a horizontal e-marketplace majoring in import and export business. Therefore, Alibaba is eager to enter into a strategic partnership with Yahoo! China because they have very strong complementary abilities. According to strategic alliance theory, the effect of strategic alliance will exist for a long time until the complementary abilities disappear (see Figure 2).

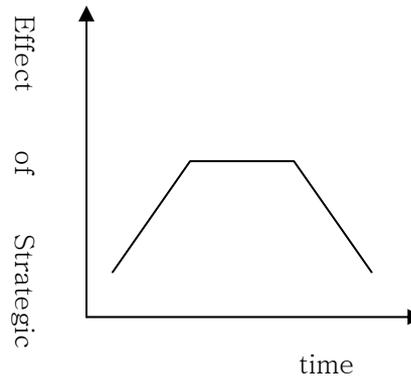

Figure 2 Effect of Strategic Alliance

IV. 2 Setting a Good Example for International Cooperation in Online Industry

In the past, seldom did international internet giants see real cooperation between local companies and them. They attributed this to policy barriers or discrimination. However, the successful alliance between Yahoo! China and Alibaba could be a symbol for gaining support from the Chinese government for real partnership. This merger can greatly reinforce the confidence for international institutional investors in IT field and set a good example for international cooperation in online industry.

IV. 3 Promoting Imports and Exports for Chinese Companies

After Yahoo! China was merged into Alibaba.com, Ma Yun, the CEO of Alibaba started to specialize the searching technology to support his customers in identifying both potential commodities and potential customers. In fact, since most of Alibaba's customers are dealing with import and export activities, the stronger searching technology will significantly strengthen the competitiveness of Alibaba and therefore promote the export activities for Chinese manufacturers and the procurement of international buyers.

V. Conclusions

Even in online industry, the companies should abide by laws and principles that are frequently used in traditional

industries such as the power of strategic alliance, cost advantages and so on. In other words, the traditional economic rules can also be well embodied in online industry.

The partnership between Yahoo and Alibaba has announced the failure of traditional business model in online industry. The Internet portals can only realize its value through the combination with the “real” business like what Alibaba is dealing with.

The partnership between international Internet giants and local companies of China has also shown the strengths from both capital and market. The international Internet giants represent the power of capital while the local companies of China represent the power of the market. The partnership aiming at obtaining both strengths is a completely ideal combination and will probably result in a great success.

Strategies for B2B Electronic Markets: Delivering Business Value to Buyers and Sellers

Chia Yao Lee

School of Information Systems, Deakin University, Melbourne, Australia
chia.lee@deakin.edu.au

Abstract: This paper discusses the key elements of effective and successful strategies for organisations engaging in Business-to-Business (B2B) Electronic Markets. Existing literature have concentrated on developing schemas for categorising B2B Electronic Markets, and evaluating the innovative business models they employ, with less focus on understanding the business value of B2B Electronic Markets from a multi-stakeholder, business strategy perspective. In the present business climate, business managers and executives are keen to discover strategies to maximise performance improvements associated with ICT adoption. Based on case studies of B2B Electronic Markets, this paper discusses the importance of (i) creating and distributing business value among the various stakeholders, (ii) determining a pragmatic approach for engaging in B2B Electronic Markets, and (iii) managing the transformation of business processes associated with B2B Electronic Markets. The study contributes to practice and research by presenting rich empirical insights into the operations of B2B Electronic Markets, and providing suggestions for future research in the topic area.

Keywords: Case Study in E-business; Electronic Markets; Business Value of IT; Business Strategies.

I. Introduction

Over the past two decades, B2B Electronic Markets have attracted substantial attention from practitioners and academic researchers, for they represent an economic model that promises to transform traditional ways of doing business, influencing organisational practice and the make-up of industries [2, 12, 13, 20]. Predictions have been rife that B2B Electronic Markets will quickly become a strategic necessity for organisations, and in turn become an important part of an industry's infrastructure [2]. In reality however, B2B Electronic Markets have had less profound effects. Several prominent B2B Electronic Markets that became the posterchild of the Dotcom era have fallen victim to acquisitions, mergers, or failed altogether [4], thus bringing into focus the problem first raised by Wise and Morrison [20] that *"The use of the Internet to facilitate commerce among companies promises vast benefits: dramatically reduced costs, greater access to buyers and sellers, improved marketplace liquidity, and a whole new array of efficient and flexible transaction methods. But if the benefits are clear, the path to achieving them is anything but."*

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 187 - 192.

This paper addresses the important issue of how and why organisations derive business value from engaging in B2B Electronic Markets. The research question that underlies the study asks,

"What are the important elements that underpin effective and successful strategies for B2B Electronic Markets?"

The paper discusses the roles B2B Electronic Markets play in inter-organisational relationships, and highlights the need for developing a pragmatic approach for participating in B2B Electronic Markets. The inability of B2B Electronic Markets to focus on issues beyond transaction cost reduction has narrowed the prospects of many B2B Electronic Markets during the Dotcom period, and limited their ability to achieve long-term sustainability. The present study addresses a call in existing literature to regard the Internet and other relevant Information Technologies as a complement to, instead of a cannibal of, traditional ways of competing [16]. Highlight is also placed on effective management of the business process transformations that accompany B2B Electronic Market adoption [3, 11].

II. Literature Review

Research in B2B Electronic Markets draws on accumulated knowledge in economics, management, marketing, and information systems, due to the cross-disciplinary nature of B2B Electronic Markets, and the loci of the impact and implication of B2B Electronic Markets. Several theoretical frameworks from different research streams have been adapted and modified for studying B2B Electronic Markets. These theoretical frameworks include the Transaction Cost Theory [19], the Network Externality Theory [9], the Diffusion of Innovation Theory, and, Game Theory [18]. Individually, these frameworks are inadequate, and insufficient for explaining the richness of the B2B Electronic Markets phenomenon, nor the depth of its implication [1]. Amit and Zott [1] summarised that *"research on e-business and, more generally, on competition in highly networked markets, will benefit from an integrative approach that combines both strategy and entrepreneurship perspectives."* This paper addresses the above problem, by drawing from different theoretical approaches, and not being constrained by any particular theoretical framework. Using the resource-based view of the firm to develop a descriptive model of the value generating process, Melville et al. [14] defined IT Business Value research as *"any conceptual, theoretical,*

analytic, or empirical study that examines the organisational performance impacts of IT". Lee and Corbitt [10] proposed an analytical framework that uses Aggregation, Matching and Integration as the key sources of business value of B2B Electronic Markets.

Existing literature have concentrated on developing schemas for categorizing and classifying B2B Electronic Markets [8, 15, 16]. These schemas enable organisations to better understand the characteristics of various B2B Electronic Market models, and develop strategies to maximise the related business value [8]. Operators of B2B Electronic Markets reasoned that the adoption of ICT would improve communication and coordination among organisations, favouring a shift towards market-type structures for governing inter-organisational commerce. However, too much emphasis has been placed on the issue of reduced cost of transaction. This undermined opportunities to study the impact of B2B Electronic Markets on inter-organisational relationships and on complex inter-organisational business processes [3, 7, 11], independent of the implication of the Transaction Cost Theory.

The Game Theory [18] has been used to model participant behaviour and organisational strategies in B2B Electronic Markets [5, 21], by describing how participants will pursue strategies that will deliver optimal returns in a given environment. While it has been obvious that the ability to produce and sustain a Win-Win situation is an important factor that heralds the success of B2B Electronic Markets the issue at hand that is equally important is how do B2B Electronic Markets achieve this ability? Thus, practitioners and academic researchers are keen to understand strategies that lead to just and fair creation and distribution of business value among participants, in a B2B Electronic Market environment.

As Jap [6] and Kambil and Van Heck [7] have found, unless all major stakeholders are better-off, a B2B Electronic Market system is less likely to succeed. The Network Externality Theory [9] has also been used regularly for describing the rollout and adoption of B2B Electronic Markets. The central argument is that the more participants there are on the networked system, the greater the benefits an individual participant will gain, especially from interacting with the existing participants. Hence, logic would predict that for B2B Electronic Markets to succeed, they need to attain a critical mass, especially in the number of participants. In terms of economics of scope, this translates to a substantial range of business functionalities being facilitated.

Porter [16] considered B2B Electronic Markets from a competitive strategy perspective. He surmised that, bar some fragmented industries, if B2B Electronic Markets do not provide additional value to buyers and sellers, as an intermediary, B2B Electronic Markets may find themselves disintermediated if buyers and sellers transact directly.

In [3, 7, 11, 20], it was found that substantial benefits from engaging in B2B Electronic Markets lie in an organization's ability to automate internal and external

business processes, and subsequently integrate the automated processes across organisational boundaries. The transformation of business processes produces organisation-wide impact, thus, presenting opportunities for organisations to streamline complex procedures, especially those that require frequent human intervention. The transformation of business processes requires delicate management, due to the diversity of the stakeholders involved, and the complexity of the transformations. In addition, the potential for uneven creation, distribution and capture of the business value may adversely influence the participation by stakeholders.

There is little doubt that the value propositions presented by B2B Electronic Markets continue to evolve and shape organisational strategies. Issues which have arisen from recent studies suggest that managing the transformation of business processes, and the ability to adapt business strategies to extract value from the transformations, may hold the important elements to effective and successful B2B Electronic Markets strategies.

Building on prior work in B2B Electronic Markets [2, 3, 6, 8, 13, 16], this study explores the following issues in detail:

- (1) the creation, distribution and capture of business value amongst stakeholders;
- (2) the determination of a pragmatic approach for engaging in B2B Electronic Markets; and
- (3) the management of B2B Electronic Markets-enabled process transformation.

III. Methodology

This paper describes part of a comprehensive exploratory study into the strategic sources of business value of B2B Electronic Markets. Six case studies of B2B Electronic Markets were conducted. The study adopts a qualitative approach to gain a deep insight into these case study organisations [15]. The typology of B2B Electronic Markets involved ranges from Private Electronic Markets used for procurement and distribution purposes, to Independent Electronic Markets that provide one-stop buying and selling solutions for organisations. Semi-structured interviews were conducted with 16 executives who were actively involved in the operations and implementation of the B2B Electronic Markets. The hermeneutic process [15] was employed for analysing and synthesising data collected. A summary of the six cases is illustrated in Table 1.

Table 1. Summary of Case Studies

	Description	Market Ownership model	Business functionality facilitated
Case 1	Reverse Auction site	Privately operated by the buyer	Sourcing, Procurement, Price Determination
Case 2	Life science Electronic Market	Independent, 3 rd party market-maker	Information exchange, Marketing, Sourcing, Ordering
Case 3	Steel Electronic Market	Independent 3 rd party market-maker	Information exchange, Auctions, Sourcing, Procurement, Ordering, Insurance & Transportation.
Case 4	Electronic Distribution Channel	Privately operated by the supplier	Inventory management, Information exchange
Case 5	Indirect supplies Electronic Market	Privately operated by a buyer, but backed by a consortia	Catalogue, Auctions, Sourcing, Ordering
Case 6	Healthcare Supplies Online Catalogue	Privately operated by a supplier-cum-intermediary	Access to pricing and inventory information, Catalogue, Ordering

IV. Research Findings

The six B2B Electronic Markets studied can be broadly categorised into (a) Private, and (b) Independent B2B Electronic Markets. Private B2B Electronic Markets are typically established, operated, and financially-backed by a focal organisation, which plays the primary role of a market-maker. The market-maker has substantial influence in the market segment, and is a prominent member of the supply chain community, such as an Original Equipment Manufacturer (OEM), a retail chain, or an assembler of products. As the name suggests, participation in Private B2B Electronic Markets is restricted to the trading partners of the market-maker. Usually, Private B2B Electronic Markets are implemented to address a specific need of the market-maker, e.g. procurement or sales.

In contrast, the market-makers in the case of Independent B2B Electronic Markets are typically neutral third parties. The market-makers do not have a direct stake in the transaction, they are neither a buyer nor a seller. Participation in Independent B2B Electronic Markets is open to a variety of organisations, depending on the structure of the Electronic Market – vertical or horizontal. Cross-case analysis of the case study data suggests that the business

strategies adopted by the market-makers, the buyers and the sellers, vary considerably, depending on the market ownership model used.

Strategies for Private B2B Electronic Markets

In analysing the business strategies deployed by market-makers, buyers and sellers, it was observed that the creation, distribution and capture of business value among stakeholders in Private B2B Electronic Markets are more likely to be uneven, with the market-makers emerging as the main beneficiaries. By channelling a substantial portion of their existing business via Private B2B Electronic Markets, the market-makers have consolidated their existing channels for sales and procurement, eliminating inefficient and ineffective processes and practices. For example, the market-maker in Case 1 had developed the Private B2B Electronic Market for sourcing and procurement purposes. Adoption of the Private B2B Electronic Market enabled the market-maker to benefit from economies of scale, by aggregating its internal purchases, and negotiating bulk discounts with suppliers. The market-maker organisation also experienced economies of scope benefits through reusing the same Private B2B Electronic Market for sourcing a variety of supplies. As noted by an executive in Case 5, the adoption of Private B2B Electronic Market for procurement reduces maverick purchases. Employees are less likely to place deals with non-preferred suppliers, or miss out on existing deals negotiated with the preferred suppliers.

From the perspective of buyers and sellers, the adoption of Private B2B Electronic Markets is political, and viewed with a degree of scepticism. Some small buyers and sellers viewed participation in Private B2B Electronic Markets as a pre-requisite for trading with large organisations. The participation issue becomes a strategic necessity for the small organisation, rather than a competitive advantage. However, large organisations which have participated in Private B2B Electronic Markets established by their major suppliers or customers have also attempted to avoid, or bypass the Private B2B Electronic Market. For example, a major supplier in Case 1 had commented that they were willing to match and better an offer listed in the Private B2B Electronic Market, but unwilling to place a counter-offer to the bid listed. The supplier perceived making pricing and inventory information available to competitors and customers as a loss of competitive advantage. Also in Case 1, a supplier which had secured a contract tendered on the Private B2B Electronic Market negotiated with the market-maker to extend the duration of the relationship. The supplier argued that they wished to increase business certainty in the medium term while saving themselves the trouble of having to renegotiate new supply contracts online regularly.

The issue of uneven creation, distribution and capture of business value among stakeholders is more of a concern among participants of Private B2B Electronic Markets, due to the biased orientation of the trading environment. While the smaller-sized buyer and seller may benefit from gaining

access to trade with a major supplier or customer the additional resources required in planning, managing, and transforming their internal business processes to accommodate Private B2B Electronic Markets are often overlooked, or underestimated. In addition, market-makers need to consider the suitability of Private B2B Electronic Markets on a case-by-case basis, taking into account the attributes of the product, the existing relationships with trading partners, the economic climate, and a host of other ancillary factors, to ensure the outcome is optimal.

Strategies for Independent B2B Electronic Markets

Past studies indicated that the sustainability and success of Independent B2B Electronic Markets rely on a number of factors, such as the volume of transaction processed, the type and range of business processes supported, and the number and diversity of the participating organisations [8, 20]. Like Private B2B Electronic Markets, Independent B2B Electronic Markets rely on the market-maker to generate the required volume of transaction and attract the right mix of participants albeit without the backing of a major supplier, manufacturer or customer.

The Independent B2B Electronic Markets studied have had to fend off competition from other B2B Electronic Markets. The market-makers are constantly motivated to present a unique set of value propositions to their clients that cannot be easily replicated by competitors. At the same time, the market-makers have to employ strategies to attract the right crowd, the right mix of buyers and sellers to the independent trading environment, while maintaining a reliable and sustainable business model. Independent B2B Electronic Markets thrive in highly fragmented market segments whereby buyers and sellers could quickly and inexpensively extend their reach, and expand their capabilities to trade with a greater pool of trading partners. Data from Case 2 suggested that the market-maker diversified its revenue stream by branching into print publication and advertisements to supplement revenue collected from membership and transaction fees from the electronic market.

The market-maker in Case 3 sought to expand the scope of business functionality supported by becoming a one-stop shop for buyers and sellers. It provided a range of value-added services, such as payment processing, product inspection, and logistics through its allied partners. The underlying rationale is that by expanding the scope of business functionality supported, it provides additional revenue streams and presents a set desirable value propositions to its clients. Many B2B Electronic Markets, both Private and Independent, have pursued this path, by morphing their intermediary and brokerage model into a one-stop solutions provider model.

From the perspective of buyers and sellers, Independent B2B Electronic Markets were employed as a low-cost channel for spot transactions, e.g. unplanned purchase of out-of-service equipments, or for getting rid of surplus inventory. Buyers and sellers also used the Independent B2B

Electronic Markets to smoothen out spikes and shocks in demand and supply cycles. Although market-makers have concentrated on providing an extensive scope of functionality, it was observed that the participating organisations seldom utilise all of the value-added services. Participants of the Independent B2B Electronic Markets engage in these trading systems for a specific purpose, such as accessing new trading partners in a highly fragmented market to quickly accessing vendors of urgently required items or to inexpensively dispose of excess inventory. The increasing number of organisations that utilise eBayBusiness.com, a B2B-centered eBay, for similar purposes confirms this empirical finding.

The issue of uneven creation, distribution, and capture of business value is less of a concern to buyers and sellers in Independent B2B Electronic Markets. Challenges remain however, for the Independent B2B Electronic Market to fend off competition by rival B2B Electronic Markets, and the threat of disintermediation by direct interaction between buyers and sellers. The other challenge for Independent B2B Electronic Markets lies in their ability to attract and maintain the right mix of buyers and sellers. While healthy competition among the participants is encouraged, intense price competition quickly erode the competitive capability of participants, and overly-friendly inter-organisational relationships may lead to collusion.

Table 2 summarises the important elements of the business strategies employed by buyers, sellers, and market-makers for participating in B2B Electronic Markets.

B2B Electronic Markets and the Transformation of Business Processes

Data from the six case studies indicated that the transformation of business processes due to the implementation of B2B Electronic Markets is an issue that all parties have to address. The difficulty in quantifying the business value of B2B Electronic Markets, is likely related to the challenges that lie in understanding the transformation of business processes due to B2B Electronic Markets.

Kambil and Van Heck [7] posited that using a stakeholder-process framework enables one to better understand how and why an Electronic Market system transforms business processes, and thus delivers value to the different stakeholders.

In this study, a similar approach was adopted, and the adoption and implementation of B2B Electronic Markets were evaluated by identifying the business processes they transformed, from the perspective of the stakeholders they impacted. It was found that additional incentives were required, such as collaborative sharing of inventory information, and sometimes in the form of additional monetary assistance, to encourage trading partners and customers in particular to participate in B2B Electronic Markets. The reduction of transaction cost alone is insufficient as an incentive.

The results indicated that a pragmatic approach is crucial

for the success of B2B Electronic Markets, especially from the perspective of the market-maker. The B2B Electronic Market model adopted must be clearly defined and the business functionalities and processes supported have to be fully understood. This is to ensure that the limitations of the

B2B Electronic Markets are known in advance, and the market-makers do not have a mentality that “if we build it, they will come.”

Cost reduction is of particular concern for many organisations. The question they face is whether they are

Table 2: Stakeholder Strategies in B2B Electronic Markets

	Private Electronic Markets	Independent Electronic Markets
Strategies for Market-maker/Operator	<ul style="list-style-type: none"> (i) Channel a substantial proportion of existing transactions through the Private Market. (ii) Avoid confrontational style in encouraging trading partners to engage in Private markets. (iii) Strategies to redistribute business value are especially important, due to the uneven creation and capture of business value. 	<ul style="list-style-type: none"> (i) Rely on increasing transactional volume, and increasing the diversity of participants. (ii) Present a different set of value propositions to buyers and sellers. (iii) Diversify and broaden the business functionalities supported, to counter competition from private markets, and other independents.
Strategies for the Buyer	<ul style="list-style-type: none"> (i) Improve inventory management through collaborative planning, etc. (ii) Consolidate sourcing channels, and standardise purchasing processes. (iii) Gain access to important market information, such as the availability of products 	<ul style="list-style-type: none"> (i) Conduct spot purchases to overcome unforeseen demand spikes. (ii) Gain access to a greater pool of sellers, vendors.
Strategies for the Seller	<ul style="list-style-type: none"> (i) Gain access to greater business certainty and security by securing major contracts. (ii) Move away from price-based strategies, and concentrate on product differentiation to prevent commoditisation of products. (iii) Improve relationships with customers, such as through collaborative planning and design. 	<ul style="list-style-type: none"> (i) Get rid of excess inventory, (ii) Use them as a low cost channel for accessing non-existing trading partners, especially if the buyers are fragmented, and difficult to access.

willing to incur the additional cost of participating in B2B Electronic Markets, simply to enjoy a marginal cost reduction from savings in transaction cost. For major buyers and sellers, the volume of their transactions may justify this decision easily, but for those that have less volume, or already have well-established relationships with existing trading partners, the decision for joining B2B Electronic Markets requires an evaluation of whether it aligns with the organisation’s core business, and how it will improve its core business.

From the perspective of an individual buyer or seller, the decision to join a B2B Electronic Market is frequently influenced by decisions by its major trading partner to join, or a group sign-on by its trading community. While the network externality effect may describe the typical network benefits for the individual buyer or seller, these organisations must be prepared to perform substantial modification or transformation of their existing internal processes. Integration of internal and external business processes represents a major hurdle for some organisations, but also an incentive for those that intend to pursue process automation.

V. Conclusion

The paper contributes to practice and research by presenting rich empirical insights into the operations of B2B Electronic Markets, and providing suggestions for future research in the

topic area. It also highlights the importance of the traditional process for formulating business strategies, albeit one that is adapted for a faster-paced B2B Electronic Markets environment.

In conclusion, the study found that an important element to effective and successful strategies lies in the ability of the B2B Electronic Market system to foster collaboration, and encourage participating organisations to draw synergy from mutual strength and expertise. Pitting participating organisations against one another to achieve price-based reduction is but a short-term tactic. As interest among participating organisations to compete on price wanes, the viability of the B2B Electronic Market is threatened. For market-makers in particular, the ability to generate and distribute business value fairly provides additional motivation for stakeholders to participate.

Secondly, the adoption of B2B Electronic Markets requires business strategies that are not much different to adopting new business innovations. For participating organisations, an important element to effective and successful strategies for B2B Electronic Markets is to have adequate long-term planning, and be able to focus on measurable and achievable goals. Frequent recalibration and readjustment to business strategies are indicators of inadequate planning, or the lack of understanding of B2B Electronic Markets.

Last, but by no means least, the paper highlighted the need for managing business process transformation that

accompanies B2B Electronic Markets. In-depth understanding of existing business processes, and the capabilities of B2B Electronic Markets, prevent hasty strategies that require frequent recalibration. In addition, these three major findings represent areas that require further research in order to determine qualitative-type effects of B2B Electronic Markets.

How Smart Card Technology Could Be Used for Dynamic Pricing in Transportation Network?

Ting Li, Eric van Heck, Peter Vervest

Department of Decision and Information Sciences

Rotterdam School of Management / Erasmus University, The Netherlands

{tli, evanheck, pvervest}@rsm.nl

Abstract: The past decade has witnessed an increased application for dynamic pricing in transportation industry, where firms use various forms of dynamic pricing to respond to market fluctuations and uncertainty in demand. In light of the success in the airline dynamic pricing practice and given the advancement of the ICT technology, the question is raised as follows: can technology adoptions, such as smart card, help the transportation companies, especially public transport operators, to approach the dynamic pricing in an innovative way? By using the case of the smart card adoption in the Dutch transportation industry, this article articulates the opportunities the smart card brings to the dynamic pricing design and use. It is demonstrated that the smart card data gives a dimensional view on the travellers, where both the market segmentation and the travel behaviour could be better studied. It is also argued that the rich segmentation information on the travellers and the increased understanding of the travel behaviour could lead to the level of refinement of the dynamic pricing strategies for the transportation companies. Furthermore, a number of dynamic pricing strategies are proposed that correspond to the discussed smart card dimensions.

Keywords: Emerging technology, case study, smart card, dynamic pricing.

I. Introduction

The past decade has witnessed an increased application for dynamic pricing in transportation industry, where firms use various forms of dynamic pricing to respond to market fluctuations and uncertainty in demand. One particular example is the dynamic pricing strategy used in the budget airlines (some examples are easyJet and Ryanair in Europe and jetBlue in the U.S.). These airlines typically offer only one type of ticket on each flight, a non-refundable, one-way fare without advance-purchase restrictions. However, they offer these tickets at different prices for different flights, and moreover, during the booking period for each flight, vary prices dynamically based on capacity and demand for that specific departure [16].

The other transportation companies, especially public transport operators (PTOs), however, are in the dilemma and having difficulties in fully taking advantage of the dynamic pricing. On one hand, there is a definite need. Transportation

planners and public transport operators alike have become increasingly aware of the need to diffuse the concentration of the peak period travel. Dynamic pricing is argued as one of the most preferred revenue management method [16] to both reduce the peak travel requirement and increase the capacity utilization. And on the other hand, there is a practical limitation. Without deploying booking and reservation system as the airlines do, PTOs are not able to manage the variable demand of the heterogeneous travelers and spread them over the course of the day or the week.

At the same time, the rapid development of information communication technologies (ICT) and the expansion of the Internet have deeply affected the way in which various transport operators deploy and exploit their products and services in the transportation marketplace [6]. The advent of the emerging transportation ICT technologies, such as automatic vehicle location and tracking (AVLT), automatic data collection (ADC) and automatic fare collection (AFC), from the travelers' perspective, has provided enormous travelers' transit information (i.e., real-time traffic information) and enhance the quality of their travel experience. From the transport operators' perspective, they are striving to adapt their business processes to take advantage of the possibilities that these emerging technologies offer.

In light of the success in the airline dynamic pricing practice and given the advancement of the ICT technology, can PTOs be inspired to get out of the dilemma? Specifically, will the transportation ICT technology help the PTOs to approach the dynamic pricing in an innovative way? Unfortunately we are still a long way from fully understanding the possibilities as we have only begun to recognize the potential of these transportation ICT technologies. Before we can design the strategy (i.e., dynamic pricing) to take maximum advantage of the new and emerging technologies, we need to have a clear picture of what such emerging technology could offer. The answers to the above questions are sought in a case study approach. By using the case of the smart card adoption in the Dutch transportation industry, this article offers a contribution by outlining several dimensions of the smart card attributes along which a number of pricing strategies are proposed.

The reminder of the article is organized as follows. The article starts with a review on the existing literature on ICT adoption and dynamic pricing. These two theories are developed into a conceptual framework. Next, an explanation of the empirical setting in the smart card adoption in the Dutch transportation industry is given,

together with research method and data. This section is then followed by presenting the empirical analysis, which emphasises on the smart card attribute dimensions and the innovative pricing strategies that linked to each dimension. The article ends with conclusions and suggestions for further research.

II. Literature Review and Conceptual Framework

This section discusses dynamic pricing and ICT operational adoption, which appear to be essential for this article. These two theories are then developed into a conceptual framework.

II.1 Dynamic Pricing in the Transportation Industry

Dynamic pricing can be formally defined as the selling of goods in markets where prices move quickly in response to supply and demand fluctuations. Charging different prices for the same product is price discrimination [5]. One type of price discrimination, second price discrimination, is based on identifying the willingness to pay of different groups of customers through their purchasing behaviour. Economic theory argues that dynamically changing prices is inherently good for the profitability of the firm, because it allows the firm to capture a larger share of the consumer surplus. Consumer surplus is viewed as the difference in the price that the customers are willing to pay and the actual price that they end up paying. Price discrimination moves some of the customer surplus to the suppliers.

It has long been the tradition of transportation companies, especially airlines, to use the flexible pricing strategies to manage their perishable inventory efficiently. Argued by Boyer [5], transportation companies are in an especially good position to engage in price discrimination. This is mainly because that it is generally possible for the transportation companies to satisfy the characteristics that are common to the applications of the dynamic pricing [12]. These characteristics include the following: 1) managing relatively fixed and inflexible capacity; 2) the inventories are perishable; 3) existence of variable and uncertain demand; 4) the customers are heterogeneous, however, could be segmented; 5) the companies have appropriate cost and pricing structure; 6) the data and information system infrastructures are available.

II.2 ICT Adoption in the Organization

The impact of general ICT adoption in the organization has been extensively studied in the past decades. Three major research streams in regard to the impact on the organizational performance could be identified. 1) Cost reduction. Many researchers have argued that ICT is particularly useful in information-intensive activities, since the use of ICT might lead to the reduction of coordination costs and therefore, decrease transaction costs [10]. 2) Revenue generation. Some authors have investigated how the use of ICT might affect revenue generation in

information-intensive activities. For example, Bakos [3] supports the claim that using ICT supports new pricing strategies. 3) Increase flexibility. Some authors have stressed the possibilities of ICT to increased interorganizational flexibility [13,21].

The ICT technologies that are adopted in the transportation industry have been systematically analysed by [9]. Furthermore, their paper also offers a more general view on the impact of the ICT adoption on both personal travel and commercial vehicle operations. In the smart card literature, although there are comprehensive reviews of smart card technology and its commercialisation [15], many of the papers have focused on either technological aspect or the payment aspect [18] of this ICT adoption. Only until recently, the smart card adoption affects on the data collection process have been studied through Bagchi and White [2] empirically examination in the UK bus operation.

Being one type of ICT adoption, smart card based automatic fare collection systems are being introduced all around the world in the transportation companies. Being the first setup, Hong Kong's "Octopus" card has more than 5 million active users since the adoption in 1996. Singapore's "EZ-Link" card also reaches a 5 million user base since 1999. Transport for London (TfL) adopts "Oyster" card on its London transport system that covers tube, bus, trams and national rail services, and have attracted 7 million users. The widespread adoptions have undoubtedly exemplified the great interests of PTOs on the smart card technology. Now the question is: are the adoption of the smart card technology in the transportation companies could leverage the opportunity of the dynamic pricing?

II.3 Conceptual Framework

The following conceptual framework depicts the potential influence that the adoption of smart card in the transportation companies may influence the design and use of the dynamic pricing. Based on the literature review we formulate the following proposition.

Determining the "right" price to charge a customer for a product is a complex task, requiring that a company know not only its own operating costs and availability of supply, but also how much the current customer values the product and what future demand will be [7]. Therefore, to charge a customer the right price, a company must have a wealth of information about its customer base and be able to set and adjust its prices at minimal cost.

The term dynamic pricing is used in this article to broadly encompass tariff structures that adopt differentiated pricing [5], in which different buyers may receive different prices, as opposed to the auction pricing mechanism that has prices and conditions based on bids by market participants [11]. The practical motivation for developing dynamic pricing options can probably be traced to the need to reduce the peak load requirement, the variable and uncertain demand, as well as the profitability of the firm.

Tremendous data could be obtained through the usage of the smart card by the transportation companies. These data

can be used to derive the detailed traveler information over the cost that users are willing to undertake. Unlike the traditional time-consuming survey method where the changes are observed slowly because of the information delay, the smart card becomes a powerful tool for almost instantaneous consumer feedback. The key advantage is that it provides a detailed understanding of willingness-to-pay and traveler characteristic information. This should provide more accurate price-demand projections than are attainable via the traditional survey methods. Transportation companies could then design their pricing strategies to separate the higher and lower price segments: to separate the travelers that are sensitive to the price change (recreational traveler) and people that are insensitive (home-work traveler).

The adoption of the smart card in the transportation companies provides 1) increased availability of traveler data, 2) opportunity to change the prices more easily, and 3) potentials to combine with the decision support tools for analyzing the demand data. These improvements allow the PTOs to design and use the dynamic pricing strategies that they are not capable earlier, when the companies had limited ability to track information about their travelers and faced high costs in changing prices [7]. Thus, we have:

Proposition 1: Smart card adoption of the transportation companies leads to the design and use of dynamic pricing.

In light of the smart card adoption in the Netherlands, the PTOs have many questions concerning the impacts of the adoption, including technological, social, environmental, commercial and operational aspects. Because of the limit in space, this article will mainly focus the relationship to the dynamic pricing, which distinguishes itself and also makes an important contribution to the similar research of this kind [1,4,17].

III. Research Context and Research Method

This section elaborates the research context and the research method. The above-mentioned conceptual framework will be studied based on the case of the smart card adoption of the Dutch transportation industry,

III.1 The Context

The way in which people use public transport in the Netherlands is changing – as it is in cities and countries across the globe. Trans Link Systems (TLS) plans to deliver a seamless ticketing and fare collection system for the complete public transport system throughout the Netherlands. The system will initially be rolled out in Rotterdam in September 2005 and extended to cover the whole country by the end of 2007. Using smart card and readers' technology, this all-encompassing contactless ticketing infrastructure will cover trains, metro, trams and buses – providing travelers with increased convenience and added satisfaction. At full implementation the system will have to contend with

an estimated 1.5 billion transactions each year.

III.2 Research Method and Data

Case study research is chosen to test the proposition as it investigates a contemporary phenomenon within its real-life context [23]. The rationale for selecting the single case - the smart card adoption in the Dutch transportation industry - for is being representative [23]. And at the same time, it satisfies two criteria for the case selection: 1) the smart card technology is being implemented, and 2) different pricing strategies are being considered while the introduction is taking place.

Data was collected through personal interviews, documents, websites and previous researches. Taking the full strength of the case study method, this data collection approach also tries to enhance the validity of the research. In total, 12 interviews were carried out with people from marketing, commercial, research and logistics departments at different management levels in transportation companies as well as public institutions.

IV. Analysis of the Empirical Data

In this section, an empirical analysis of the gathered information will be performed. After presenting the lack of information problem that occurs in the current situation, it demonstrates the dimensional classification of the smart card data attributes. As a result, a number of dynamic pricing strategies for the railway travel are proposed that correspond to the discussed dimensions.

IV.1 Lack of information in the current situation

There are mainly two ways for the PTOs to gather the travelers' information in the current situation. First, the PTOs would have some records of their frequent travelers who left their details after their purchasing. Second, different surveys are conducted every year or every few years to cover different aspects of the travelers' information. For example, there are surveys that look at the characteristics of the travelers, the frequency of the travel and the preferred time of the travel. However, the questions concerning what type of product their travelers use and when exactly they use it are still largely remain outdated, inaccurate and even unknown.

IV.2 Smart Card Data Dimensions

Each time the smart card is used, either to make a trip or to purchase/renew a travel product that loaded to the card, details of the trip and/or product made with the card will be captured and linked to that smart card or the individual if the smart card is registered under that individual. The smart card, hence, gives the PTOs the opportunity to capture the behavior of the travelers more easily.

The information extracted from the smart card data consists of the origin and destination of the travel, the travel time at the origin and the destination, and the transport services that the travelers use. The transport services include

the mode of the transport and the vehicle type of that particular transport mode. For example, for the train travel, the vehicle type may vary from international train, intercity train, fast train, and slow train. If the smart card is not “transferable”, which means only the card holder is allowed to use the card, it may also contain the profile information of the card holder, for example, age, gender, name, address and maybe profession. Privacy concern would be relevant in this context, however, is out of the scope of this article.

The smart card data attributes (depends on the specific implementation) could be classified into five dimensions (see **Table 1**). The categorization is largely based on the smart card data attributes that are presented by Bagchi and White [1]. The categorization gives an indication on how the travelers could be segmented. For example, in the spatial dimension, travelers could be segmented based on different origin-destination route; peak and off-peak period travel segments the travelers in the temporal dimension. The five dimensions are:

- *Temporal dimension*: time and date of departure and destination;
- *Spatial dimension*: departure and destination of the travel;
- *Service dimension*: travel mode and vehicle type;
- *Personal dimension*: traveler’s name, age, gender, address and profession;
- *Buying dimension*: travel product purchase time/date, location and price;

Table 1: Smart card data attributes and its dimensions (adapted from Bagchi and White, 2004)

Smart Card Attribute	Smart card	Temporal dimension	Spatial dimension	Service dimension	Personal dimension	Buying dimension
Card number	x				x	
Cardholder name and address	x				x	
Cardholder age	x				x	
Cardholder gender	x				x	
Travel origin	x		x			
Travel destination	x		x			
Time / day of departure (origin)	x	x				
Time / day of arrival (destination)	x	x				
Transport mode and vehicle type	x			x		
Product purchase time and date	x					x
Product Purchase location	x					x
Type and price of product	x					x
Travel purpose						

Travel purpose: The travel purposes that are now collected with the travel survey cannot be captured with the smart card.

IV. 3 Dynamic Pricing Strategies

As one of the most important price-based revenue management techniques, dynamic pricing has a direct, and sometimes dramatic, impact on operations and vice versa [8]. Dynamic pricing is one possible method to manage demand and reduce the peak load requirement. In this section, a number of dynamic pricing strategies for the railway travel are proposed that correspond to the previously discussed smart card data dimensions. For each strategies proposed, an explanation on how it works is given together with specific examples on the pricing scheme.

Table 2: Smart card data attribute vs. tariff structure

Smart card data dimension	Dynamic pricing strategy
Temporal dimension	Time-based pricing; (time-of-day; day-of-week)
Spatial dimension	Directional pricing; Regional pricing;
Service dimension	Usage-based pricing; Demand-based pricing;
Personal dimension	Age-based (e.g., 65+); Profession-based (e.g., student);
Buying dimension	Periodic fare product promotion

Temporal dimension: *Time-based pricing* is by far the most frequently used pricing strategy among all the proposed ones by the transportation companies.

Time-based pricing. In the Netherlands, the morning peak hour is defined as between 7:00-9:00am each weekday. The periods after 9:00am and the weekends are defined as off-peak. In practice, a reduction card is available for the travellers who travel during the off-peak, which gives them a 40% reduction on the travel. This reduction policy is an example of time-based pricing. It is argued that giving discounts to travelers during the uncongested off-peak should attract much less opposition than an extra (punitive) fare on peak-hour travellers [20]. Other example of this time-based pricing strategies are: for the time-of-day strategy, introducing the pre-morning peak (cheaper fares before 7:00am); for the day-of-week strategy, introducing lower weekend fare; There are many time-of-day priced services already in practice, including telephones (cheaper evening and weekend rates), movie theatres (the matinee show) and restaurants (the “early bird” special).

Spatial dimension: Dynamic pricing strategies that are designed by using the spatial dimensional data are: directional pricing and regional pricing.

Directional pricing. Apart from the time-dependence of the travel demand, the directional imbalance, which means unequal demand in both directions, also heavily impacts the load factors of the PTOs. In a normal weekday, the railway operation data shows that during the peak hours the trains are crowded while moving to the direction of the big cities, whereas they may be almost empty on the other direction. In fact, majority of the travelers who travel in the morning peak are the ones who either work or study in the destination city but live in another city. As expected, the dataset for the afternoon peak between 16:00 to 18:00 demonstrates an opposite directional pattern. PTOs can apply several

strategies to accommodate this imbalance [14], among one of them, direction-dependent differentiated pricing could be expected to have a positive effect on improving the load factors as well as the profit.

Regional pricing. Similar to the zone-based pricing in some cities for the bus and the metro transport, regional pricing in the rail transport could be thought of as applying different regional tariff to each region. For example, a differentiated price could be charged for the traveling to and from the most important cities in the *Randstad*. (*Randstad* is the metropolitan area in the western part of the Netherlands, including major cities, such as, *Amsterdam, Rotterdam, The Hague* and *Utrecht*. It has high work availability, many multinational corporations and universities that attract many people to work and study.) Hence, the travel demand of this region is significantly higher than the average demand of the rest of the country. van Vuuren [19] has proved that peak hour seat kilometres on dense tracks are underpriced, both from the profit-maximizing perspective and from the welfare-maximizing perspective. In fact, it has been considered of adding an additional unit of tariff to the current tariff for the people traveling to and/or from *Randstad*. Another option is to reduce the price of travelling in the less populated area, such as the east of the country. To make it even more sophisticated, different prices could be charged for different origin-destination pairs. This is because the trains on some tracks are more crowded than the others.

Service dimension: two innovative pricing strategies, namely, usage-based pricing and demand-based pricing are introduced in this dimension.

Usage-based pricing. For the travel card holders, who have month card, trajectory card, etc., there is no fare charged for the additional travel. Thus extra travels, such as returning home to lunch from work, weekend family visit etc., are “free”. An earlier empirical analysis [22] has shown that the travel card has lower price elasticity than the single ticket. This means the travelers that have travel card are less price-sensitive than those of the single ticket. With the introduction of the stored-value-ticket, these travelers who travel more than the average will choose to stay with the travel card. While on the other hand, people who use the travel card less than the average will switch back to the single ticket. In the usage-based pricing scheme, travelers are billed on the actual travel kilometers during any given month. There are a number of options for implementing this usage-based pricing. 1) Pay-as-you-go. Fixed costs are charged for every kilometer a person travels. 2) Contract for fixed amount. A contract is signed between the traveler and the PTOs for a fixed amount of kilometers given a certain price. 3) Product bundle. It is a pricing scheme that consists of a premium and a charge for the additional travel being made.

Demand-based pricing. Assume the travelers’ boarding information is captured at virtually real time, the PTOs then know the total demand and consequently the utilization of the transport vehicles. The demand-based pricing proposes to let the tariff vary based on the travel demand. In that case,

the PTOs could decide on for example, lowering the prices for the traveler when the total travel demand exceeds certain level or the utilization is higher than a given rate.

Personal dimension: Different travel cards could be designed for people in the different profile group. For example, student travel card or travel card for senior people above 65 years. Some of these are already implemented in practice.

Buying dimension: Periodic promotions to attract new travelers are considered as the pricing strategy that fits into this dimension.

IV. 4 Refined Conceptual Framework

Based on the analysis of the dimensionality of the smart card attributes and the proposed dynamic pricing strategies that map into the dimensions, a refined conceptual framework (see Figure 1) is developed through a set of refined hypotheses.

Hypothesis 1: Smart card adoption in the transportation companies provides rich information on travelers’ segmentation.

Customer segmentation is the practice of dividing a customer base into groups of individuals that are similar in specific ways relevant to marketing. Using segmentation allows companies to target customer groups effectively.

The smart card data provides rich information on travelers on the discussed dimensions. These data and/or together with other data sources could then be used to analyze the segmentation of the travelers. There are many ways to segment the market as can be seen from the number of data attributes along different dimensions. Travel purpose is by far the most frequently used segmentation in the transportation industry. Although the data on the travel purpose will still not be possible to obtain by using the smart card, it is generally available via survey method. For example, distinctions could be made between commuters (home-to-work or home-to-study traveler), business (first class traveler), and recreation (holiday or shopping).

Hypothesis 2: Smart card adoption in the transportation companies leads to better understanding of the travel behavior.

Travel behavior research is the study of what people do over space, and how people use transport. The questions studied in travel behaviour are broad, such as, how many trips do people make? Where to they travel to and from? What mode do they use? When is the trip being made? etc. These information are traditionally obtained by using travel surveys. Conducting survey, especially large scale travel behavior survey, requires big efforts and spans long period. Smart card data enhance the ability of the PTOs to know where the people travel to and from, at what time, and at what price. It is important to note that the revealed segmentation information of the travelers is different from understanding the travel behavior. The latter concerns some issues in a broader scope. Besides the ones mentioned, other travel behaviour related questions are: what is the pattern of

trips? Would the price increase of the public transport affect the travelers decision making on mode choices? Is the crowdedness an important factor when people making mode choice? Answers to these questions could not be given unless more insights into the behavioural aspects of the travel are gained.

Hypothesis 3: Rich information on the travelers' segmentation leads to the level of refinement of dynamic pricing strategies.

Various empirical analyses have shown that the demand for the train transport during the peak hours is inelastic, while the demand during the off-peak is elastic [19]. According to van Vuuren [19], the motivation plays an important role for this. As the travelers usually do not have many alternatives and therefore cannot easily switch to other modes or another departure time or another track, resulting in relatively low price elasticity for the demand during the peak hours.

Price elasticity is defined as the percentage change in consumption of the good (change in demand) caused by a one-percent change in its monetary price or other characteristics, such as service quality. The gathered data from the smart card and other sources could be used to derive the elasticity information for each traveler segment. As a result of it, transportation companies could tailor their dynamic pricing strategies to different market segments in a more refined level and allocate their marketing resource more effectively.

Hypothesis 4: Better understand the travel behavior leads to the level of refinement of dynamic pricing strategies.

An example of using proposed time-based pricing strategy is to introduce an afternoon-peak (16:00-18:00) price. Instead of paying the off-peak reduction price, travellers that travel during the afternoon-peak would be charged to a higher price. The introduction of this policy is in an effort to even-out the peak travel concentration. Then the question is: would this policy shift the demand of the travelers to a less-crowded period of the day? Or will the travellers change to a different mode of travel? Answers to these travel behaviour related questions would be essential to assess of the pricing policies. And more importantly, it will lead to a more refined level of pricing strategy design.

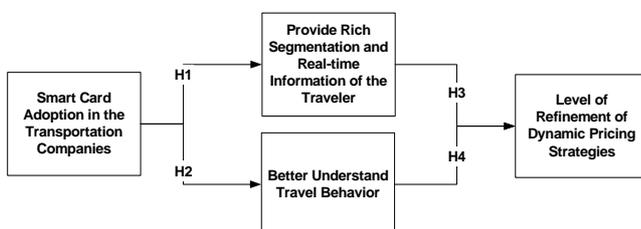

Figure 1: Refined Conceptual Framework

V. Conclusions

Based on the case study result from the Dutch transportation

industry, this article argued that the adoption of the smart card by the transportation companies on one hand provides rich segmentation and real-time information of the travelers. And on the other hand, it leads to the ability to better understand the travel behavior. As a result of it, an improvement on the level of refinement for the design and use of the dynamic pricing strategies could be achieved.

There are several suggestions for further research on the relationship between smart card adoption and the design of the dynamic pricing.

First, a number of pricing strategies have been suggested in this article. An evaluation of the potential effectiveness of the strategies needs to be tested.

One of the hypotheses suggests that travel behaviour leads to better pricing design. In order to better design the dynamic pricing strategies, PTOs should first understand their travelers in regard to their travel decisions. Despite the potential of differentiated pricing to ease the peak period public transport demand problems, there is little quantitative evidence of its ability to influence the behavior of the travelers. Therefore, future research could emphasis on answering the questions, such as, how do travelers respond to time-dependent pricing strategy during the day? Are they shifting to a cheaper period or are they paying the higher price?

Third, though the adoption of the smart card in the transportation companies offers tremendous opportunities to design sophisticated dynamic pricing strategies (i.e., individual-level price discrimination), in practice, the pricing structure has to be simple and easy to communicate to the travelers.

Fourth, it is clear that the above proposal on dynamic pricing are based on a rather idealised travel markets and only the transport operators' profit-maximising objective is considered. Travelers may express an objection for crowding, unfairness and fare complexity, which consequently might change their willingness-to-pay. To bring the models closer to reality, the future research could focus on understanding the travelers' behaviour change under the influence of the dynamic pricing, and the cost of complexity.

Email: lpau@rsm.nl

Abstract: The needs as well as the bottlenecks are analyzed in the deployment and use of wireless services in a networked environment of companies sharing some common supply chain processes. The specific case is the multi-enterprise networks around the Port of Rotterdam, researched as part a large project on value-added wireless services in this environment, sponsored by KPN Mobile. New services, operational requirements, decision processes as well as tariff and organizational problems are reported.

I. Introduction

This paper summarizes the main results of a large sponsored project entrusted to Rotterdam School of Management (RSM) by KPN Mobile, in collaboration with the Port of Rotterdam authorities. Its focus was on identifying drivers and bottlenecks in the usage and creation of wireless services in the Port of Rotterdam.

It also aimed at creating an understanding for the decisions and demand processes amongst port users and different groups. For the Port of Rotterdam and its partners: the goal was to have a third neutral party elicit the use of GPRS and 3G wireless services, and propose business processes making best use of basic and value-added/customized 3G wireless services; this analysis applies to services as they exist or could be developed by the Port or its associates. RSM, in collaboration with the Erasmus Center for Maritime Economics, was in such a position to be able to extend the qualitative comparison to the identification and survey of the wireless activities at about 16 other ports worldwide.

The project was organized into three basic focused tasks addressing more specifically:

- *Logistics processes and competitive impact*
- *Basic 3G voice and data services*
- *New 3G voice and data services*

The work method used was the following. A sequence of thematic interaction sessions took place on each of the three focus tasks, aimed at eliciting key issues, opportunities and difficulties from different angles. The field work, involving each time 2-3 different RSM researchers, took place at over 80 companies or public institutions with interviews based on

thematic questionnaires and evaluation criteria. The interviewed parties were all at management level, which is rather exceptional. Contacts were also made with an additional set of 70 companies via questionnaires, and contacts or meetings were held with 25 companies outside the Netherlands. As to the research methodology, a systematic identification of bottlenecks and opportunities at the multi-enterprise business process level was carried out in all the three basic tasks above.

The verification and discrepancies were revealed by the interviews and common questionnaires/evaluation criteria. For lack of space reasons, this article only reports on the overall conclusions (Section 2), some of the findings and cases from the task on logistics (Section 3), before dealing specifically with New wireless services for port operations (Section 4). It continues in Section 5 with the related business models and organizational issues (Section 6). Readers not familiar with this sector are referred to [1], [2] for terminology.

This short presentation is not research focused but brings value to research on the difficulties in introducing 3G services into multi-enterprise environments. For obvious reasons there is not much academic literature on this subject, and even less on wireless operations in harbors.

II. Context and Overall Results

II.1 General

The Port of Rotterdam is economically an important worldwide logistics hub present in the Netherlands and involving many small and large companies and organizations to whom wireless operators would like to offer capabilities and services. The Port of Rotterdam holds one of the top ranks worldwide for a large number of major logistics and supply chain processes (and tops total port throughput in tonnage worldwide), the sheer diversity of which poses some significant challenges for wireless services (generic as well as value-added services). Furthermore, the largely decentralized nature of the actual operations and information flows, besides a consensus based nature of local decision making, and very tight operating budgets everywhere, make it difficult organizationally to map the demand for advanced wireless services with sufficient business revenue base. KPN Mobile asked to put the emphasis on 3G wireless services and their demand, which later expanded in the project to GPRS based services,

inevitably revealed a significant lack of flexibility and even resistance amongst most private actors in the Port (including shipping lines) in terms of technology migration. Furthermore, most uses of wireless communication are still tied to mobile field workers who drive a bottom up adoption process, meaning that in the best case GSM, and in some rare cases GPRS, are still “good enough” and that no specific investment budgets exist for service creation or wireless information gateways.

II. 2 Logistics and Competitive Position

For the actors inside the actual physical supply chains, as investigated as part of the focus task on “Logistics and competitive positioning”, the general finding is that there are no indications that they will adopt 3G on a large scale in the short term. Nevertheless, the identified logistics development trends driving the adoption of 3G services amongst these actors are the administrative complexity and exception handling, the migration from voice to data, and external drivers like US safety/security regulations. The bottlenecks were insufficient wireless dependability, back office and broadband fixed Internet as alternatives, and the politics and power of supply chain relationships.

II. 3 Basic Services

For all users (service focused or physical flow focused) of generic wireless services, covered in the related focus task “Basic services”, whether small and middle sized enterprises, large organizations, or those with very unique service contexts, the dominant issue is one of perceived (or observed) GPRS and 3G tariffs, as they risk to impact field operations and permanent operations which should not in their minds be charged per minute or MB. Even if public sector users may have less concern for tariffs and may be earlier adopters/pilot sites, the likelihood that their adoption will spill over to 3G services is minimal. Another important factor is that, in significant cases, the decisions to adopt GPRS or 3G basic services, are not made in the Port area at all but elsewhere in the Netherlands or abroad which render local marketing of generic services ineffective. Other limiting factors are the difficulties or costs to find specialized terminals working in a dependable way in a Port context, as well as the lack of truly experienced custom mobile application integrators with logistics understanding able to develop reliable solutions.

II. 4 New Wireless Services

The field of new wireless value-added services benefiting the Port of Rotterdam business environment is rich in concepts and interested parties, but poor on actions and players leading integrative projects for wireless information distribution, or for productivity gains. When some analysis or prototyping has been done, GPRS value added services are still preferred over 3G for the foreseeable mid-term future, not the least because too few business processes in the Port (except safety related) demand high data rates or close-to real time performance. Also, other major bottleneck

factors are the lack of a single trusted neutral party for information services, and the absence of revenue based thinking as opposed to cost cutting and/or passing on costs (such as wireless services) to customers.

The comparison with other ports shows that a centralized accountable actor or a dominant user, are always factors for faster adoption of wireless services on sound cost/revenue basis, as opposed to “nice to have” basis.

The research has also shown that alternative technologies and services to 3G such as WLL, WIMAX and even WiFi, are a real threat when driven by sound business models (such as managed services), clear trusted ownerships, and above all low costs to users, for same or better dependability and security.

II. 5 Proposed Approach

To unlock this situation and allow for Port users to gain the benefits of 3G, the most pragmatic approach seems to involve one or two business and revenue driven focused private sector deployment initiatives of innovative services with a clear leader driven by short terms commercial benefits to just a few partners. This can very well happen if a major actor decides top-down for the productivity gains of linking better his operations in the Port with his traditional and closest suppliers or customers. Reinforcing the feasibility of this approach would be the availability of customizable tools for cost and revenue modeling of New 3G services, supplied either by the mobile operator(s) or, better, by a neutral party. Also, well publicized, and “simple to understand” tariff packages for closed subscriber groups using generic 3G services, seem necessary with minimal bureaucracy/sales efforts, e.g. using subscriber self-care options. Beyond, a policy discussion should enable the framework for one party in the Port to emerge as the sole fully trusted for information collection and selective sharing, without commercial conflicts as derived from e.g. privatization.

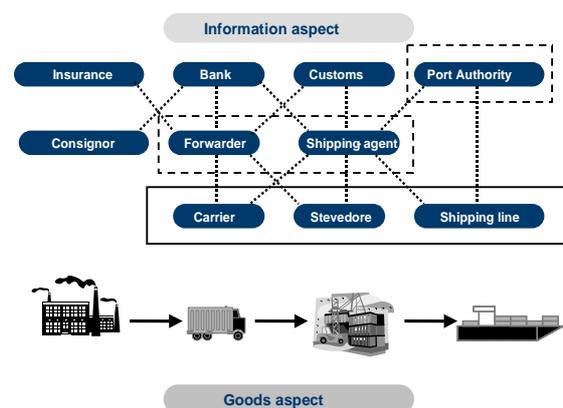

Figure 1: Information and goods views of Port interactions

III. Wireless Usage in Port Logistics and Supply Chains

III.1 Introduction

Supply chains extend over the globe from sourcing raw materials and supply of intermediate parts and products to delivery of goods to end customers, and collection of product returns for environmentally conscious recovery and disposal. As a node in these global supply chains, the port of Rotterdam accommodates transshipment between deep-sea vessels and transport modes that service the European continent and hosts production and other value-adding services. (Figure 1)

Transport modes or means of transport are feeder, short sea shipping, barge, train, truck and pipe lines, supplemented by air cargo. The cargo varies from liquid and dry bulk to (containerized) discrete products. Next to being an enabler, the port of Rotterdam also needs to guarantee health, safety and security of cargo, traffic, industrial complexes and the city. Recent developments here are tightened food safety regulations and anti-terrorism regulations and measures.

III.2 Administrative Complexity and Exception Handling

Although the physical process of transshipment seems simple, the linkages between the organizations and resources involved constitute a complex network (figure 1) [3], [4]. For example, in the port area, hundreds of trucks each send out numerous messages related to (pre-notifications of) arrivals and departures at terminals, pick-up and delivery of cargo, etc. A distinction needs to be made between messages that confirm planned execution and messages that contain alerts indicating that planning could not be met. Another case is given:

FIELD EXAMPLE 1: FOOD AND CONSUMER PRODUCT SAFETY AUTHORITY

Current Situation

After an on-site cargo quality inspection visit by the Food & Consumer Product Safety Authority, the cargo is either cleared for further transportation or a sample is taken to be inspected in the laboratory at the back office. This notification is presently done by voice through a mobile phone. After establishing contact, the planner may provide the inspector with planning adjustments. Upon returning to the back office, the inspector is responsible for uploading (so called signing-off) the inspection data from his laptop on the computer system for further processing. Planners are, next to ensuring and adjusting smooth inspections planning, responsible for providing the inspector with necessary information and giving input for the planning of laboratory activities. These activities cannot be handled efficiently under the current circumstances.

Wireless enabled vision

Forthcoming European legislation, called the General Food Law, requires import and in-transit cargo to be inspected in the country of entrance, instead of in the country of clearance. Since the Port of Rotterdam is a major port of entry for large cargo volumes with destinations all over Europe, this would result in an increase in the

number and diversity of inspections, and possibly more ad hoc inspections to be conducted by the cargo quality inspectors in the Netherlands. The present staff of 10 inspectors may increase fivefold. Such an increase would make the planning of inspections and scheduling of inspectors extremely difficult. Perceived opportunity here are 3G services, especially when coverage in the Netherlands is assured.

III.3 Integration of Mobile Resource Support Systems and Mobile Communication Systems

Mobile resources such as pilots and truck drivers use electronic devices that support decision making at remote locations. When mobile communication is required, one can expect additional benefits when decision support and communication possibilities are integrated. Two field examples are summarized:

FIELD EXAMPLE 2: PILOTAGE PORTABLE PILOT ASSISTANCE (implemented by Loodswezen in Rotterdam since May 2004 using 3G and GPRS)

Prior Situation

Pilots control the boarded vessel and navigate it in a safe and efficient manner to the destination terminal in the port. Efficient and safe management of vessel traffic is highly dependent on the availability, reliability, timeliness and accuracy of data. These data are generally of three types: (1) environmental information: metrological and hydrological data (real time and forecasts), tides reporting scheme, (2) vessel information: both static and dynamic data, e.g. vessel characteristics and restrictions, to be provided to tugboat companies for towage requirements, and (3) (surrounding) traffic information: traffic density expectations, path predictions, traffic image, port and waterway infrastructure (opening times of locks, berth allocation, etc). Traditionally, the pilot relied on information by sight, voice radio communications (VHF) and radar. The information provided to the navigator originates from the vessel itself and from external sources, which is not really real-time.

Wireless enabled vision

To be able to achieve the needed improvements, the pilots are equipped with an advanced mobile device: the PPU (Portable Pilot Unit) made of a laptop with 3G data cards. The amount of data transmitted under current circumstances is 70 Mb during a time period of several hours. The data consists of hydrological data, meteorological data and a track table or traffic image of the VTS. The pilots would like to receive additional data on reporting, passage plans, metrological data from other 'sensors', information about hazardous materials, predictions of traffic flows and traffic intensity, and meteorological and hydrological data currently 'owned' by the Port Authority. The operational trials confirmed that UMTS can provide the needed bandwidth to support these users.

3G / RFID PROTOTYPE: TRACKING CARGO STATUS VIA RFID

For logistics service providers, applying RFID tags on goods could be useful, especially for theft-sensitive goods. Now these goods are loaded in a sealed part of the truck. With a camera in combination with RFID tags these goods could be better monitored and thus better service to the customer could be provided. Continuous matching of the RFID tag on the product with the order destination (e.g. coupled to the board computer and mobile communication) provides better security possibilities. Goods security can be made easier, also loading and unloading can go much faster in the warehouse. With RFID tags and readers, retyping of stock lists and one by one reading of barcodes is not necessary anymore. However, given the lack of global standards, the initial investments and relative high costs (e.g. compared to barcodes), as well as the needed redesign of the supply chain processes, RFID is still seen as a technology of the future by the companies interviewed., although prototypes are built .

III. 4 Bottlenecks

Legacy Systems and Projects

Quite a few organizations in the Port are actively developing applications of IT in order to improve the performance of their logistics operations. Although this attitude may facilitate adoption of 3G, recent or on-going innovations within these organizations hinders adoption of another technology such as wireless.

Back Office and Fixed Network

Mobile resources usually need to communicate with their back office on a regular basis. However, when employees regularly have a fixed data network connection at their disposal, a mobile data connection may be redundant. Perceived security problems with mobile communication contribute to the fact that the described situation is considered satisfactory. For the same reason or for operational control, communication via back office may be preferred over direct communication between mobile resources and other organizations.

Supply Chain Relationships and Assessment and Redistribution of Benefits

Information exchange in the Port with mobile resources involves several organizations in most cases. Moreover, in order to coordinate supply chains, information needs to be integrated beyond organizational borders. Sharing of operational data meets resistance when parties do not trust each other. Because 3G mobile services are part of an inter-organisational system, where data needs to be shared, this bottleneck needs to be taken into account. A clear distinction in access rights, authorisation levels and (re)distribution of benefits is needed to achieve adoption, especially in cases where one organisation needs to make the investments and the other gains the benefits.

Network Scope and Coverage

A main bottleneck is the dependability of the 3G basic service coverage. If the wireless network is not 100% reliable, the service will not be adopted. Even a low-QoS

event can be disastrous for the operations performed and the revenues of Port parties. Therefore, UMTS will be an option when other parties start using it as well in an integrated manner, possibly on a port community level, which is connected to service creation and private VPN's, port authorities and partners.

IV. New Value-Added Wireless Services For Port Operations

Although not all interviewed parties had any concrete ideas or plans, some did, and to better understand the business drivers and bottlenecks, they are mentioned here in Table 1.

NEW SERVICE CATEGORIES	Description
Generated by interviewed parties	<ul style="list-style-type: none"> •Image transmission of damaged goods with images taken by camera associated to a mobile phone, or a mobile terminal with built-in camera; so far the image quality, the cost of transmission and sometimes low perceived security, are inhibitors •“Virtual fencing” security services by connecting in a wireless way cameras, biometric card readers, guarding towers and tours, need to know and information handling •Gate-in gate-out image collection of containers: this was mentioned but it was unclear what the gain was as containers had to be opened •Mobile arrival/departure notification: SMS broadcast of ship arrival or departure information, as a free information service to users in the Port; broadcast, or send on request, actual real time arrival/departure times and locations for ships, barges, trains •Tracking and tracing information distribution about containers and some other freight, either for one single port operator, or across parties; while the first is possible, three actors in the Port have it or plan it (one port operator, two logistics supply-chain companies) and it is deployed elsewhere, the second looked unlikely for information sharing reasons; track departing and arriving containers by physical location and administrative handling status; compartmentalized eventually by line or container fleet owner; report back by voice+data about special conditions/anomalies •Workforce assignment and localization; this involves sending dispatch and destination orders to staff in the field; this has been prototyped with GPRS and requested deployment in 2006 timeframe; the GPS localization aspect was mentioned, is already applied to vehicles, but here are questions as to need to and privacy issues relating to extending it to the handheld terminals •Mobile VPN tunnelling is deployed, but not by mobile operator, but inside applications; in one case an additional crypto facility was enabled to the tunnelled messages •Wireless distribution in the field, with text search facilities before downlink, in huge textual data bases (legal procedures, safety procedures,

	<p>etc)</p> <ul style="list-style-type: none"> •Multimedia wireless dangerous goods inspection with data retrieval •Integrated dispatch, technical action, reporting, and financial settlement in field support tasks; one such system is already deployed using GPRS and will stick with GPRS for 10 years •Maintenance logs about ship engines or elements •Passenger lists •Ship or vessel location services, for both port operations as well as for ship passengers
Generic services	<ul style="list-style-type: none"> •Managed VoWi voice over WLAN hot spot areas, in areas where voice traffic intensity would yield to high costs if 3G was used; interoperability with 3G/PSTN/(in future: VoIP) wide coverage basic services •IP-to-PSTN breakout service to pipe voice calls across a company or home office or home WLAN network •Picture data archive filing and management service, with batch sorting / compression /indexing / distributed access control
Content/information distribution based new services	<ul style="list-style-type: none"> •Distribution of long-term agreements and tariffs to shipping lines' account managers while meeting customers; this service is rivaled by Internet access and put back by the need to handle paper copies •Generic customizable wireless staff dispatching application: Staff and special equipment/ vehicle dispatching orders and acknowledgments; organized by domains and/or terminals •Fleet management application with content managed by fleet owners and operators
Business process support	<ul style="list-style-type: none"> •Exception alarms sent by SMS; this was mentioned, but not in a specific application context, and is/can be handled without a value-added application if data entry (voice or message) are made easy •Accident insurance claim evidence and reporting assembly and distribution, including multimedia evidence •Cleaning/refueling/resupply/personnel landing/etc. information dispatch service for a specific ship arrival across company partnerships •Emergency service coordination (fire-fighters, security, police) on Port premises, with pushed-down info about vehicle/ship/truck

Table 1: New service ideas generated

The only prior Pilot at the Port of Rotterdam was a Customs X-ray container scan with wireless transmission of scanned images. Although a feasibility prototype was built for the Port of Rotterdam Customs in 2001, with GPRS for image transmission and resulting productivity gains, this was never put in service because the transmission time of the huge image files was too long; this would not change much with 3G.

V. Business Factors and Models for Adoption of New Wireless Services in Port Operations

The main business drivers for ideas and concepts of new services were:

- a. information services benefiting eventually organizational capabilities and flexibility
- b. outright productivity gains linked to faster and acceptable mobile access to employees, thus reducing physical transport, in a way similar to mobile field support operations; to this category belong ship and goods inspection and field support tasks, which both have significant volumes of process instances (typically 8000 task instances/year and higher); GPRS or 3G effective data speeds were a gain, but far less important than the gains obtained by the sheer wireless access and its end consequence of speeding up in the field the different work procedures

Surprisingly enough, in the first category a) no business or revenue models were envisaged in a clear way to recoup the cost of development and operations of such new wireless information services; this effect is not due to the analysis method at all, but to another factor discussed below. The major concern was more one of control and influence. In terms of cost, all were looking to "Port (authority) money" to cover expenses, stating that these costs would be merged inside handling fees paid by the ships. In this first category a), an underlying issue with both positive and negative outcomes on business adoption, is the question of which is "the most trusted", or the "best trusted" party for information collection and distribution. If one such party emerges and is accepted in this role, new services of type a) may be deployed and adopted widely.

In the second category b), and if the existing services to be enhanced existed already with their organization, the major concerns were dependability and costs. Apparently, the perception is that 3G new services "may not work", especially as eventual GPRS based forerunners already have dependability problems. In other words, users want services which "work" and not "wonders".

The net effect of the effects discussed above for a) and b) type new services, is that those persons or groups spelling out in clear terms the business gains from 3G new services, are generally been seen as "dreamers", and adopters will "scale back" the ambitions to at best GPRS and sometimes even value added GSM services. An example thereof, is the ultimate preference of the owners of 3G Pilot at Loodswezen (supported by KPN Mobile) to use GPRS instead of 3G, as "GPRS is good enough" (as in other harbours with the same application).

VI. Organizational Factors and Bottlenecks around New Wireless Services

By far the overriding bottleneck was the organizational framework for wireless new services (GPRS and 3G) in the Port of Rotterdam in the private sector. The factors of this restriction are varying mixes of:

-A: the complete lack of easily customizable cost and revenue models for new 3G services

-B: absence of actual operational leadership, contrasting the multitude of wishes to “get involved”; this is of course linked to the fact that no specific budget is yet proposed or approved in any umbrella or public organization catering to the private sector companies operating in the Port. Any new GPRS/3G service will involve content/data sources, content/data owners, service developer (engineering), service developer (business), operations and management, revenue and cost aggregation, and last (but not least) wireless infrastructure owner. But who will be the project owner and project manager? All parties interviewed realize this bottleneck and point at the Port of Rotterdam Authority, but do not see any decisive leadership from it yet, as the Port Authority has many more pressing issues to handle

-C: the investment reluctance of most private sector companies to carry out service creation and trials together with other parties; the noticeable exception are some select few shipping lines or international container handling operations which have, or plan to have soon, global wireless operators contracts alike those they have for satellite communications.

-D: in the context of interoperability: the absence of any single body able to impose basis IT, or wireless application interface standards (PARLAY etc), application integration standards (XML, CORBA, OMA...), and document format standards for new services; the result is the risk for lack of interoperability and higher new service application integration costs.

-E: some degree of traditional mistrust as to disclosing some information about ships or containers to third parties; even in terms of the definition, establishment and management of closed user groups, mistrust is present. For governmental organizations, the first remark A) also applies, due to the multiplicity of stakeholders: Ministry of Transport, Ministry of Finance, Ministry of Agriculture, Ministry of the Environment, Ministry of Economics, Ministry of the Interior, EU Directorate general Enterprises, and finally the Port of Rotterdam Authority at a lower level. The deployment of new wireless services might be linked to a government transactions portal initiative, where there is an appointed leader: Ministry of Finance.

Another bottleneck for new service deployment is one due ultimately to cultural roots associated with physical transport, and not valuing information assets or the business processes around information handling. The consequence is in the Port of Rotterdam that, whereas in some other ports the new service owners and/or operators get also revenue from new services, these services are in Rotterdam considered at best as a cost item, the cost value of which must be minimal and bundled together with other services, some of which perceived to be more urgent than wireless services. As one institution said: “highest priorities are in-house systems, followed by Internet services and with later future plans for new wireless services”. Another facet of the

same culture is that “repeated simple processes are profitable, and flexible ones are expensive”.

In addition, and mentioned by some interviewed parties, the perceived total costs and tariffs for new services are dissuasive in the private sector, although the public sector operational divisions do not seem to be concerned. For almost all interviewed parties from the private sector, they considered that GSM data was far too expensive, GPRS was too expensive, and 3G also; they wished tariffs which, for same data amounts and QoS, should cost the same as on a corporate LAN (Ethernet or WiFi), with data flow reductions outweighed by mobility/ubiquity gains.

Whereas CDMA-2000 and DAB were not mentioned, WiFi, WLL and WIMAX were indeed seen by over ten interviewed parties as a way to achieve lower costs and independence from public 3G operators. Around WLL, a consortium including a power utility (which was granted a 12 years WLL license), a security company, an equipment vendor and some partners, have assembled a consortium aiming at offering managed video based security services for any party in the port. Some of the consortium members are already the largest GPRS users in the Netherlands, and have deployed segment specific GPRS based VPN solutions, besides their staff has been familiarized already with mobile capabilities. The managed service could be offered by this consortium to the Port Authority, which would then sell managed services as a proxy for a supplier consortium, or by the consortium if it got the license and a legal structure. It should be highlighted that the concept of a managed service relieves the end user from up front investments and operations, and allows this end user to “pass on” the cost to his own customers without loading the balance sheet. WLL can also be considered as an access media for on-site cameras etc with a significantly better bandwidth and transmission cost than 3G. Finally should also be mentioned that what brought these parties together was a top-down business concept, i.e. compliance with the ISPS security codes and procedures across the Port of Rotterdam. This consortium is one of the very rare ones to have taken seriously the issue of revenue as well as costs. They also see as a business driver the fact that their customers will perceive that the service supplied is managed for them, the users.

VII. Conclusions

While other such cases exist, such as in the oil and automotive sectors [5], multi-enterprise wireless VPN’s demand first organizational and trust issues to be addressed, then costs, and only finally the technical capabilities.

E-service in the Public Sector

Mehdi Asgarkhani

Faculty of Commerce, CPIT, Christchurch, New Zealand

AsgarkhaniM@CPIT.ac.nz

Abstract: E-technologies are increasingly being recognised as effective tools that can foster an environment of improved service, transparency and improved governance within the public sector. Today, access to information and communication technologies (ICTs) plays an essential role in economic and social development. As public interest in the Internet and e-technology solutions continues to grow, there is an increasing expectation that they will be utilised in national and local governments for more efficient supply and value chain management and for improving public access to information and services. E-technology has become a catalyst for enabling more effective government through better access to services and the democratic process. There is much debate over the role and the value of e-service within public sector organizations. This paper examines the effectiveness of e-services within the public sector with a focus on four specific facets of effectiveness: the view of management and e-technology strategists; social, cultural and ethical implications; the implications of lack of access to e-technology infrastructure; and the customers' (citizens') view of the usefulness and success of e-service initiatives with reference to a case study of a local government e-service initiative within New Zealand.

Keywords: Case Study in E-service/E-business, E-service, Digital Government, E-readiness

I. Preview

The most prominent of the recent advancements in Information and Communications Technology (ICT) has been the emergence of the Internet, Web-based technologies (e-technologies) and global networked economies. Today, e-technologies play an increasingly significant role in our day-to-day lives. They have fundamentally transformed the technological, economical, political and social landscapes.

The competitive imperative of the private sector has driven businesses into the digital world. As a result, the private sector has steadily set higher standards of service (through the application of e-business and e-service solutions) both domestically and internationally. The most significant reform in the public sector has been that of revolutionizing the supply chain management and the value change management through the application of e-technologies.

To deliver the products and/or services in a timely and cost effective manner, the private sector has had to increasingly streamline business processes. The supply chain

is a network of facilities for obtaining raw materials, transforming raw materials into intermediate and/or finished goods, and distributing the final products to markets. Typically, the supply chain integrates manufacturing, distribution, conveyances, retail outlets, people, and information through functions such as procurement or logistics so as to supply goods and services from the origin (source) through to consumption (markets). Supply chain management is considered as the linkage of all the activities that are involved in processes and functions that were mentioned above. It brings together supplier, distributor, and customer logistics requirements into one cohesive function with a focus to reduce time, eliminate redundant functions, and minimize inventory costs.

The value chain is a connected series of value adding processes throughout the production of goods or delivery of services – including: inbound logistics; production operations; sales and marketing; support services and finally outbound logistics. A value chain model can highlight specific processes within the business where the application of e-technologies can impact the business in a strategic fashion.

Digital (electronic) private sector corporations are capable of moving beyond traditional strategic ICT-enabled solutions so as to benefit from digital links with both other organizations and people alike. They can build supply and value chain management systems using Intranets, extranets, or special supply and value chain management solutions. The strategic value of e-technologies in order to enable speedy and cost effective delivery of products and services is outlined in Figure 1.

Public sector organizations deal with complex network of suppliers (and distributor) and sophisticated value chain systems on a daily basis. As public interest in the Internet and e-technologies continues to grow, there is an expectation that they will be utilised in national and local governments (similar to that of private sector corporations). Consequently, many innovative public sector agencies world-wide have had to create new ways in which to use e-business and e-service solutions (known as electronic or digital government) so as to enhance citizens access to information and services, improve the efficiency of processes within business units and establish more productive relationships with both citizens and private sector agencies alike.

The introduction of e-service solutions within the public sector has primarily been concerned with moving away from traditional information monopolies and hierarchies. What's more, e-service and e-business (through digital government) have fundamentally transformed the ways in which the logistic processes and supply chain dynamics are managed

within the public sector. However, e-service remains a challenge to both citizens and public sector agencies alike. Governments must not only maximize the benefits that are offered (through the application of digital government and e-service) but must also avoid the many pitfalls (economical, social and cultural) associated with rapid technological change. That is to say, even though ICT-enabled government and e-service have become a catalyst for better government, the challenges to effective government within today's knowledge society are profound.

Figure 1. The Strategic Value of e-Technologies

Efficiency	
Time	Accelerating business processes and activities
Distance	Reducing geographical and distance inhibitors/barriers
Creativity	Enhancing existing business processes and activities
Effectiveness	
Time	Improving the flow of information and business intelligence throughout the supply and the value chain components
Distance	Enabling integrated control of the supply and the value chain processes
Creativity	Enabling new (and/or modified) processes
Growth	
Time	Obtaining early market entry/presence
Distance	Introducing new products to new markets
Creativity	Developing new products and services

Recently, there has been much debate over the value and effectiveness of e-service within the public sector. This paper elaborates on the strategic role, the value and the effectiveness of digital government that enables e-service. Four specific facets of effectiveness have been examined:

- Effectiveness from the point of view of management and ICT strategists (concerning the implications of ICT and e-service in the public sector).
- Effectiveness as it concerns social, cultural and ethical implications of e-service and e-business.
- Effectiveness with reference to differences in access to ICTs (digital inclusion/exclusion).
- Effectiveness from the point of view of citizens - a preliminary study of the citizens' view of e-service and e-business.

The paper is presented in two parts. Part one (based on a review of previous studies and analysis of digital government and e-service cases such as: [2], [3], [4], [5], [6],

[7], [10], [12], [13], [14], [18], [20], [22] and [35]), reviews the fundamental concepts of digital government and e-service followed by discussing the effectiveness as outlined in (a), (b) and (c).

Part two of the paper is based on a case study of a digital government and e-service project within the Canterbury region of New Zealand. The case study examines the effectiveness of e-service, efficiency of logistic processes and relevance to e-technologies as outlined in (d). The methodology for gathering information included interviews with project sponsors (and a number of other stakeholders) and a combination of formal interviews and surveys of several focus groups of users.

II. Digital Government and E-service: An Overview

This paper views the term 'governance' as a guiding process for decision-making and managing day-to-day activities and interaction with one another (within organizations, groups or societies). *Digital Governance (e-governance)* is a term used to emphasize the application of Information and Communication technologies (ICTs) in governance systems and processes. *Digital Government (e-government)* is the use of ICTs in general and Web-based technologies in particular, in order to: promote and motivate a more operationally efficient and cost-effective government; facilitate more convenient government services (and information) to citizens and businesses; enhance economic development; reshape and redefine community and government processes; and make government more accountable to their citizens. Digital government often consists of digital service delivery, digital governance and digital democracy.

E-Service refers to solutions and processes that allow electronic delivery of services (such as providing information, consulting, support, initiating processes – to name but a few) mostly through digital government/ governance initiatives. *E-Service* (in public sector) as discussed in this paper is closely associated with digital government initiatives.

Technology is the backbone of the required infrastructure that supports digital government. Yet there is a danger in placing too much emphasis on technology. Technical innovation on its own is not enough to drive the development of digital government and e-service solutions.

The political and financial support for e-service can be accompanied by rhetoric and hype. It is fair to say that the potential benefits of digital government and e-service can only materialize when initiatives are introduced as part of a well-planned and properly supported social and cultural environment. There is also a need for considering tools and metrics (performance measures) in order to not only assess progress and effectiveness on an ongoing basis, but also to ensure that rhetoric of e-service is matched by reality.

E-service and digital government/governance is not primarily a technical exercise, but rather an attempt to improve the political and social environments and to introduce a fundamental change in the ways in which public

sector functions (e.g. value chain and supply chain processes) are performed. The essence of government centres on relationships. Hence, an effective model for developing digital government solutions needs to view digital government and electronic delivery of service to citizens as a hub whereby e-technologies are introduced so as to interconnect the various domains of governance.

Extensive research has been carried out (by various practitioners and advisory/interest groups such as the International Centre for e-Governance – www.icegov.org) in order to examine the right level of integration of governance domains and the role and capacity of government (e.g. [4], [3], [24], [25], [22], [26], and [29]). Overall, there can be no one particular answer that can address all cases of e-service and digital government across the board.

As the application of ICT and e-technologies in the public sector within the developing nations becomes widespread ([3], [4], [35] and [29]) we begin to observe a progression through the various stages of digital government that enables e-service:

- **Stage 1** - Improving internal functional efficiency through the application of ICT.
- **Stage 2** - Improving internal communications (through the application of electronic mail) and introducing workflow management systems for increased process efficiency.
- **Stage 3** - Providing access to information with regards to services and the democratic process (initial stages of enabling public/social inclusion).
- **Stage 4** - Putting in place applications that would not only enable citizen participation through feedback, but would also allow for transactions between citizens to government (C2G), businesses to government (B2G) and government-to-government (G2G).
- **Stage 5** - Introducing digital democracy – technological solutions that would enable participatory action and democratic processes.
- **Stage 6** - Introducing integrated electronic or digital governance.

III. What Motivates E-service within the Public Sector?

Overall, the public sector's view (national or local governments) of e-service through the introduction of digital government initiatives is likely to include:

- Automating government systems and the online delivery of services
- Adopting network-based technologies and migrating government functions to the Internet
- Introducing electronic capabilities and practices to government so as to reduce costs, reduce fraud, and increase efficiency
- Adopting ICT so as to foster economic growth and

conduct business

- Improving (re-engineering) the structures of government and the nature of public administration
 - Adopting ICT to foster constituents' engagement, improved political accountability, and e-democracy
- Local governments (e.g. see [30], [5]) seem to concentrate on:

- *Prompt, accurate service* – Local governments can potentially receive millions of calls per year. Resolving a high percentage of these calls the first time they occur can result in significant efficiency gains and cost savings.
- *Improved quality of service* - One client of a local government can potentially generate up to dozens of files in different locations. Local governments are seeking to convert these to one secure and accessible file in order to help provide continuity and coordination of local government support.
- *Removing barriers and tackling social exclusion* – Local governments are aware that many clients do not have the skills to use electronic services. Local government agencies need to set up networks of learning centres in community centres so as to teach people the relevant Web technology skills.
- *Local access points* – It has been shown [30] that up to 20% of customer queries cannot be addressed immediately. Clients often need to meet with a “professional.” Local governments can benefit from the setting up of community access points to allow clients to meet ‘professionals’ through online video links.

Figure 2. Forces That Motivate e-Service through Digital Government

Driving Force	Average Score 5: Essential 0: Not important
Perceived benefit to local people	4.3
Authority's strategy	4.1
Influence of officers	4.05
The need to modernise services	4
Influence of members	3.7
Best value	3.5
Central government initiatives	3.5
Potential cost savings	3.3
Influence of suppliers	2.9

A survey of potential motivators of digital local government and e-service [30] indicates that *improving service to constituents* is rated as being the most important factor (Figure 2).

IV. Effectiveness of E-service: the View of Strategists and Technology Practitioners

The influence of strategists and practitioners' view on public perception of digital government can impact upon the successful implementation of e-service initiatives.

A review of various viewpoints over the implications of digital government (e.g. [3], [5], [35], [9], [19], [23], and [34]) indicates that there are at least four schools of thought:

- pure optimism
- optimism with some concerns
- pessimism
- technology viewed as a tool only - but not a driving factor on its own

The optimists argue uncompromisingly that the use of technology in governance represents a major once-and-for-all improvement in the capabilities of governance ([23], [21] and [35]). The only cost is considered to be the investment on the ICTs and the day-to-day operational costs. This optimistic view appears to be based on the classical cybernetic theory [32].

The second group accepts at least the possibility of greater control, quality and rationality in decision-making. However, they argue the efficiency gains through digital government come at a price. They believe unless safeguards are put in place, digital government may result in compromising citizens' rights such as:

- the right to individual liberty and privacy
- the right to influence governmental decision-making ([35] and [19])
- losing control over politicians' decision-making agendas [34]

The pessimists argue that the application of technology in government will actually compromise the quality of decision-making. They are concerned that excessive demand for policy analysis based on many categories of information will cause delays in action – “paralysis by over-analysis.” There is a fear that due to mechanical rule following, overly simple modelling, the cultivation and the exercise of judgement in decision-making will be downplayed.

The followers of the last school of thought view technology as a tool and argue that the impact of ICT solutions and e-technologies cannot be viewed in isolation. They view both continuities and changes in governance as being driven socially and politically, and not by technology itself. Technology is seen as a tool for either changing or preserving the styles of governance (e.g. [15] and [11]).

Each theory that has been mentioned above has some empirical support - although most empirical studies have been of a rather limited scope and are not in general designed to test, let alone falsify these rival theories.

Overall, accepting any of these viewpoints as being applicable to every case concerning e-service and digital government would be unrealistic. The viewpoint(s) that can best describe the parameters that influence digital government and e-service strategies depends on numerous factors - such as social and cultural aspects; the

technological infrastructure; past experience with the application of ICTs; the level of education and interest in the political process, to name a few.

Some other social, cultural and ethical aspects of ICTs and e-technologies that may hinder the rollout of e-service (and digital government) initiatives can include:

- concerns on individuals' rights and privacy
- concerns over information security
- impact on jobs, workplaces and social interaction

V. E-Readiness: Access, Availability and Affordability of E-technologies

Today, access to e-technologies and ICT is critical for economic and social development. Some international organizations including the International Telecommunication Union (ITU) have been making efforts to bring together policy makers in order to agree upon commitments to strategies towards socially and digitally inclusive societies worldwide. In 2003, the World Summit on Information Society (<http://www.itu.int/wsis>) organized by the ITU made progress towards establishing an agreed upon set of strategies to enhance social inclusion (access, availability and affordability).

There is much optimism that we are facing myriad of digital opportunities where the means exist to broaden participation in the network-based economy and to share its benefits. At the same time, differences in diffusion and the use of ICTs and electronic networks appear to be deepening and intensifying the socio-economic divisions amongst people, businesses and nations. This phenomenon (known as the *digital divide*) can lead to: divides between countries; social divides within countries (related to income, education, age, family type, and location) and business divides (related to sector, region, and firm size).

A review of some of the studies concerning *digital inclusion/exclusion*, *digital divide* and *e-readiness* (e.g. [28], [1], [7], [8], [12], [16], [29], [33], and [27]) indicates that there are significant differences in the adoption of ICTs, network economy and digital government worldwide. This section of the paper outlines a small sample of these studies.

META Group [16] examined the digital commerce (e-commerce) competitiveness of 47 countries. According to the author of this study (Howard Robin), “Traditional industrial-age measures of production and performance have lost relevance in the information age. Currently, information processing capability is a better indicator of national competitive advantage.”

The research by the META Group ranked 47 countries in five different categories in order to establish an overall ‘*information age technological competitiveness*.’ These categories included knowledge jobs; globalisation; economic dynamism and competition; transformation to digital economy; and technological innovation capacity. The results confirmed differences in the adoption and the use of ICTs and electronic networks within the countries that were studied.

The first fifteen countries in the overall ranking of 'information and technological competitiveness' included: the USA, Japan, Germany, France, Finland, Canada, the United Kingdom, Australia, the Netherlands, Taiwan, New Zealand, Belgium, Spain, Sweden and Hong Kong (SAR).

Information Society Index (ISI) involved 23 parameters in its study of the use of ICTs and e-technologies within 150 countries [27]. The study concluded that 55 out of 150 countries accounted for 98 percent of the total ICT resources. The top 55 countries were classified under four categories – including:

Skaters – countries with advanced ICT and social infrastructures.

Striders – countries that appear to be moving purposefully into the information age, with much of the necessary infrastructure in place.

Sprinters – countries that are moving forward in spurts before needing to catch their breath and shift priorities due to economic, social and political pressures.

Strollers – are those moving ahead but inconsistently, due to limited financial resources in relation to their vast populations.

The 'skaters' were: Sweden; Norway; Switzerland; the USA; Denmark; the Netherlands; the United Kingdom; Finland; Australia; Taiwan; Hong Kong (SAR); Japan; Singapore and Canada. Figure 3 displays the summary of ISI research.

A survey of online governance conducted by UNESCO [29] outlines a number of key inhibitors to the successful implementation of digital government and e-service initiatives – see Figure 4.

Numerous other studies (e.g. [29], [30], [5] and [5]) indicate that many other factors can hinder the successful introduction and effectiveness of e-service digital government solutions – some of which are outlined in Figure 5.

A relatively small sample of research outcomes cannot be applied to all countries/regions. However, it appears that many countries are at the initial or halfway stages of adopting Web-based solutions in order to introduce e-service.

It is fair to say that unless the barriers to access, availability and affordability of ICTs within nations are addressed, the success of *bringing to reality the vision of e-service through digital government* would be limited. The causes of digital divide can limit the successful implementation of digital government.

VI. E-service in Local Government: A Case Study

One of the parameters that can potentially impact upon the successful introduction of e-service would be that of the public's view (sometimes based on previous experience from digital government solutions) of the effectiveness of

digital government. To date, there appears to be little evidence of the citizens' view of digital government that enables e-service. This section is based on a case study that examines the users' view of a digital government initiative within New Zealand.

New Zealand's e-government strategy (<http://www.e-government.govt.nz>) emphasizes the role of the Internet and e-technologies as the dominant means of enabling ready access to government information, services and processes. This strategy envisages the implementation of a single 'one-stop shop' portal to all New Zealand government services that are seamlessly integrated with the government's back office – comprising of the Inland Revenue Department, social services agency, local bodies and a number of other government departments.

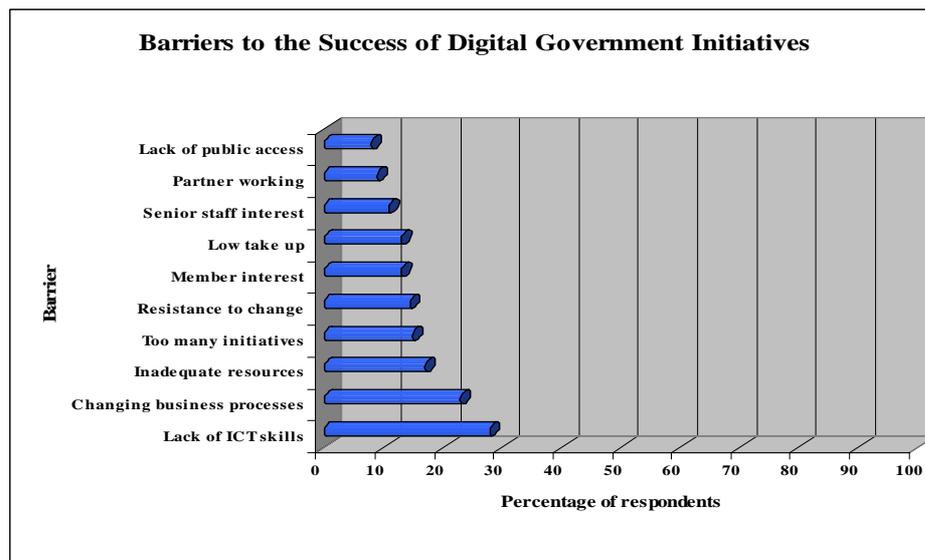

Figure 3. ISI 2002 Summary by region

REGION	SKATERS	STRIDERS	SPRINTERS	STROLLER
North America	14.3%	-	-	-
South America	-	-	7%	23%
Europe	50%	75%	31%	7%
Australia	35.7%	16%	6%	38%
All other regions	-	9%	19%	32%

Figure 4. e-Service Inhibitors

The key inhibitors to the development (or effectiveness) of digital governance/government in developing or underdeveloped nations	Percentage of Respondents
Lack of infrastructure	60%
Lack of resources	47%
Low level of ICT literacy	33%
Lack of awareness at policy level	20%
Low public incentives	27%
Low Internet penetration	20%

Figure 5. Barriers to Success of e-Service through Digital Government

The approach to electronic (digital) government and e-service within the New Zealand local government has been a collective integrated strategy – by establishing the New Zealand Local Government Online in 1997 (<http://www.localgovt.co.nz/LGOL>). Local Government Online Limited (LGOL) is a joint initiative of the Society of Local Government Managers (SOLGM) and the Association of Local Government Information Management (ALGIM). LGOL, owned jointly by SOLGM & ALGIM, owns the Website and offers Internet related services to the local government sector. These services are developed and operated under a collaborative approach that engages economies of scale in order to achieve cost and operational efficiencies and to encourage an integrated approach to the re-engineering of the supply and the value chain. LGOL’s current mission is “to help local government transform into e-local government through innovative leadership and by providing leading-edge services and facilities.”

The Website receives over 280,000 requests for information each month and mailing lists provided with services for Councils generate in the vicinity of 45,000 email enquiries and responses within the sector each week. LGOL offers the product ‘Community On Line,’ a template website carefully crafted to meet the e-government requirements of a local authority. Economies of scale have been engaged in order to be able to offer this product at a “cannot be refused” price with a monthly hosting and development charge to allow for continuing development and expansion into the e-commerce area. LGOL has established itself as the pre-eminent provider/facilitator of Internet services to the New Zealand local government with the Website acting as the primary portal to all local governments within New Zealand.

This pilot study (case study) of e-service from the users’ viewpoint was conducted after a review of a number of digital government cases (e.g. see [2], [5], [7], [14], [18],

[20], [31] and [17]).

In developing and rolling out e-service initiatives, it is essential to develop performance measures in order to assess progress, effectiveness and success. Performance measures should be developed with stakeholders’ input and should be documented and communicated to all parties involved. Performance measures can include: financial parameters (e.g. ROI), productivity factors and citizens’ satisfaction (better service), to name a few. This section of the paper concentrates on the citizens’ view of effectiveness with reference to the results of the study mentioned in Part (b) above.

As mentioned earlier, this section is based on a digital government and e-service project within the Canterbury region of New Zealand. This project reflects the trends in local governments worldwide - in the development of e-technology solutions so as to enhance communication and the information flow between governments and their citizens. The key objective of this particular project is to facilitate improved two-way exchange of information and to enhance its public image as a professional customer service oriented organisation.

The local government that initiated the project (referred to as the Council hereafter) seems to be conscious of distinguishing between political rhetoric and the reality of digital government – as demonstrated through measuring the success of the project on an ongoing basis. The performance measures that have been considered include:

- Website hits – which are monitored on an ongoing basis so as to determine the utilization of services
- Customer feedback through the service web sites
- Quantifiable efficiency benefits (e.g. cost savings, time savings, and service level impact and so on)

Overall, *Web-site hits* are not an effective measure of

usefulness and usability of a web site – unless it is combined with statistics concerning the number of users who actually proceed to access services past the *home page*. *Customer feedback* through service websites can be a more effective measure of user satisfaction. However, it would be beneficial to include feedback from other sources (e.g. phone calls). *Quantifiable efficiency benefits*, as a measure of success does not directly reflect public access to e-service.

A review of the electronic services delivery site indicates that the Council is an example of Stage 4 of the progression of digital government initiatives (as discussed in Section “Digital Government and e-Service: An Overview”).

E-services (and information) provided on the web site can be seen as being placed in two categories:

Providing Information:

- Current issues of significance (Hot Topics) – e.g. area plans, recent policy changes, annual report(s)
- General information with regards to services – rates information, street maps, rubbish collection, projects in various areas, jobs at the Council, forms, weather, library catalogue, Art Gallery, bus timetables, leisure centres and the link to govt.nz
- Specific Council information – about the mayor, councillors, community boards, council meetings, meeting agenda and proceedings, public notices, and newsletter
- Events – events calendar, tourism and visitors’ information, online guide to the city, clubs and groups

Communication and/or feedback:

Contact the Council, Ask us, Quick Answers and Have Your Say (feedback RE council projects)

A survey was conducted in order to assess public awareness and their views of the Council’s electronic service delivery initiatives. Sixty one percent of the participants were between 18 and 34 years, 26% were between 35-49 years and the rest were aged 50 years and over. It appeared that 76% of the respondents were aware of the digital governance services that are provided by the Council online.

Approximately 87% of the respondents who were already aware of the Council’s online services and 81% of those who previously did not know of the Council’s web site considered access to online services as being helpful.

It appeared that the majority of respondents (49%) were aware of the Council’s website through word of mouth – followed by Web surfing or search engines (32%) and advertising (19%).

Respondents seemed to have accessed library information, agencies’ hours of operation, and events in the city and city maps more frequently than other online information – as seen in Figure 6.

As you can observe from Figure 7, immediate access to information anytime and anywhere appeared to be the most important reason (77%) for the perceived usefulness of the Council’s digital government and e-service initiative.

On the issue of difficulties in using the Council’s web

site, 32% found the link to be slow whilst 8% could not locate the relevant information and 7% found the navigation to be complex.

Figure 6. Frequently Accessed Information

Type of Information Available	Percentage of Respondents
Library information/catalogue	42%
Services - hours of operations	38%
Events in the city	32%
Maps	31%
Community services/events	30%
Rates information	25%
Bus timetable	23%
Permits	13%
Art Gallery	12%
Job advertisements/applications	11%
Water resources	10%
Population statistics	7%

Figure 7. Reasons for Effectiveness

Reason for Effectiveness	Percentage of Respondents
Immediate access to information anytime/anywhere	77%
Time saving - no need for time consuming telephone calls and/or visiting the Council	55%
Access to relevant information with reasonable details (yet simple to follow)	40%
High level of usability	27%
Links to relevant pages/sites	25%
Easy to navigate	20%

Figure 8. Future e-Services Requested

Desired Online Services	Percentage of Respondents
Rate payments	37%
Online submission of applications (e.g. building permits, resource consents and so on)	30%
Multimedia streaming of local events	30%
Fee payments	27%
General Council related information	25%
Online voting facilities	23%
Interactive online services such as discussion groups and online forums	23%
No reply	6%

Many respondents expressed an interest in enhancing (broadening) the Council's online services to include rate payments and online transactions – as outlined in Figure 8.

Participants were asked to state their concerns about using online services. Results show data security is the greatest concern for customers (71%) – followed by concerns about confidentiality of data (66%); lack of appropriate technical infrastructure (24%); and document incompatibility (6%). It has to be noted that 19% of the participants expressed no concern at all in using online services.

The respondents rated the contents of the Council's e-service web site as 7.18 (out of 10 – with 10 being highly desirable). The quality of services that are being made available online was rated at 7.52. The rating for the value of access to online services in the public sector in general was 6.93.

In brief, even though the results of this pilot study are not to be considered as final, it appears that this particular e-service initiative is rated favorably.

It would appear that there is support for carrying out future digital government and e-service strategies based on the experience users have had from the Council's existing electronically delivered services. However, it should be noted that these results cannot be viewed as being applicable to other e-service solutions that are being provided in other countries.

VII. Summary and Conclusions

Within the past few years, much has been debated over the key factors that would impact upon the implementation of digital government and e-service strategies. Overall, practitioners and management scientists tend to agree that the trend for government transformation through e-technologies is irreversible. Yet there is also a danger. Technical innovation on its own is not enough to drive the development of e-service and digital government solutions. The potential benefits of e-technologies for improved service and better government can only materialise when the solutions are introduced as part of a strategically planned process, adequately supported environment for both citizens and businesses alike and with a focus on locally relevant objectives. Successful e-service initiatives through digital government need to:

- encompass the improvement of service delivery to the citizen, the creation of economic activity and the safeguarding of democracy.
- be orientated towards the citizen. The citizen does not need to be aware of who in the government provides the required service. That is to say, inter-agency and intergovernmental e-governance dimensions are essential.
- be made available to all citizens (not just to a minority who can afford to have access to the required electronic infrastructure).

- provide an opportunity for business process re-engineering of supply and value chains – merely automating existing services is inadequate and does not necessarily produce satisfactory results.
- provide opportunities to build viable and sustainable partnerships between the private and the public sectors - where each party would be responsible to provide e-capacity in order to achieve a competitive advantage.

This paper examined some of the parameters that influence the successful implementation of effective e-service and digital government solutions – including:

- The view of management, theoreticians and ICT practitioners with regards to the implications of digital government and e-service – ranging from the optimists who view digital government as being an effective tool (without any concerns) to those who view technology as a tool only (arguing that technology on its own cannot be a driving force for service effectiveness).
- The implications of the digital divide and e-readiness – the success of carrying out digital government strategies in a country rely on its state of digital readiness and the ways in which the barriers to the *digital divide* can be overcome.
- The citizens' view of experience with e-service initiatives – a pilot study of digital government within the Canterbury region of New Zealand indicated that local citizens rate digital government and e-service solutions as being effective. However, these results are not final and cannot be taken as being applicable to other digital government solutions introduced in other countries/regions.

In conclusion, access to the right technology for delivering e-service in the public sector is essential but insufficient. Even though most of the shortcomings (as they concern the effectiveness of digital government) can be resolved by improving the technology infrastructure, technology by itself does not necessarily result in better, more efficient, and service orientated government. Technological advancements are only effective if they are considered alongside other key parameters such as social structure; cultural values and attitudes; ethical considerations; business process re-engineering and the political culture within the public sector.

Abstract: Lithuania has a well-developed transportation system. Its geographically strategic position is very important to European transport corridors. In Lithuania, there are various important factors that contribute to shaping the sector's characteristics — lack of knowledge, a low level of computerization and Internet usage — that cause 'e-business possibilities' not to be used. An appropriate analysis of effective e-business usage for the development of competitive advantage between transportation companies is a very important task which requires theoretical grounding and research of practical possibilities. The purpose of paper is to analyze the use of e-business in Lithuania's transportation companies. The survey was supposed to act as a guideline to the future of Internet usage in the Lithuanian transportation industry. The survey tried to find out considerations about the Internet, how it had affected their business and activities and what might happen in the future.

I. Introduction

Lithuania has a well-developed transportation system. Its geographically strategic position is very important to European transport corridors. The EU's Transport Commission has designated Lithuania as the region's transport hub, with 2 out of the 10 priority corridors in Europe intersecting Lithuania. A network of European-standard 4-lane highways link major industrial centres. Road construction is underway for connecting with the Trans-European transportation network. It will be part of the transportation system around the Baltic Sea and a transportation axis linking Russia and the Baltic Sea. The country offers 4 international airports and an ice-free port on the Eastern Baltic. In this context Lithuania's transportation facilities play an import role in the country.

Considerable attention is paid to the development of transport and communications through Government approved programmes. One of the basic provisions of this programme is to create a long-term strategy for the development of different transport sectors within the national transport system to meet core strategic objectives of the European common transport policy. The use of ICT and e-business in transportation companies allows them to offer more competitive services to their consumers.

ICT based e-business can influence logistics and transportation activities. There indications that development in information technologies have reached a level of maturity

where with available systems there are little constraints on what may be possible to achieve in logistics. Despite the availability of advanced information systems and technologies for use in the sector, there remains the issue of knowledge for using these. 'E-business' can be considered as one of those tools (Persson, 2003).

Problem. *This article is focused on the study of the role of e-business in Lithuanian transport sector enterprises. The new opportunities for companies, which can be achieved by using e-business become vitally important for competing in the market. In Lithuania, there are various important factors that contribute to shaping the sector's characteristics — lack of knowledge, a low level of computerization and Internet usage — that cause 'e-business possibilities' not to be used.. An appropriate analysis of effective e-business usage for the development of competitive advantage between transportation companies is a very important task which requires theoretical grounding and research of practical possibilities.*

The purpose of research. *The purpose of the research reported in this paper is to analyze the use of e-business in Lithuania's transportation companies.*

II. The Internet and E-business in Logistics

In most cases, e-business and e-commerce has been focused on the fulfilment of customer orders and the distribution process. It was, and still is, believed that e-business and the increased connectivity of the Internet will give rise to new customer behaviour and that this will have serious implications on the whole industry. This has been confirmed from various sources (e.g. Lancioni et al., 2000; Barua et al., 2001; Javalgi and Ramsey, 2001). In an investigation from 2000 it was concluded that the most popular use of the Internet for supply chain management was in transportation, followed by order processing, managing vendor relations, purchasing procurement, and customer service (Lancioni et al., 2000).

More sophisticated customer demand chains and e-business processes pose new challenges to logistics service providers. Research & development into new logistics service concepts are required regardless of the line of business both in B2B and B2C environments. Unless products are non-material, physical distribution logistics is one of the key challenges for the supply networks of e-marketplaces. The development of effective e-business processes will increase the importance of particularly delivery accuracy, delivery frequency and delivery time.

A prerequisite for effective relations is the extensive use

of information technology. Partnering would never have emerged in its present potent form without the explosion in information technologies, which enabled companies to merge critical elements of their business systems with relative ease and speed. Only then could they capture the efficiency and effectiveness benefits of tearing down the boundaries between firms. The Internet is an ideal medium to use as a backbone in any partnership. An example of a company that has structured its relationships around the Internet is Dell Computer Corporation.

E-business opens up an entirely new market for actors in the logistics field. Logistics and distribution systems that function efficiently and effectively in all respects will be crucial for the success of the companies involved. This implies that manufacturing companies, and especially logistics companies, must identify and create effective logistics solutions in order to compete in the marketplace.

III. Research Results

The empirical research carried out among Lithuania’s transport companies has been conducted using questionnaires. A questionnaire was sent to Web-present Lithuanian companies in this industry. The purpose of the survey was to investigate how transportation companies use the Internet and what sort of problems it brings. A total number of 113 respondents participated in the survey. The survey was supposed to act as a guideline to the future of Internet usage in the Lithuanian transportation industry. The survey tried to find out considerations about the Internet, how it had affected their business and activities and what might happen in the future. The survey also intended to find out the purpose of respondent companies Internet investment, which individual was behind it and what problems it brought.

The results show that most of the enterprises surveyed use e-business rather recently, only 21% of enterprises participated in the investigation use e-business for more than three years. 30 % of enterprises use e-business less than one year and 49 % - for 1-3 years. Thus e-business in Lithuania is rather young phenomenon and this fact largely influences these results.

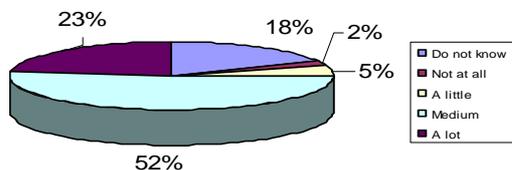

Figure 1. Internet effect on companies activities

The companies in the survey were asked questions on how the Internet has affected their company or what kind of changes it has generated. 75 percent said that the Internet

had affected internal communication to a ‘medium’/‘a lot’ extent. Contacts with customers, suppliers and partners also seem to have been greatly affected. However, the Internet does not seem to have influenced either profit nor competitive advantage or development of new products/services so far. These results indicate that most companies have not fully begun to use the Internet’s advantages, i.e. for more than as a communication tool.

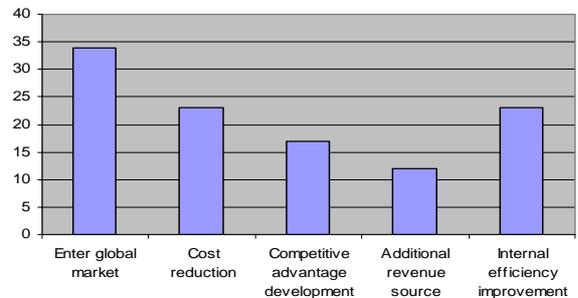

Figure 2. Objectives of e-business decisions

Companies participating in the survey were also asked to evaluate the Internet and e-business influence on the future company’s activities. Many companies reported that communication, both internal and external, to be greatly affected by the Internet. Moreover, many companies see the potential with of Internet as a communication tool. Moreover, 61 percent believe that it might generate new customers and reach new markets. The Internet is also perceived to affect the development of new product/services as well as giving a higher quality of service. However, it is noteworthy that many companies think it will greatly affect profits – 61 percent believe profits will be affected to a medium extent or a lot while 37 percent think a little or not at all.

Less than half of the companies in the survey have an Internet strategy while the other half has none. On the other hand, in most companies Internet-related issues are often discussed at a top management level, 41 percent do this to a medium extent or a lot compared to 42 percent who do not discuss these issues at all or just a little. This leads us to believe that many companies have now realized that the Internet will have future impacts on the industry. Only few companies have a special e-business department – only 11 percent compared to 89 percent who have not. However, many perceive the Internet to be a natural part of future strategies as well as an important tool for establishing future competitive edge.

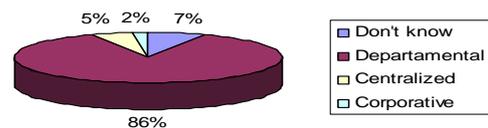

Figure 4. Level of e-business solutions

In few enterprises surveyed e-business solutions are accepted and implemented in a centralized way, i.e. decisions for e-business use, objectives, technologies selections etc., are made by the top management. A large proportion of the enterprises state that e-business solutions do not cross boundaries of division, department or section. Thus in order to achieve higher development stage enterprises should pay particular attention to e-business decision-making and the implementation of systems. The most important aspect in this respect is that not only one department or division, not only top management, but all employees of an enterprise should be involved into the decision-making and implementation of a company's e-business.

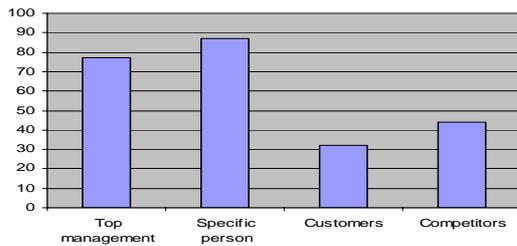

Figure 4. E-business investment drivers

It appears to be top management or individual persons that are prime movers for an Internet investment. 77 percent answered that top management was the driver, which gives an indication that the Internet is considered to be of importance for the industry. However, more said that a specific person had had a great influence on the investment. However, only 44 percent said that competitors activities greatly influenced the Internet investment with 20 percent claiming they had a medium impact.

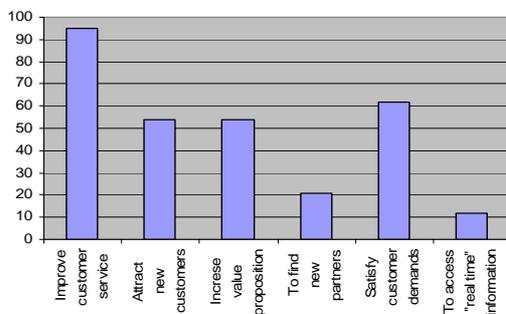

Figure 5. Marketing activities improvement using e-business

Internet investment is primarily seen as a marketing tool and as a tool to improve customer service. A total of 95 percent thought this to be of importance. 54 percent also claimed that the investment was supposed to attract new customers as well as increasing the value of existing services. However, it does not seem to be of interest in the industry to partner with online companies. Only 29 percent claimed partnering to be of medium interest or very interesting while 79 percent thought it was of little or no interest. Instead, 62 percent said that they had invested in the Internet in order to satisfy customer demands.

Many discussions about the Internet concern security

and complexity issues and one could assume that many companies would consider these to be some of the major problems with their the Internet investment. The majority of the companies in the survey did not seem to share this apprehension; instead 63 percent claimed that an obstacle was the difficulties with measuring the effects of the investment. Moreover, half of the companies said the customers did not request it while the other half claimed they did. In general, no particular problem was emphasized.

IV. Conclusions

Summarizing the research results, it can be stated that thus far the Internet has primarily been perceived as a communication tool, both for internal as well as external use in the Lithuanian transportation sector. This is also regarded to be of considerable future importance though the companies also see e-business solutions as a way to attract new customers. Another field of application for e-business is marketing as well as a tool for development of new products and/or increasing their values. Only half of the companies in the survey seem to have a specific Internet strategy whereas the other half has not. However, for a majority of the companies surveyed, Internet related issues are often discussed at a top management level leading us to believe that the industry has realised the importance of e-business to their sector. Most companies consider the Internet to be a natural part of future strategies and a significant contributor to future competitive advantage.

For most companies, the prime movers for an Internet investment have been either top management or a specific person at their company. The purpose of the investment was to attract new customers, improve customer service, and increase the value on existing services, sales and to satisfy to customers' expectations. However, not as many respondents as expected claimed the purpose of the investment to be efficiency improvements. The majority of the companies did not appear to have any specific problems with their e-business investment.

Identifying Micro Projects for Improvement of E-Readiness of Sri Lanka

Velauthapillai Dhayalan *, Reggie Davidrajuh **

* Computer Science, Bergen University College, Norway, vdh@hib.no

** Electrical & Computer Engineering, University of Stavanger, Norway, Reggie.Davidrajuh@tn.his.no

Abstract: This paper focuses on identification of micro projects for improvement of e-readiness of Sri Lanka. First, the proposed strategy by the Government of Sri Lanka is presented. Second, from the proposed strategy, requirement analysis is done to draw a set of requirements, using two approaches: a) E-readiness measurement, b) System analysis using the theory of connection. Third, from the requirements, a set of projects are identified that can improve e-readiness of Sri Lanka; though different types of projects are identified, emphasis is given to micro projects that are people-centric, low-cost, and sustainable.

Keywords: E-government, e-Sri Lanka, e-readiness, micro projects.

I. Introduction

In November 2002, the government of Sri Lanka launched *e-Sri Lanka* – the information and communication technology development roadmap to achieve e-governance by the year 2007. According to the official document, the main purpose of e-Sri Lanka is to achieve the desired levels of development by enhancing national competitiveness, and to reduce or eradicate poverty by realizing enhancements in the quality of life of its citizens [5]. The government of Sri Lanka believes that the vision will take the dividends of information and communication technology (ICT) to every village, to every citizen, to every business and also transform the way Government works. However, studies show serious shortcomings in the proposed strategies [4]. Studies also reveal that proper measures for improving e-readiness of Sri Lanka has not been identified or put into practice [4].

The main purpose of this paper is to identify micro projects that can improve e-readiness of Sri Lanka. To do this, a scientific approach is used in this paper that consists of four steps: First, the proposed strategy by the Government of Sri Lanka is presented; this serves as the needs analysis. Second, from the proposed strategy, requirement analysis is done to draw a set of requirements; this is done using two approaches: a) E-readiness measurement, b) System analysis using the theory of connection. Third, from the requirements, a set of projects are identified that can improve e-readiness of Sri Lanka; though different types of projects are identified, emphasis is given to micro projects that are people-centric, low-cost, and sustainable.

The uniqueness of this paper lies in the scientific

analysis of the proposed strategies for e-Sri Lanka in order to identify the projects that can be implemented to raise the e-readiness.

Structure of this paper: Section-2 presents the need analysis; in this section, the proposed strategy for e-Sri Lanka is presented. Section-3 presents the requirement analysis, analyzing the proposed strategy. Section-4 identifies the micro projects that can give a lift to e-readiness of Sri Lanka.

II. Need Analysis

This paper starts with the need analysis for e-Sri Lanka, as the authors believe that any system cycle or system engineering process should begin with the identification of a need based on a want or desire for something arising from a deficiency [1]. The need in this case is the gap between current and desired (or required) level of e-readiness or the gap in results between what is now and what should be after (successful) completion of e-Sri Lanka. Needs analysis is a process of determining the reasons and causes for a need so that appropriate interventions may be identified and later selected.

Rather than using surveys, questionnaires and interviews for the needs analysis, we present or restate the government of Sri Lanka's strategy for e-Sri Lanka. However, the strategy is presented in a highly intelligible format so that requirement analysis and implementation can be done in later sections.

II. 1 The Needs Assessment

In November 2002, the government of Sri Lanka launched *e-Sri Lanka* – the information and communication technology development roadmap to achieve e-governance by the year 2007. Sri Lanka's first ever e-government conference was held in May 2003. The event was given utmost importance by the government of Sri Lanka, and was supported by some of the inter-governmental organizations such as the United States Agency for International Development (USAID) and the Swedish International Development Agency [9].

According to the official document, the main purpose of e-Sri Lanka is to achieve the desired levels of development, by enhancing national competitiveness, reduce or eradicate poverty by realizing enhancements in the quality of life of its citizens [5]. The government of Sri Lanka believes that the vision will take the dividends of information and communication technology (ICT) to every village, to every citizen, to every business and also transform the way Government works [9].

Zhou [12] identifies that in a model of e-government, a

society has three constituents: government, citizens, and businesses. Accordingly, we classify the benefits of e- Sri Lanka pointed out in [5] into three different category; the benefits of e-Sri Lanka are:

For the government:

- Empower civil servants with information and communication tools, to facilitate coordination across government agencies, and to improve competition and transparency in public procurement.
- Integrate marginalized regions and communities within an equitable resource distribution framework, to facilitate effective decentralization and broadening of public participation in development policy formulation and program implementation, and to transform government services cost-effective and citizen-centered.
- To provide quality education at all levels and to all parts of the country. To provide students and teachers throughout the country access to world-class educational curriculum via the Internet.

For businesses:

- To revitalize Sri Lanka's main and traditional industries like agriculture, tourism, and apparel, so that the share of value-addition to the end product is increased, and to penetrate into new markets via Internet-based sales channels.
- To emerge as a major transportation hub for air and sea cargo, by modernizing ports and by developing a modern trade net that dramatically reduced the transaction costs for importers and exporters. To enable businesses to become increasingly competitive and to attract foreign investors.
- To reduce transaction costs to businesses.
- To create a communication environment that allows optimal opportunities for businesses to engage in all forms of e-commerce

For citizens:

- To improve the delivery of public services, and knowledge and education to all, and to make government accessible and accountable to the average citizen
- To create a communication environment that allows optimal opportunities for all Sri Lankan citizens to participate fully in the global information economy, and for all citizens to support their economic, learning and personal needs.
- To facilitate inexpensive contact with family abroad via email and voice over Internet via Cyber Cafes in all towns.

III. Requirement Analysis

This section starts with the results of the needs analysis done

in section-2, and performs the requirement analysis. By the requirement analysis, we are trying to establish a statement about the proposed system that will make all stakeholders agree to it so that the system can be adequately solved [6].

The requirement analysis is done in two steps:

1. Identifying the primitive system: We further dissect the need assessment from section-2 further so that the primitive elements (or the basic building blocks) of the system become visible. This is done in subsection-3.1.

2. Identifying the current status of the system: For this purpose, we measure the e-readiness of Sri Lanka. This is done in subsection-3.2.

From these two steps, we identify corrective measures that can lead to a better solution

III.1 Dissecting the Proposed Strategy

The implementation strategy for e-Sri Lanka is further dissected in order to find the primitive system; a primitive system consists of the primitive elements or the fundamental building blocks of a system [3]. Dissecting the strategy into programs, subprograms, and actions, is presented in Table-1.

From the analysis given in table-1, we can already recognize some of the primitive elements: government officials and employees, experts and technologists, computer hardware and software resources, entrepreneurs, and general public. To see how the individual programs influence the primitive elements, we check each program and subprogram of the five-program strategy against the primitive elements; the results are summarized in table-2. In table-2, abbreviations HRD, GO, T, GP, IE, BIF, HID, SID, ICTP, SMEs, CCs, BF, EDU, RF, S, and ER stands for human resource management, government officials, technologists, general public, investors and entrepreneurs, building information infrastructure, hard infrastructure development, soft infrastructure development, ICT parks and cyber zones, small to medium-sized enterprises, Internet service providers and telecenters, banking and financial institutions, educational institutions, regulatory framework, Source, and E-readiness, respectively.

Table-2 indicates that the proposed implementation strategy is very influential on human resource development, especially on ICT education. This has two effects, a positive one – the population becomes more IT-literate, and a negative one – surplus computer professionals but lack of inventors and entrepreneurs. A country's capability for innovations and internal improvements cannot be flourished by IT education alone; production technology, supply- and demand chain management, economics, and psychology are all too important in the digital economy era.

III.2 Measuring the E-readiness

Figure-1 (taken from the authors previous paper [4]) depicts detailed benchmarking of e-readiness of Sri Lanka based on the eight major factors. For comparison, values for Norway are also shown in the figure. In Sri Lanka, demand forces

(capability of the people) are about the average value. However, supply forces and societal infrastructure are poor. In some of the areas (English language usage, tertiary enrollment, high-tech exports, GDP per capita, computers per 1000 people, and telecom costs) Sri Lanka performs poorly.

Some other indicators (political stability = 1.0, and government effectiveness = 1.0) show that there is a serious problem in running the country. In addition, investment in ICT sector is low. After many technology investment debacles, private investors are not so enthusiastic about telecom ventures. The government has also problems in investing in technology sector mainly due to ever increasing health care costs.

III. 3 The Requirements Analysis

The analysis done in subsections 3.1 and 3.2 shows that the policy makers have not given proper consideration to the concept of “domestic digital divide”. For example, from figure-1, it is clear that e-readiness measures gauge disparities that exist between countries (the “international digital divide”). Thus, improving e-readiness of Sri Lanka means improving its stand on the ICT usage compared to the developed countries. However, figure-1 indicates nothing about the domestic digital divide - the gap between citizens of a country in knowledge, access, usage, and mastery of ICT and the Internet. E-readiness improvements may push a country to a better position in competing with the other countries, but it is not clear whether all the citizens of that country will enjoy the benefits due to the improvements. The following examples are on the effects of e-readiness improvement on domestic digital divide:

- Sri Lankan example: Though the government of Sri Lanka believed in reduction of both international and domestic digital divide by its e-government initiatives, however, two official reports recently published prove the opposite results on domestic digital divide, though effects on international digital divide is on Sri Lanka’s favor [3][11]. For example, the share of national income of the poorest 10 percent of the population fell from 1.3 percent in 1997 (before the induction of e-Sri Lanka) to 1.1 percent in 2004. For the richest 10 percent, their share rose from 37.2 percent to 39.4 percent over the same period [3].
- Indian example: Referring to e-government implementation processes in India, Sharma and Soliman [8] reports similar unintended negative effects on India’s domestic digital divide.

From the above examples, it is clear that e-readiness improvements should benefit all the citizens of a country, especially if it is developing country.

IV. Micro Projects

Figure-2 shows a classification of e-readiness improvement projects. Based on the magnitude of the project or on the size of the projects, the projects are broadly classified as

national level projects and community level projects. Also, depending on the complexity or newness of the adopted technology or mechanisms, the projects are classified as incremental projects, innovative projects, and radical projects. We define micro projects as the community level projects that fall into incremental and innovative types. It is the micro levels projects that mainly uplift the lower masses (“don’t-haves”) of a country; thus, the micro projects not only improve e-readiness of a country, it also reduces the domestic digital divide of that country.

Given below are some of the micro projects that could improve e-readiness of a country [10]:

- Community Restoration and Development Projects
- Women's development, rehabilitation, and job training
- Rehabilitation efforts of Irrigation development project
- Skill Development Programme
- School building projects
- Micro Projects on income earning
- Village upliftment projects
- New technology adoption (e.g. solar power, wind mill)
- Grid supplied electric power to everyone

V. Conclusion

This paper proposes a scientific analysis to identify micro projects that can improve e-readiness of Sri Lanka. By this approach, while improving national e-readiness, domestic digital divide that exist between the citizens can also be minimized.

Program	Subprograms	Actions
A:Building implementation capacity	(A)	Forming control and coordinating committees, to advise the Cabinet of ministers: A top-level consultative committee will be formed, made up of secretaries of key ministries, industry leaders, etc., to advise the cabinet. In addition, an agency will be established to look into the intricacies of capacity building.
B:Building information infrastructure	B1: Hard infrastructure	Building <i>hard</i> infrastructure to provide affordable telecommunications services for various users.
	B2: Soft infrastructure	Building <i>soft</i> infrastructure to support the Sri Lankan software companies, such as stimulation of domestic demand for software applications, establishment of ICT parks and ICT development zones.
	B3: Learning capacity	The government will recruit multinational companies to invest and partner with the local counterparts
C:Development of human resources	C1: Software industry	To increase the supply of ICT professionals, a new policy will be devised on issuing of visas for foreign ICT professionals; Providing incentives for leading ICT multinationals and training institutions to invest in Sri Lanka
	C2: Educational establishments	Training programs on ICT tools in primary and secondary schools for students and teachers; Increased undergraduate intake for ICT courses in universities; Increased training to university staff
	C3: General public	ICT awareness programs for general public; Tertiary education on ICT, and e-learning
D:Delivering citizen services through e-government	D1: G2G	Establishing a government wide-area-network supporting email linking every government institution and employee; Development of fundamental databases of citizen data; Establishing a Sri Lanka Portal for global front-end as administration and service delivery channel
	D2: G2B	Establishing G2B interface that will facilitate interaction between businesses and the government
	D3: G2C	Establishing G2C service delivery infrastructure; establishing a government call center for voice based interactive support to citizens
E: ICT as a key lever for economic & social development	E1: Rural development	Establishing a national fund to support new technology adoption Skill development programmes , Vill job training establishment of telecommunication centers for public access to information and communication services
	E3: Mass media	Sri Lanka's mass media and multi media policy will be revised so that they adhere to internationally established principles

Email: peder.i.furseth@bi.no

Abstract: Many companies that have physical channels now also do transactions with consumers online. However, a large part of these companies do not succeed online even if they succeed offline. The literature of explaining and giving advice on such an important challenge is growing, but is still limited. This paper contributes to this field.

In this paper eight strategic opportunities are identified when traditional companies go online. These opportunities are based on personal interviews of general managers who have strategic responsibility for implementing the companies' online channel. While most papers focus on the important role of IT to succeed, the unique findings reported in this paper show that cultural and organizational factors are of higher importance. The paper spells out in detail the content of such factors. In an empirical part at the end of the paper data indicates that the focus on cultural and organizational factors do give higher conversion rates and online sales.

Keywords: E-business Entrepreneurship, E-commerce Management.

I. Introduction

This paper reviews the innovative opportunities available to retailers and banks that sell goods or services online as well as offline. The retailing industry is in a dilemma because companies are afraid of missing an epochal opportunity (Christensen and Tedlow 2000: 42). In this paper the topic is pursued by interviewing experienced managers about the factors they believe to be critical for generating profitability in terms of the online channel. Based on such interviews with managers, this paper presents unique data about managers' perceptions of factors that have a bearing on the integration of online and offline channels. With reference to the same companies that employ the managers, consumers are interviewed about various issues such as online spending and satisfaction with online solutions.ⁱ

There are different views about what the Internet is. Basically, it is a channel for taking orders, for marketing and for searching for information about products and services. That interpretation underpins this paper. Channels other than the Internet can perform the same functions, for example stores, telephones, faxes, mobile solutions, direct marketing, and interactive TV. Unlike the store channel, however, the

Internet channel is available only through a set of technologies.

Some people see the Internet as a technology. The Internet is typically defined as a world-wide network that provides electronic connections between computers, enabling them to communicate with each other using software such as electronic mail, telnet, Gopher, www browsers (e.g. Mosaic or Netscape) and so on. The Internet is in this respect not a single network, but a collection of interconnected networks.

Finally, some people consider the Internet to be a business model for guiding the decisions of companies that are seeking profit. Elliot (2002: 9) presents various types of B2B and B2C business models and classifies them along two dimensions: by degree of innovation and level of functional integration. The e-shop, which bears the greatest resemblance to the kinds of companies in the current study, is classified as having a low degree of innovation and few functions. In my opinion, this categorisation is rather misleading for people who are trying to develop Internet strategies for e-shops. Appropriate strategies for these companies seem to be much more complicated than an overview of business models would lead us to believe.

II. Phases of Business Development

It is the Internet channel as such and not the business done there that is new. However, new strategies need to be developed for the channel. For example, online auctions are not really new. There have always been marketplaces like the stock market and other places where auctions have been held.

This paper departs from the theoretical perspectives that present the various phases of business development with a view to electronic commerce. There is not much available on this topic. In fact, the concept of multi-channel business that figures in the media rather often does not have any accepted definition in the literature.ⁱⁱ

Michael Earl (2000) pointed out that becoming an e-business is an evolutionary journey for most firms. He described the six-stage journey companies are likely to experience. The first two phases are external and internal communication, stage three is e-commerce, and stage four is e-business. The final two phases are called e-enterprise, and transformation. While these steps are stylistic, they present companies in terms of their progress in the work that needs to be done to get a presence online, but they do not give any

hard advice to managers about what challenges they will face or how to handle them.

The benefits of e-commerce arise from the way in which tasks and activities are performed in the retail channel (Burt and Sparks 2003: 284). Burt and Sparks also point out that consumer reactions are not fully understood. In a study of phases of multi-channel retailing, it is therefore important to consider consumers' actions in the light of the way the strategies among companies with transactional websites develop. I will try to move a step in that direction in this paper.

In a recent article, Aldin et al. (2004: 55) pointed to three phases of business development within electronic commerce: Companies initially started with changes on an activity level, followed later by changes in more holistic, business and chain or channel-wide restructuring in an effort to reap the full benefits of electric commerce applications. In the first phase, activities are refined to promote internal efficiency. In the second phase, companies change processes to increase integration and reduce time and costs, enabling service improvements and promoting interplay between the two. In the third phase, companies reshape structures and penetrate new segments and markets. These stepwise refinements are appealing, but they seem too compact in the sense that there are too many factors in each phase, making it impossible for companies to identify appropriate steps in the direction of an online channel. In our opinion, business integration between offline and online channels is a question of degrees. This view is presented in Figure 1.1.

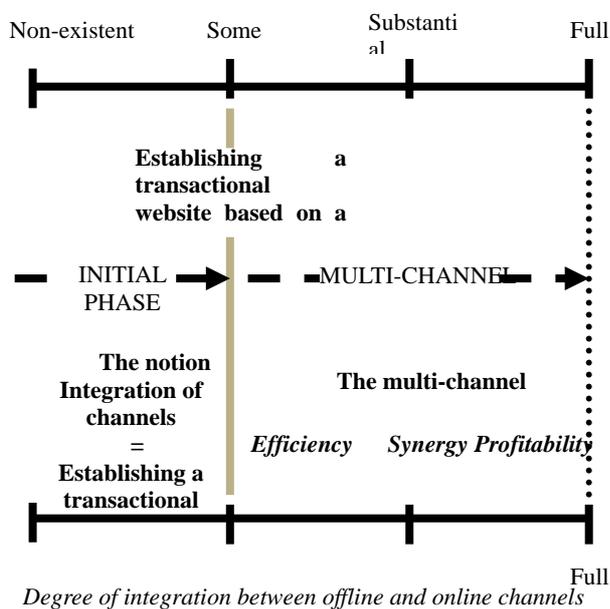

Figure 1.1 The two phases of multi-channel retailing

Some degree of integration should be taken to mean that a company that has a physical outlet also sells goods or services online. This is the degree of integration found in most companies with an online channel, and this is the

degree experienced by the companies in this study. However, although there are stronger degrees of integration, I will not focus on them here.

First of all, companies need to establish a website. Websites are generally used for information, marketing or transactional purposes. Companies then need to align their IT strategy with their company strategy. The companies included in this study have launched transactional websites. Although websites for information and marketing are also important and represent challenges, such challenges cannot be avoided for companies that have transactional websites. Accordingly, this paper will focus on the challenges facing companies with transactional websites.

Once a company has established a channel for selling goods or services online, the multi-channel strategy starts. Multi-channel goals include making the online channel more efficient, developing synergies between offline and online channels, and achieving profitability in all channels. To reach the multi-channel stage, companies need to take advantage of certain innovative opportunities that are addressed in the current paper.

III. Method

Eleven retail chains and banks in Norway were selected for the purpose of interviewing managers as well as consumers. These companies represent a microcosm of the retailing and banking sectors. A total of 11 of the 13 companies in the research project had transactional websites, five of which were traditional retailers: books, electronics, wine, flowers, and sport equipment. There were four banks or banking service companies among the 11 companies as well as one airline and one cruise line with transactional websites. The 13 included just two companies with websites for information purposes.

Personal interviews of the managers in these companies were carried out in October 2003. The insights from the interviews were presented to all the managers at two different meetings, giving them an opportunity to discuss all the insights and to try to arrive at the content of the eight factors. The paper subsequently reports the insights that are common among the managers. These insights were implemented in the managers' own companies, although to somewhat different degrees. Key figures such as online sales and conversion rates were collected from the companies on a monthly basis from December 2002 until October 2004. That facilitated a comparison of online sales and conversion rates before and after the personal interviews were conducted with the managers. Finally, about 300 customers in each of the retail chains and banks were surveyed in June 2004, receiving a response comprising some 3155 questionnaires.

In the event these customers were to buy more about a year after the managers decided on the success factors, I would be inclined to believe that the success factors the managers pointed out may be a relevant source for

explaining an increase in online sales. Please note that there is no causal relationship between the success factors and consumers' actions. However, as managers were interviewed in a number of industries, their insights may have a bearing on other industries in retailing and banking than those named above. For example, one of the companies sells flowers. They are fresh products like milk and bread, so the insights of the flower company represent some of the same challenges facing online grocers.

IV. Why It Is Interesting to Study E-Commerce in Norway

Norwegian consumers are innovative and adopt new technologies faster than consumers in almost any other country. Twenty-five per cent of Norwegian Internet users have ordered a product and/or service online during the past 30 days. This is one of the highest percentages in Europe. Furthermore, Norwegian customers plan to order a lot more on the Internet. Fifty-four per cent of Norwegian Internet users will shop online in the next 12 months. Most customers who shop online spend NOK 1000 to 5000 per month. Customers expect well-known retailers to offer a website with information as a minimum, and a large group of customers even expect retailers to offer a transactional website. Figures from Gallup indicate that 20 per cent of Norwegian customers use the Internet prior to a purchase in a physical store (*Gallup Interbuss* 2003). About 75 per cent of all Norwegian companies have a website and a little over 30 per cent of them have a transactional website (e-Business Watch 2004: 38). These are among the highest percentages in Europe, where only Denmark has higher figures than Norway.

V. Eight sources of innovative opportunities

This paper will present eight sources of innovative opportunities, or success factors, that managers indicated were of key importance when establishing a transactional website. Each factor presents a choice that companies need to make.ⁱⁱⁱ There are two ways to increase a company's competitive advantage, that is positioning and operational effectiveness (Porter 2001), and those eight factors are related to this.

The managers suggested eight innovative opportunities. It appears to me that the first four factors seem to be linked to positioning while the others are linked to operational effectiveness. Some factors are specific and concrete while others are intangible. They are listed here in increasing order of reliability and predictability. The first factors are the ones managers know the least about so special consideration is given to them in this paper. This became apparent during our interviews with the managers.

The first four factors refer to positioning, or to doing different things than its competitors do. These are:

- business culture; my or our customers. In many cases people in stores and banks have personal relationships with customers, but Internet channels make these relationships more distant.
- internal organisation; should there be a separate Internet department? If so, how high up in the organisation should the Internet initiative be located?
- assortment; should assortment in the online channel be the same as in the physical channel. If not, should it be wider or narrower?
- price; should a company charge the same price for identical articles sold online and in stores, or should prices differ?

The second set of factors for innovative opportunities refer to operational effectiveness, or to doing better the same things as competitors do. There are four factors here as well:

- logistics; should a company have a central distribution centre or should it ship goods from stores?
- customer history; how best to make use of customer data.
- IT/ERP; should a company use its original system or should it invest in a new system aimed at taking online orders?
- marketing; should customers see the company as one across various channels, or should the company conduct its marketing in different ways in different channels.

For some of these eight factors, the lines will be blurred and there will be considerable overlap. This will become apparent when the factors are presented in more detail later. Each factor has its own characteristics and therefore requires separate analysis.

VI. Four Innovative Opportunities Related to Strategic Positioning

Although each of the eight factors presents new challenges, the interviews with the managers indicate that the following four factors need careful consideration when managers identify Internet strategies. During the interviews, when presenting these insights to the managers, it became apparent that these factors were harder to handle than the other four.

The first innovative opportunity is *business culture*. Companies seek a situation where the employees feel ownership in respect of the Internet channel as well as other channels. Companies also want to get divisions and employees to move away from a situation with my customer and over to our customer. This is typical for retailers and banks. For example, when an item is sold online in an area where the retail chain has a store, the manager of that retail store believes the online sale represents a loss for the store.

Management therefore believes it is crucial to have employees understand the benefit of shopping on the Internet, as the consumer sees it, and to indicate that the Internet channel represents a synergy and does not represent a conflict between channels.

One manager of a retail company said:

I would have used a lot more time on each employee in the stores when we launched the Internet channel. That is very important, because you cannot succeed with transactions online if the storekeepers and other employees don't support the online channel and present it to customers in a favourable way.

A manager in another retail company said:

We tell our employees that customers who shop in more than one of our channels visit us more often, spend a higher amount and are more loyal to our retail chain.

Launching an Internet channel therefore represents cultural challenges to a great degree. Apparently, no matter how well a company solves problems of a technical nature, it cannot succeed with online sales unless their store employees have accepted the channel and support it.

Company management believes customers should perceive the company's contact points as one integrated company. However, in the early phase after the launch of the Internet channel, there are typically various opinions inside each company about whether the Internet channel should be an information channel or be for transactional purposes. Companies have experienced that the level of channel conflicts has become lower, but they also realise it takes time to get acceptance for the Internet as a channel in the companies.

As regards *internal organisation*, companies build their organisation around the Internet channel in various ways, but it seems clear that the Internet division has gained a more distinct role in companies over the past few months. A number of companies will also establish service centres in connection with increased internal focus on online sales. The evaluation underlying these choices is that companies are organising to meet customers' needs as well as possible. The availability of customer service for the consumer is a key issue. Experience with these considerations varies among the companies. A growing number of people in the Internet division allow latitude for conflicts, but the experience of the managers in this dataset indicates that the division has also contributed to positive results.

As far as *assortment* is concerned, the companies have different strategies. One company has 20 per cent of its stock keeping units (SKUs) for sales online (in the sporting goods business), other companies have the same assortment both online and offline, while yet other companies have more items online than offline (books for example). Most companies take account of customers' wishes when choosing their online assortment strategy. At the same time, the assortment online is influenced by costs and internal resources. One manager says that: 'It is neither practical nor feasible to sell all products in all channels'. Another manager points to the fact that some products are easier to

handle through online transactions. This represents a risk, however: 'If you choose to have fewer SKUs online than offline, you at the same time choose to turn a great number of customers away from the Internet-channel'.

The companies say they will continue being market-oriented as regards what part of the assortment will be available online. Customer feedback is considered useful for determining which products should be sold online.

The fourth innovative opportunity that the managers pointed to was *price*. The majority of the companies initially use lower prices online than offline in an attempt to draw customers to the online channel. This is typical for retailers and travel companies as well as banks. One retail manager says that:

To drive traffic to the website, with the increase in rivalry among competitors, it seemed obvious to us we needed to introduce lower prices online.

A representative from a bank says that:

The most important technique to motivate consumers to visit the website is a lower price online than offline. For example, we charge NOK 1 when a consumer pays a bill online, but NOK 20 when he or she pays a bill in the branch office.

Generally speaking, companies that set different prices online and offline do so to attract sales online, and to meet the strong competition from online players. They believe online sales cost less than offline sales.

However, most other companies are convinced that having similar prices online and offline is an important part of their strategy. They fear that consumers may get into the habit of expecting lower product prices online, and that in the long run this would undermine the business model of the company.

The companies that use similar prices in both channels do so partly to boost efficiency and partly owing to a desire not to cannibalise the various channels.

VII. Four Innovative Opportunities Related to Improving Operational Effectiveness

I now turn to the innovative opportunities related to improving operational effectiveness. The first factor here is *logistics*, which is a challenge for retailers in particular. Companies state that the integration of systems and the automation of processes are important. Furthermore, managers believe that customers should be given a larger number of delivery options when ordering online. What lies behind these strategic considerations is the fact that logistics is an area where the companies have identified huge potential economic gains. However, several of them have experienced problems realising these potential gains. Their experience is that establishing real-time in-stock databases and an automated flow of products is perceived as a large and challenging process. However, the managers believe that success in this area entails a huge potential for increasing profits.

When it comes to *customer history* it is apparent that

most of the companies collect information. Banks in particular practise this, since customers give a lot more information to banks than they do to retailers. Most companies have customer database systems and CRM systems. Companies also want to merge databases for traditional stores and online stores. Yet the companies in our sample used this information to a very small degree, if at all. Very few companies have the IT systems required to accomplish this kind of integration since they have old systems, but they realise that such databases are necessary for creating loyalty and sales across channels.

As far as *IT/ERP* is concerned, companies believe these systems should be built with a focus on the new distribution channels and the Internet in particular. Most companies develop systems based on internal resources and competence, while one of 11 companies said that it relies on vendors because it has plans to change its whole IT system. One reason most companies use their own resources to alter their IT systems is that they want to maintain control. The companies realise, however, that their current IT systems often complicate the multi-channel process. The companies realise that upgrading their IT systems is a more time-consuming process than they originally believed.

Finally, as regards *marketing*, many believe that companies need integrated marketing across the various channels. They see a considerable potential for making use of the Internet channel to build company and product knowledge in the market. Most companies want to be perceived as a single brand and a single voice in the market, even if they have channels in addition to the store. The rationale behind this is that companies want consumers to have the possibility to shop through multiple channels. It is believed that customers who shop in more than one channel are more profitable. Most companies report good results from placing strong emphasis on the Internet as a sales channel. This has led to an increased number of visits as well as sales online. Companies have also identified a tendency towards a larger degree of selling across the channels. That being said, efforts to become a multi-channel retailer are clearly perceived as being demanding.

In summary, based on personal interviews and two meetings at which the managers discussed their insights, companies tended to select the following strategies for each of the eight factors presented in Table 1.2.

According to the interviews, companies can be positioned better first by making sure that each employee feels a customer is our customer and not his or her personal customer, regardless of the channel in which a transaction takes place. This is an important element in changing company culture for the better once the Internet is launched as a channel for that particular company. It is also important to link the management of the Internet channel to the company's executive management. Most managers point out that a company should present all its products on the online channel as well, then explain it to customers if all items are not sold online.

Finally, as an important element in doing things

differently from most companies, prices should be similar online and offline. Most of the companies that participated in the study implemented these strategies. At the beginning of the data collection period, in December 2002, some of the companies had lower prices online than offline, but that was not the case at the end of the period. The implementation of this strategy means companies have completed the first phase referred to in Figure 1.2 when it comes to factors that will engender a strategic advantage by positioning them better. In fact, some of the companies penetrated the multi-channel phase slightly, finding that the same prices online and offline increased efficiency.

Table 1.2 Strategy suggestions based on the innovative opportunities

Eight innovative opportunities	Suggested strategies for creating a strategic advantage by positioning the company better
Business culture	Make sure each employee feels a customer is ours and not mine regardless of the channel in which a transaction takes place
Internal organisation	Link the management of the Internet channel to executive management of the company
Assortment	Present all items in the stores in the online channel, and include an explanation if all items are not available online
Price	Similar prices online as well as offline
Logistics	Suggested strategies for creating a strategic advantage by improving operational effectiveness Give customers as many delivery options as possible
Customer history	Have moderate ambitions regarding the integration of customer databases with CRM systems
IT/ERP	Buy a new IT system sooner rather than later
Marketing	Project your company as representing one voice and one brand no matter which channels the customer meets

There was greater consensus among the managers in this project about factors that would create a strategic advantage by improving operational effectiveness. It is important to give the customers as many delivery options as possible to facilitate convenient delivery for them. Most companies should keep their ambitions for integrating customer databases with CRM systems at a moderate level. In fact, most companies realised that they were in great need of a whole new IT/ERP system rather than building more solutions on top of their original systems. Finally, a company should be presented as having one voice and one brand regardless of the channel in which customers meet the company. The managers pointed out that these decisions

belong in the initial phase of the two phases of multi-channel retailing. For companies to be able to develop synergy, which is one of the three goals in the second phase, the marketing strategy entailing one brand and one voice needs to be in place. In fact, some of the companies adopted such a marketing strategy after the interviews had been carried out. Nonetheless, the companies had barely begun to enter the second phase. I can therefore conclude this section by saying that in the current study, these companies are in transition between the first and second phase of the multi-channel process. The opportunities and strategies presented in Table 1.2 indicate what companies need to do to penetrate further into the multi-channel process.

VIII. Consumers' Response

Until now the innovative opportunities available to the managers and what they chose to do in terms of each of them have been presented. The next question is what results were achieved about a year after these innovative opportunities were identified. Did consumers buy more from these companies and did they express a higher level of customer satisfaction, or was there no change? Figures 1.4 and 1.5 present key figures from six of the companies participating in the study; the retailers and the cruise line. These figures refer to online sales and conversion rates from December 2002 through October 2004. They enable us to compare month-by-month trends for the two indicators.

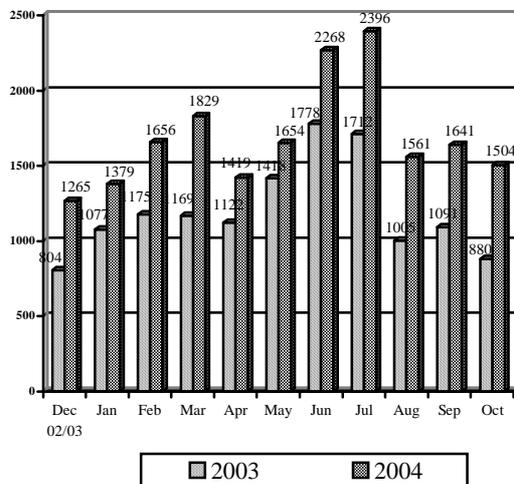

Figure 1.3 The number of online orders among the companies in 2003 compared with 2004

Figure 1.3 indicates that the number of online orders the companies received increased during the period in question. There was an increase in the average figures from 2003 to 2004. Furthermore, there was an increase in the number of online orders from each month in 2003 to the corresponding month in 2004.

The managers were interviewed in October 2003, and

they also shared their insights among themselves at two meetings held right after the interviews. During the period prior to the personal interviews, there was an average of 1203 online orders per month. That figure increased to an average of 1524 online orders per month in the period after the interviews. This represents a 26.7 per cent increase in the number of online orders. The fact that these insights were established does not, however, necessarily explain the increase since there are other variables not accounted for in this study which could influence the number of online orders and conversion rates, for example, the positive e-commerce trend and the fact that consumers are becoming more mature in their use of the Internet.

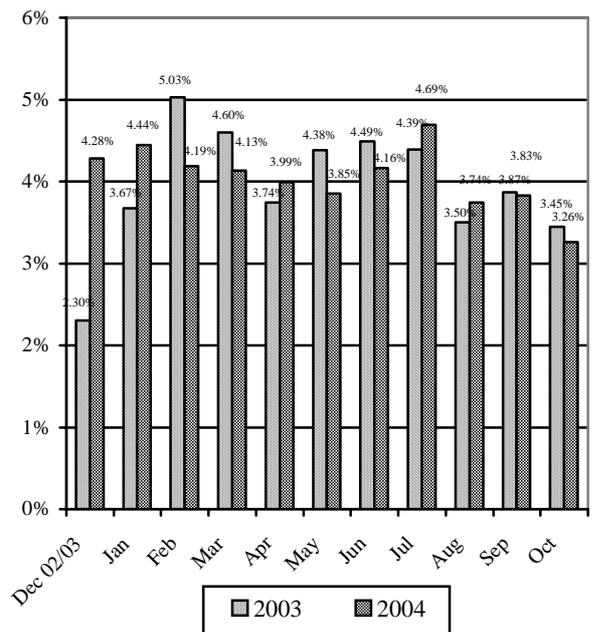

Figure 1.4. Conversion rate among the companies in 2003 compared with 2004

Figure 1.4 presents some results related to the conversion rate, that is, the percentage of website visitors who buy something online. The chart indicates an average conversion rate of 4.5 per cent. In other words, for every 100 people who visit the website, 4.5 people make a purchase there. There was an increase in the conversion rates for half the months in 2003 compared with the corresponding months in 2004, but there was generally little difference from one month in 2003 to the same month in 2004.

Even though the conversion rate remained more or less the same throughout the entire period of data collection, it should be pointed out that the number of unique visits doubled. This means that although the conversion rate remained the same, the number of orders doubled compared with Figure 1.3.

Figures 1.5 and 1.6 refer to a different dataset collected in June 2004. These data were derived from interviews of shoppers or consumers in the companies covered by the

current study. Here the amounts of these consumers' spending online as well as figures that indicate customers' level of satisfaction with the transactional websites of the companies in the current study are presented.

Figure 1.6 compares the amounts customers spent online for retailing and travel with the companies in the current project. The data indicate the amounts of consumers' purchases each time they buy something online. Almost 43 per cent of consumers spend between NOK 200 and 500 each time they buy something from a retailer online, while 23 per cent spend between NOK 500 and 1000 each time. About 20 per cent of consumers spend more than NOK 1000 each time they buy something online from a retailer. Only 3 per cent spend more than NOK 5000.

Consumers spend more online with companies in the travel sector. In fact, 21 per cent of the online customers in the travel sector spend more than NOK 5000. More than 50 per cent of online customers in this sector spend more than NOK 1000. Of the consumers who took part in the survey, on average 33 per cent spent between NOK 1000 and NOK 5000 every time they bought something online.

Products and services typically cost more in the travel sector than in the retail sector. The logistics are often easier for products sold in the travel sector; no matter how much a ticket costs, it can easily be slipped into an envelope, while retailers usually have more logistical problems with the products they sell.

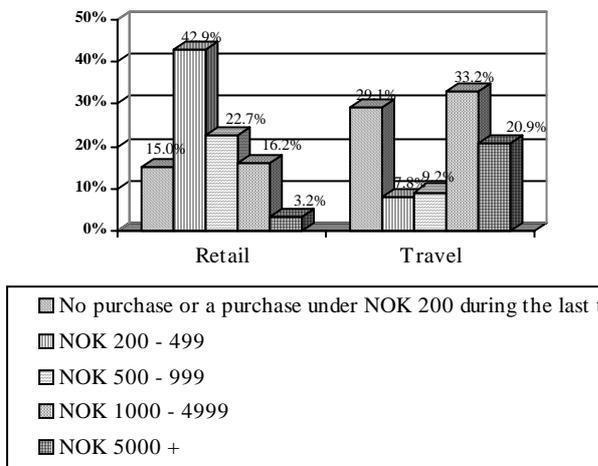

Figure 1.5 Comparison of amounts of consumer purchases for online retailing and travel in Norwegian kroner (NOK). The figures are average amounts each time a consumer buys something online from April through June 2004 (n = 1231)

The next chart examines customer satisfaction when buying online from the companies that took part in this study. The retail, travel, and banking sectors are compared.

Generally speaking, across three sectors consumers are typically either satisfied or very satisfied when they buy something online from the companies participating in the study. As many as 80 per cent of customers in each of these sectors are either satisfied or very satisfied when buying

online.

Customers in the banking sector appear to be the most satisfied when the three sectors are compared. More than 87 per cent are either satisfied or very satisfied when buying online. The banking sector has spent more time and resources in developing multi-channel solutions than the other sectors. It is interesting though to find that consumers are nearly as satisfied with the multi-channel solutions in the retail and travel sectors as with the banking sector.

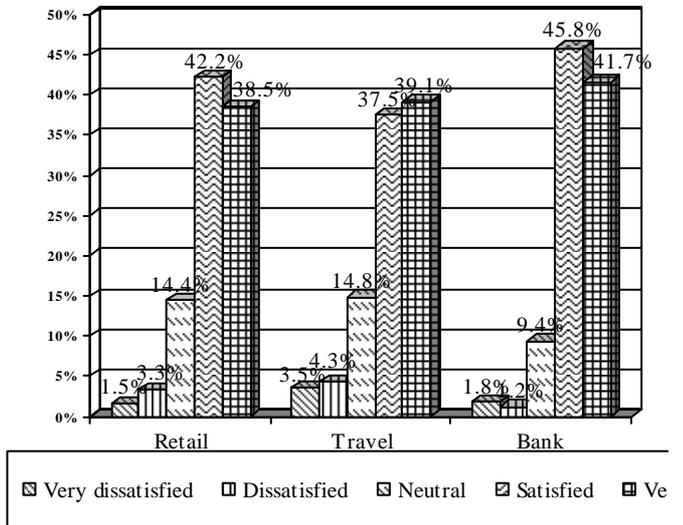

Figure 1.6. Customer satisfaction when buying online: a comparison of three industries (n = 1797)

The numbers presented in the Figures 1.2-1.6 indicate that, generally speaking, the strategies identified by the managers of these 11 companies, as presented in Table 1.2, should not be rejected. Figures 1.5 and 1.6 indicate that consumer spending in these companies is quite high, and that consumers are satisfied with the transactional websites of the companies. It is not possible to determine which of these eight strategies work for increasing orders online and which, if any, do not. Accordingly, they are presented as a set of strategies that should work together.

IX. Conclusion

Table 1.2 presents eight innovative opportunities and strategies companies can follow when establishing transactional websites. The opportunities were collected and identified through personal interviews conducted in October 2003 with 11 managers who were responsible for developing e-commerce in each of their companies. These managers also shared their insights among themselves, arriving at agreement on which factors are most important and how to use each factor when establishing a transactional website. Key figures relating to online orders and conversion rates were collected from these companies over a 10-month period prior to conducting personal interviews with the managers. Such figures were then collected during a 12-

month period subsequent to the personal interviews. In June 2004, about 300 consumers who shopped in each of the companies were interviewed.

The following insights appear to be the most important for helping a company position itself online. Keep the same price online as offline; have a large assortment online; include the Internet department in the executive management of the company and work with company culture so that all employees care about all or most of the companies' customers and not just his or her customers. Online orders increased by an average of 27 per cent during the 12-month period subsequent to the personal interviews, compared with the 10-month period prior to the interviews. When consumers in the participating companies were interviewed almost a year after the managers had presented information about innovative opportunities, they indicated clearly that they were satisfied with the companies' transactional websites.

All in all, the figures for online sales and customer satisfaction turned out to be positive for these companies. This does not, however, present proof that the eight factors listed in Table 1.2 are among those that drive these positive elements, even though the managers themselves tend to believe in these factors. It is hard to establish these eight factors as the cause of the positive developments or even as a cause of these developments. There may be other explanatory factors, such as the positive development in consumers' buying behaviour online and consumers' maturation in terms of online shopping.

However, I would argue that companies should view the eight factors as a set of factors that should be implemented, [9]

if possible, at the *same* time. The results regarding consumer satisfaction online and the number of orders indicate that the managers have been successful in developing e-commerce. At any rate, I would claim that the strategies presented in Table 1.2 should be considered by managers interested in boosting online sales.

Abstract: The functionalities required for successful deployment and operation of online auction site can be broadly classified into two categories: *core features* and *complementary features*. Core features are essential for the existence of a site, whereas complementary features enhance a users experience with the site. Since a site has to have the core features, it is the complementary features that contribute to the popularity of the auction sites. We have conducted a survey of 100 auction sites to study 23 features. We found out the similarities among these sites based on their feature vectors. Three distinct groups are formed in the process. The groups are found to be distinct with respect to the core features. We also compared the complementary features of these sites. The results of the chi square tests revealed that the groups do differ with respect to most of these features. We propose a model to assign weights to the features distinctly for three auction site categories. Pareto analyses show important features that contribute to eighty percent of the weights in each group. We next define *Site Evaluation Index* based on these weights. The analysis shows that the sites with higher site evaluation index are indeed the popular ones, as per their ranking in the results of search engines. The highest scored sites can serve as a benchmark to choose the value adding complementary features to guide the upcoming auction sites.

I. Introduction

Increasing participation of end-users in e-commerce has led to enormous popularity of online auctions. Online auctions present many interesting and challenging research issues from studying software architecture and security to understanding the user behavior on the auction Web sites.

In this paper we focus on the functionalities required for successful deployment and operation of online auction sites. Such functionalities for features can be broadly classified into two categories: *core features* and *complementary features*. Core features are essential for the existence of a site. Besides having these features the auction sites also provide many complementary features to enhance users experience with the site. Today, there are hundreds of Web sites dedicated to online auctions. But not all the sites are as popular as that of eBay or uBid. It is interesting to study what features make a site successful. Since a site has to have

the core features, it is likely that the presence or absence of complementary features contributes to the popularity of the auction sites. Our study explores this issue by surveying the complementary features of 100 auction sites.

The rest of the paper is organized as follows. In the next section we present a brief review of the related work. We then describe our survey followed by results and conclusions.

II. Related Work

Online auctions are a blend of technology and tradition, Bapna, *et al.*[2] are of the view that, auctions are as modern as today's technology, yet as old as mankind. Unlike traditional auctions that were limited in scope, online auctions have brought this mechanism to masses. Almost all the traditional auction models have been implemented on the Internet. As identified by Dans [6], 11 different auction models were found to be in use. These include traditional formats like English and Dutch auctions or their variants like Japanese and Yankee auctions. Lucking-Reiley [10] classified auction formats into four major categories: English, Dutch, sealed-bid, and double auctions. He identified various formats in these four categories, for example in sealed-bid auction he found two formats, first price and second price.

The segment benefiting most from online auctions is the business sector. There are three major business models prevalent on the Internet that are used in auction: B2B, B2C and C2C. The most common of these as stated by Dans [6] and Lucking-Reiley [10] also had similar observation. A report by Forrester Research [10] shows that B2B segment underwent "triple digit growth" during 1998 - 2002. According to Parente *et al.* [11] B2B online auctions totaled \$109 billion worth of transactions in 1999 alone and that number was expected to grow to \$2.7 trillion by 2004. This shows the growth and evolution of Internet auctions from plain C2C format to a sophisticated format enabling business to achieve new levels of efficiency. A new trend in business models was identified by Bapna *et al.* [2], as a C2B model for an auction Web sites called *Priceline.com*, which collects information from customers and provides it to companies.

Unlike traditional auctions, online auctions allow users to sell almost any product or service they want. From collectibles to latest brand new products users of online auctions are selling everything. Bapna *et al.* [2] states that

eBay sells goods in over 18,000 categories and sub-categories. Beam and Segev [4] identified that nearly 26% of goods auctioned on the internet are “non-physical” goods, consisting of some kind of software or information. This shows how the Internet has affected the auctions and giving users capacity to put a price on their knowledge also.

Security is a very important factor which must be considered while participating in online auctions. Beam and Segev [4] especially studied security in online auction Web sites and state that only 27% of auction Web sites offered secure transfer of user’s information and only half of these Web sites mentioned security issues on their Web sites and some Web sites offered users to give their credit-card information over fax or telephone. According to Wareham and Cecil [14] auction frauds represent the biggest form of online frauds. Curry [5] identifies more than 13 forms of frauds that take place in auctions online. Bajari and Hortacsu [1] discuss how Web sites can help in reducing online frauds and what measures are currently taken by the Web sites.

eBay is the most popular online auction Web site. According to Beam and Segev [4], eBay accounts for nearly 70% of online auctions in C2C category. Considering the large size of this Web site, studying how eBay operates and how auctions take place on eBay is a topic of interest for many researchers. Since eBay makes its auction data available online for about 30 days after the auction has closed, it makes it easier for researchers to get precise data about user behavior in online auctions. Shah *et al.* [12] study how eBay accepts bids from its users and how users engage in shill bidding and methods to identify shill bidding. Shumeli and Jank [13] developed a tool STAT-zoom to understand how eBay operates.

Wellman and Wurman [15] target the processing of huge amount of information on auction Web sites and how to synchronize the data processing. Kumar and Feldman [9] address the issue of designing a secure and easy to use auction Web site. They have developed a generic software model that can be used in many situations for any auction format. Huhns and Vidal [7] address the issue of agents and advocate the use of standard XML based protocols to allow better use of agents. Wurman [16] discusses the issues related to the temporal and data intensive behavior of the auction system that a developer or an auction service provider must consider. He says that though all the auction system provide same core functionality of bid processing, they differ widely in providing complementary features, which requires a very flexible system.

Dans [6] surveyed over 300 auction Web sites in 1998 to identify the auction and business models used. A similar survey was conducted by Lucking-Reiley [10]. Using 142 Web sites, he studied the economic features like the value of goods sold on a particular Web site, presenting an economist’s view on auctions. He also studied eBay and compared it to new auction Web sites, Yahoo and Amazon. To find the current state and changes in online auctions Beam and Segev [4] surveyed 100 Web sites to identify current practices, new trends and business models in online

auctions. Barnes and Vidgen [3] assessed the quality of four popular Web sites based on its customer’s survey. They developed WebQual a tool for assessing the quality of internet sites.

III. THE SURVEY

The survey covered 100 auction Web sites operating on the Internet and studied 23 core and complementary features of these Web sites. The aim of the survey is to understand the current state of online auctions, studying the features and services provided by the auction Web sites. The survey was done during January and February 2005.

III. 1 Selection of the Sample

The sample was selected using Google (www.google.com), Yahoo (www.yahoo.com), Khoj (www.khoj.com) and Rediff (www.rediff.com) search engines and auction site listings at Rediff and www.internetauctionlist.com. Rediff and Khoj were used for selecting Indian Web sites. Google and Yahoo search engines were used for searching for other Web sites. Internetauctionlist.com lists all the auction Web sites around the world, both traditional and online. Since all the references considered for this work, surveyed almost similar number of Web sites, the sample size selected for this work is considered reasonable. The overall sample demography consists of 11 Indian Web sites, 2 Canadian Web sites, 7 European Web sites, 2 Japanese Web sites and rest are from US. The names of the Web sites have been provided in Appendix B.

While selecting the sample it was found that though there are many auction Web sites that have been included in auction listings and search results, some of these Web sites no longer operate. In some cases as many as 60% of the links were false. When some of the links given by Lucking-Reiley in 1998 [10] were checked they were not working properly. Hence it can be said that most of the Web sites that are not popular, last only for few years. In our survey also 100 Web sites were found fully functional after considering all the possible sources of information. Beams and Segev [4] had a similar result, when they say that nearly 31% of the auction Web sites they surveyed were less than a year old, 27% were less than two years old and the rest 39% were more than three years old.

Online auctioning segment is dominated by some popular Web sites. When selecting the sample it was found that many Web sites use the resources of the popular auction Web sites to conduct auctions for them. For example, www.artstall.com redirects to the arts section of www.baazee.com. Air Sahara uses www.indiatimes.com to conduct its auction for airline tickets. These few popular Web sites have multiple domain names registered with them, for example, two domain names that lead to Baazee.com are www.baazee.com and www.bidorbuyindia.com. So, even though there are many domain names and search results that show up while searching for online auctions, the segment is

actually dominated by few popular Web sites.

Finding 100 auction Web sites proved to be more time consuming than expected because the search results and Web site listings include a lot of Web sites of offline auctioneers. These Web sites do not host any auctions and were simple Web sites for traditional auction houses. So, even though all the auctioning is not done through Internet, traditional auctioneers do realize the power of Internet, and feel the need for online presence. Sotheby's, which is the second largest auction house in the US realized the threat that auction Web sites pose to them and declared that they too will be expanding into the Internet domain. In the survey www.teletrade.com is a Web site which engages in both online as well as offline auctioning.

III. 2 Selection of features

The selected Web sites were studied for various core and complementary features. The survey of the literature helped in identifying four core features and nine complementary features. They are listed in Table 1. EBay, [18] being the most popular site and the choice for many such studies was used as a representative Web site to select one more core feature and nine other complementary features. Thus a total of 23 features were studied. Appendix A gives the list and descriptions of all core and complementary features. Most of the features were checked for their presence and absence only, marked by 1 and 0 respectively. However, features like, business models, auction format, phases of auction, payment methods, scripting language were marked for each category in these features. Text-graphics ratio was approximated for each Web site based on the design of its home page.

Table 1: Feature References

Core features	
1.	Business models: B2B, B2C, C2C [6]
2.	Auction formats: English, Dutch, Buy-it-now, Sealed bid, Reverse [6]
3.	Number of products categories [4]
4.	Payment options [16]
Complementary features	
5.	Faulty user identification [16]
6.	Seller's ranking [16]
7.	Search facility [8][16]
8.	Advertisements [8]
9.	Career oriented services [8]
10.	Auction update notification [16]
11.	Text-graphics ratio [8]
12.	Security [7]
13.	Sitemap [8]

III. 3 Collection of Data

All the Web sites were visited and scanned for relevant data. Particularly Home page, Help and support pages, Site map, and Registration page for both seller and buyer along with few other pages provided most of the information needed. In

most of the cases homepages provided information for the features like, faulty bidder/seller identification, search facility, advertisements, career oriented services, links to other sites, help and support, customer feedback forum, language customization, sitemap, other services, customer counter, book marking, scripting language and text to graphics ratio. Help and support pages provided information for business models followed, auction formats used, payment method available. Site map was used for finding broadly what categories of products were auctioned on the Web site. To get information about newsletter and auction update notification, registration pages for both buyers and sellers were visited. Besides this, a few auction pages were visited to know about shopping basket and phases of auction.

IV. Results

This section is divided into five subsections. We first present observations based on each feature. We then perform a cluster analysis and group the Web sites followed by across group comparison of complementary features. We then present the benchmarks for complementary features.

Feature-wise Observation

Business models: The distribution of the business models were 19%, 62%, and 58% respectively for B2B, B2C and C2C. B2C and C2C dominate the auction segment. There is a very high percentage of overlap between these two categories. In B2C model Web sites that sell their own products and/or allow other businesses to use their site to auction their products are included.

Auction formats: In the survey, 6 popular models (English, Dutch, Yankee, Buy-it-now, Sealed bid and Reverse) were searched for in the Web sites. The distribution of these models is: 90% English, 78 % Dutch, 72% Buy-it-now, 2% Sealed bid, 2% Yankee and 16% Reverse auction. English auction is found to be the most popular format, followed by Dutch and Buy-it-now auctions.

Categories of products: For the purpose of surveying the products were divided into 18 broad categories. Most of the Web sites offered products from multiple categories. However, a few Web sites auctioned items from a single category (e.g. auction.newline.com). The divisions of Web sites according to the number of product categories they offer are: 1 category 33%, 2 to 5 categories 37%, and more than 5 categories 30% of the sample.

Payment methods: The B2C and C2C auction Web sites are just a medium for hosting Web sites. These Web sites do not sell their own items to the users. Hence, these Web sites only facilitate item and money transfer between the bidders and the sellers. For this purpose almost all the B2C and C2C Web sites use Pay Pal service. Web sites give sellers option to select the payment options they are comfortable with. These options include money orders, cheques, bank drafts etc. In this case Web sites do not have any role to play. In case of B2B Web sites and B2C Web sites that sell their own

products, credit cards are the most used form of payment.

Phases of auction: Online auction proceeds through four phases, namely, Registration, Bidding, Payment, and Dispute handling. All the Web sites surveyed follow the above sequence of phases.

Seller's rating and faulty user identification: Auction Web sites collect user feedback based on their interaction with the sellers on their Web sites as a mechanism to prevent frauds. This feature is limited to C2C Web sites primarily and B2C Web sites that allow other businesses to sell on their sites. 79 Web sites are found to offer this feature. When customers deal with a direct seller site such as Onsale or uBid, they do not have to worry about fraud because they are buying directly from the auctioneer.

Shopping basket and search facility: Among the Web sites surveyed 79 sites had shopping basket feature. Almost all the Web sites had search facility.

Advertisements and career oriented services: Revenues for any e-commerce Web sites not only come from the product they are selling but also from advertisements. In the survey, 35 Web sites had advertisements. Only the homepage of the Web sites were used to judge this feature. Most of the Web sites that had this feature were C2C and B2C. The auction sites use their Web sites as a medium to advertise the job openings they may be having. It was found that only 12 Web sites advertised their job postings on their sites. These few Web sites are among the most popular auction sites. These include eBay, Onsale and Baazee.

Links to other sites and other services: Some auction houses have multiple Web sites. For example, eBay has more than one Web site. Apart from one, other eBay Web sites are dedicated to a single product category like auto auctions. In the survey 11 Web sites were identified that had multiple Web sites. 21 Web sites are not dedicated to auctioning alone. They are offering other services like email, news, shopping etc. Some of these Web sites are *auctions.yahoo.com* and *auctions.indiatimes.com*.

Newsletter and auction update notification: Almost all the popular Web sites had a newsletter that they circulate among its users. To check the presence of this feature Web site's registration pages were checked. Usually Web sites ask the user's preference to subscribe to a newsletter. Auction update notification means that Web sites inform the users about the updates that have taken place in the auction they are participating. For this purpose Web sites collect user's email address. All the Web sites in the survey notified users about the updates via email.

Help & support and sitemap: Almost all the Web sites had some sort of help pages, but the quality information varied widely between big and small Web sites. This could be one of the reasons why a few Web are more popular than others. Sitemap was found to be present in all the sites.

Feedback forum and book marking: B2C Web sites have a large number of customers across globe. To get feedback from them and to keep users hooked to their sites, they provide discussion forums as an additional feature. Web sites also provide link that allow users to book mark their site

easily for future use. In the survey, 14 Web sites had users' discussion forum. Most of these 14 Web sites were popular Web sites like eBay, Yahoo and indiatimes. The book-marking feature was provided by 16 Web sites.

Language customization: The European Web sites that were surveyed provided this feature. These Web sites could be seen in almost all European languages. None of the other Web sites had this facility. This may be probably because the European languages are very much similar in writing, they use the same script so programs can be easily written that translate one language to other.

Scripting language and text-graphics ratio: This feature was studied to study what scripting languages are used by the auction Web sites. Five different languages were taken and their use in the auction sites was measured. The distribution of sites according to the scripting language is: 46% use ASP, 23% use PHP, and 31% use JSP, CGI and Cold-fusion. Text to graphics ratio was measured to know the level of usage of graphics in the Web sites. It was a general observation that popular Web sites like eBay and Onsale used much more images and graphics in their Web sites as compared to other Web sites.

Security: There are various aspects of security that Web sites must take care of, to protect their users. In this survey Web sites SSL security was studied. Among the Web sites studied 69% had SSL security. All the Web sites that had SSL security were using to encrypt only user sensitive information, but *www.ebidderz.com* is fully SSL secured. So, even when a user is simply browsing the Web sites he can be sure that he is visiting a secured Web site. In contrast Segev and Beams [4] reported that in 1998, only 27% of auction Web sites had this security feature. This clearly shows an increased concern among the Web sites to safeguard their user's sensitive information.

Grouping the Web sites

To further study and analyze the Web sites features we try classify them based on certain characteristic(s). But it was found that the Web sites were overlapping in many features, hence, it was not possible to divide Web sites into groups by considering differences only in a few features. To solve this problem we performed a cluster analysis of all the 100 Web sites.

All the Web site features except number of product categories, phases of auction, help & support, search facility, scripting language and text-graphics ratio were used in clustering the Web sites. These features were not used because either they were similar in all the Web sites, like phases of auctioning, help & support and search facility, or they were not measured in a 0/1 scale such as number of product categories, scripting language used and text-graphics ratio. Based on cluster analysis, three groups were identified. The distribution of Web sites in three groups is: Group 1 consists of 32 Web sites, Group 2 of 29 Web sites and Group 3 consists of 39 Web sites (Appendix B). Figures 1, 2, and 3 show the distinct characteristics of the groups based on three core features: Business Model, Auction

Model, and Payment Methods respectively. Figure 1 shows that the dominant models of Group 1, 2 and 3 are B2C, B2B and C2C respectively. These sites also support other business models to enhance their functionality. For example, a site in group 3 may adopt a B2B model to operate its supply chain while at the same time may directly interact with the end users by adopting a B2C model. Figure 2 shows the difference between websites based on the number of product categories they auction. For example Figure 2.b shows Group 2 sites, dominant in B2B model offer fewer product categories compared to other two groups. It is natural for single businesses to have limited product offerings compared to the market places with multiple buyers and sellers (B2C and C2C sites). Figure 3 (Key: On Pay: Online payment option, Off Pay: Offline payment option, No Opt: No payment option) shows only some of the B2B sites have nonpayment options. This may be due to the fact that some businesses might be continuing with the traditional mode of payment with their existing business partners. Appendix C shows examples of some interesting sites in each group with unique features.

Across group Comparison of Complementary Features

The previous analysis shows the differences and similarities that exist among the Web on the basis of their core features. We use chi-squared test to study complementary features. The features, scripting language and text-graphics ratio were however excluded, since they are measured differently. Table 2 gives the p values for the chi-square test. We test the Null hypothesis that *the proportion of Web sites having a particular feature is equal in all three groups* against the alternative hypothesis that *at least two of them are not equal*. Asterisk (*) marked cell entries indicate the features in which the three groups differ. The difference in features like services, career and advertisements can be attributed to the different business models that the groups follow. For example, in case of services, group 1 and 2, the groups dominant in B2C and B2B models, have the highest percentages of Web sites offering services other than auction. These services included Web site hosting service as in *www.afternic.com* or email services from *www.indiatimes.com*. Only Web sites that cater to Businesses or are dependent on businesses for their products offer these services. C2C Web sites (group 3) have the least number of Web sites offering other services. Features like seller's ranking, newsletter and users' forum are different because of the customers the Web sites cater to. For example, in case of seller's ranking B2B Web sites in group 2 offers the least number of Web sites having this feature, probably because the users of these Web sites are authenticated before they participate in auctions on these Web sites. B2C Web sites have a large number of users, so to keep the users hooked to their Web sites; they provide features like newsletter and forum. Other feature in which the Web sites differ is the links to other Web sites feature. This is so because of the fact that group 1, which has the

highest number of Web sites having this feature, contains many popular Web sites, like *eBay* and *yahoo*. These popular Web sites have specialized Web sites devoted to a product category or a separate Web site for other country.

Relative Importance of Complementary Features

We define relative importance of the complementary features in each group by associating weights. The weights are defined as follows:

$$w_i = \frac{NOF_i}{OF} \times 100 \quad \text{For } i = 1, 2, \dots, 16$$

where,

w_i is the weight assigned to a feature i ,

NOF_i is the number of occurrences of a feature i in all Web sites of the group, and

OF is the number of occurrences of all features in the group

Table 3 gives the weights for complementary features in the three groups. It also the ranks of these features based on their weights.

Pareto Analysis of Feature Weights

Pareto Analyses, presented in Table 4, identifies the features that add up to 80% of the weight in each group. These features are shown in *italic*. It can be seen that many of the features are common in the three groups. Common features are: help & support, search facility, seller's ranking, shopping basket, auction update, security and sitemap.

Benchmarking the Complementary Features

In order to have a benchmark for complementary features, we first find out the *Site Evaluation Index, SEI*, (defined later) of all the Web site. The sites with highest SEI can serve as Benchmarks. Based on this benchmark we evaluate the design characteristics of the 11 Indian auction sites.

Finding the Site Evaluation Index

$$SEI = \sum_{i=0}^{16} w_i \times f_i$$

where w_i is the feature weight in a particular group and f_i is 1 or 0 according to presence/absence of the feature

Based on this index the Figure 4 gives the distribution of sites in the groups. Table 5 gives the maximum, minimum and the average values of the evaluation index.

In many cases sites with high value of SEI are popular sites on the Internet. Though there is no direct proof for this statement, here we cite some resources that support it. EBay the world's most used online auction website, recently completed its 10 years of existence. On this occasion many of the world's leading news-sites wrote articles. BBC has

written an article titled “eBay's 10-year rise to world fame” [19]. Similarly, *Indiatimes*, which has a high score among the Indian sites (SEI 86), is the most popular Indian site as per a US-based market research firm, *Ranking.com* [20]. *Superbrands India Ltd.* rated *Indiatimes* as among the 60 business superbrands [21]. *Bidz.com* which has a high SEI (96), is a leading online auctioneer of jewelry, art and collectibles according to *Market Wire*, a leading company news distribution company [22]. *CQout.com* is the UK's second largest auction site in terms of sales and has a high SEI (92) [23]. *Indiamart*, India's leading B2B marketplace was featured on *CNBC* as analysed by *McKinsey & Company*, as a successful online business model that survived the dotcom bust during 1999-2001, has an SEI of 86 [23]. Other than news sources search engines also provide certain measure of the web site's popularity. Today search engines use advanced techniques to analyse the importance of a web site, with reference to the search query. When *Google.com* is searched for “online auction” or “auction” keywords, the first 10 results that are displayed include *eBay*, *ubid* (SEI 94), *Yahoo auctions* (SEI 84), *QXL* (SEI 95) and *Cqout* (SEI 90). All these auction web sites have a very high SEI in our analysis as indicated in the parenthesis. Similar effect has been observed with other leading search services like *Yahoo* and *MSN*.

Where do Indian auction sites stand?

Table 6 gives the score of Indian Web sites in all the groups. It can be seen that Indian B2C-C2C sites (*www.bazee.com* and *auctions.indiatimes.com*) present in Group 1 have a very high score compared to B2B sites in other groups, which have scores less than their respective group's average score. Indian B2C-C2C sites are very feature rich, compared to other Indian Web sites. Only one Indian B2B Web site has a very high score. This Web site offers auctioning surplus inventory (*auction.indiamart.com*).

V. Conclusions

In this work we broadly classify the functionalities of online auction sites as core and complementary features. We conduct a survey to study the existence of these features on a set of 100 online auction sites. We applied a clustering technique to group the sites into three groups which are distinct in most functional and complementary features. We describe a scheme to assign importance weights to the complementary features in the three groups. It is found that the new featured considered by us (Table 1 and Appendix A) like help and support, shopping basket etc. are among the important ones. We propose a model to evaluate web sites based on these feature weights. We provide some anecdotal evidences to show that the sites with very high site evaluation (SEI) are indeed the popular ones. Therefore we conclude that the proposed model can be used as a benchmark to evaluate the functionalities of online auction site.

Appendix A

Auction Web site Features

Core features

1. Business model
 1. **B2B**: they target business customers instead of individual consumers.
 2. **B2C**: These are sites that either offer their products to consumers, or act as intermediary between merchants and consumers.
 3. **C2C**: This is also known as person-to-person. The auction site acts as an intermediary.
2. Auction formats
 1. English: Bidders offer increasing price, aware of previous bids
 2. Dutch (multiple unit auction): More than one similar items being auctioned. Bidders bid for one or more units, usually more than one winner.
 3. Buy-it-now: Seller specifies a minimum price. Any bidder offering to pay that price wins.
 4. Sealed bid: Bidders submit bids unaware of other bids
 5. Yankee: Similar to Dutch, difference is in Dutch winner(s) pay the lowest winning price, but in Yankee, winner(s) pay what they bid for.
 6. Reverse: Demand comes from the buyers, and sellers bid their price.
3. Number of product categories: number of categories in which Web site had divided the product it was auctioning
4. Payment options
 1. Online payment: PayPal, credit card and online money transfer.
 2. Offline payment: cheques, money orders, cash.
 3. No payment option
5. Phases of auction
 1. Register-Bid-Pay-Dispute sequence of events.

Complementary features

6. Faulty user identification: Warning users about faulty users on the web site.
7. Seller's ranking: Auction Web sites collect users feedback based on their interaction with the sellers on their Web sites. On the basis of this feedback Web sites rate the sellers, so that other bidders can get information about the sellers.
8. Shopping basket: In order to help bidders keep track of their bids Web sites have a feature called shopping basket. Using this feature bidder can track items without even bidding for them.
9. Search facility: facility to search the Web site
10. Advertisements: advertisements of other companies or Web site's own services.
11. Career oriented services: information on career opportunities and current job openings
12. Links to other sites: links to country sites or sites dedicated to a special product category

13. Help and support: help content for users to make full use of the Web site
14. Newsletter: circulating newsletter among registered users, containing current happenings on the Web site
15. Auction update notification: Notifying users with update about the auctions in which they are participating
16. Customer feedback forum: forum for users' to discuss the Web site
17. Language customization: facility to view Web site in other language
18. Sitemap: categorization of Web site links
19. Other services: services other than auction, being offered by the Web site
20. Book marking: facility allowing users to book mark the Web site for future use
21. Security: use of SSL security by the Web site
22. Scripting language: the language used by the Web site for programming
 1. ASP
 2. PHP
 3. Other (JSP, CGI etc.)
23. Text-graphics ratio: approximate ratio of text-graphics as they appear on Web sites home page

Appendix C

Examples of Web sites

There are thousands of Web sites on the Internet. Hence it is very important for a Web site to have some distinguishing features, which make it stand apart from the crowd, and attract customers. In all the three groups that were formed, such features were observed. Here is a list of Web sites from each group along with the special features they have.

• Group 1

1. <http://www.auctions4acause.com>: auctions for charity, auctioning brand new items
2. <http://www.qxsmartbid.com>: uses a new auction format, with multiple sealed bids, where highest (or lowest) unique bid wins
3. <http://www.bidway.com>: uses less commonly used Vickery auction format
4. <http://auction.indiatimes.com>: popular Indian auction Web site, many big businesses, like Air

Sahara and Philips, use it to auction their products, like in this case airline tickets and electronic goods

• Group 2

1. <http://www.winebid.com>: allows a seller to offer its products in a “parcel” which may comprise several lots of wine
2. <http://www.patentauction.com>: auctions patents, only Web site found with this product category listed separately
3. <http://www.golfclubexchange.com>: offers users 48 hours inspection period for the products they have won before they pay for it
4. <http://auction.newline.com>: auctions items used by actors in Newline Cinema films

• Group 3

1. <http://www.eggbid.com>: provides a separate page warning users about spam which contains Web site’s name
2. <http://www.bidshot.com>: first m-commerce enabled Web site
3. <http://www.baymore.com>: enables users to organize private auctions, where only bidders submit bids by invitation through the seller
4. <http://www.ebidderz.com>: the whole Web site uses SSL security, thus protecting user’s privacy

Abstract: The skill of successfully utilizing the Internet as distribution channel for non-life insurance products is examined by comparing the web site usability of three different types of insurance providers from the UK. A long-established, traditional insurance company is benchmarked with a pure online insurer and a groceries retailer that diversified into online insurance. The study is conducted from the consumer's perspective by using expert evaluation techniques and a grounded theory approach. The findings suggest that the newer types of insurance providers outperform the traditional type and therefore represent a significant competitive threat to the insurance industry as we know it today. The theoretical findings suggest that frameworks for analysing web site usability are highly sensitive to context, and in the case of insurance services, *appearance* of the web site and *assistance* to the consumer while using the web site are evaluation criteria that are more important than expected and need to be included when analyzing non-life insurance web sites.

Keywords: E-Business Models and Enterprise E-services Architectures, Usability, Distribution Channels, Internet.

I. Introduction

The Internet is becoming an ever more important channel for business-to-consumer insurance services worldwide. Insurance companies have put their efforts especially to developing electronic insurance services for non-life insurance. Comparing non-life insurance, such as home, car, travel, and legal insurance, to the life insurance business, at least two characteristics are facilitating the development of electronic services within non-life insurance. First, products are less complex which makes the absence of personal contact in service encounters somewhat less critical and second, transaction frequencies are higher. Since business-to-consumer (B2C) customers also perceive the online service channel as essential alternative to offline channels at least in the non-life context [1], insurance companies are eagerly learning how to better utilize the Internet for insurance products and services. Thus, the strategy of insurance companies has been to get B2C customers engaged in the electronic insurance service environment.

Unclear or confusing service offerings might cause cust-

omers to switch providers, especially on the Internet, where consumers can compare prices and conditions rather easily from their desk at home. Therefore, one of the most essential conditions for getting customers committed to a particular insurance provider and to electronic insurance services in general, is to have a B2C interface with good usability and hence, to have a web site that consumers perceive as pleasant to use and to be at.

Along with the rise of the Internet as a service channel, the competitors within the insurance industry have become more versatile. In addition to the electronic service offering from long-existing traditional insurance companies, newer types of service providers have appeared in recent years, for example in the United Kingdom, the United States, and Germany, where groceries retailers, mail-order businesses, and pure online insurance companies have started selling insurance online [20].

These different types of online insurance providers are competing in the same market and often for the same customers. Hence, the question is whether long-established, traditional insurance companies are well-suited to meet the new competition from novel types of insurance providers, or whether the traditional firms have disadvantages, for example due to their previous way of doing business and the resulting set of competencies. We assume that succeeding on the Internet demands a set of competencies which is more likely to be found at the new entrants, such as pure online insurance providers or retailers with previous Internet experience. However, the new competitors might have shortcomings in their skills to provide insurance services and products because of a lack of experience in such business activities. This context of traditional insurance providers competing in a new environment and new insurance providers competing in a more familiar environment provides an interesting research setting and provides opportunities to benchmark the competitor's capabilities with each other.

In order to benchmark these different types of insurance companies, the web performances of three different types of insurance companies from the UK are examined. The UK was chosen as the empirical setting for the present study because of the versatility of different types of insurance providers serving B2C customers. In addition as to the quality of their web sites the UK can be considered overall as the most advanced market for electronic insurance services at this time [20]. Therefore, the UK also provides a useful benchmark for other insurance markets. The categorization of the insurance companies is based on a

previous study [20] about the effect of existing physical distribution channels on online distribution channels in the insurance industry.

The three categories are:

- 1) *Traditional insurance providers* - insurance firms such as Prudential (UK), which have a traditionally strong physical distribution channel but which offer services now online as well.
- 2) *Online insurance providers* - pure online Insurance firms, with the sole purpose to provide their products and services through the Internet, such as Esure (UK). These firms do not use physical distribution channels.
- 3) *Idiosyncratic insurance providers* - providers of online insurance, which have grown out of mail-order firms, or consumer goods retailers, such as Tesco (UK). Tesco recently diversified into financial and insurance services. Firms of type 3 never owned a physical sales channel (at least not for insurance products and services) – but might have experience in selling other products offline and/or online.

The reason for choosing these three particular companies was that each of them represented the best performer in their category [20], and therefore they provide interesting benchmarks for their domestic competitors and international markets as well.

The objective of this study was to evaluate the usability of web sites of the three types of companies in order to a) find out what customers perceive as critical issues for the usability of insurance web sites, and b) whether the newer types of insurance providers (type 2 and 3) have an advantage on the Internet compared to the traditional insurance firms, and what that could mean for the competitiveness of traditional insurance providers.

We therefore assume that a large extent of the firm's skills and abilities to utilize the Internet as novel sales channel is reflected in the usability of its Internet pages. In addition to evaluating the differences in performance levels, the goal also was to assess whether the companies have a new approach to online insurance, and how these companies - and the insurance industry in general - could benefit from that approach.

II. Theoretical Framework

In this chapter the main theoretical elements of the study are discussed. Theoretical framework of the paper is constructed by combining the aspects of distribution channel theory, resource-based strategy, and usability theory.

II.1 Distribution Channels

Distribution channels can be defined as “networks consisting of interdependent actors involved in the process of

making a product or service available for consumption or use” [16, p. 2]. Distribution channels continuously evolve and change in order to serve their markets best [16]. The Internet can be regarded as the most recent innovation that brought change to the distribution strategies for insurance products and services. While earlier, most insurance products and services were offered through physical sales channels such as by agents and brokers, the Internet is a new alternative for insurance firms to offer especially non-life insurance products to consumers.

Therefore, numerous insurance firms have adopted a multi-channel strategy by offering their products and services simultaneously through their existing channels of sales agents or brokers, telephone sales, and the Internet. These multi-channel strategies reflect the general change of consumer's purchasing patterns and reflect in particular a trend of consumer's preference for multi-channel sourcing of products or services [3]. Cespedes and Corey [3, p. 75] point out “Customers may wish to buy a product through different channels at different points in time depending [...] how urgent a particular order is, or whether the purchase is an initial buy, a routine buy, or a modified rebuy”. Travel insurance for example, is often taken out urgently before the start of a journey, and because it is of low product complexity, customers often perceive it as more convenient to purchase it via the Internet.

In addition, the consumer's choice of distribution channel is affected by prior product knowledge and the frequency the product is purchased with. Consumers with prior knowledge about insurance products can be expected to be more likely to purchase insurance through channels that do not offer face-to-face assistance. In order to provide access to Internet-based insurance not just to expert-like consumers but to a wider range of consumers, web sites need to feature high customer friendliness and usability that is compensating for the missing face-to-face contact physical channels are offering.

II.2 A Resource-Based Perspective on Channels

When firms perform business activities, they develop task-specific capabilities [13; 19; 5] and when entering a new set of tasks, a new set of capabilities needs to develop that allows the firm to perform well in the new tasks.

Therefore, engaging in a new type of distribution such as the Internet, demands the company to develop new tasks and task-specific capabilities, such as how to present its products on the web site (content and appearance), to enable customers to find the information easily (navigation), and to provide customers with the right support, in case they need a sales person to talk to (assistance).

Because traditional insurance companies have been conducting their business for many decades through physical sales channels it might be more difficult for them to succeed on the Internet because it demands a set of skills including not just knowing *what content* needs to be displayed on the web site, but also *in what manner* this has to be done. Naturally, this requires a new set of skills and thinking

when entering a sales channel that is fundamentally different compared to previous channels. In addition, the company might find it difficult to decide on its Internet strategy because existing channels might perceive the new channel to have the potential of cannibalizing existing channels, although it can also be perceived as complementing them.

Pure online insurance providers are usually backed by well-established companies due to the complexity of the Insurance business and large amount of capital that is involved. Therefore, the pure online insurance firm does have insurance expertise at its disposal and is not a newcomer to the insurance business *per se*. However, the company usually is a newcomer to the Internet and therefore it needs to develop the set of skills that are required for this particular sales channel. From a strategic perspective, being a pure online insurance provider should enable the firm to focus on its core competence and concentrate on developing the necessary skills.

The third type of companies diversified into the insurance business through opening a new Internet channel in addition to their already existing online channels. Here, the company is a newcomer to the insurance business, and therefore needs to develop the skills to provide that kind of business, often in cooperation with established insurance firms and by hiring staff from the industry. However, the advantage the company has is that it possesses a certain set of skills that enabled it to provide other products and service through the Internet successfully, already. Therefore, the understanding of the Internet as a sales channel might be more sophisticated for such a company, which could lead to a significant competitive advantage if the company gains sufficient understanding of the insurance business as well.

II. 3 Usability

The goal of web site usability is to provide what potential users would consider to be a successful experience [6]. According to Hennemann [6, p. 133], “Usability exists when the design of the system matches what the intended end users need and want, i.e. when systems operate in the way users expect them to work”.

A corporate web site with low usability may require users to find alternative methods to contact the company in order to do business, or to even choose a competitor. Therefore, corporate web sites are an important part of an organization’s communication and distribution strategy and web site usability represents a key success factor for companies that offer their products and services to consumers via Internet.

Therefore, especially among IT professionals the usability of information systems and web sites in particular, has become an important issue in recent years but academic literature has not given sufficient attention to the subject, yet [2].

Usability studies that use the consumer’s perspective include aspects such as health, safety, efficiency, and enjoyment [14]. Further studies about usability include learnability, efficiency, memorability, errors, satisfaction

[10], and aesthetics [6]. Van Laan and Julian [17, p. 6] define usability as “the practice of taking human physical and psychological requirements into account when designing programs and documents”. In their opinion, the purpose of usability is to improve products and services and make them more intuitive for the user.

Several authors have developed lists of criteria for assessing the usability of commercial web sites [6; 10; 14] but web site evaluations need to be acknowledged as rather context specific, and therefore, usability criteria often differ based on the nature of products and services that are provided through the web site.

Due to the high complexity of products within insurance industry – even for non-life insurances such as car, home, travel, and legal insurances – the lists of usability criteria from previous studies [6; 10; 14] need to be re-evaluated. To pay attention to the context of insurance products and services, a list of twelve usability criteria can be suggested [20], including the following criteria:

- *Efficiency* - Does the user save time by using the web site?
- *Security* - Is data transfer through this web site secure?
- *Informativeness* - What is the amount and quality of information displayed?
- *Aesthetics* - Does the web site look “likable”?
- *Clearness* - Is the information clearly displayed?
- *Learnability* - Is it easy to learn to use the web site?
- *Memorability* - Can the user find its place quickly after glancing away?
- *Supplementary services* - What additional useful services could the consumer get on this web site?
- *Interactivity* - Can the user communicate with a company representative for example through chat or a 24h telephone help line?
- *Enjoyability* - Is it enjoyable to use this web site?
- *Intuitiveness* - Is the firm able to imagine what its users want?
- *Assistance* - Does the web site offer the user assistance?

While this list of twelve usability criteria has proven helpful for evaluating the usability of online insurance web sites, an alternative, more cumulative model is deployed in this study, proposed by Scharl and Bauer [14], which includes as evaluation criteria *content* (presentation of the information), *navigation* (navigational clues), and *interactivity* (nature of the interaction between the user and the site).

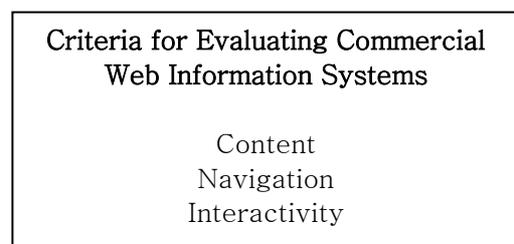

Figure 1 Criteria for evaluating commercial web sites [14]

III. Methodology

The research methods and the execution of the empirical research are discussed separately in order to provide a better insight into the research design and to contribute to the improvement of usability research methods. Here, a novel way of analysing usability is introduced through using a combination of heuristic evaluation [11; 12] and grounded theory approach [4].

III. 1 Research Methods

When it comes to evaluating the usability of web sites, an important distinction between the objective ease of use and the perceived ease of use needs to be made [18]. While the objective usability is determined by the systems' usability features, the perceived usability also depends on the individuals' proficiency with the system. Hence, this study approaches usability from the consumer's perspective.

This study focused on the perceived usability, because although usability research methods are used, our main focus is on service business research within electronic insurance environment. The three selected insurance companies' web sites are evaluated with the help of a group of 28 students. The perceived usability is assessed by following an expert evaluation (i.e. heuristic evaluation) technique [12; 11], meaning, that the students are evaluating the web sites themselves by inspecting user interfaces with a set of guidelines or questions [11]. The key elements of the heuristic evaluation technique are combined with the usability evaluation framework by Scharl and Bauer [15] and adapted to the insurance context.

As to the quality of the results the aim was to get as competent responses as possible but, on the other hand, the responses should also represent the opinions of consumers. Therefore, the participants were chosen from a group of university business students with insurance sciences as their major subject.

For data analysis, the data was transferred to a software program designed to handle qualitative, non-numerical, unstructured data, called NVIVO. With the help of this program, a grounded theory approach [4] was applied to derive usability categories. The grounded theory method allowed us to keep flexible during the analysis and let the relevant usability categories emerge from the data in inductive steps rather than approaching the subject with predetermined assumptions.

III. 2 Research Execution

The empirical data was collected in two phases. The first evaluation round was conducted in November 2004 with nine, and the second in February 2005, with 19 students.

Before the students started the evaluation process they were briefly instructed about the content and process of the empirical study. The phases and tasks were completed one at a time. The progress of the evaluation is depicted in figure 2.

Figure 2 Evaluation process

First, they were asked to shortly answer to six open questions in order to express their opinions on offering electronic insurance services in general.

Second, they had altogether 45 minutes time to get themselves familiar with the web sites of the three insurance companies. After the browsing phase students were instructed to write a one-page review about the three companies and a conclusion where they also indicated how they rank the companies according to their own preference.

Third, after the students had completed writing the review they were given a set of three specific tasks related to home insurance. This phase also meant that they were not just browsing anymore but were challenged to go deeper into the web site and actually try to work with it. Their tasks comprised: 1) finding general information, 2) finding a specific piece of information related to compensation in damage situation, and 3) to retrieve an online quote for a home insurance product. While processing with the tasks the students were evaluating the functionality of the web sites for each of the three companies at a time.

Fourth, the students were asked to reflect on the review and ranking they had written in phase two, and to consider whether their opinions had changed after they had to execute the tasks. In addition, the students were asked to reflect on the six open questions they answered in phase one. In order to investigate how the students perceive the usability and functionality of the web sites, their opinions had to be captured *before* and *after* they had tested the actual functionality.

All 28 students evaluated the performance of all three companies, resulting to altogether 84 evaluations that were included in the empirical data. For all phases, data circulation was used to increase the reliability of the study, meaning, that in order to ensure that every company will be equally evaluated, three different evaluation orders were formed so that every company was evaluated as first, as second and as third by, approximately, 12 students.

IV. Presentation of Findings

In order to emphasize both practical and scientific results of the research this section is divided to present theoretical and practical results separately.

IV. 1 Theoretical Findings

While Scharl and Bauers' [14] categorization is meaningful for a general evaluation of commercial web sites, for online insurance services it needs to be extended by two more categories, namely, aesthetics and assistance.

The reason for extending the existing list of criteria by the appearance criterion is that half of the empirical data that related to the presentation of content was in fact related to aesthetic aspects, such as colour and design. The other half referred to the information or contents itself, meaning, how the company presented product information and the like.

Especially insurance product information - which is often perceived by customers as difficult to comprehend - requires a distinction between the substance that a document contains and the way this substance is displayed.

Assistance is added to the list of criteria because seventy percent of students indicated they would have needed to call the insurance company or enter an online chat at least at one point during the process. About half of these seventy percent would have needed to do so even though they felt they completed the task successfully, for example to make sure they executed the task correctly, chose the right product, or whether the system calculated the correct price.

In figure 3, a list of criteria is proposed for analysing the usability of web sites based on Scharl and Bauer [14] but extended by the two insurance context-specific criteria, namely, appearance and assistance. To a large extent, this list of criteria is a result of the grounded theory method that was chosen in order to let the relevant categories emerge from the data instead of testing pre-defined expectations.

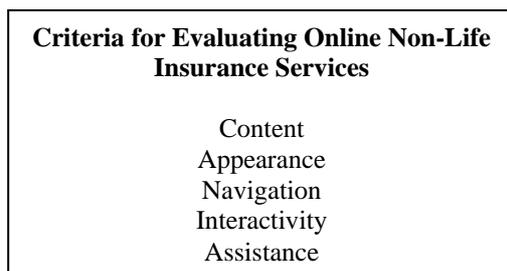

Figure 3 Criteria for Evaluating Online Non-Life Insurance Services

Through proposing a list that includes not only content, navigation, and interactivity, but also appearance and assistance, the requirements of a certain context, namely, the non-life insurance industry are acknowledged because a web site is a platform for presenting a company, which, as part of an industry, shares certain characteristics with firms that are engaged in similar activities. Therefore, the applicability of such a list of criteria is usually limited the context of a particular industry or product group.

The following definitions for the items on the list of criteria are proposed. *Content* refers to the amount and nature of information, including the choice of words. *Appearance* refers to the aesthetic appeal of the web site, its colours, and clarity of design and structure. *Navigation* refers to the ease of navigating, browsing, searching, and accessing information on the web site. Interactivity and assistance are defined in a rather context specific way.

Therefore, *interactivity* refers to the tools that can be used on the web site, such as calculators. *Assistance* refers to the help and advice services that can be used if needed, through telephone and online chat, preferably available 24 hours a day.

IV. 2 Empirical Findings

The opinions of the students are presented in tables 1 and 2 through citing critical episodes, which means reporting those events capturing a problem, misunderstanding, or difficulty in the user's interaction with the web site [2]. For making the comparison between the companies easier the citations are sorted by company. Referring to the theoretical framework, the citations are also divided into five categories: content, appearance, navigation, interactivity, and assistance.

The most essential findings from the phase *before the students had tested the actual functionality* are presented in table 1 and summarized as critical episodes. In this phase the results indicate that Esure was generally perceived as the best company, Prudential was perceived to have a more traditional and trustworthy image of the insurance business, and Tesco was perceived as non-insurance-like and even immature in terms of insurance business.

The most essential findings *after the students had tested the actual functionality* are depicted in table 2. The tasks changed the opinions of the students quite dramatically. The traditional insurance approach (Prudential) was now characterized by complexity and information overload and was outperformed by what was perceived as fresh non-insurance-like approach (Esure and Tesco).

V. Discussion

When comparing the results of the student's pre-task opinions and post-task opinions, a significant change can be observed that is also expressed in the ranking of insurance providers, illustrated in figure 4.

The pillars in figure 4 indicate that Esure maintained a position on the top from the beginning to the end, although it lost some of its appeal after the second evaluation. Tesco was perceived as the least favourable company after the first ranking but in the end it was ranked as the top performer, being even slightly better than Esure.

Looking at the reasons why Tesco improved, students claimed that the amount of information was sufficient and showed a matter-of-fact approach to insurance information that was pleasant to experience because of the joyful web site appearance. The clear site structure and design also enhanced the navigability of the web site, which made it possible to easily search and access the information needed.

Prudential was seen as trustworthy and matter-of-fact, traditional insurance service provider in the beginning. However, those very characteristics typical to traditional insurance business were criticised after the students had to execute the tasks, and Prudential's web site became

perceived as to be “too traditional” or the layout being even “boring”, and that too much information is available which makes the site “complex”.

It also needs to be stressed that many test persons felt indifferent about whether there was not enough information *per se*, or whether it just was not accessible in the right way. Here, the lack of product information or lack in its accessibility can decrease the trust in a web site. Prudential's site structure that was originally praised, was perceived as unclear and confusing after the tasks, and as a result of that, students claimed the site to be very difficult to navigate.

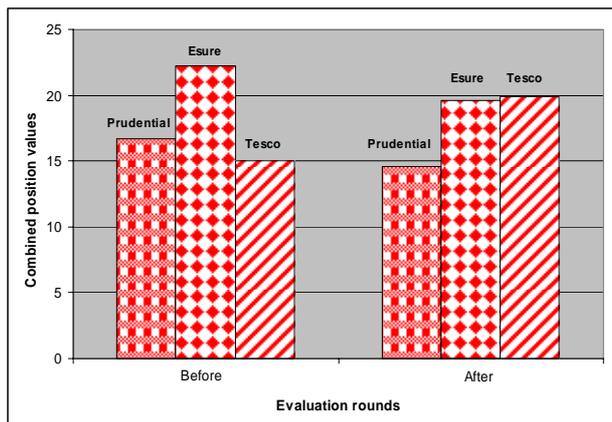

Figure 4 Ranking of firms before and after the task phase

In Esure's case, many students complained that besides the clear site structure and pleasant appearance, the amount of information was insufficient. Here, it was interesting that the small font size made the information hard to read, which created discomfort among most of the test persons. Hence, the fact that information was hard to find or perceived as insufficient largely comes from the company's choice of too small font size on the pages behind the front page.

One of the key issues that need to be addressed for improving the usability of web sites is the content. The content significantly affects the ability to navigate on a web site. Sites with good content but too small font-size for example drop in their usability significantly, even if they have a clear structure, such as Esure had.

Aesthetic elements, such as color and clear design are important issues as well especially when giving a first impression to the consumer. In addition, color and design are key attributes for making content accessible and making a site easy to navigate.

Solid appearance, such as sophisticated looks, structure and colors, is important for the image an insurance company needs to convey, but lack of clearness in design can cause the customer to get lost on the web site, as has happened in Prudential's case. In addition, Prudential's trustworthy image that was conveyed originally, conflicted with the consumer's perceived lack of information and difficulties with getting access to it, making them feel lost and perceive the company as not transparent enough.

Ease of navigation and sufficient information has been the key of Tesco's success. While its image is non-traditional and can be perceived as immature by some consumers, insurance information is matter-of-fact and easy to access, showing that Tesco has skills in presenting the essential features of an insurance product.

From a theoretical perspective, the findings indicate that the task-specific capabilities these three insurance providers developed through their rather different business activities affect their ability to create a user-friendly web site, and provide online insurance successfully. Therefore, a distinction needs to be made between different competitive advantages in the context of online insurances.

Prudential represents a traditional, long-established insurance company, which, through its business activities, has developed a certain set of skills and capabilities that allows the company to serve customers with its comprehensive knowledge about the insurance business. This knowledge, however, leads in the absence of experience with the Internet to a bureaucratic approach to information and content, which especially affects the navigability of the web site.

More traditional insurance firms also have to manage the Internet parallel to their physical channels. Here, the awareness can prevail that the Internet is an opportunity since it can complement other channels, but there could also be a channel conflict because the Internet might also be perceived as to cannibalize, and therefore take away business that would otherwise be made through physical channels. Therefore, conflicts about the distribution and redistribution of resources within the company and among the channels might reduce the necessary attention from the online channel that it needs to outperform other competitors, for whom it is more natural to have electronic sales channels, such as Esure and Tesco.

Esure can be assumed to have the best preconditions for a successful online insurance business from a usability perspective, because its sole focus on insurance business and the Internet as distribution channel allows the company to concentrate its resources and build up core competencies. The opportunity to start fresh and build an insurance web site where insurance information is displayed in a customer-friendly way, as well as with a fresh appearance and good understanding of the importance of clear web design, certainly gives the company an advantage over its more traditional competitor, Prudential. However, the resources of Esure as a niche player are more limited and its larger competitors do have advantages in economies of scale and scope.

Tesco certainly represented a surprise after it was able to slightly outperform Esure and clearly outperform Prudential not only in appearance and navigability, but also in content, assistance, and interactivity. Tesco, with its successful online business for groceries and non-food retail goods has diversified into financial services successfully, through using its widely recognized brand and its experience with electronic channels. Therefore, it provides a good example

for a company which is not only able to transfer and utilize its capabilities related to online channels from one product category to the other, but it also demonstrated that it is able to acquire new, industry-specific knowledge for distributing insurance products and services.

VI. Conclusion

The key characteristics of insurance business, such as the complexity and abstract nature of products set significant challenges to the development of electronic insurance services. Thus, such usability issues as appearance, clearness, appropriate amount of information, and assistance should be considered even more than in some other service fields.

To summarize the results of our study, some general tendencies related to the web site usability of insurance companies need to be brought up.

First, insurance as a business is based on transferring information and a feeling of security to customers. Thus, it is important to provide an amount of information to the customer that is both – comprehensive and comprehensible. Therefore, providing all information possible cannot be the answer because it easily leads, especially in the insurance business, to information-overload because of the complex nature of the product and the terminology that is involved. Regarding web site usability, providing too much information also makes it difficult to create clear content and design on the web site which significantly affects navigability and, too much information can make customers feel confused and overwhelmed.

Second, lively and non-insurance like layout especially at Tesco's pages was perceived as a rather positive approach to insurance business. Insurance as a business should also create trust between the insurance company and the customer and therefore, a matter-of-fact approach on the web sites has, at least so far, remained widely applied within the insurance field. This study suggests that in addition to the traditional insurance-like approach, there are also other approaches to successful delivery of electronic insurance services, as demonstrated by Tesco. However, service providers should recognize the thin line between a very upbeat or lively look that might give an immature impression and a "refreshing but still matter-of-fact" approach in developing the future electronic insurance services.

Third, small things matter. In environments with relatively large amounts of information necessary and available, clear, visible paths that enhance the access to information are crucial. However, through small details in web site design, consumers can easily get confused or lost, or might not be able to retrieve the information they need, at all. For example, in case of Esure some test persons that originally ranked Esure as best company became confused during the task phase when new information always opened in separate windows, which lead to a more negative evaluation for the company. In this case, Esure, the company

with originally the clearest design still managed to confuse its users through a detail, which could have been avoided.

The change in opinions after the students had in fact used the electronic services was one of the most interesting findings of our study, and one of the key themes of this paper. The user's perceptions from browsing the web site or actually performing tasks show a clear difference between superficial ease-of-use and real usability.

Finally, as already pointed out the results clearly indicate that insurance business does not necessarily have to be characterized by complexity and conservativeness. Insurance service can also be offered by following a different kind of logic based on simplicity and easy-to-use as, especially, Tesco, with its roots in the retailing business has proven.

Traditional insurance companies can learn their lessons from non-traditional insurance providers, such as Tesco, and these new competitors have the potential to become a threat to the traditional insurance business. In the light of previous research [20] and this study, we propose developing the electronic insurance service concept by benchmarking the traditional insurance companies with the non-traditional ones. This might also foster the insurance industry's understanding of how to make customers more committed to using electronic insurance services.

Table 1 Critical episodes and evaluation parameters after the browsing phase but before the task execution phase

Company	Criteria	Critical Episodes
Prudential	Content	the site was extensive, a lot of information and functions
	Appearance	matter-of-fact and conservative looking layout, trustworthy, caring
	Navigation	clear, moving around is logical and it is easy to go back to the previous screen
	Interactivity	good calculators on the pages; the "quick search" is good
	Assistance	the contact information is displayed well
Esure	Content	there is right amount of text so that you feel you can read it through
	Appearance	it didn't feel at all like insurance business, the pictures were funny
	Navigation	start page is very clear and you surely find the information you want to find
	Interactivity	the calculators and other tools are well-defined and comprehensible
	Assistance	there is advice available if needed
Tesco	Content	the product supply of Tesco is fairly good
	Appearance	the animated pictures decrease the credibility and trustworthiness
	Navigation	the pages are easy to use and I didn't get lost once
	Interactivity	there is no sitemap or quick search on the start page
	Assistance	if you have any questions, there is advice available

Table 2 Critical episodes and evaluation parameters after the task execution phase

Company	Criteria	Critical Episodes
Prudential	Content	pages are rather unclear because there is an incredible amount of different information
	Appearance	matter-of-fact and conservative looking layout, maybe a bit boring
	Navigation	menus were not clear and visible enough, which makes it hard to move on the pages
	Interactivity	the calculator could work just as well without your personal contact information
	Assistance	the questions which begin the product section are quite horrifying but help is available
Esure	Content	easy to open the headlines but from there on the information was scarce
	Appearance	it opened my eyes that insurance doesn't have to be stiff to make a good impression
	Navigation	I can only move back and forth in filling out information but not get to general menus
	Interactivity	the suitcases on the upper bar let you how close to the end you are
	Assistance	I would call to make sure, because my case is maybe a special case
Tesco	Content	there is sufficient information on the products
	Appearance	modern, up-to-date, new and fresh; important how to present things visually on the net
	Navigation	easy to move on the pages and I didn't get lost, the "quick search" is very practical
	Interactivity	they make it easier for the customer to reach a decision by offering calculators
	Assistance	I would call to make sure the sales representative calculates the same price as I did

Using GIS and CRM to Develop Intermediary Portal E-Business Model: The Case of Automobile Industry

Lihua Zhao
School of Marketing
The university of New South Wales
Sydney, Australia
Email: Lihua_zhao@unsw.edu.au

Abstract: As Internet-based and other virtual technologies are being used more and more for procurement, supply chain management, product development, customer relations, and other business functions, and as they are proving to be efficacious, e-business has undoubtedly become an integral element in the business and engineering strategies of many automakers and suppliers. What e-business can provide to an automotive cooperation has been well stated for improving product quality, reducing costs, and shortening time-to-market cycles.

In this paper, Renault Australia is used as an example of where the automobile industry is currently positioned in relation to E-Business. Online WebGIS-based Marketing Support System, developed as a portal e-business model, is designed to assist information and knowledge exchange between the market analysis business and decision makers (and sales people) in auto industry. Incorporating marketing information gives rise to a better understanding of the potential of particular market areas or target markets, and helps identify the strengths and weaknesses of the competition in particular market areas or among particular target market segments. Such market analysis strategies obviously provide competitive advantages. Sharing information and obtaining market analysis outcomes through the Web will provide business decision makers with up to date information and knowledge. This solution will not only reduce costs for business planning, but also help to avoid the cost of wrong decisions.

Keywords: E-Business models, GIS, CRM.

I. Introduction

In the automotive industry, retail dealers are independently owned and have a quasi-franchise agreement with vehicle local manufactures or distributors for imported cars. This structure has been in place in most western countries since the 1920s. However, increasing competition and wide adoption of e-business technologies have, recently, challenged the traditional automobile retailing and marketing. Most automobile firms have conducted the transformation to e-business using Web technology.

What e-business can provide to an automotive cooperation has been well stated for improving product

quality, reducing costs, and shortening time-to-market cycles [5]. As Internet-based and other virtual technologies are being used more and more for procurement, supply chain management, product development, customer relations, and other business functions, and as they are proving to be efficacious, e-business has undoubtedly become an integral element in the business and engineering strategies of many automakers and suppliers. Although the automotive industry has comparatively slower e-business progress than other industries, both survey and research have suggested that e-business is becoming and will become more critical in the near future for many automotive companies [5], [10].

In order to meet these challenges most automobile firms have created an integrated and cross-functional e-Business structure, comprising Internet-related activities in the four e-Business domains (B2C, B2B, B2E and e-vehicle). Currently, most automobile firms, such as Renault, Ford and Toyota, have their well designed web sites which provide a good interface with potential customers and aim mainly at marketing their products, reducing operational cost, and managing value chain. However, few opportunities have been provided to potential customers to order vehicles on line. This direct linkage with customers is rarely available at present, however, it will be an essential feature of e-Business for the automobile industry in the next few years. Aligned with this e-business opportunity, managing customer relationship and gaining market intelligent information can be valuable business opportunities as well. These opportunities could be enhanced by using GIS and CRM technologies and implementing atomic e-business models.

In this paper, Renault's e-business suite is analyzed, using atomic e-business models proposed by Weill & Vitale [11], to highlight the current e-business value to Renault and additional e-opportunities.

II. The Current E-Business Strategies and Suites in Automobile Industry

Different automobile corporations have their own different e-business development strategy; however, in essence, they have similar e-business offerings at current stage. The following cases of Renault and Ford demonstrate these similarities.

In February 2000, Renault announced the launch of its E-business Program and the expansion of its electronic-commerce activities [7], [8]. The goal of the e-business program is to develop a comprehensive Renault e-commerce

offering. The program focuses on four areas:

- business-to-consumer;
- business-to-business;
- e-vehicles (production of “communicating” vehicles);
- business-to-employee

“From the start Renault was looking to transform its business processes, both internally towards the company’s employees, and externally towards dealers and consumers on the one hand, and suppliers on the other” [2]. Currently, e-business development is playing a key role in Renault’s B2B business activities, and the B2E area as well. For the area of B2C, “this site (main website) enables end customers to browse the range of models, ask questions, and even configure their own individualized car. From there, they can contact a dealer directly either online or by email.” Although this system cannot provide a real online transaction, the dealers have the prospect of receiving valuable and highly qualified leads. “Not only did this promote contacts between end-customers and dealers, it also shortened the sales cycle for dealers, thus freeing up resources for additional sales,” explains Thierry Moreau, Director B2C. Renault is constantly looking for new opportunities. Some offer immediate promise of success such as the transformation of B2E, the introduction of supplier services, and the improvements to existing B2C projects. Some have a more long-term perspective such as the e-vehicle project comprising online services in the vehicles [8].

Meanwhile, Ford, since the fall of 1999, has been working on an e-business strategy that will link the dealer and the customer as well as the engineering and manufacturing functions to allow a vehicle to be custom-built through the Internet, the so called “order-to-delivery”, which is similar to the Dell model. Ford’s e-business vice president, described Ford’s plan to rebuild itself as a move to “consumercentric” from “dealercentric,” and stated that Ford would transform itself from being a “manufacturer to dealers” into a “marketer to consumers.” But the move is slow, Forrester Research [4], based in Cambridge, Mass., estimates that only about 1 percent of B2C trade were conducted through online marketplaces in 2000. There were many obstacles in Ford’s path. Eventually, Ford has shifted its focus to the B2B model, while keeping the vision on B2C implementation [3], [5].

Based on the e-business development strategies, e-business technology has supported each automobile firm’s e-business suite with easy to use interface, well organized front page as single point of contact for e-business customers to conduct activities related to their purchase and service process such as, products display, online enquiry and newsletters for managing customer relationship, etc. The value of these e-business suites offered can be analyzed using Atomic e-business model framework proposed by Weill & Vitale [11].

For example, Renault’s front web page

(www.renault.com) contains web links to the web sites of Renault in different countries (such as www.renault.com.au, www.renault.co.uk), and links for different services, for example rental of Renault cars in Europe (www.renaulteurodrive.com.au). In this front page model, communication with customers quickly moves to the business unit in different region or different business type. Creating this umbrella web page as a front page has coined the front page whole-of-enterprise model suggested by Weill & Vitale. Renault presents an array of products, services, and solutions to all important parts related to one’s Automobile purchase life (e.g., products category information, test-drive, finding a nearby location to purchase and/or have services). This integrated implementation has a consolidated customer interface. The customer is then able to navigate wide-range offerings to find suitable products and services. All these suggest the integrated whole-of-enterprise atomic business model has been implemented. The value proposition of the models is to increase customer intimacy and service level, and consolidate the brand recognition. The revenue could be generated from the repeated purchases of loyal customer, or out-of-mouth recommendation to new customers, although there is no tangible and quantitative revenue generated directly from using the web sites.

Renault’s B2B e-business strategy is the same as the concept of Value Chain [9] – the set of activities through which a product or service is created and delivered to customers. Renault operates simultaneously both in the physical and virtual worlds. In the physical world, Renault products and services move along the physical value chain from Renault manufacturers/distributor to dealers to customers. In the parallel virtual world information about members (dealers and suppliers) of the physical value chain is gathered, synthesized, and distributed along the virtual value chain. Based on the *Value net integrator model* displayed in Weill & Vitale [11], Renault, as a value net integrator, receives and sends information to all other players (dealers and suppliers), manages relationships with customers and all major dealers and suppliers via using its trusted brand recognized at all places in the value chain. The Net integrator model adds value by means of bidirectional communication, ease connectivity – all at making business activities more cost effective and electronic data interchange. For example, Renault might use information about consumer to increase profit margin by meeting customer need; by using information about suppliers, Renault can reduce cost by cutting inventories. The value proposition provides to increase brand awareness and improve relations with all dealers and suppliers in the value chain. Furthermore, the virtual electronic procurement lowers telecommunication costs, enables effective reduction of administrative cost.

Each automobile firm uses a content management solution (Content Provider) to support the management, distribution and delivery of its branded vehicle products content, that is distributed through its distributors and

dealers in different nations and regions, including the products catalogues and marketing brochures via electronic and physical distribution. The revenue could be the benefit to dealers by directly reducing cost of content production and distribution, alternatively, by providing all professional information to relevant Renault products without direct benefit, the company can avoid at least some portion of the expenses for marketing its products.

Applying Virtual Community model to host virtual space would help to find and retain members who share common interest regarding branded products and services. The activity in virtual community can be in multiple formats, for example, chatting room for customers to ask questions, FAQ for searching answers to common questions, e-learning and e-training regarding the products and offering, newsletters sent via email list, etc. This e-business model can increase the company competencies by discovering customer needs and understanding the value of customers; building an intimacy sense of community, and building loyalty to the community by providing attractive content. Renault could not generate profit from the virtual community directly, but consider it as a cost of brand building and loyalty maintenance.

In summary, using Weill & Vitale's framework, the most commonly used atomic e-business models in Automobile industry are Content Provider, Value Net Generator, Virtual Community, and Whole of Enterprise/Government, however, still more e-business opportunities could be further developed and incorporated into their business models by using Direct to Customer and Intermediary portals models.

III. Additional E-business Opportunities in Automobile Industry

III.1 Direct-to-Customer

At present, most automobile firms do not sell vehicles online directly to the end customers. Implementing online sales provide business opportunity for Renault to realize its "New Distribution" project, which aims at made-to-order production chain. These represent a dramatic change in the automotive industry. Building Made-to-order, instead of for dealers' showroom, Turban *et al* [10] estimated that tens of billions of dollars annually could be saved just from inventory reduction. Online sale has been predicted to be one of the main sale channels after 2007 [5], [10].

Adopting the direct-to-customer model, automobile firms will gain leverage from three sources – relationship, data, and transaction – relative to their current place-based business. Owning the customer relationship, will provide Renault powerful position and influence where the customer looks to the relationship holder for trust and brand reinforcement. Owning customer data will provide the potential to develop powerful insight into its customers' needs and desires, therefore help products development and increase competitive competencies. Owning the transactions

will provide the company more profitable revenue not only in sales of new products, but also with service revenue.

The main sources of revenue will be attained by gaining higher margins of products sales compared by means of cutting steps out of the distribution dealers and reducing the commission to the dealerships. More importantly, having relationship, data and transaction could improve Customer Relationship Management (CRM), the indirect value can be generated from identifying opportunities for increased sales or product offerings, therefore enhance the competitive capability by improving their intelligent, branded e-market analysis.

III.2 Using GIS and CRM to Develop Intermediary Portal E-business Model

Portal, under the general definition of "access point for aggregated information", is continuing to expand, and will be a feature of e-business for some time [11]. The ability to customize a portal allow users to modify the content and format of the information provide by their portal. Applying Portal (Intermediary) atomic e-business model, automobile incorporations can take advantage of rich information, collect, maintain, and share market intelligence with business partners. For example, in the case proposed in this paper, market analysis displayed on maps in appendices can be provided by a e-business portal which is supported by a WebGIS-based Marketing Support Systems. Such e-business portal is designed to assist information and knowledge exchange between the market analysis business and decision makers (and sales people) in auto industry.

A WebGIS-based Marketing Support System uses Geographical Information System (GIS) technology as the backbone. GIS is a digital mapping and spatial analysis system capable of assembling, storing, manipulating and displaying geographically referenced information. The power of a GIS in business decision support areas is its ability to manage spatial data from a number of sources, to display spatial data, and provide spatial analysis modelling [1]. A Web GIS platform provides a powerful online data process and display system. However, much of its usage for online e-commerce has been to explore initial ways of querying and acquiring geo-referenced data or images (e.g., online maps for tourists). Our innovation is to integrate CRM (Customer Relationship Management) techniques into a Web GIS platform, providing dynamic database management and market analysis.

There are three distinct advantages in adopting GIS and CRM technologies in market research. First is the ability to overcome the weakness embedded within each system by integrating GIS capabilities with the power of CRM. Second is the ability to use effectively data from different sources for market analysis, such as Census. Third is the advantage for users of being able to visualise spatial data in different forms; for example, to visualise the spatial distribution of data on maps prior to further market analysis. In this way the application of GIS and CRM in market analysis can be seen as decision support tools for reaching a desired solution, and

therefore could be used widely for solving practical marketing problems related to retail chain network planning based on demographic analysis, marketing positioning, and consumer targeting.

Incorporating marketing information gives rise to a better understanding of the potential of particular market areas or target markets, and helps identify the strengths and weaknesses of the competition in particular market areas or among particular target market segments. Such market analysis strategies obviously provide competitive advantages. Sharing Information and obtaining market analysis outcomes through the Web will provide business decision makers with up to date information and knowledge. This solution will not only reduce costs for business planning, but will also help to avoid the cost of wrong decisions.

Using the Web GIS-based DSS will help decision makers undertake automobile market segmentation to create a new vision of how particular markets are structured and operate, and will uncover the needs and wants of their targeted segments therein. Therefore, it is expected that use of the online system to conduct the B2B e-commerce will improve business planning processes in the automobile industry in the following ways:

- Better understanding of consumer needs in each of the segments, resulting in the identification of new marketing opportunities.
- Develop a market and/or advertising campaign to attract business in a particular market area or among a target market. Budget marketing expenses more effectively, according to needs and the likely return from each segment.
- Use precision marketing approaches. The company can make finer adjustments to the product and service offerings and to the marketing appeals used for each segment.
- Use specialist knowledge to enable the company to dominate particular segments and gain competitive advantage.
- Assist local dealerships with their understanding of the right mix of quantities for each type of vehicle. The product assortment can be more precisely defined to reflect differences between customer needs.

Developing the Web GIS-based DSS as an e-commerce solution could address broad benefit to e-business development from three aspects: .

Firstly, it uses existing Technologies in an innovative way. There is clear support for the development and use of GIS and Data Mining techniques for database marketing linked to company CRM systems [6]. However, while there is the potential for integrating these techniques within wider business process applications, this paper aims at bringing the benefit of information and knowledge exchange through B2B e-commerce to a diverse range of targeted automobile businesses, allowing decision makers to interact more efficiently with the information and the knowledge provided from market analysis and reduce the costs involved through

online solutions. The business model proposed ought to identify and overcome the barriers to e-commerce use by creating a platform for business growth and met the needs of automobile Industry.

Secondly, it leads to increased industry competitiveness. Use of the proposed online systems could help firms to generate revenue (through a better understanding of actual and potential market demand) and/or reduce costs (through efficiency gains). The proposed system uses maps and graphics to help communicate these results, enabling a distributor / dealership to see at a glance their current and target market shares (See Maps in Appendices). These results can be used by either an existing auto dealer or manufacturer, or by someone thinking of opening an auto dealership and trying to select the right geography and target market. All these courses of action would be expected to lead to increased industry competitiveness. The results of sales performance analysis in different geographical regions also provide relevant information to distributors/dealers, who can maintain an improved supply mix for possible demands of different brands and amount of sales in their business regions.

Thirdly, it delivers broad benefits e.g. reduced costs, improved information flows and efficient business processing. The cost of using market analysis information and knowledge in the manner proposed here is affordable for auto businesses when compared to the cost of employing or contracting a specialist. As the project will demonstrate, through the application of information technologies and e-commerce, small business can be helped to be successful and overcome their problem of inadequate market knowledge. Sharing Information and obtaining market analysis outcomes through the Web will provide business decision makers with up to date information and knowledge. This solution will not only reduce costs for business planning, but will also help to avoid the cost of wrong decisions for new entrants. The Information flow delivered to business decision makers could be improved through the advanced analysis technologies, analysis dimensions and time frames. Figure 1 illustrates some of these information flows, for example:

Information could be delivered to DMs using spatial and analysis technologies

- Overall analysis of automobile industry
- Sales by brand, time, and postcode
- Advertising expenditure by test drive campaigns
- Top sellers by postcode
- Difference analysis (by brand/time)
- Pump in / pump out analysis for a dealership's PMA
- Customer locations in postcode / CCD
- Demographic distributions in postcode / CCD
- Market potential within 20 minutes zones around service station, etc
- Information could be provided through different Analysis Dimensions:
- Time: current & historical market, future forecast

- Geographical Boundaries: (Market share in different Postcodes areas)
- Location Data: (Customer Locations)
- Demographics: Sex, Age, Income, Occupations, Number of Vehicles per Household, etc.
- Information for User-defined analysis scheme
- for example: combining different dimensions and/or VFACTS defined vehicle sales:
- Competitors market penetration for a model
- Selling patterns of one or many models

Segments and components analysis at a time frame for postcode areas

IV. Conclusion and Recommendations

Automobile manufacturers/distributors have been actively engaging in the transformation of the business using E-business technology. Renault's e-business case, based on the information from its Web sites, has shown that the company has gained the benefit and competitive advantage by adopting the following current e-business strategies:

1. establish online single point of contact for the e-business customers
2. establish e procurement system with trading partners
3. fully integrate the e commerce systems with its normal financial systems
4. establish customer information database from online information

Although direct sales of automobile products via internet to customer is still in the initiative stage. In the future, as business endeavours to develop e-business as the normal means of trading with customers and other businesses, there will be large cost efficiencies gained by the process of business reengineering. Examples of efficiencies will be standard product catalogues, simple online shopping facilities and direct linkages with customers.

In general, despite automakers desire to build relationships with Internet consumers, it will take time to do so because of existing dealers place distribution strategies, and the situation that dealers may be reluctant to espouse online purchasing for various reasons, including a lack of recognition for the need to commit to the channel and a fear

that the channel conflict.

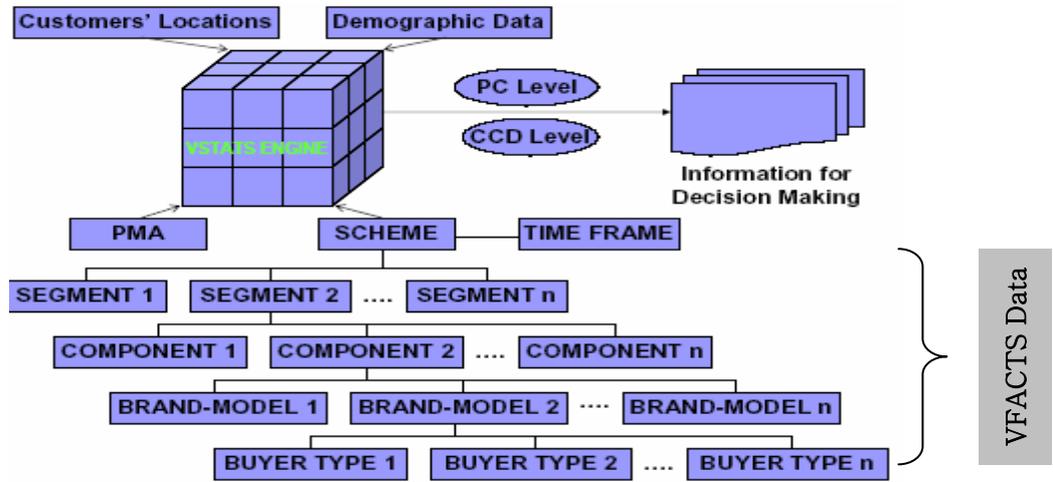

Successfully migrating to a click-and-mortar business model has been suggested as a major change, the direct-to-customer model will affect every aspect of a firm including channel and dealership management, customer segmentation, organizational form, incentives, skills, IT infrastructure, culture change, and a convergence of business processes, workflows, infrastructure, and data assets.

Furthermore, while there is the potential for integrating techniques within wider e-business process applications, this paper has argued on bringing the benefit of information and knowledge exchange through B2B portal e-commerce model to a diverse range of targeted automobile businesses, allowing decision makers to interact more efficiently with the information and the knowledge provided from market analysis and reduce the costs involved through online solutions. The business model proposed ought to identify and overcome the barriers to e-commerce use by creating a platform for business growth and met the needs of automobile Industry.

Virtual Process and Data Flow: A Case Study

Nasrin Rahmati, Pankaj Periwal
Clayton School of Information Technology, Monash University
nasrin.rahmati@infotech.monash.edu.au

Abstract: The competitive global business has encouraged many organizations to save cost by moving to virtual processes. Virtual processes outsourced are completed by distributed teams in the context of matrix organizations. Projects are run by teams which are constantly changing in structure according to customer demands. Given the rapid expansion of business process outsourcing, it is important to understand more about the operations of these companies and this has not been very visible. This paper is a report on a case study of one virtual process completed by a vendor organization for a client company. The focus of the study is on the changes in the data during the process completion. The study examined the teams, their functions, their support structure and the outcome of the project. The study provides visibility of virtual process outsourced by the client organization.

I. Introduction

While Enterprise Systems were behind the move towards process oriented organization, outsourcing was the force behind a new type of organizational move towards virtual processes. 'The pyramid' - that is, the form for organization where strata of executives direct permanent divisions consisting of specialists fulfilling specific purposes is replaced by combination of different distributed teams working on different organizational processes. These are organizations built from projects, projects run by teams, which are constantly changing in structure according to customer demands. The driving force is that this type of organization as a rule cuts costs from the client's (the company outsourcing certain parts of its activities) point of view, and it also means that the work outsourced can be handled quicker and more precisely by the project oriented company towards the customer [1].

Expert knowledge is focused, and both the project oriented company and the company outsourcing parts of its business can concentrate on accumulating knowledge and focusing on their core lines of business. Project-oriented organizations have a linear structure at the top so that after the completion of a project the main team members refer to the linear structure to be provided with a new project for which they have to form a new team. The present study examines an outsourced business process which is a telemarketing project. The study examines a typical project, the team members, dataflow, reporting, and the outcome. The study examines how projects are completed and how

distributed team structure provides the required flexibility to complete a project on time and on budget. In the organization of our case study projects are called campaigns.

Primary data consist of interviews with people in key positions in the companies, notes from visits and information material used inside these companies. Secondary data have been collected from articles, books and the Internet.

The recent advances in Information Technology have enabled some of these project/matrix organizations to work with virtual teams. A successful example of cooperation between a local authority and a call centre would be the information service CALLskoga [2]. The information service, and the form for cooperation, is an example of a new approach, aiming to create a positive helix, spreading and in that way showing new possibilities and concretizing the use of new information technology for the town inhabitants.

II. Business Process Outsourcing

There are many reasons why companies outsource. It has been suggested that only those functions classified as non-core activities are outsourced. Outsourcing should be considered when certain support functions can be completed faster, cheaper, or better by an outside organization. It is believed that outside vendors possess economies of scale and technical expertise to provide these services more efficiently than internal departments. This is especially true about those functions for which there is an unclear value. Some of these functions are actually considered as overhead, or an essential cost but one to be minimized [3]; [4]; [5]. Many of these reasons are unique to specific firms and industries. Lankford and Parsa [3] believe that in the current environment of right-sizing and a focus on core business activities, companies can no longer assume that organizational services must be provided and managed internally. Managers relate outsourcing decisions to the organization's competitive business strategy. Companies have outsourced traditionally accepted non-core business processes (functions such as cleaning, catering, transport and facilities management) for decades to generate savings and to allow greater focus on core processes. Recent advances in enterprise systems were the force behind the use of 'best practice' in re-defining the organizations business processes. The combination of cost and efficiency consideration is motivating the organizations to follow the business model of retaining what's core and outsourcing processes that are considered to be non-critical [6].

Outsourcing has moved today to other areas such as

finance, HR, manufacturing and even call centres. Outsourcing non-critical activities saves a lot of management time which can actually be diverted to core business activities. Outsourcing is related to efficiency as well. Senior managers feel that even if they pay more for a task by outsourcing it, they know that the job will be done on time and also in a predictable fashion [3].

The economic downturn of the early part of this decade has forced the companies to try to reduce the cost at non-core processes. The best way to decrease the cost of such processes is to profit from the considerable wage discrepancy around the world. There are destinations such as India, China, Philippines, and Malaysia with highly qualified low-cost labour [7].

The last decade witnessed a rapid decrease in the cost of telecommunications due to various factors such as widespread use of Internet and the dramatic improvements in the supporting technologies. This in turn enabled the companies to re-define their existing business processes and execute whole or part of the processes in low-cost destinations [7], [8].

The potential for lower labour cost and greater efficiency are two important factors as companies consider Business Process Outsourcing (BPO). One of those two factors alone isn't enough to create sustainable value because skilled labour and technology are the most important cornerstones of any business process and both must be optimized to create lasting value and maintain a competitive edge. Industry analyst Gartner predicted BPO to grow to more than \$173 billion by 2007 [8].

III. Call Centre - Telemarketing

In call centre terminology, "outsourcing refers to the process of having all call centre activities handled by an outside organization or a teleservice outsourcer" [9].

Call centre are one of the biggest areas which businesses seek to outsource. In fact companies in the west have now started off shoring their call centres to countries like India, Philippines and South Africa. The reason for this is that most nationals in these countries speak English. The labour available in these countries is also comparatively less expensive. However we should be aware that outsourcing and offshoring would not have been possible if it were not for the advances in technology that have occurred over the past many years. The introduction of Wide Area Telephone Service (WATS) by AT&T in 1961 gave rise to toll free calling. The advances in telecommunications with cellular, wireless and satellite technologies have also boosted services. This has been further augmented by the Internet and the World Wide Web and the Computer Telephone Integration (CTI). This has also led many call centres to evolve to contact centres where basic telephone services are complemented by services in other media such as e-mail, fax, webpages, or chat [8].

Du Toit [9] has outlined many reasons why call centers are outsourced. The first of these is cost savings for the

company that outsources its call centre activities. Outsourcing can lead to lower costs due to economies of scale for the client company as the vendor is usually experienced and has the technology and resources that would usually be very expensive for the client to acquire.

Secondly, outsourcing results in reduced risks for the client. In many cases these risks are shared for the client as a result of consultation with an expert vendor.

The third reason outlined is scalability and flexibility to the client. Depending on the amount of work that the client has at a particular moment, casual staff can be taken on or laid off by the vendor as required.

Lastly, outsourcing allows process re-engineering and implementation of best practices benchmarked against similar operations worldwide. As many call centre outsourcers tend to utilize the most advanced technology available to stay efficient, the client gets access to new systems and applications which may otherwise have been unaffordable.

Telemarketing is one of the largest outsourced services in the industry today. According to Spiller and Baier, "Telemarketing is defined as a medium that uses sophisticated telecommunications and information systems combined with personal selling and servicing skills to help companies keep in close contact with present and potential customers, increase sales, and enhance business productivity."

Telemarketing is a direct marketing tool which allows organizations to reach their customers in a personalized manner. Telemarketing allows for personalized selling without the face-to-face aspect. Telemarketing also is the most effective medium of direct marketing. In the USA, telephone marketing sales for both business and final customers accounted for \$764.9 billion in 2003 and these figures have risen tremendously.

Telemarketing has the advantage of providing immediate feedback and is also very productive. More customers can be reached over the telephone in a given period of time than by having to send a sales representative to each individual customer. The telemarketing industry has one of the highest labour turnarounds because the nature of the job involves frequent rejection and intense personal interaction.

Technical Issues

Telemarketing can be classified as **inbound**, where customers call to place an order, to request for more information, or for customer service, or **outbound**, where a firm calls customers to offer a product or service.

Outbound calls are referred to as proactive telemarketing. The company wanting to sell a product or offer information about a product initiates the call. Outbound calling requires more experienced and well-trained employees as compared to inbound calls.

Outbound calls can further be classified as cold calls and warm calls. Cold calls are made when there is no existing relationship with, or recognition of, the direct marketer [9]. Warm calls on the other hand are made when there is an

existing relationship between the prospect and the direct marketer.

Major technologies have been developed to support the telemarketing industry. Apart from the ones outlined above, there are two more systems that are very critical. These are the Dialed Number Identification System (DNIS) and Automated Numbering System (ANI). The DNIS identifies for the receiver what number was dialed by the caller. This may help organizations to keep track of the number of calls that are dialed to a particular number and thus companies can forecast the number of employees that are needed to handle call on that line. The ANI identifies the telephone number of the person calling. This number can then be matched against a name in the company's database so that all details of the person calling can be populated when an agent actually speaks to the person calling. This can actually save a lot of money for the organization in terms of the amount of time an agent spends speaking to a single customer.

Another very important technology for outbound calling is the predictive dialer. The predictive dialer is a computer that actually dials calls and connects this call to an agent who is free only if a live person answers the call on the other side. It is considered to be predictive because it anticipates when an agent will become available, and when the next human response will be detected [10]. The predictive dialer greatly improves efficiency by maximizing the amount of time agents spend speaking to customers.

A well planned telemarketing program requires that the telephone operators are well trained and also they are provided with well designed scripts. "A telephone script is a call guide to assist the telephone operator in communicating effectively with the prospect or customer" [9].

It is suggested that in Business Process Outsourcing the person or the team who manages the day-to-day relationship with the outsourcer plays a major role. This person or team needs to understand the companies own strategies as well as how the outsourcer operates and would be the source of all communication between the outsourcer and the organization [11].

IV. This Study

Outsourcing literature in Information Systems does not follow any single research question or a single method or theory. It has been suggested that from an academic perspective, the practice of outsourcing IS functions is a practitioner-driven phenomenon [5]. This is illustrated by the fact that the first research papers on the subject did not appear until 1992, over three years after Kodak's landmark decision to outsource its IS functions [12].

The present study is an interpretive study. These are studies that seek to understand the deeper structure of a phenomenon through different approaches such as trying to understand the meaning an act has for the actor himself, trying to understand the observed world reflected by written or spoken text, or trying to understand the meanings that a

particular behavior signifies to the subjects [13]. According to Orlikowski and Baroudi [14], in interpretive studies researchers adopt a non-deterministic perspective where the intent of the research is to increase understanding of the phenomenon, and the phenomenon of interest is studied in its natural setting from the perspective of the participants. For that purpose, in interpretive research often case studies and action research are used. The aim of such research is to get close to research subject and explore its detailed background and life-history [15].

Case studies typically combine data collection methods such as archives, interviews, questionnaires, and observations [16]. Case studies are frequently used to explore a problem that is not well defined or understood [17]. This method helped us collect information on a particular campaign in a particular setting that could not be otherwise collected.

The project (campaign) was divided into different sections. Different groups of people concerned with the campaign were interviewed. The study used interviews in combination with observation of the teams involved in the operations of a selected BPO in the outsourcer settings. Interviews, observations, and archival sources are particularly common in case study data collection since they provide a stronger substantiation of constructs [16]. The observation of the particular business process involved taking field notes on the role of different teams and the changes to the original data provided by the client organization.

This study was conducted over a period of five months. Most case studies are conducted over a fairly short period of time—usually less than a year, although it is possible to conduct a case study over a much longer period [17].

The Project (Campaign)

The present study focuses on the changes in the data through one outsourced project to a vendor. The selected vendor organization is a medium sized organization with a combination of temporary and continuing staff of about 3000. They are located in three locations in South East Asia. They offer services from initiating and receiving the end customers' calls, to managing the entire back office and support services common to most organisations. In view of their particular organizational structure they can tailor solutions to suit their clients' needs. Each provided service is flexible and can be used independently or in association with their other offerings. Figure 1 shows the basic structure of the selected organization pointing out the support structure available to different virtual processes run by this organization. For the purpose of this study outbound telesales campaign was selected as the outsourced process.

A telemarketing campaign is a project. The external party is the client who has outsourced the telemarketing campaign. The internal team members are the divided into two groups. Those who are working exclusively on this campaign, we call them *campaign members* and those who provide services to support all running campaigns, we call

these *service members*. At the beginning of the campaign the campaign manager would be provided with Business Requirement Specifications (BRS). The BRS would specify the KPIs, the number of hours a campaign needs to function, number of staff and also the criteria for QA involvement. The BRS would also give an indication about the script.

The data would be reviewed by the Implementation Manager so that s/he can arrange for the right set-up before the campaign is up and running.

At each point of time there are several campaigns running simultaneously in the telemarketing company. The number of outbound telesales is approximately 10 separate campaigns with their own campaign. The following are the campaign members:

The Teleoperators: At the bottom of the ladder and have to meet some standard KPIs for each campaign. **KPI** stands for Key Performance Indicators are set by the client to be achieved during the course of the contractual period. These are directly related to agent productivity. Clients prior to venturing into a partnership with an outsourcer build their own business models assuming the level of productivity required to make the venture viable.

The Group Leaders: each campaign has several group leaders who are usually in charge of five to six teleoperators.

The Campaign Manager: Each campaign has a manager who has usually worked as a group leader for several years.

The following are the *service members* who support all running campaigns.

The Quality Assurance group: These are the group who are in charge of checking the quality of any agreement made on the phone before the positive results are considered as a success.

The Information Technology Services: The unit is divided into different sections. These include Business Analysts, Infrastructure, Voice (outbounding diallers, enterprise routing and voice portals) and the CRM Application.

For a specific campaign, the customer data (records such as their phone numbers, name, the product type and age) is provided by the client company. This data is sometimes sent from a washing agency to ensure that all the data being sent is correct and that things have been matched up. Washing means checking the quality of the data before they actually dial the number.

IT would do all the validations on the software to ensure that the flow of the scripts and data is all correct. There are two type of software used here. The first one is CRM software and the second one is the software which is directly connected to diallers. The data provided is then stored in two databases, the CRM and the database connected to diallers. In the database which is connected to diallers, we store information like the phone number, the customer ID and the campaign ID. The project company has a unique code for each campaign and customer for that campaign. In the CRM database all information about the customer including call history is stored.

The data for a campaign is provided in an RTF file. The project company then provides a campaign number for that list and the script for CRM is configured. Also a customer ID specific to the project company is provided for each customer in the database. The script in the CRM software is dynamic as there are many script variables which get loaded based on information in the its database. The client provides the script which is then formatted by QA. IT then converts the script to the right file format to be uploaded into the software.

The project company through IT has access to two kinds of diallers. These are Predictive and the Progressive dialler. The predictive dialler is the one most often used and it results in higher productivity. The trade off with predictive diallers is that it can result in drop calls. The progressive dialler is not used very often. With this, one dial is made for every agent waiting. It may not result in an efficient hit rate. The CRM software is independent of diallers. The diallers use their own specific algorithms to dial. The speed of the diallers can be altered based on the time of the day or the requirements of the campaign. The dialler usually throws a call to an agent who is free when it makes a hit. The call outcome is reflected both in the CRM software and the database connected to diallers. The CRM software is updated based on the diallers' database call outcome or the diallers' database code for the call disposition.

Analysts would be concerned with the scripts and how script variables are loaded on the software. They are also concerned with productivity and KPIs. They support the campaign manager achieve the desired KPIs. They make sure that the scripts are ready for a campaign on time. In addition they help campaign manager by controlling factors like wait time of agents, their talk times and the wrap times. Analysts are also concerned with resource planning and forecasting. They are more concerned with the results of the campaign.

The CRM database contains all information about the customer. The diallers' database is concerned with the call outcome of each call dialled.

Training Services: We noticed that the training team is in charge of training members of different campaigns. They obtain all the information required for training different campaign members. They train different levels differently. There are some basic training workshops for the campaign managers, group leaders and operators which are conducted in separate sessions. They divide the training workshops into two sections, the sale section which they cover and the product section that in some cases they conduct the workshop on the basis of the material provided by the client and in some particular situations the training is covered by the outsourcing organization themselves. There are several campaigns running simultaneously. This means that the training team are conducting workshops for different teams and different levels in each team all the time. In training sessions of the group leaders and the training sessions of the operators the specific information is provided by the campaign manager. This is on the basis of the expectations

of the client.

Quality Assurance: Quality Assurance (QA) team have two different functions. One is toward the client (the outsourcing organization) in terms of meeting the targets and the other is to ensure that the project organization abides by rules and regulations. This could be the Fair Trade Practices Act or the FSRA for financial products. QA is the team who ensures the Service Level Agreement entered with the client is met. From an organisational context, they make sure that the project organization obeys rules. From a campaign context, they make sure that the business follows client specific targets. It is interesting to note that QA is not really a legal team. They work on the presumption that scripts and expectations given by the client have been checked by a legal team. They document what the client expectations are.

It is important for QA team to have a right definition of the successful call for each campaign. The criteria are given to the QA team by the Campaign Manager who deals directly with the client. The criteria can be very specific to a campaign. Some of the criteria for a specific campaign may be relevant to the way the script is read by the operator, the number of rejections on one call, background noise, mistakes or incorrect or missing information, and that customer to be told s/he is being recorded.

QA's communication with the campaign manager is very interactive. In different campaigns, QA provide essential support for the campaign manager. QA would support campaign manager in areas such as recruitment process; rewards and recognition, hours of operation. In the particular project examined in this study QA team provided the campaign manager with support in: Call monitoring and making sure mistakes are corrected, Verifying or bouncing sales and then providing feedback on what went wrong, Direct feedback to operators on the campaign and performance reviews to address any problems.

Outcome – Reports: Once the call is considered to be successful, the result will be checked by QA team for quality and then sent to the client organization. The day after the successful call all the necessary documents regarding the sales will be sent for the customer by the client organization. The outcome for the project organization is updated database to be provided for the client organization upon request and different types of reports. When a call is successful, it gets documented in a system (in-house). The details that are stored here are information such as Customer ID, Customer Name, Name of operator who was responsible for the sale, Length of recording, Campaign ID, Bounce reason if any and QA comments if any.

Data Flow: The database is updated on the basis of the responses by the customers. The response to the calls made is sent as daily reports to exclude the name and details of the customers already purchased the product/service. This will avoid calling the same customer for the same product/service.

Operational: The extract of a successful call is sent to the client the day the sale has been made. The client is responsible for sending the policy document. Also the

Product Disclosure Statement (PDS) and Financial Services Guide (FSG) are sent to customers by the client.

There are two types of reports, external reports and internal reports. External reports are provided by the project organization for the client and internal reports are for the management of the operation inside the project organization.

External Reports: Reports to the client can be of different types:

- **Daily Activity Report:** This summarises sales, hours, dispositions (the result of the call), and productivity level on day in comparison to month or week.
- **CSP:** Every operator productivity level on a daily basis in comparison to their monthly results.
- **Age Summary:** This report is important in Financial Services. It would be used as a data mining tool to connect age with the number of successful calls. This will help the client company target the correct age group for their future campaigns.
- **Premium Levels and Card Types (specific to the project of this case study):** This report matches premium level to Card Type of the Customer. This is also used for data mining purposes. This will help the client to focus their future campaign target the right market segment.
- **Daily Extract:** This report contains data for sales of the day. It would contain information such as which customer signed and at what level and what price, who sold the cover, what time it was sold and the customer ID.
- **End of Campaign (EOC):** This would be accumulative data about the performance of the campaign. The call outcomes are summarized in the EOC.

Internal Reports: Internal reports are for people within the organisation and are usually less cosmetic. These reports are usually system generated. Internal reports can be intra-day, daily, weekly, monthly and end of campaign (EOC).

Figure 2 maps out different steps completed in each virtual process completed by this organization as a vendor organization.

V. Discussion

The study selected one outsourced process of a vendor organization with matrix organization and followed the dataflow through this particular process. These organizations are usually experienced in a particular business process and have the technology and resources that would usually be very expensive for the client to acquire. The vendor has a project oriented structure. The project oriented organization is ideal for this type of organization and in practice it saves their clients time and money. In most cases such as the project examined by this study permanent team members were acting as business analysts on behalf of their clients. The building block of these organizations are virtual teams who work on a particular campaign.

The vendor organization usually can work on a very low cost due to the economies of scale and particular characteristics of this type of organizational structure. The

lowest rank on the ladder of team members have a very standardised work. All the questions are coded. All the possible outcomes are coded too. This is a very standardized work. The calls are automatically dialed and then automatically directed to the operators. They do have all the questions and answers. Once the sales is made the result is checked by very standardised process by QA members and forwarded to the client. The cost is kept very low. The process is completely standardised. For each campaign the values of the parameters are changed according to the requirements of that particular campaign and by the end of the campaign all the right information have been forwarded to the customers by the client. The only remaining function would be to provide some additional information for the client to be used in their future campaigns.

The study documented a sample virtual process from the data provided by the client organization to the completed reports and the updated database sent for the client company. The next step would be to look at this whole process from a knowledge management point of view and to examine different concepts in such a virtual process such as data ownership and security.

GLOSSARY

- **Abandoned call** – A call that customer hangs up before even speaking to an agent.
- **Agent** – see TSR.
- **Calling List** – A table containing information regarding customers to be called.
- **Campaign** – An outsourced telemarketing venture for a specific client.
- **CM** – Campaign Manager. A person/s responsible for the day to day activities concerned with a campaign at the outsourcer.
- **Contact Penetration** – A KPI which sets the percentage of contacts to be achieved based on the number of records provided in a list.
- **CPH** – Contacts per hour. A KPI which sets what is the minimum number of contacts that an agent needs to make in an hour.
- **CTI** - Computer Telephone Integration. Technology which allows the telephone to be integrated with the computer.
- **Disposition** – A call outcome. After a call to a customer is finished with, the outcome of the call is saved in the form of predefined dispositions. Examples of dispositions would be Answering Machine, No Answer, Call Back, Sale, etc. The dispositions are set either by the predictive dialler or the agent with the help of conclusion codes.
- **Dropped call** – A call that is answered by the customer but cannot be answered due to agent unavailability.
- **EOC Reports** – End of campaign reports. These summarise all the activities during the course of the campaign and provide figures for the client who can compare them to the KPIs they have set.
- **Extract** – A record of a particular customer from the calling list.
- **FSG** – Financial Services Guide. A legal document which is mailed to a customer and contains information about all the parties involved in providing a financial product to the customer over the telephone. It has to be mailed to a customer before he/she can be contacted over the phone.
- **Hit Rate** – The contact to dialled rate.
- **IVR** - Interactive Voice Response. A computerised system that allows a telephone caller to select an option from a voice menu.
- **KPI** – Key Performance Indicators. The specific factors that the client sets its business partner to achieve during the course of the contractual period. These are directly related to agent productivity. Clients prior to venturing into a partnership with an outsourcer build their own business models assuming the level of productivity required to make the venture viable.
- **PDS** – Product Disclosure Statement. A legal document which has all description about a product being offered over the telephone including costs, eligibility, exclusions, etc. It has to be mailed to a customer before the customer is contacted by telephone.
- **Predictive Dialler** – A computerised systems which dials calls from a list and only forwards those calls it thinks to be a valid answer to an agent on the floor. If it cannot find an agent to forward the call to, it simply drops the call.
- **QA** – Quality Assurance. A department at the outsourcers end which is responsible for verifying the legality of recorded sales.
- **SPC** – Sales per contact. A KPI which sets what is the minimum percentage of sales an agent needs to achieve based on the number of contacts made.

$$SPC = (\text{Total number of sales} / \text{Total number of contacts}) * 100$$
- **SPH** – Sales per hour. A KPI which sets what is the minimum number of sales an agent needs to make per hour.
- **Telephone Script** – A call guide used to assist an agent to communicate effectively with a customer.
- **TL** – Team Leader. A person who manages a small group of agents and is responsible to see that agents belonging to his/ her team are meeting necessary KPIs.
- **TSR** – Telesales Representative. An agent who takes calls forwarded by the dialler and speaks to the customers

Abstract: Across Australia the pharmacy industry is undergoing major reform and re-structuring. Emerging technologies like e-pharmacies, new low cost players, pressures from supermarkets, doctors, consumers and politicians have changed the nature of this industry. Such pressures are causing the industry to unite, to draw all its component players together, and to deliver a new disruptive solution set that will likely radically change the status of competition. A service value network (SVN) framework is discussed as the likely scenario, and its major underlying dimensions are detailed. Such a SVN approach may eventually lead to better strategic alignment, higher industry performance (capabilities and delivery), greater value-adding solutions, increased customer satisfaction, and more competitive pricing.

Keywords: E-Business Models and Enterprise E-services Architectures, network, e-pharmacy.

I. Introduction

Recent research by the Siegel [33] at US Sloan's School of Management indicate that all players in an industry benefit from aggregation or sharing of information, ideas, and knowledge. They suggest a wealth of knowledge may be garnished by combining organizational expertise. Aggregation analysis delivers relationships with greater combined competitiveness. It was further posited that it is prudent for organizations, like the pharmacy industry, to consider their e-strategy, and to add aggregated information and knowledge capabilities into their competitive frameworks [33],[38]. This supports emerging new business models involving multiple aggregations like e-pharmacies, and the proposed concept of a service value network (SVN).

Emerging technologies often deliver disruptive solutions that may radically change the status of competition [5], [11]. For example, e-pharmacies, networked medical services, direct customer targeted solutions, fully integrated supply chains, logistics solutions, and other efficiencies constitute genuine threats to existing pharmacy industry business structures. In particular, competitive threats from Australia's supermarkets, the Australian Medical Association, and the

Australian Consumers' Association are encroaching on the pharmacy industry, with the aim of opening up this traditionally protected pharmaceutical industry allowing free and open competition. One way in which the industry has responded is through the creation of e-pharmacies. In our research an e-pharmacy may be defined as a virtual shop front pharmacy, often working collaboratively with a physical pharmacy outlet to enable rapid selection and distribution of customized and generic pharmaceuticals and associated products. Since 2000, four major e-pharmacies ePharmacy.com.au; HomePharmacy.com.au; PharmacyOnline.com.au; and PharmacyDirect.com.au (see appendix 1). have emerged in Australia.

This emerging business model creates new challenges of value creation and modes of interaction for customers. Of particular interest is the notion of the underlying service value network (SVN) [16],[17] and its partners, and dimensions and issues that shape its customer interface, service offering, and enabling service delivery system; the identification of which will be the focal point of our research.

The service value network (SVN) in an e-pharmacy setting is hereby defined as a collaborative network of supply chain partners (such as pharmacists, drug companies, distributors, beauty care suppliers, health and natural product suppliers, medical practitioners), sales channels (website e-sales, direct over the counter sales, and referrals), operational and network administration personnel, and customers.

This research identifies major dimensions, drivers, and enablers underpinning the development of a holistic SVN for e-pharmacies. Currently, service offerings are delivered through individual stores or groups of stores, and are largely dependent on the communicative skills of the sales, or front counter, person. A SVN complements, enhances, and value adds to this solution. It is designed as an information storage and retrieval system that is 'datamined', prioritized (deploying approximations using fuzzy logic), and has the capability to deliver additional customer information. Such information may then be used to enhance the dialogue between the business and the customer. Service related value added solutions may include: relevant drug options, possible co-drug side effects, packaging options, consumer allowable limits, claim options, delivery options, nearest doctor, hospital, medical insurance options, tax benefits, local preferences, etc. In addition, this data is directly accessible

via the pharmacy industry website where customers may source/request annual tax return data, doctor's surgery bookings, local hospital information, health and pensioner claims, and the like.

Figure 1 displays a global perspective of the industry, and the capabilities required from a SVN. Here a national data storage solution is developed that may be accessed by individual stores, store groups, store chains, or e-pharmacies. Development of such a SVN solution requires industry-wide information sharing, and will eventually lead towards cost savings and enhanced value propositions [16],[17].

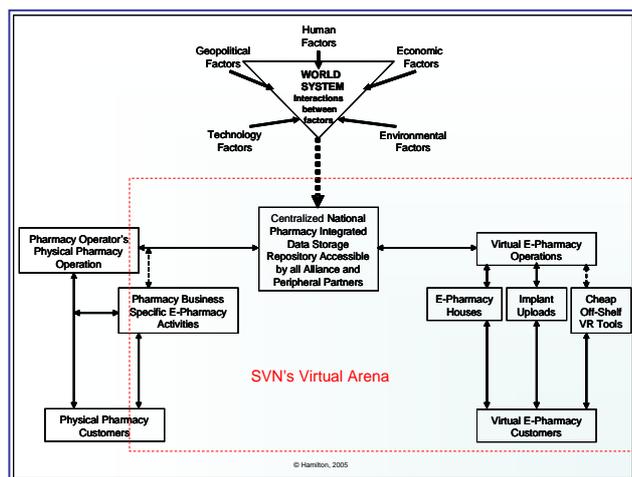

Figure 1: The Service Value Network – Global Perspective (adapted from Anwar & Hamilton [1])

The SVN is designed and managed by a central SVN coordinating group, which in a pharmacy setting might be taken up by the National Pharmacy Guild. Another example is the Australian Tourism Export Council for the Australian Tourism Industry, which is currently compiling a national database in preparation for linking up its industry partners under a SVN-like framework. The generic SVN model is detailed in the following section.

II. Service Value Network

The service value network for the pharmaceutical industry is comprised of a service strategy that drives three dimensions of the virtual service encounter: the services provision, customer targeting, and the underlying operational IT-infrastructure. In turn the virtual service encounter may interface with the physical, when a sales assistant accesses the database, for example to fill in customer prescription details, or to access specific drug information for the customer.

Interactions within the SVN can be viewed from an internal business perspective among supply chain partners in delivering and fulfilling customer orders, for example, a pharmacist replenishing out-of-stock items. On the other hand, the SVN responds to external customers such as a local nursing home initiating bulk drugs supply directly via the SVN. Both internal and external perspectives need to be

considered separately, as they need to be aligned in order to accurately respond to customer needs.

The proposed generic SVN model is displayed in Figure 2.

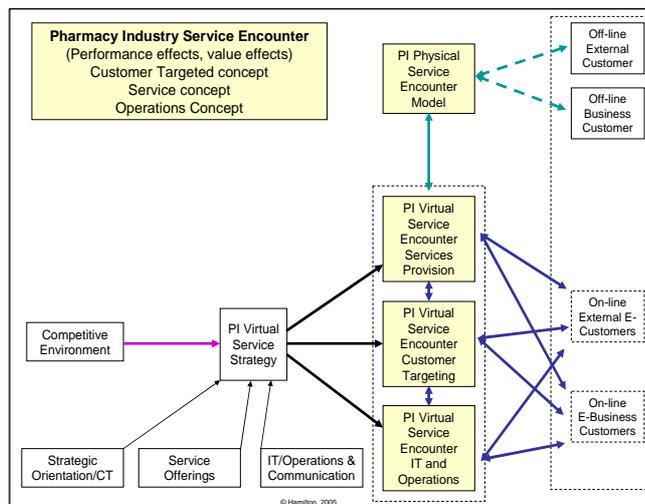

Figure 2: Service Value Network (adapted from Hamilton, [15])

III. Service Value Network (SVN) Dimensions

This paper aims at identifying the various dimensions of the SVN, such that designed service provision, customer targeting, and underlying IT and operations infrastructure are aligned with the set service strategy. The underlying dimensions can be grouped as follows:

1. the impact of competitive environment on the industry.
2. the dimensions of IT/operations and communications, integrated customer targeting systems, and service offerings in determining an industry strategy as set by the SVN Coordinating Group.
3. dimensions of the service delivery system within a virtual network, and the impact of virtual network delivery on potential service performance.

Each of these dimensions will now be discussed below.

IV. Competitive Environment

The competitive environment, displayed in Table 1, is influenced by external forces. It may be enhanced strategically by becoming a first mover, by differentiating, by focusing on specifically defined niches, by being the low cost provider, or by being the dominant player.

The industry strategy will need to be developed, such as to having the agility to adapt quickly to governmental rule/regulation changes. In the pharmaceutical industry this may relate to i.e. new packaging regulations. The SVN will

also need the capability to respond to changes in levels of competition. An example in Australia is the recent introduction of pharmacies within low cost retail chain stores/supermarket chains. In addition, the SVN requires the ability to create and work in supplier partnerships to either capture particular capabilities, or benefit from operational scale effects. As the health care market is growing rapidly because of an aging population, scale effects may become increasingly important. An example is the integration of specific health insurance cover information with pharmaceutical prescriptions.

The SVN should stay abreast of technological evolutions and keep its technological capabilities aligned with its customer and competitive requirements. Furthermore, customers become increasingly better informed and demanding. The pharmacy industry may respond by enhancing its service offerings and/or reaching the customer through various response channels. An example is the recent development of on-line medical encyclopedias in e-pharmacies.

Table 1: Competitive Environment

Competitive Environment	
Dimension	Operational Characteristic
Political	Speed to adopt governmental rule / regulation changes
Economic	Capability to respond to competition changes; Efficient cost conscious scaling of operations
Environment	Respond to competitive changes; Respond to new innovations
Cultural	Cultural monitoring of Cultural targeting
Technology	Industry wide; Networked solutions; Latest offerings; Quick accurate responses

Inputs to Industry Strategy

The Inputs to the pharmaceutical industry strategy are displayed in Table 2. They have a vital connection to the virtual service encounter. If the strategy is one of low service integration then the business will not be delivering high levels of value added service, but rather will deliver more standard service offerings.

Table 2: Inputs to Industry Strategy

Inputs to Industry Strategy	
Dimension	Operational Characteristic
Corporate	POS related Initiatives; Market positioning; Degree of service networking
Competitive	IT capability; Customer understanding; Range of service offerings
Financial	Networks; Customer knowledge; Services offerings
Customer Targeting	Customer demands met; Communicate culturally; Datamine stored information
Service	Industry wide; Networked solutions; Latest offerings; Quick accurate responses
Technology/IT	Customer delivery; Customer analysis; Customer services
Environment	Reactive to business changes; Reactive to customer changes; Updating continuous

Partnering businesses throughout the virtual service value network, position themselves strategically among competitors. They align their strategies internally with fellow value network partners and work towards a common set of strategic goals.

The supply chain side of the physical and virtual service network encounter becomes a cohesive partnership of integrated players working collaboratively as a network. Immediate competitors either mimic aspects of the service network approach, or develop their own solutions. Hence, new points of difference and competitive strategies emerge. Alignment of the service value network, with its alliance partners, to a common set strategic goal and a balanced set of strategic performance measures, is paramount.

Three major classes of inputs to the service strategy are: the underlying IT and operations / communications infrastructure, the customer targeting system, and the service offerings to be delivered. Each of these are detailed below.

IT/operations and Communications

This encapsulates the technical areas of software, knowledge management, business intelligence, and communications. The system must be capable of delivering the demanded customer requests, and of interpreting the request and delivering sensible added value complementary features to the customer.

Since the late 1990's, the five largest software providers: HP, IBM, Microsoft, Oracle, and Sun, in conjunction with a few innovative new entrants, began promoting new standards, new web services platforms, and new activities environments. The internet protocol version 6 (IPv6) software [7], Microsoft's '.NET' and IBM's WebSphere have offered new potential for communication and business operating systems platforms, which may further enhance the virtual environment. In addition, new ways to interpret, interrogate and deliver customer requirements are unfolding, and 'intelligent', responsive websites are emerging. Future applications, such as temperature sensors in clothing linked to illness monitoring devices, may represent yet another possible application area of intelligent information sharing.

In order to enable a value-add virtual encounter with customers, it is paramount that the overall process is driven by top management. IT investments need to be made for building integrated IT networks in order to improve connectivity with customers, and information delivered to customers. The resulting service offerings and customer targeting practices use numerous channels, such as internet, email, SMS, POS transactions, and supply chain partner referrals. Moreover, the IT infrastructure needs to be agile to respond to changes in IT requirements.

Customer Targeting System

The knowledge and data capture concerning the customer is crucial to delivering appropriate services. Site personalization and high levels of recognition may enable the business to enlist its affiliates and jointly target the customer. It may also deliver the identification of new

markets.

The service network customer encounter dimensions include the internal business-to-business customers and the external business-to-end users (or customers). Frohlich & Westbrook [14] have researched some internal business-to-business customer effects, but the business-to-consumer dyad has not been empirically studied [4].

The customer, marketing and advertising based studies have investigated websites with a view to determining effectiveness [2]. Rohm & Sultan [29] have explored strategies to increase customer engagement (time), and thereby strengthen brand-customer relationships. Others [6] in conjunction with their channel partners, have attempted to match the urgency (or criticality) of their customers' varying needs. They aimed to develop buyer life-cycle ownership value, and to deliver intensively loyal groups (segments) of customers. Still others [20], recognized that virtual business solutions (including website purchasing) are moving towards customer empowered, on-line, self paced, exploration of the service (or product) variations, prior to purchase. The customer's readiness to adopt new service value chain approaches also varies, and some customers may desire website interactions that are 'tailorable' to their actual customer requirements. The modern day customer is increasingly more demanding of the business, and its service provisions. Cross [9] suggests over 50 % of consumers are too time-pressurized to enjoy traditional shopping. Foley [12] says this time shortage necessitates targeted, personalized communications specific to their individual needs. Wolfe [37] suggests the statistical averaging of customers is the most failure-prone fault-line in transactional marketing. Hence personalized solutions remain a key to customer targeting. For example:

1. Similarity and dissimilarity [30] – where dissimilarity leads to dislike. Here need satisfaction [8] (where sexual, social and financial needs require matching), and a pleasant experience [23], contribute to the two way communication;
2. Exchange – where the complementary emphasises of value partners contributes to the relationship [36];
3. Human courtship – where targets, goals and the risk of non-compliance of the participants must converge [3];
4. Impression formation – where the emerging model captures first impression or 'wow' factor, incorporating the scripting of information and the richness of the media incorporated [24];
5. Flow theory – where 'perfect dialogue and merging of actions between participants exists [18];
6. Business networks interaction – where the flow of information between participants calibrates the relationship between them repeatedly [13];
7. IT interactions and personalization – where clarity, personalization, trust, dynamic adaptation of content [22], visual systems (that deliver and adapt

to continuously change information) [19], and a full range of text, video, audio, and graphics that deliver real-time 'telepresence' [34] - where the customer is mesmerized for a time [18] are evident.; loyalty and retention interactions – where the business must understand and react to their target market.

Rigby [28] evaluated spending patterns and consumer loyalty and concludes businesses cannot break-even on one-time shoppers' solutions. Customers must be empowered, seduced and converted into lifetime relationships [31]. Feedback loops [21] to direct marketing, and targeting most valued customers, can increase both customer loyalty and retention [27]. Customers demand more reliable services and products, and they expect to have their needs met in shorter time frames [10]. This customer perspective is dynamic and subject to change [32]. Consequently, the business must become agile and more capable of delivering what the customer needs and wants [35].

Customer targeting in a pharmaceutical setting first and foremost focuses on a broad understanding of what customers desire, requiring continual collection and mining of customer data and customer activities. The SVN approach takes this market research information not only to target and better market for specific customer segments, but also to broaden its service offerings by leveraging the unique capabilities of supply chain partners. As such, knowledge building of the customer base is a key activity within the SVN, either directly by the central SVN coordination group, or by sharing information by supply chain partners. Information on customer connectivity and relative use of channel medium are analysed as well.

Service Offerings

The decision as to the level of service is vital to the business. The levels of networking, agility, flexibility, customer targeting, and business supply chain focusing will vary depending on the choice of strategy. The quality of the service, the extent of added value offerings, the level of external partnering, the degree of environmental response, and the like contribute to this dimension.

The virtual strategy for specific service offerings could generically follow the traditional strategy classification by [25],[26] of differentiation, focus, and cost, in addition to a strategy based on flexibility/agility. This in turn will have an impact on the resulting service offerings and their respective customization. The business may be an innovator (like eBay.com), an early adopter (like RealEstate.com), a follower (like Zuji.com), or even a bandwagon copier (like many government departments). In today's highly competitive global environment many models exist, but the business must maintain some points of difference, or risk being out-competed. As such, the pharmaceutical industry may take on a role of innovator, leader, or follower in the underlying technology that enables that particular service offering. For example, a new Australian pharmacy chain

called 'V' Pharmacy is developing a service value network approach as its competitive focus. It is surveying the industry, its customers and the general population to set the frameworks from which it will deliver its customer-centric offerings. It aims to deliver highly personalized solutions in conjunction with its pharmacy script medicines. These will include detailed medical information, optional treatment approaches, linked 'Medicare', health and tax related data. This information will be readily accessible to the customer upon request, or at appropriate times (like a tax time report). 'V' Pharmacy is also building robotic pill dispensing facilities to allow the pharmacist greater time advising and consulting directly with customers or on-line customers.

Relevant metrics on the service offering need to be collected and managed, such as cost, ROI, service rate, and the like. As the service offering in SVN may involve many connectivity modes and SC partners, dependability of the service becomes a key parameter to monitor and manage. From a supply chain perspective, a knowledge base of the supplier network in terms of performance metrics on quality, efficiency, effectiveness, and agility needs to be developed. In addition, web layout, linkages to SC partners, and response times need to be carefully designed and managed. From a demand chain management perspective, automation, internal assistance, and Customer Relationship Management (CRM) all play an important role as well.

V. Inputs Virtual Network and Service Performance

The network dimension of the embedded connectivity of SC partners through varying sales channels implies that delays, incorrect information, and/or security breaches can have a leveraged negative effect on the overall service experience. Alternatively, a synchronous delivery by all partners involved may create a unique competitive edge through elevated service offerings. The quality dimension of providing relevant and targeted information, dependability of the service offering by each SC partner, flexibility to incorporate new updates from suppliers (ie product information), agility to deploy new hardware/software applications, quick response time to information requests, ease of access, security with built-in privacy protection levels, are all factors that enable or impair service delivery in a SVN framework. Table 3 displays the dimensions of the virtual network and its service performance.

Examples of resulting service offerings typically applying to Table 4 may include:

- An on-line pharmacist via
 - a video phone or video conference or teleconference
 - a personal chat room
 - Email or SMS.
- An evaluation of medical and cost alternatives to a prescription
 - A 'side-effects' report

- A home deliver service.
- A doctor - pharmacy direct link so that your prescription could be ready when you arrive, or be home delivered.

A database list of localities of nearby doctors and their current available appointment times.

Table 3: Virtual Network and Service Performance

Virtual Network and Service Performance	
Dimension	Operational Characteristic
Cost	IT networking cost; Customer servicing cost
Quality	Internal information sorting; External customer product delivery
Dependability	Reliable business networks, Reliable customer services
Flexibility / Agility	Capability to change; Uniqueness capability
Response time	Ability to service customer
Personalization	Ability to individually target customer; Ability to individually respond to a customer
Convenience	Multiple customer access modes; Multiple customer response modes
Style fashion	Ability to deliver added value solutions
Ethics	Security and privacy of business information; Security and privacy of customer information
Technology	Strategically operationalize latest technologies

Table 4: Dimensions Influencing Elevated Service Delivery

Dimensions Influencing Elevated Service Delivery	
Dimension	Operational Characteristic
Cost	Access medical & cost alternatives evaluation report to a prescription
Quality	Analyse & identify new markets, customer options, business opportunities
Dependability	Offer a possible drug 'side-effects' report, &/or a home deliver service
Flexibility / Agility	Allow home deliver of prescriptions
Response time	Doctor → pharmacy direct link so customer prescriptions instantly prepared
Personalization	Link secured areas to each customer's personal medical, hospital, ambulance, tax, insurance, banking, etc information & allow emergency in response to a car accident injury that required hospital intervention
Convenience	Provide access to on-line pharmacist by: all methods eg. video phone, video conference, teleconference, personal chat room, Email or SMS
Style fashion	Keep abreast of latest trends
Ethics	Continually learn from individual customers & use knowledge acquired to better assist customers to meet their PI/related areas preference needs
Technology	Allow direct computer access by local doctors, thereby guaranteeing prescription communication accuracy and delivery

Specific attributes/knowledge bases of a pharmaceutical SVN also applying to Table 4 may include:

- Linking of secured aspects of individual customer personal information to medical-, hospital-, ambulance-, tax-, insurance-, and banking information to enable a full emergency response service related to a car accident injury that required hospital intervention.
- allowing direct computer access by local doctors, thereby guaranteeing prescription communication

accuracy and delivery

- delivering personal prescription information (or a purchase), offering new knowledge to the customer about a purchase, and performing all levels of related interactions eg. pill recognition, reaction time, insurance ramifications, deals, best price, etc.

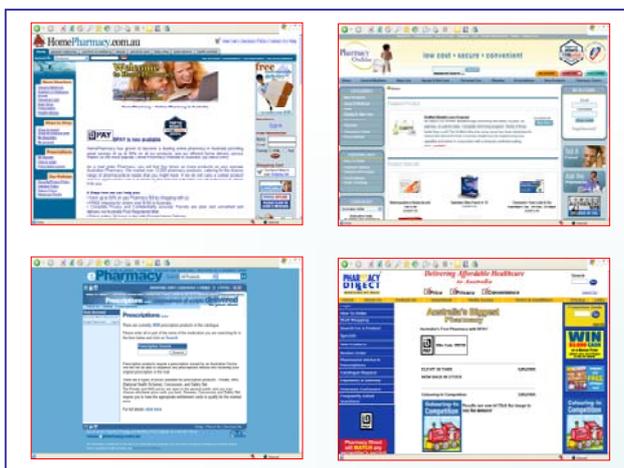

VI. Areas for Future Research

Thus far major dimensions of a generic service value network approach to e-pharmacy were identified. In Australia, on-going research is delivering the components of the pharmacy industry SVN. Future research would need to construct specific relationships among drivers, enablers, and outcomes of such a SVN-framework, and empirically test these for the pharmacy industry at large. Currently, the deployment of a full scale SVN methodology is definitely on the horizon, but still in its infancy.

VII. Conclusions

The concept of a Service Value Network for the pharmacy industry was discussed, along with the major underpinning dimensions. Such a SVN approach may eventually lead to better strategic alignment, higher industry performance (capabilities and delivery), greater value-adding solutions, increased customer satisfaction, and more competitive pricing. Within the Australian pharmaceutical industry, the emerging e-pharmacies are a partial response to industry restructuring and competitive positioning. This evolution was put in context of a SVN approach, and resulting elevated service offerings were described.

Do E-Business Investments Create Competitive Advantage: Perspectives from the Australian Banking and Financial Services Industry

Sally Rao Indrit Troshani
School of Commerce The University of Adelaide
233 North Terrace, Adelaide, SA 5005 Australia
Email: {indrit.troshani, sally.rao@adelaide.edu.au}

Abstract: Are advantages provided by e-business vanishing as IT becomes ubiquitous and affordable? Is it losing its strategic value and, therefore, its potential for strategic differentiation? This paper proposes a conceptual framework to assess strategic IT investments for e-business. The framework captures several business, human and time dimensions. It is argued that the interaction of these dimensions with IT is hard to be imitated by competitors, and has therefore, the potential to generate and sustain competitive advantage. We attempt to answer these questions by using the perspectives of IT practitioners in Australian financial service industry in the first of a multi-stage study.

Keywords: e-business, e-commerce, competitive advantage.

I. Introduction

The underlying technologies of e-business, such as computing technology, network communications, etc. are developing at exponential rates and becoming cheaper [6,27,29]. These technologies underlie basic e-business functions such as data storage, processing and transport. Currently, these functions are easily imitable and have become homogenised and “available and affordable to all” (Carr, 2003, p. 42). These are, therefore, becoming increasingly indistinguishable among different organisations. Because of the ‘vendorisation’ of hardware and software, universal technical standards are now forced onto users [6]. Hardware and software costs have decreased, and therefore, IT has become more susceptible to commoditisation, and is likely to become like rail transport, electricity or telephone service.

As e-business models are heavily reliant on IT, they may no longer provide firms with strategic differentiation. Many argue that investments in e-business are a competitive necessity rather than a source of competitive advantage. These views are also substantiated in recent e-commerce research with specific applications of IT, such as enterprise resource planning systems (ERP) [11,21,33]. For instance, Lengnick-Hall et al. (2004) argue that on their own, ERP systems are insufficient to provide sustainable competitive advantage. Also evidence suggests the average Fortune 200 organisations spend 20-40% of their budget on IT just to

stay competitive [26].

Even in the cases where e-business was found to enhance competitive position, the nature of the interaction between pre-existing business and human resources on the one hand, and e-business applications on the other, is poorly understood and has not been clearly specified [12,37,41,42]. Thus, the aim of this paper is to propose a conceptual framework which consists of factors that can generate and maintain competitive advantage through the quality interaction of e-business applications and other resources. This is expected to be the first step in addressing the gaps in the current literature. Preliminary findings of research carried out with firms operating in the Australian banking and financial services industry are also reported.

II. Key Concepts and Literature Review

The concept of competitive advantage has a long tradition in the strategic management literature. A fundamental goal for businesses is to develop a means by which they can perform better than their competitors. South (1981) defined it as “the philosophy of choosing only those competitive arenas where victories are clearly achievable” (p. 15). Much of the focus of recent research has been on identifying such sources of competitive advantage. For example, Porter (1985) argues that competitive advantages can be generated through a cost leadership, a differentiation advantage which will in turn lead to relatively higher performance. That is, productivity, performance and profitability are the antecedents of competitive advantage [31,40].

There are two mainstream schools of thought in theory development of IT-generated competitive advantage. The resource-based view essentially argues that firms allocate resources to acquire IT-related products because it is assumed that these investments provide economic returns to a firm. There are a number of resource typologies. For example, resources can be organisational, business and technological. Organisational performance depends on the integration of resources across these categories. Some of these resources interact with IT to produce sustainable advantages. Grant (1991) and Makadok (1991) emphasise that while resources by themselves can serve as the basic units of analysis, firms create competitive advantage by assembling these resources to create firm specific capabilities. These capabilities, embedded in organisational processes, provide economic returns because the firm is more effective than its competitors in deploying resources [14,23].

The second school of thought is represented by the

transaction cost theory which focuses attention on the exchange relations between buyers and sellers where the term transaction represents a transfer of goods 'across a technologically separable interface' (Williamson, 1985, p. 1). Firms make decisions in order to minimise their transaction costs by engaging in exchanges with other firms or individuals. Therefore, markets and hierarchies represent polar extremes on a continuum of exchange [24,44,45]. The choice an organisation can make between these two extremes depends on the outcome of the interaction between "human elements" and "environmental factors". Information technological developments allow organisations to be engaged in network behaviour to reduce transaction costs, increase coordination, thus efficiency. Electronic interconnection is both possible and desirable. For example, Malone, Yates and Benjamin (1987) argue that market coordination is enhanced through electronic communication, electronic brokerage and integration effects.

However, the transaction cost theory has limitations which have been highlighted in a growing number of empirical studies. Transaction costs and benefits associated with the exchange process have been recognised as difficult to isolate, particularly when the transactions involve more than two members. Transaction cost theory uses the competitive paradigm to refer to exchange participants as economic units. This is one of its major weaknesses as it ignores the long-term interactions within economic and social relationships [18]. Indeed, exchanges between firms have become increasingly characterised by non-market governance such as long-term associations, contractual relations and joint ownerships.

III. Developing a Theoretical Framework

Based on extant literature of the two schools of thought a theoretical framework can be proposed. This is important because the framework constitutes an attempt to reconcile aspects of different schools of thought into a single synthesis. The factors in the proposed framework are discussed next.

Alignment between e-business and Overall Business Strategies. E-business strategies should be consistent and well matched with the overall organisation business strategy, if they are going to provide competitive edge to organisations [17,19,32]. Consistency should also exist between business strategic planning and e-business planning [3]. However, consistency may be necessary but not sufficient. For instance, Powell and Dent-Micallef (1997) examine numerous sources which conclude that e-business and overall business strategy can become a symbiotic integration, and therefore, constitute a "potential advantage-producing complementarity" (p. 381). This alignment is likely to be difficult to replicate because both e-business and overall business strategies are likely to evolve uniquely for each organisation. E-business applications can support collaboration by bridging the traditionally socially complex gaps between functional departments. This, in turn, can enhance an organisation's competitive position and its ability to create strategic value in several ways, including productivity enhancement and service quality [22,25,30,32,42].

Inter-Organisational Linkages. Inter-organisational linkages refer to the organisation's ability to strategically use electronic linkages such as EDI and extranet to establish

upstream partnerships with suppliers and downstream relationships with customers [8]. Generally organisations are not internally self-sufficient; this requires resources from the environment. Therefore, organisations become interdependent with those elements of the environment with which they exchange resources. Organisational and ecological theorists argue that organisations develop internal and external strategies seeking to minimise the uncertainty arising from dependence on the environment for resources [15,16].

Using e-business applications to enable such linkages is likely to facilitate complex interactions and cultivate collaborative relationships. The nature of these interactions as well as the way these are used to handle environmental complexity are likely to be unique, and therefore, more likely to survive competitive imitation. From an e-business perspective, the value chain model highlights the interdependence between organisations along the value chain where competitive strategies can be best applied and e-business is likely to have strategic impact. Recent research, however, shows that trust is essential if partnerships and relationships are to be effective and enduring in generating competitive distinctiveness [38].

E-business Integration with Business Processes. Business processes can contribute to the overall business efficiency, and therefore, be a source of advantage. Increasingly, business processes are becoming standardised and embedded in e-business applications. As a consequence, these become replicable and subject to competitive imitation. However, innovations in the business processes and in the ways these are integrated with e-business are likely to be organisation-specific, and therefore, less likely to be easily replicable by competitors. It follows that e-business investments can have strategic effects when addressing sustained initiatives for innovating business processes [39]. Marchand et al. (2000) substantiates this idea with examples of banks that "have focused on getting e-business support for key processes in place to manage customer and product information for sales support, cross-selling, and customer service. From this base, they [19] have developed sophisticated systems and databases for management support, product innovation and business strategy formulation." (p. 75).

Organisational Agility. E-business can be a primary enabler in providing the necessary support for developing an organisational capability to be agile in adapting in an ever-changing environment [2]. This includes flexibility and responsiveness, which are necessary for organisations to respond quickly to the fluctuating customer needs and competitive landscapes. E-business applications can facilitate significant alterations to rigid traditional hierarchies. For example, the intranet can assist in the development of "shallow structures [which] may increase likelihood of success since they may improve communications, help achieve process orientation, and indicate less bureaucratic management." (Chaffey, 2004, p. 445).

Leadership style may also be easily changed from coercive or directive to consultative or collaborative [9], which in turn can result in effective and efficient team orientations [34]. E-business applications also facilitates, rapid project development and deployment and the capability to undertake strategic change [2]. However, in different

organisations, these alterations encounter varying degrees of managerial resistance, flexibility and inertia which are likely to result in different levels of organisational agility. These differences can constitute a source of distinctiveness among organisations.

Management Commitment and Support. Management commitment and support is important because it has the potential to differentiate successful from unsuccessful e-business investments. Research shows that lack of awareness and understanding of the potential benefits and value to be gained by e-business investments can be a significant barrier for successful strategic implementations [30]. Managers with negative orientations toward e-business are likely to exhibit negative attitudes, which adversely affect their commitment to strategic IT implementations, and subsequently, resource availability and deployment [1,25]. This suggests that lack of management support is likely to have little impact on competitive position. In contrast, strong management support is likely to affect organisation-level competitive advantage positively [42].

Interactions between IT Professionals and E-business Application Users. Organisational performance is increasingly affected by the nature of the interactions between IT professionals and end-users. When interactions are based upon rich and cooperative dialogue, end-users are more likely to enhance their understanding of the potential IT has to offer. Likewise, IT professionals are more likely to better understand the problems the end-users face [10]. Consequently, rich and quality interactions can be the source of innovative insights, which are vital for developing supporting applications, and are therefore, considered as a key success factor of e-business investments [36]. However, patterns of interactions between IT professionals and end-users are different in different organisations which suggest that innovative insights are likely to be unevenly distributed. This constitutes an opportunity for asymmetric distinctiveness across organisations, and therefore, the accomplishment of competitive advantage becomes possible.

Organisational Culture. Organisational culture is important as it affects the employees' orientation towards innovations in general [28,36]. It also creates a climate for either encouraging or discouraging risk taking and experimentation with e-business applications [3]. Boddy et al (2001) argue that there are different types of cultural orientations that can be identified in different organisations. Accordingly, culture is affected by several factors, including the environment, degree of formality, openness, consensus, team and collaborative orientation [25]. All these factors are

likely to create unique cultural profiles for different organisations [5,8]. Consequently, these profiles affect e-business decisions and use patterns in inimitable ways, therefore creating a potential for strategic differentiation among organisations.

Intellectual Resources. Intellectual resources include organisational human resources with technical and managerial IT skills. The relatively high mobility of IT employees suggests that some e-business skills may become accessible to competitors [20]. However, Bharadwaj (2000) and Wade & Hulland (2004) argue that due to their distinctive and tacit nature and organisation-specific interpersonal relationships which take years to be perfected, application development, technology integration skills, corporate-level knowledge assets and managerial human resources become difficult to acquire and highly complex to imitate by competitors. Therefore, these resources are likely to produce unique idiosyncratic casually ambiguous capabilities which serve as source of sustained competitive advantage [35,42].

In table 1 we summarise the factors discussed above into two major categories, namely, business and domain factors.

We argue that the factors themselves should be assessed both qualitatively and quantitatively in terms of the reactive nature of interactions among the factors and the extent to which competitive advantage is generated and sustained. Black & Boal (1994) suggest that the result of the interactions includes three types of relationships, namely, compensatory, enhancing, and suppressing. A compensatory interaction exists when a change in one factor is offset by a change in another factor. An enhancing interaction exists when the presence of one factor amplifies the effect of another factor. Suppressing interactions exist when the presence of one factor adversely affects the impact of another [4]. Further, the factors identified above can affect competitive position in different ways. For example, while organisational linkages may be relatively strong in creating competitive advantage, they may also be relatively weak in sustaining it because they may be easily imitated by competitors. Efforts have been made to assess the ability of e-business to generate and sustain competitive advantage. However, these are only hypothesised rather than proven [42]. In addition, the time dimension over which competitive advantage persists may depend on several factors, including but not limited to industry specific variables, product lifecycle, intellectual property copyrights and patents [43]. Therefore, the measurement of the contribution of time dimension requires special consideration as well.

Table 1 – Business and Human domain factors

Business Domain Factors	Human Domain Factors
- Alignment between IT and overall business strategies (ALIGN)	- Management commitment and support (MGT)
- Inter-organisational linkages (LINK)	- Interaction between IT professionals and end users (INTERACT)
- IT integration with business processes (PROCINTEG)	- Organisational culture (CULTURE)
- Organisational Agility (AGILITY)	- Intellectual IT resources (INTELRES)

IV. Methodology and Results From Pilot Interviews

To explore the factors included in the proposed framework, the qualitative methodology of convergent interviewing was used. This choice of methodology was justified for its theory-building capability [7]. This research is exploratory because we need to gather insights into the phenomenon and to provide a better understanding of the issues involved. The convergent interviewing process involved conducting a series of in-depth interviews in which data was collected during each interview, analysed and used to refine the content of *subsequent* interviews. That is, the process was structured although the content of each interview remains unstructured or semi structured to allow for the flexible exploration of the subject matter without determining the answers [7,13]. This process identified important information on which further research may be based (Dick, 1990). The convergent interviews were undertaken with Chief Information Officers (CIOs) and IT managers of the companies in the Australian banking and financial services industry. These managers are key informants because they are closely involved in e-business planning and implementing process in their respective firms and had an understanding of the entire decision making process. A number of 9 interviews have been carried out so far. Participants were from a variety of financial service firms including investment and merchant banks, mortgage and savings banks, building societies, credit unions, and insurance. There are signs of convergence in terms of data patterns on most issues.

Overall, the findings from the convergent interviews provided evidence that e-business application do provide competitive advantages to varying degrees for different organizations, depending on how they have been integrated with the identified factors in the framework. However, e-business applications do not change the general nature of a business. For example, one interviewee commented: "the term e-business can be misleading...there is only business, not e-business...e-business applications are simply tools that a business can use to improve its performance." a

Although top management's support and commitment vary at times, most firms in the financial services industry are committed to e-business and have invested heavily into IT and e-business applications because e-business take-up is considered crucial in this industry. Nevertheless, several participants were consistent in indicating that investments in e-business solutions should be made if they add value to the business rather than to just "stay up to date". The impact of e-business investment on overall business performance vary amongst firms depending largely on the core value proposition and the overall business model. For example, for a startup online bank, success planning and implementation of e-business applications is considered vital as one of the participant stated, "it is a matter of surviving or dying...". Most of the participants took the periodical, systematic

review approach to updating e-business systems. However, IT practitioners generally experience difficulties in keeping up with e-business application developments. One way of doing that is through industry forums where they meet on a regular basis and discuss relevant issues. Although some of the participants encountered resistance from users in the organization in implementing new e-business applications, they generally overcome the resistance rather effectively through structured training programs and providing rationale for the new application well in advance.

There was a general consensus that e-business solutions should be customer-centric and service-oriented. Business process improvement was seen as the main driver of e-business investments. Further, in organizations where working legacy systems are still in use, e-business solutions were seen a means towards their aggregation with the aim of improving business process automation and overall information accessibility. In addition, crucial determinants of the successful implementation and use of e-business systems were a fluid business culture and a continuous involvement of key stakeholders in the development of e-business solutions.

Generally, the preliminary findings described in this paper are consistent with the literature. However, after the research issues have been fine-tuned in stage one, stage two will test for statistical generation across the population of the organisations in the Australian financial services industry, using the methodology of a Web survey. Multiple regression will be used to analyse the survey data to examine the interdependencies of variables.

V. Conclusion

There is a general consensus that e-business has become pervasive and relatively easy to acquire in competitive markets. This, however, does not mean that e-business has lost its potential to provide competitive advantage. We argue that potential for distinctiveness exists in the way e-business applications interact with a selected, but non exhaustive list of business and human domain factors within specific time frames. Such interactions are unique and may result in organisation-specific capabilities which may be hard to duplicate. As such, unique interactions constitute a source of competitive advantage. Clearly more systematic empirical study and more detailed formal analyses are needed to confirm and measure these interactions and their resulting contribution to enhance organisational competitive position.

The Critical Success Factors and Integrated Model for Implementing E-business in Taiwan's SMEs

Chen Te Fu *, Yi Chen Lan **

* PhD Candidate, School of management, University of western Sydney
Lecturer, Cheng Shiu University, Taiwan
Email: phd2004_05@yahoo.com

** Senior Lecturer, School of computing and IT, University of western Sydney
Email: y.lan@uws.edu.au

Abstract: Purpose - To date, identifying barriers and critical success factors (CSFs) and integrating business model in implementing e-business for SMEs have not been systematically investigated. Few existing studies have derived their CSFs and business model from large companies' perspectives and have not considered the needs of integration for smaller businesses. This paper is aimed to bridge this gap. **Design/methodology/approach** - Existing studies on CSFs and e-business model were reviewed and their limitations were identified. By integrating insights drawn from these studies as well as adding some new factors, the author proposed a set of 18 CSFs which is believed to be more useful for SMEs. The importance of the proposed CSFs was theoretically discussed and justified. In addition, a case study was conducted to evaluate the extent of success of this proposition. **Findings** - The overall results from the case study assessment were positive, thus reflecting the appropriateness of the proposed CSFs and integrated model. **Practical implications** - The set of CSFs and integrated model can act as a list of items and an easy to follow model for SMEs to address when adopting e-business. This helps to ensure that the essential issues and factors are covered during implementation. For academics, it provides a common language for them to discuss and study the factors crucial for the success of e-business in SMEs. **Originality/value** - This study is probably the first to provide an integrative perspective of CSFs and integrated model for implementing e-business in the SME sector. It gives valuable information, which hopefully will help this business sector to accomplish e-business visions.

Keywords: e-business, e-transition, CSFs, SMEs, e-commerce.

I. Introduction

Indisputably implementing and maintaining e-business for those large organizations is just another routine operation for their IT departments to ensure the business activities are performing efficiently. Nevertheless, small and medium-sized enterprises (SMEs) have far less resources and budgets to invest in IT enabled operations or the e-business vision.

According to the figure reported by the IDC Taiwan in

2003, there are 1,060,000 SMEs in Taiwan and just fewer than 40% of them have involved in e-business activities (having financial transactions through the Internet). This signifies that at least 636,000 SMEs have not engaged in e-business operations. However it does not mean that these SMEs have not considered the implementation of e-business operations. Most SMEs have recognised the need to change their current business processes to achieve the capability to engage in web based e-business activities. However, lacks of resources and budgets have prevented them from pursuing or continuing the e-business activities.

The key question this study tries to answer is what is the real factor that affects in implementing e-business operations in SMEs? This paper starts with surveying the e-business literature and identifying possible hurdles of transforming SMEs into e-capable (electronic capable) business operations. It is followed by categorising those factors or hurdles into two recognition phases. In addition to the hurdles, numbers of CSFs for SMEs to conduct e-business operations are identified and discussed. Through the literature study and investigation of various e-business transformation models, the authors have identified the components required for SMEs to transform into e-business operations successfully. A case study was introduced to verify the hurdles as well as the CSFs. This paper concludes with the proposition of an integrated e-business model to amalgamate all required components and provide e-business implement steps for SMEs.

II. Literature Review

The use of the Internet does not automatically mean placing a barrier between the firm and its customers and/or its suppliers. Revolve around inter-firm relationships. Many firms have invested in these relationships, sometimes over generations, and these relationships are key assets of the firm. The challenge is to leverage off these assets to a new level of competitiveness not to undermine them.

O'Keeffe (2001) outlines what the Internet can or cannot do by exposing seven myths. These are presented in Table 2-1, the myths and realities of e-commerce and discussed below.

Table 2-1: The myths and realities of e-commerce (O'Keeffe, 2001)

The myths	The realities
1. The Internet destroys relationships	Manage relationships as intangible assets
2. The Internet disintermediates	Value is more transparent
3. Simply reduce transaction costs	Focus on process costs
4. The Internet is about public information	Private information flows can be enhanced
5. A single hardware purchase	A dynamic relationship with a solutions provider
6. High risk and high investment costs	Amortised costs and low risk trial adoption
7. The Internet levels the playing field	The Internet leverages investments in reputation and relationship assets

The Internet is not about dis-intermediation but companies who do not add value or who have not invested in relationship or reputation assets are certainly under threat by the Internet infrastructure. The Internet infrastructure allows firms to manage the boundaries within the firm and between the firm and other players in the network to a new level of effectiveness and efficiency.

The e-commerce platform is not simply about adoption with current inefficiencies, but about re-engineering the total system. There are further opportunity savings as buyers and sellers can develop new accounts and invest in developing new relationships and strengthening current relationships. It is all about relationships as assets.

Hence, it is clear that the Internet is not about levelling the playing field, quite oppositely the Internet poses a competitive threat to those companies have lack of strategies or those with poor reputation or relationship assets. The Internet does provide the infrastructure for firms to unleash the power of past investments in their relationship and reputation assets and to develop these assets even further for long-term competitive advantage. The Internet provides a breakthrough technology in managing the boundaries of the firm both within the firm and with other firms in the network (O'Keeffe, 2001).

The literature in e-business strategy has addressed a wide spectrum of issues with regard to transforming an organization into e-business operations. (Mirchandani & Motwani, 2001; Davy, 1998; Alexander, 1999). Furthermore, researchers have also discussed e-business adoption in various industries (Korchak & Rodman, 2001), regions (Beveren & Thomson, 2002; Gani, 2002; Walczuch et. al., 2000), and detailed technical steps involved in the transformation process (Eduard, 2001).

When analysing SMEs in e-business adoption, we have identified various factors that prevent them from using the full potential of the World Wide Web. The first contribution of this study is to identify the hurdles that affect the adoption of e-business operation in both pre- and post recognition phases. Furthermore, the second contribution of this study is

to propose a set of critical successful factors for SMEs and an integrated model through a case study. The following sections outline the discussion of each factor within the associated phases and illustrate the development of e-business model.

According to Clayton (2000) more than 60% of the small companies do not have a plan for their business strategy. Although the remaining companies have such plans, there is no indication that e-business operation strategy has been incorporated. Lack of such incorporation or recognition of e-transition strategy in business plans is considered as the major barrier in the success of e-business establishment.

In the case studies conducted by the NOIE (National Office for the Information Economy) and Earnest and Young (2001), they have identified a number of factors that prevent SMEs moving to online operations, which are outlined as follows:

- Difficulties in finding reliable information that supports the e-business establishment;
- Difficulties in finding appropriate resources for a successful implementation;
- Difficulties of getting cost effective rates from ISP's (Internet Service Providers);
- Higher costs of payment gateways for online transactions; and
- Difficulties of finding and arranging suitable logistic solutions for product deliveries.

However, these factors merely represent the impediments in a single domain, which falls under post-recognition of e-transition strategy, and have no hurdles been discussed prior to the recognition. Hence, the factors need to be further categorised into two domains, namely "pre-recognition" and "post-recognition".

II. 1 Factors Affecting Success

The e-transition recognition model introduced in Figure 2-1 brings all the hurdles in the pre-recognition and the post-recognition phases into a big picture. The proposed model is to be applied by SMEs to identify the bottlenecks and develop an appropriate practical plan, which will lead them to the success in e-transformation vision. The following sections explain the components of e-transition recognition model including recognition stage itself and pre- and post-recognition phases.

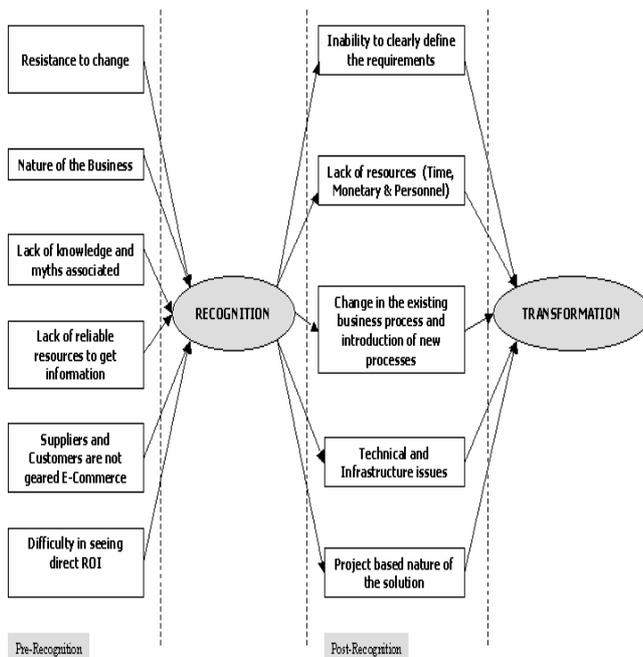

II.1.1 Pre-Recognition Phase

Based on our experience in working with SMEs in Taiwan in the e-transformation activities, we have identified the six factors in pre-recognition phase. In most situations these factors tend to strengthen each other making it further difficult for a small company to find solutions to the e-transformation puzzle.

1. Resistance to change.
2. Nature of the business.
3. Lack of reliable resources to get the correct information.

4. Lack of knowledge and myths associated with it.
5. Suppliers and customers are not geared e-commerce.
6. Difficulty in seeing direct ROI.

There has been some effort made to set up a mechanism to calculate the ROI of e-business initiatives (Edurad, 2001), but there is no one single formulae that can be easily applied to suite every SME.

The factors in the Pre-Recognition phase converges into the biggest barrier the "Recognition" and after the recognition it diverges into the factors in the Post-Recognition phase. In the case of a particular Micro Company it could be one or a combination of factors in both phases that might affect its E Transformation.

In the following section we will discuss these factors in detail with few real life examples.

Figure 2-1. E-transition recognition model

II. 1. 2 Post-Recognition Phase

After successfully passing all the hurdles discussed above, SMEs would have recognized the need of e-transformation in order to be ahead in the competition. At this point they might have preliminary plans to carry out the transformation tasks.

We have identified five hurdles that might prevent a SME actually implementing the e-business operations. As in the pre-recognition phase, factors in the post-recognition phase also have impacts on each other, which strengthens its affect and prevent the e-transformation becoming a reality.

1. Inability to clearly define the requirements.

It is unclear as to what it means to the business community and even to the most of the web community. None of

the above is considered as truly e-transformed organizations. Only when the internal information systems are fully converged with the external/online information systems the e-transformation is achieved (Khandelwal et. al, 2004).

2. Lack of resources.

These resources are time, funds and personnel.

3. Change in the existing business process and introduction of new processes.

In case of a site where the customers can place on-line orders it would be important to have new business processes to handle orders and proper logistics to deliver goods. Inability to handle these changes or allocating resources to handle these new processes would result a failure in e-transformation.

4. Technical and Infrastructure problems.

SMEs operate in remote areas where the IT and telecommunication infrastructures are not available for getting access to the Internet or services from ISPs.

5. Project based nature of transformation and maintenance.

Most SMEs without in-house IT staff would need to outsource the development of e-business operations. Generally these types of activities are carried out in a project-based format where the project ends with the handing over.

II. 2 Factors Achieving Success

Identifying the CSFs (critical success factors) allows a firm to realize the full advantages of achieving e-business solutions. We have highlighted six CSFs based on the literature and our experience as follows.

- The first CSF is to identify a suitable vision for the firm. This vision is important as it provides everyone in the organization with the future direction.
- The second CSF is that the firm must also have an e-business champion who will help make the vision a reality. This person must be a strong leader who owns the e-transformation process at a company, and must also be visual, energetic, and passionate about the transformation.
- The third CSF is the creation of a healthy company culture. With this energized corporate structure, all employees will be involved in the corporate decision-making process.
- The fourth CSF is the development of a plan to achieve the e-transformation (Marzulli, 2000). This plan needs to be in document form and include milestones and metrics that describe the e-transformation journey. The e-business champion and senior management should review this plan regularly.
- The fifth CSF deals with corporate communication (Marzulli, 2000). A rigorous communication strategy must

be implemented within the firm. This allows the organization to receive more feedback from constituents. This is imperative when e-business solutions are complex.

- The sixth CSF for an e-business firm is its ability to create flexible e-business solutions. This will allow the firm to grow in the future as well as personalize to various suppliers and customers.

If an organization can observe all of the above critical success factors, the expected e-business solutions can be achieved.

Furthermore, KITE identified nine CSFs relevant to the competitive performance of small businesses entering the e-commerce market. This list took as its starting point a number of CSFs that were suggested to us by one of the reviewers (van Rijsbergen, 1998). The original list was expanded and refined in the light of experience with the Web Corporation in KITE. A further two factors (commitment and partnership) were derived from the interviews with the best practice sample. The final list of 11 factors is shown in Table 2-2.

Table 2-2: Critical success factors (Jeffcoate, Chappell, and Feindt, 2002)

CSF	Description
Content	The effective presentation of a product or service offered over the Internet
Convenience	The usability of the Web site for the purpose for which it was designed
Control	The extent to which organizations have defined processes that they can manage
Interaction	The means of relationship building with individual customers
Community	The means of relationship building with groups of like-minded individuals or organizations
Price sensitivity	The sensitivity of a product or service to price competition on the Internet
Brand image	The ability to build up a brand name for the e-commerce business, and its products and services
Commitment	A strong motivation for using the Internet and the will to innovate
Partnership	The extent to which an e-commerce venture uses partnerships (value chain relationships) to leverage Internet presence and expand its business
Process improvement	The extent to which companies can change and automate business processes
Integration	The provision of links between underlying IT systems in support of partnership and process improvement

By eliminating repetitions, a core group of recommended actions for each CSF was derived. These were grouped by category so that Web Corporation could focus on the recommendations applicable to them.

II. 2. 2 The New Stage by Stage of CSFs

By integrating the abovementioned factors, the authors propose a more comprehensive model of 15 factors and separate into three stages for implementing e-business in SMEs (see Table 2-3).

Table 2-3: A set of new stage by stage of CSFs

Stage	CSFs
Start-up phase	Vision, company culture, a plan to achieve the e-transformation, commitment, content, price sensitivity and convenience
Growth/transition phase	e-business champion (leaderships), Corporate communication, control, interaction, community and brand image
Maturity phase	Ability to create flexible e-business solutions, partnership, process improvement and integration, strategic positioning in KVC, mobilization

In order to achieve the success in e-business transition the above CSFs could be segmented into three stages. Once an e-business has determined its strategy and stage of development, it can identify the CSFs that are applicable to it.

It is necessary through "stage by stage" to build an optimal model in implementing e-business. When SMEs develop their e-business model because they are lacked of resources, personnel and monetary. Besides, an optimal business model could help firms to form sustainable competitive advantage because unique business model is hard to be imitated by competitors. Therefore, referring above CSFs, the study further reviews a stage model which can describe the logical evolution of e-commerce involving different stages of development, each stage being better in some sense than the previous stage, can be useful in providing a roadmap for improvement to companies. A stage model, we believe, can do this.

II. 2. 2 A Stage Model for E-commerce Development

To achieve the goal of becoming an "e-SME", the Local Futures Group (2001, cited in Dixon *et al.*, 2002) suggest that firms must cross two digital divides:

1. The first divide involves acquiring basic ICT skills and technology to operate e-mail and simple brochure Web sites.
2. The second digital divide is the threshold to e-business proper, and requires advanced technology and IT skills (including R&D) and a wide range of specialist business skills and knowledge in areas such as management, strategy

and marketing.

It implies that all SMEs have the need and opportunity to follow one prescribed course; with the implication that not to finish the course (cross the divides) is some kind of

failure.

Furthermore, Subba and Glenn (2003) proposed that e-commerce development takes place in four stages (see Figure 2-2):

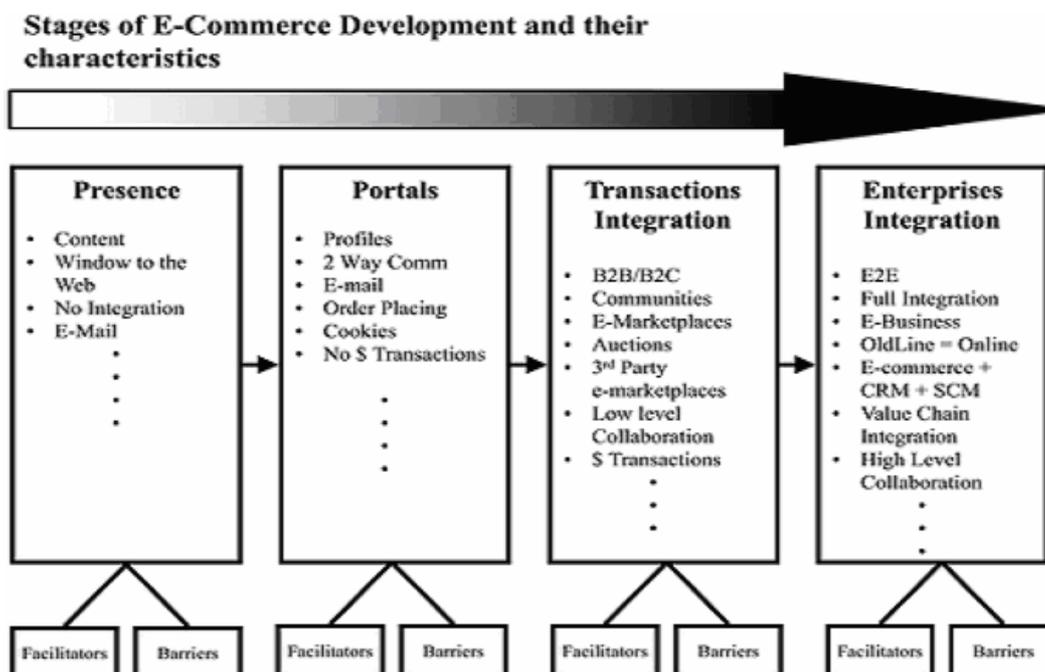

Figure 2-2: A stage model for e-commerce development (Subba and Glenn, 2003)

The four stages are listed below:

- (1) Presence (no integration).
- (2) Portals (no \$ transaction).
- (3) Transactions integration (low level collaboration).
- (4) Enterprises integration (value chain integration and high level collaboration).

The study argued that SMEs could start in any stage of abovementioned, it depends on their resource, personnel, technological support, and so on. The model allows for a company to enter at any stage. It is not necessary that a company begins at the presence stage and then progresses through subsequent stages although the stage model as proposed appears sequential. It depends on the degree of increasing awareness for technology and e-commerce. The point is what factors promote and what factors inhibit or retard e-commerce development and implementation at a particular stage. S. Subba, Glenn, Carlo A., (2003) call these facilitators and barriers to e-commerce development and implementation. If the primary impact of the factor is internal and within the control of the SME, they classify it as a facilitator since the enterprise can improve its readiness for a given stage. On the other hand, if the primary impact of the factor is beyond the control of the enterprise they have generally classified them as barriers.

II. 2. 3 Information Value Chain

In e-commerce operations, information is not viewed as a by-product of the strategic activities performed around the physical value chain. It is viewed rather to play a strategic role in itself. For this reason, strategic activities in the virtual value chain are performed in conjunction with information. This is well explained by Rayport and Sviokla (1995), with the concept of a "virtual value chain".

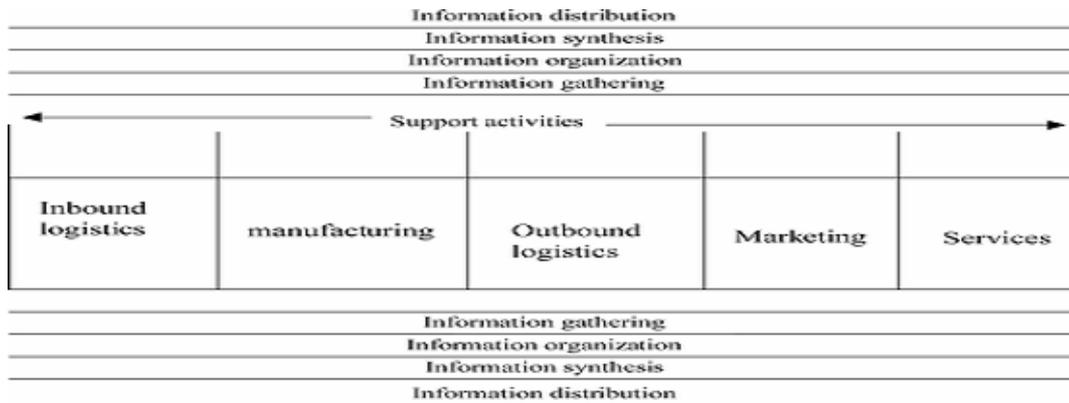

According to Rayport and Sviokla, a virtual value chain consists of "gathering, organizing, selecting, synthesizing, and distributing of information". Hence, it becomes imperative that businesses amalgamate virtual chain activities with physical activities to become fully integrated business operations to offer customized products and services, as shown in Figure 2-4. While virtual value chain enables companies to access information and finalise transactions, physical value chain ensures the order fulfilment and delivery of products and services to the customers (Rayport and Sviokla, 1995).

To be brief, the success e-commerce operations will depend upon the ways the physical value chain and the virtual value chain activities are matched and integrated into an information value chain.

It is obvious that merely integrating virtual value chain with physical value chain does not guarantee organizations in sustaining the competitive challenges. To take one step further, the optimal approach is for an organization to create its knowledge assets as knowledge turns into the main

source of competitive advantage (Miles, 1993; Miles *et al.*, 1994). The following section reviews knowledge value chain

and proposes the convergence of information and knowledge value chains.

Source: Adapted from Porter (1985) and Rayport and Sviokla (1995)

Figure 2-4: Integrated framework of virtual chain activities with physical activities (Rayport and Sviokla, 1995)

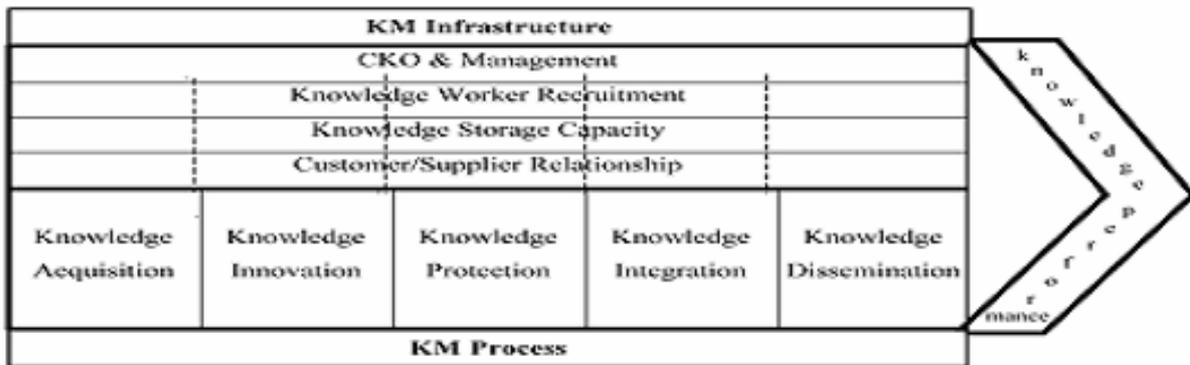

Figure 2-5: Knowledge value chain mode (Lee and Yang, 2000)

II. 2. 4 Knowledge Value Chain

Employing Porter's value chain analysis approach (Porter, 1985), Lee and Yang (2000) proposed a knowledge value chain model (figure 2-5).

These infrastructure components and activities are the building blocks by which a corporation creates a product or provides service valuable to its customers.

II. 2. 5 The Integration of KVC and Business Value Chain

As the value chain itself implies, each element of activity can create value and then all the value flows to the endpoint of the business value chain and joins together, forming the overall value of business, which is usually expressed as a margin (see Figure 2-6).

According this model, Lee and Yang (2000) proposed that the added value comes from the competence of element activity itself, which in turn comes from specific sub-KVC of itself, sub-KVC in inbound logistics (IL) operations (OP),

outbound logistics (OL), marketing and sales (MS), and service (SE) activity enables business to gain the competence, and then the added value follows. Finally, all the sub-KVCs are integrated together into the whole KVC. In the process of knowledge integration, the competence of knowledge infrastructure is gradually forming. In the end, corporation competence follows KVC. By analyzing the above, Lee and Yang (2000) note that competence is after all the measurement of each sub-KVC. KM is a process that transforms information into knowledge, it is suggested that competitive advantage grows out of the way corporations organize and perform discrete activities in the knowledge value chain, which should be measured by the core competence of the corporation.

The characteristics of the enterprises integration stage include all e-commerce and non e-commerce aspects of the enterprise. At this stage they become melted together to a single system that serves all the needs of the enterprise.

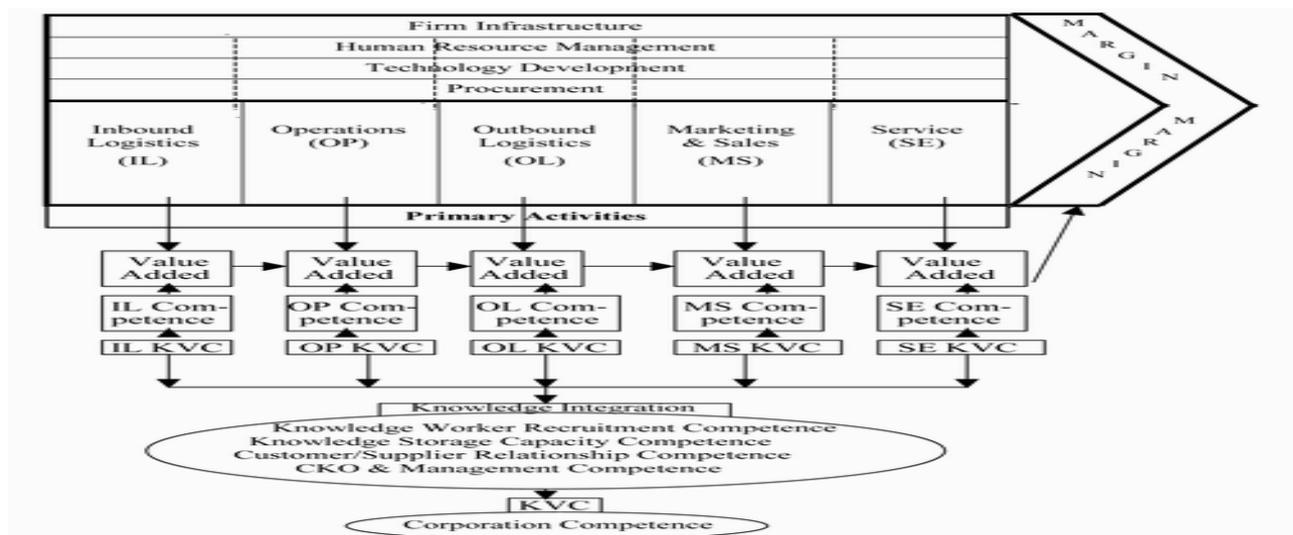

Figure 2-6: Relationship between business value chain and KVC
Source: Lee and Yang (2000)

II. 2. 6 EAI (Enterprises Application Integration)

Successful players in the EAI stage will be able to distinguish themselves if they:

- Intimately understand their partners' current and future/strategic needs.
- Work proactively with their partners to create solutions that address these needs.
- Use information sharing; and
- Have long-term contracts (Lacerra *et al.*, 1999; Krause *et al.*, 1998).

It is argued that significant opportunities for improvement often lie at the interfaces between the various supply chain member organizations (Handfield and Nichols, 1999). Whether an order is initiated by a Web-based customer or a mail order customer does not matter. At this EAI stage the e-commerce departments disappear and all business processes are fully integrated across internal systems and external participants (suppliers, business partners, and customers).

II. 2. 7 K-Business

While e-business gives us new access, exchange, and sales opportunities relative to information, k-business turns knowledge assets within a system into products, services, and profits. For e-business moves up to k-business, David Skyrme (2001) proposed ten Ps offer tips on online marketing that emphasize positioning, packaging, portals, pathways, pages, personalization, progression, payments, processes, and performance.

II. 2. 8 M-Business

A few years thereafter, Microsoft amended its statement to "empower people through great software, anytime, any place on any device." Being digital is out, being mobile is in. On November 21, 2002, when *The Economist* released its story

on "Computing's new shape," the cover page featured a Nokia phone, not a Microsoft pocket PC. In *The Freedom Economy*, Peter G.W. Keen and Ron Mackintosh portray the "mCommerce edge in the Era of the Wireless Internet." Just as personal computers and the Internet have changed the landscape of ecommerce, the authors argue, mCommerce will continue to extend the way organizations conduct business, while changing the relationships between companies, customers, suppliers, and partners. To them, mobility means freedom, which creates choice and, thereby, value. The key areas for expanding value through mCommerce are customer relationships, logistics, and knowledge mobilization, or intellectual capital.

In *Beyond Mobile*, a trio of Kairos Futures' consultants (Mats Lindgren, Jörgen Jedbratt, and Erika Svensson) take the mobilization of many businesses and organizations as a given. They focus on the human aspects of mobile technology, exploring the ways that people will work and communicate in the mobile marketplace. Their bold future scenarios extend to the year 2007. According to Ravi Kalakota and Marcia Robinson, the mobile Internet is transforming employee, supply chain, and customer interaction, and providing new innovation, cost-reduction, and revenue opportunities. Their *M-Business* shows how to reposition and develop business processes and enterprise applications to take full advantage of the mobile business wave that is portrayed as compelling and complex, even if its value is needlessly inflated ("and overtaking your organization even as you read these words"). The gurus of IT-driven e-commerce business guides explore wireless revolution from a business perspective. They introduce strategies that can be exploited to adapt from tethered, PC-centric models to mobile, person-centric techniques and strategies. Claiming to focus on the bottom line, the authors explain how senior and financial managers can plan for and differentiate m-business investments.

II. 3 Research Propositions

The aim of above review was to generate a series of exploratory research propositions relating to the barriers and CSFs for SMEs develop e-business activities while to embrace the technology and technique. The propositions generated follow, and a fuller explanation will be obtained through following case study.

- P1. The first stage of E-business start-up is to identify barrier to critical successful factors for transforming to e-business.
- P2. After transform successfully, the second stage is to integrate virtual and physical value chain to form an information value chain for unleashing the power of information and relationship assets.
- P3. The third stage is to integrate information and knowledge value chain, each element of activity can create value and then all the value flows to the endpoint of the business value chain and joins together, forming the overall value of business, competitive advantage grows out of the way corporations organize and perform discrete activities in the knowledge value chain.
- P4. The fifth stage is to integrate information and knowledge value chain to k-business to create knowledge assets.
- P5. The sixth stage is through EAI to integrate all systems to achieve sustainable competitive advantage.

III. Methodology

This paper adopts a case study to assess actual barriers and CSFs to the decision to implement an e-business strategy in the context of this particular SME. The completed questionnaire, company reports/industry-specific newsletters and a depth interview created an established chain of evidence.

Based on "grounded theory" the task of the researcher is to appreciate the different constructions and meanings that people place upon their experiences, rather than searching for external causes and fundamental laws to explain their behaviour. As Jones (1987) comments, grounded theory works because:

Rather than forcing data within logico-deductively derived assumptions and categories, research should be used to generate grounded theory that "fits" and "works" because it is derived from the concepts and categories used by social actors themselves to interpret and organise their worlds.

In SMEs most business decision-making is made by the owner-manager, therefore this person became the subject of an in-depth interview. The depth interview used the unstructured "tell me about it" approach to facilitate an open, flexible, illuminating way to study the complex, dynamic interactive situations such as management e-business decision making, providing:

The opportunity for the researcher to probe deeply to uncover new clues, open up new dimensions of a problem and to secure vivid accurate accounts that are based on

"personal experience" (Burgess, 1982; Easterby-Smith *et al.*, 1995).

IV. The Case Study

The subject of the case study was a private firm operating in the IT industry sector in Taiwan since 1987. During the ensuing period it has steadily established itself as a specialist provider of a comprehensive IC design service, the supply and fitting of new and replacement layout products of computer motherboard, which include various interface cards. From this perspective, the nature of the service is highly tangible, highly customised and is available on a knowledge-based basis by skilled people.

It is a simply structured organization with 12 direct employees carrying out all responsibilities for day-to-day operations and resting with the managing director. Although locally focused, the company's main objective over the next five years was to expand the business operations in the global markets. Their customers include computer motherboard industries, which generates approximately 80 per cent of their business, and their customers almost implement business to business (80 per cent) and business to consumer (20 per cent) operations.

Internal "e" enablers

Fitting into the theme of "awareness" and potential opportunities, from the completed questionnaire the authors were able to deduce that the owner agrees that having electronic mail and a Web site is important for the business. Furthermore the owner perceived that e-commerce will become increasingly important to the company in the future. "Access" to Web-based communications is supported by an ADSL broadband connection to the Internet. The company has taken the initial step to establish its web "presence" and having their "virtual door" opened in September 1995.

Internet commerce usage

In relation to "actual" usage the owner/ managing director explains that:

"I am not concerned about cutting costs and it was not my intention to operate the business purely in the Internet platform, and it was just another way to advertise my service offering."

The owner did not perceive that having a Web site could lower costs for the business, but did in fact view his e-business decision as an added expense in the short term. The primary e-business objective is to promote the organization's name and intent, and provide potential customers with information on the service/product offering. In relation to e-business operations, the company was unsure of how much business was initiated by e-mail or its Web site. However, with an extremely low-level (basic) Web site it may be suggested that there may be limited e-business success. It is a static one-page information-based Web site (page) that gives the visitor details of company location, introduction of products and services and a brief history (five lines) about

the company. There is, however, a contact facility (an online form) to enable contact with the company. At the time of the interview the owner had no plans to improve the sophistication/functionality of the Web site.

The "real" barriers

The dynamic environment that is synonymous with e-business is a similar environment in which this company operates where complex micro issues prevent further development in e-business. It becomes evident that the e-business processes of this small business are at present isolated from the strategic e-business context where the ability to implement full-blown e-business is for this company impeded by various obstacles. Each day the owner is more preoccupied with "fire-fighting to realize and fulfil customer orders, where there is a heavy reliance on face-to-face contact". The owner also perceives a lack of the suitability of Internet commerce for business purposes:

"Our service offering is highly tangible and is not really suited to the e-business environment."

This comment would support the e-services literature where the potential for electronic selling of services/products on the Internet is positively correlated with intangibility. (Lovelock *et al.*, 1999; De-Kare Silver, 2000). The "real" issues of limited resources were cited as inhibiting e-business activities where the owner stated:

"We do not have the resources (manpower and financial), or technical capabilities to manage the demands that online orders may generate ... there is also the issue of distribution."

The owner admits that he is not technically adept and the person responsible for all the administrative duties already had a huge workload to handle each day. Consequently, although this SME has taken an initial step towards e-business, the barriers to full-blown implementation relate to:

- Lack of senior management support/enthusiasm;
- Lack of skills among the employees;
- Lack of resources; and
- A lack of awareness of the benefits of e-commerce for the business.

Furthermore the high level of tangibility of the service/product mix is viewed as one of the major impediments to future utilization of Internet commerce by this particular small business. The "ideal" factors identified by Daniel and Myers (2001) as most important for e-business adoption (senior management support, a staged implementation and a clear understanding of the benefits) are missing from the strategic "e" context of this particular SME.

To date there has been no indication of advancement through the stages of e-business growth to maturity. Subsequently, it is suggested that the e-business decision was a natural reaction (as opposed to being proactive) to much of the hype that has surrounded Internet commerce adoption, rather than any pre-conceived ideas about the benefits for the business, where this particular small

business has taken a less than risky approach in their e-business decision.

To reiterate the aforementioned observation made by PricewaterhouseCoopers (1999):

"Often SMEs equate having a Web site with electronic commerce. They set it up and it sits there as a reminder of their failure."

The inherent lack of strategic emphasis in the e-business strategy of this small business makes this comment extremely pertinent. Perhaps justified by the fact that being at the experimental/informational stage of its development, the e-business objectives of this particular firm are being fulfilled, using the medium purely as a promotional tool. Consequently they have become a "virtual" statistic ... (whether skewed or not), viewed "as something justified by a univocal, irresistible 'progress'" (Winner, 1995).

E-business implementation steps

Before implementing an e-business solution, a firm must first identify its capability of handling an e-business solution. In relation to e-business implementing steps the owner indicated five major concerns on preparing e-business, they are:

1. Does every employee can use email to communicate with colleagues and customers?
2. Can the website achieve advertisement effects to promote the company's name and intent?
3. Can the website provide electronic transaction information for customers and suppliers and recommend potential customers with information on the service/product offering?
4. Do the firm and its suppliers use universal identifiers, codes and definitions to identify products and procedures within its electronic documents?
5. Does the firm link virtual and physical value chain to leverage the power of information and relationships assets?

Answers of most of these questions are positive, and the firm is ready for e-business implementation.

V. An Integrated SME-Business Model

Through above literature review and case study discussions, the authors proposed an integrated SME-business model to be an easy to follow framework for SMEs pursuing e-business operations as Figure 5-1.

Firstly, the study through e-transition model (e-transformation) to overcome barriers and achieve critical successful factors in e-business and therefore to the integration of the physical and the virtual value chain (create channel relationships and relationships assets). Secondly, to further integrate with knowledge value chain (create knowledge assets) to achieve k-business (knowledge business) (David Skyrme, 2001). Through k-business, SMEs can integrate internal and external information and knowledge sources to create value.

Moreover, the model through e-CRM to link with customer (create customer relationships assets) and through e-supply chain to link with suppliers (create supplier relationships assets). Finally, use EAI (Enterprises Application Integration) to integrate all of information and knowledge systems. EAI refers to the complete integration of business processes to the extent that old-line business is indistinguishable from online business (Subba and Glenn, 2003).

This level of integration involves high levels of collaboration between customers and suppliers. Enterprises integration includes full integration of B2B and B2C business including value chain integration. This level of integration utilizes the e-commerce systems to manage customer relationships (CRM) and the supply chain (SCM). This level of integration is e-commerce+CRM+SCM. This stage is somewhat of an ideal concept for the "e-world" environment. Many of the requirements of this stage still have technology problems and over-whelming integration issues for SMEs.

In summary, the study through case study and literature support, proposed two more items: strategic positioning in KVC and mobilization/communication to transform e-business to SME-business (Strategic k-business + m-business + e-business) for smaller and medium-sized enterprises. This model can help firms to create value, relationship, information and knowledge assets, integrate internal and external resources and to achieve competitive advantage in the future development of e-business.

E-business implementation steps

It is necessary for an organization to carry out its own processes toward e-business solutions. A number of organizations have named a chief e-business officer to help coordinate e-business initiatives. This setting allows for centralized control of e-business across an organization, thus resulting in a greater efficiency. Companies must be cautious when they start e-business initiatives; this attitude would help firms quickly move to real-time processes (Karpinski, 1999). However, the speed of implementing these strategies has inspired strategic working alliances across a broad range of industries. This has been demonstrated through the alliances that have occurred between infrastructure organizations and Web boutiques.

Firms implementing e-business solutions should recognize the challenges that face their organizations. First, they should comprehend the dot-com advantage. This occurs as a result of clients/customers' preference for dealing with what they know and trust. This situation is often called the click-and-mortar integration; it occurs not only to the customers, but also to the suppliers. Another challenge is about catching the marketplace rules. That is, the Web will support the supply chain more than ever. The third challenge is that customers should be dealt with first. A quality e-business solution, while being electronic and integrative, should improve connectivity, knowledge management, and performance. It thus improves the efficiency of the firms.

The study identified seven steps to implement a successful e-business solution. Specifically, they are:

1. Set a vision: start from top-down. The executives in the organization must embrace the e-business initiative. A company must recognize that the e-business functionality is a business project instead of a technical task.
2. Recognize up to date: The firm must ignore all of its old ideas and rules on how business is operated and develop total new ways to conduct business. Especially what are their barriers and CSFs to implement e-business.
3. Know your markets: The firm's brand identity, customers, competition, and supply chain should be analyzed in the "know your market" phase.
4. Link: The firm must link virtual and physical value chain to form an information value chain, this way can leveraging the power of information and relationships assets.
5. Positioning: Strategic positioning what role the company in e-business and knowledge value chain will act.
6. Integrate: The firm must through EAI to integrate all various corporate systems then "create" its e-business solutions.
7. Evaluate and update anytime: The firm must modify its e-business solution anytime as speed and innovation are the keys to the e-business world.

VI. Conclusion and Future Research

Conclusions

The establishment of e-business operations presents tremendous challenges for maintenance in SMEs. The first stage of this paper is to identify barriers/factors through developing an e-transition recognition model and to find out critical successful factors through analysis of literature review. Secondly, summarize literatures review to construct a conceptual model and proposed some propositions. Finally, through case study to develop a new integrated model which can be employed by SMEs as the roadmap in their electronic business implementing process for transforming into digital business successfully and concludes with implement steps in e-business for practitioners and future researchers.

Through literature review, case study and discussion, the study due to the characteristics of SMEs to construct an integrated SME-business model, CSFs and implement steps for SMEs. There is a lack of consistent, detailed research into how and why e-business is adopted. This paper has developed a holistic perspective which embraces sets of wider critical successful factors as well as more particular, integrated model which then contribute to the development of an e-business model and research propositions in order to address the situation.

Recommendation

The next stage in the research process will be the qualitative testing of the conceptual model. A series of in-depth interviews with managers of various sectors in SMEs will be

carried out. Qualitative data analysis will allow for adjustment of the model before larger-scale quantitative testing using a structured postal survey instrument. It is also the intention of the authors to carry out comparative research in order to identify CSFs and evidence of best practice. As the e-business SME develops in international markets, one additional area might involve the investigation of the usefulness of current internationalization models.

E-Markets and Changing Trends

Mohini Singh

School of Business Information Technology

RMIT University

Australia

mohini.singh@rmit.edu.au

Abstract: This paper discusses the role of e-markets as intermediaries in the Australasian B2B e-space. The discussion and findings of this paper are from a research project that investigated the business and operational issues of these intermediaries as highly volatile business entities in 2002 and an evaluation of these same e-markets in 2005 to determine the changing trends. This paper presents business opportunities, revenue models from intermediary services, factors contributing to success and the challenges e-markets faced in 2002 and in 2005.

Keywords: B2B E-Business, net market makers, intermediaries, e-procurement, e-auctions, e-marketplace, e-markets.

I. Introduction

Since 1999 Australian businesses have increasingly adopted the Internet as a medium of doing business. According to the Australian Bureau of Statistics Report (2005) in the year 2004 75% of Australian business organisations were using the Internet and 25% had a web presence. B2B e-business in Australia is largely dependent on intermediation from net market makers either private, consortia based, national or international, to facilitate e-procurement, B2B exchanges, e-supply chain management and information sharing between business partners. B2B exchanges include various categories of market spaces, including vertical market portals, horizontal exchanges, hubs and various types of online auctions. Intermediaries generally referred to as net market makers or e-markets bring together exchange partners, organise and manage auctions, generate e-catalogues and other auxiliary services pertinent and relevant to efficient exchanges in the B2B e-space. Since 1998 Australian businesses have increasingly adopted e-procurement largely depending on net market makers to provide intermediary services and facilitate the exchange. As a result net market makers proliferated at an astounding rate because of the business opportunities in facilitating B2B exchanges. For buyers these intermediaries lower purchasing costs while reaching new suppliers. For suppliers they lower sales costs and help the supplier reach new customers.

However, as reported by Frew (2002), many of the net market makers that were announced in Australia in the year 2000 either collapsed or did not get off the ground. In the

year 2001 consolidation of some e-markets (net market makers) took place in Australia leading to B2B online exchanges becoming mostly industry specific verticals dominated by Australian buyers and sellers (NOIE, 2001). By the end of 2002 only about 100 e-markets (net market makers) existed in Australia (Frew, 2002). In 2004 several mergers and acquisitions took place and in 2005 synergistic takeovers are the trend.

Although the Internet offers great opportunities to net market makers, operational and business issues for success and survival as business entities have led these intermediaries to review and change their business and revenue models, services and operations. In this paper I present the findings of a research project that evaluated business practices, success factors and challenges faced by Australian e-markets in 2002 and in 2005.

II. Literature Review

E-markets (net market makers) offer services that facilitate transactional service needs to buyers and suppliers. Weill and Vitale (2001) and Zwass (2000) advocate that e-Markets enable easy search of products and services, information on product specifications which reduce communication costs for both buyers and sellers, dynamic pricing based on demand relationships, sales transactions that include payment and settlement, product delivery, market surveillance for stock market, auction results and enforcement of proper conduct by buyers and sellers.

Electronic intermediaries provide an information infrastructure by which traders can realise commerce over electronic networks (Lee and Clark, 1999). Deganaï and Gautschi (2002) describe net market makers as organizations that own and operate the e-marketplace. Characteristics of net market makers according to Deganaï and Gautschi are that these owners and operators may be companies that are fully independent (that is, are not also buyers or sellers) or could be major and dominant participants in the exchange as buyers and sellers. It is important for net market makers to adopt a business model that will allow them to operate the exchange and make a profit. These net market makers also depend on ancillary services to complete the exchange with support from electronic payment agencies, security system providers, and in some cases the engine (technology) to host auctions (Singh, 2004).

A business-to-business electronic marketplace has several buyers and several sellers. It is an arena on the Internet where a trusted intermediary (e-market) offers

trading functionality to registering companies (Swedish Trade Council, 2001). Whinston (1997) describes intermediary roles as facilitators of transactions between buyers and sellers with value-added services such as aggregation and distribution of product information, quality checks, and warranties. An electronic marketplace according to Archer and Gabauer (2002) is a virtual marketplace where buyers and suppliers meet to exchange information about prices and product and service offerings, to collaborate, and to negotiate and carry out business transactions. Gallagher and Ramanathan (2002) suggest that electronic marketplaces provide the basic infrastructure to allow suppliers and buyers to interact in an online environment.

Based on the above definitions, in this paper the terms net market makers and e-markets are terminologies used interchangeably meaning the same thing.

The large amount of bid, order and transaction management for the B2B procurement of parts and supplies usually require assistance from auxiliary services such as e-markets (Thomson and Singh, 2001, Laudon and Traver, 2002). An 'e-market' functions as a trusted intermediary whose well-integrated business procedures and technology save costs and streamline the purchasing and sales processes (Swedish Trade Council, 2001). They provide customers with buy and sell services to enhance business, efficiencies and competitiveness.

Three main functions that electronic markets serve according to Bakos (1998) are matching buyers and sellers, facilitation of transactions and provide trust and assurance. To match buyers and suppliers they help determine product offerings, price of goods, suppliers for the buyers and buyers for the selling companies. Facilitation of transactions includes logistics, settlement and trust. They provide trust and assurance with certification services and an infrastructure that is bound by legal and regulatory standards. There are generally different value propositions for buyers and suppliers to participate in a trading exchange or an industry consortium. Palmer (2002) suggested that buyer benefits gained from e-markets are easier and faster buying process, reduced transaction cost and time, reach to global community of sellers, easy access to a large amount of information, reduced search costs, streamlined business processes, a wider choice, quick order fulfilment and less chance of errors. For supplier benefits Palmer included cost saving and tighter inventory control, reduced transaction time and cost, broader customer base, information privacy and security, savings in time and capital, streamlined business processes, easy to update prices, availability and other product information, enable smaller regionalised suppliers a level playing field with larger suppliers and consolidation of orders onto a single invoice. Fairchild et al (2003) advocate that e-markets manage market process design, IT innovation and trust in B2B exchanges.

II. 1 Evolution of E-Marketplaces

According to Raisinghani and Haneback (2002) e-markets evolved in three waves of B2B e-business. In the first wave

there were approximately 1,000 independent online marketplaces for commodities such as paper and steel to specialised components such as airplane parts. Many of these were entirely dependent on transaction fees from a few large organizations, which could not remain in business as more organization-to-organisation dealings became possible. In the second wave large corporations formed a consortia designed to reduce bid-ask spreads and matching buyers with suppliers and enabling suppliers to trade with one another. In the third wave, exchanges customised their models based on the cost structures of various purchases. Some models focussed on collecting and distributing information, while others on reducing purchase costs and improving transactional efficiencies.

II. 2 How E-Markets Support E-Procurement

Business and government organisations in Australia and around the world are increasingly moving from paper-based traditional procurement to e-procurement, to capitalise on the efficiencies of price transparency, online catalogues, easy search for products and suppliers, and to capitalise on the benefits of technology and automated processes. While EDI has been the most common method for automating procurement, its extent was limited by its substantial cost that made it only accessible to large firms with recurring volume purchases (Pavlou and Sawey 2002). The more ubiquitous Internet, which is also economically accessible to small-scale B2B exchanges, has further advantaged e-procurement. Developments in B2B e-business in Australia has seen businesses and the government, both at the State and Federal levels adopting Web-based e-procurement to achieve volume purchase, dealing with a wider choice of buyers and suppliers, lower costs, better quality, improved delivery, and reduced paperwork and administrative costs (Singh and Thomson, 2002).

Businesses buy a diverse set of products and services, ranging from paper clips to computer systems, from steel to machinery. At the broadest level these purchases have been classified by Kaplan et. al. (1999) as manufacturing inputs and operating inputs. Business purchases are dominated by systematic sourcing and spot sourcing of goods and services. Systematic sourcing, buying through pre-negotiated contracts with qualified suppliers is relationship oriented and contracts are long term. Spot sourcing is fulfilment of an immediate need, typically of a commoditised item for which it is less important to know the credibility of the supplier (Thomson and Singh, (2001) and Chaffey, (2002) and Christiaanse, et al (2001)).

E-marketplaces or e-hubs that enable B2B purchases have been categorised by Kaplan et al (2000) as MRO (maintenance, repair, operating) hubs, horizontal markets that enable spot sourcing of operating inputs for manufacturing, labour, and advertising. Vertical exchange markets enable spot sourcing of manufacturing inputs and commodities, as well as vertical catalogue hubs for systematic sourcing of non-commodity manufacturing inputs.

E-markets support e-procurement by providing technology and governance solutions, auctions, electronic catalogue content, aggregating supplier input, industry news and standardised data access to buyers (Archer and Gabauer, 2000). Archer and Gabauer further explain that e-markets face the challenges of a balancing task as they set up solutions that satisfy suppliers and buyers ensuring that their costs do not outweigh the overall benefits they will receive from the arrangement, the need of a particular business model to determine which buyers and suppliers to recruit as participants and compete with other techniques that suppliers and buyers use to meet their needs.

II. 3 E-Markets in the Australian B2B E-Space

In the year 2000, many market makers (e-markets) proliferated in Australia due to e-procurement being the most important B2B e-business application. However, in the year 2001 consolidation of some e-markets took place in Australia due to online exchanges being new and unproven roles of these intermediaries (NOIE, 2001). A preliminary study of the e-market in Australia undertaken by Standing and Stockdale (2002) highlighted that initiatives such as 'try before you buy', free transactions, site tours and lengthy FAQ sections, strongly addressing security information were important features on e-market web sites. They also indicated that the most important means of revenue generation was a charge on transaction costs. Standing and Stockdale also suggest that Australian ownership of e-marketplaces is generally based on first mover advantage operating as intermediaries. These are either horizontal or vertical hubs enabling catalogues, auctions, exchanges, storefronts and negotiations.

Bryant (2002) is of the opinion that in Australia and New Zealand there are too many market makers for the size of the industry in this region. According to Bryant, most of these net market makers have similar offerings and flawed revenue models. Therefore to survive and expand business e-market makers need to build specialist businesses to support B2B e-business and look beyond their current business model.

E-markets in Australia do have an important intermediary role in e-procurement matching buyers and sellers, ensuring trust among participants, supporting market operations and transactions, ensuring quality control and aggregating buyer and supplier information. However, with evolving e-business models and technological developments, consolidation and liquidation of a large number of these market makers have taken place. Since 2002, e-market trends in Australia show mergers and acquisitions, synergistic takeovers and market consolidation.

An earlier research on net market makers in Australia (Singh, 2004) identified e-market intermediary business opportunities, revenue models, governance structure and e-market services in the B2B e-space. However, due to the changing trends of mergers, consolidation, huge competition and takeovers, it was imperative to evaluate e-markets to determine the changing trends in their business and revenue

models, business operations, success factors and challenges. Therefore the five e-markets that participated in the earlier research were contacted to identify changes in their business practices, governance issues, challenges and success factors. The method of investigation, findings and discussions are presented in the next section.

III. Research Approach and Methodology

This research project was accomplished via interviews, both face to face and telephone and email. Profiles were gathered from 5 companies operating as net-market makers in the Australian B2B e-space. The interviews explored company demographics, business model, practices and governance, success factors and challenges of these intermediaries operating as business entities, and changes in all of these after two years of operation. The 5 organisations investigated are those that agreed to participate in the project. Contact was made by email with the person who headed the organization, emphasising the importance of this research and agreeing to share the findings with these organizations. Five organizations were considered adequate for this study to help me identify the trends for further research. Interviews were semi-structured with open-ended questions to guide discussion about each firm's business practices, successes and challenges.

Data collected are summarised in Table One. The method of analysis is qualitative, inferences and implications of which are discussed in the following section. For reasons of confidentiality, names of companies discussed are not identified. In this paper they are referred to as Companies A to E.

Insert Table One

IV. Findings and Discussion

Company demographics, business practices, challenges and success factors identified from the findings are discussed in the following section.

IV. 1 Company Demographics

Organisations investigated were both large and small intermediaries in the B2B e-space. Companies B, C and E were privately owned while companies A and D were subsidiaries of international organisations. Companies B, D and E facilitated vertical hubs providing services to the construction, steel and supermarket industries, A and C facilitated horizontal and vertical hubs providing services to specific industries as well as exchange of commodities.

The respondents' positions ranged from senior consultant with the company to partner and director. Core services provided by these organizations included document tracking, online catalogues, strategic sourcing of suppliers, technology for online auctions, prequalification of suppliers and

facilitation of product sales in 2002. Additional services in 2005 included sourcing platforms, collaborative suites, exchange of specific types of goods such as perishables.

IV. 2 Motivation to Operate as Intermediary

Business opportunities from the Internet and e-procurement being the largest component of B2B e-business were the main motivating factors for these organisations to act as intermediaries. Company A saw a window of opportunity in the Australasian B2B e-business, thus decided to expand its operations in this region. Core services provided by these intermediaries included provision of technology for online bidding and auctions, sourcing of solutions and suppliers, document and transaction management and online catalogues. Company B capitalised on technology to reach out to global buyers of Australian Steel. Company D being a part of a large network of the supermarket industry facilitated large exchanges in the industry. Company E provided services specifically to the Steel industry and folded its business in 2004 due to a lack of participation from buyers.

In the 2002, it was apparent that opportunities arising from technology were a strong driver of net market makers to provide intermediary services and to operate as business entities. Another compelling reason to operate as a net market maker was first mover advantage in the emergent Australian B2B e-space. Although total revenue, profit and number of transactions still remain the motivating factors for e-markets, in 2005 developing B2B e-business from e-catalogues to a full suite, and supporting buyers with infrastructure was more compelling. Other reason was consolidation with industry or a take over by a more financially viable large organisation.

IV. 3 Business Models and Governance Issues

Companies A and C operated as neutral third parties supporting both vertical and horizontal exchanges, Companies B and D operated as vertical intermediaries supporting two specific industries the construction and supermarket. Vertical exchanges took advantage of the knowledge of the industry to target suppliers and buyers. Horizontal operators used advertising both formal and informal and allowed 40 % of the potential suppliers, based on prequalification and buyer selection to participate in any event. In most exchanges, the suppliers were known to the buyers due to the limited number of suppliers of some goods and services in this part of the world.

Value proposition to the buyers and sellers included transparency of information and prices, business efficiencies resulting from reduced costs of purchases, administration accuracy of data transmitted, reduced time for acquisition of products, scalable and reliable applications and improved and standardised business processes.

Findings of this research reveal that business models of intermediary operations in the Australian B2B sector of e-business are similar to those identified by Kaplan (2000), discussed earlier. However, new models of mega-

marketplace with supply chains suites are a consideration.

IV. 4 Intermediary Services

Intermediary services included provision of directories listing suppliers, their profiles and ratings; inventory listing; bulletin boards and online information browsing capability; information about the site and customer service, buyer guides and news. Creating e-catalogues and conducting reverse auctions, with online negotiations, RFQ's and document management and after event reports and payments were some of the other important services provided to buyers and sellers. Training users to use technology to bid online, access information and to negotiate online are also provided by these e-markets. Helping buyers participate effectively with technology and training support were incorporated by 2005. Other services for the horizontal smaller intermediaries included knowledge, project and tender management.

IV. 5 Revenue Model

The most common revenue model for services included a flat fee and a percentage of transaction fees charged to the buyer. Other sources of revenue included charges for technology for bidding and auctions, preparing e-catalogues and other small technology solutions. Company E charged a subscription fee for participating for servicing the construction industry. All charges were levied on the buyer. Prevalent payment methods used were traditional, although all had the infrastructure to support e-payments. Most received payments for their services 15 to 20 days after the event. Two respondents indicated that the fee charged covered costs but was inadequate. Low fees were maintained to attract business. New revenue streams identified in 2005 include fee for training, recruiting and licensing of technologies.

IV. 6 Strategic and Tactical Issues

Main business strengths identified were open source technology, skilled staff, a focused business model, technology for niche applications, holistic solutions encompassing services and technology, leveraging global knowledge base, applications of technology and first mover advantage in the industry. Competitive threats common to these organizations were other net market makers operating in the region and in the specific industry, as well as consulting organizations. Consulting organizations such as Peat Marwick and A T Carney provided B2B solutions as well as the engine for auctions. Business strategies for these e-markets focussed on business expansion, capitalising on technology, new and profitable business models, packaging of disparate issues for simplified solutions, new partnerships for business growth. To form new alliances with organizations that can support software development, content, e-catalogues, payment services and technology.

The findings in 2002 indicated that e-markets faced stiff competition, and their strategy is focused on growth and expansion. Technology can be capitalised on for

differentiated services and integrated solutions to lock in customers.

In 2005 moving onto the next round of B2B e-business with winning business models to create value for customers as well as creating profits and sustained growth in shareholder value was emphasised to be the strategic consideration. Communication hubs with supply chains and reverse logistics management to foster better participation from buyers and suppliers are considered.

IV. 7 Infrastructure Issues

Infrastructure for managing an electronic marketplace varied for all the respondents. Company A, which is a subsidiary of an international net market maker owned its e-marketplace platform called 'Bidware' which supports global markets and hosted on a server in Pittsburg. Companies B and E supported vertical exchanges with privately owned technology either developed or modified in house to support the online exchange. Company B's platform required participants to make their bids from their personal computers. Company D used technologies supported by international partners. Company E was based on open source JAVA and LINUX.

From the above it is clear that e-market services are not technology specific and can be operated from different platforms. The need for a seamless integration of procurement data and the back end system is essential for online realtime processing of information. Information technology is the backbone to B2B e-business exchanges. In 2005 this finding was the same with convergence and consolidation of technologies for additional services.

IV. 8 Success Factors

Success factors identified in 2002 were skilled and motivated employees, a focused business model, first mover advantage, open source technology, e-market technology compatibility with internal business processes, knowledge of the industry, a good value proposition to participants, and Australia's limited supplier base.

Technology and business knowledge of the market makers, need for support in B2B exchanges with the increased application of the Internet, and a well planned business model clearly lead to first mover advantages in innovations such as e-procurement and e-business.

In 2005 intermediaries operating vertically supporting industry specific exchanges were more successful in getting business. Ability to incorporate new and diversified offerings also supported business.

A regulatory framework to guide e-procurement and e-market facilitated exchanges now exists in Australia that provides assurance and trust in the application.

IV. 9 Challenges

Challenges faced by net market makers identified in 2002 were clearly more than benefits. The most common ones were the small size of the industry in which they are operating, fragmented market, a lack of belief in the industry

that e-market will work, undoing the legacy of existing markets, old inflexible back end systems, credibility issues due to the small size of the company, limited access risk capital in Australia, fear of change to a new way of doing business, negative perception created by the collapsed and unsuccessful market makers, a lack of trust, education and awareness of the benefits of e-marketplaces.

The above findings indicate that overcoming conservatism, finding a champion in the organization to promote the role of e-market services in B2B exchanges, the need for a leader company in the industry to support net market maker services, breaking existing supplier and buyer relationships, convincing buyers and sellers of the benefits achieved from intermediary services, the need for standards to support trust and security, winning investor confidence and overcoming internal resistance were hindering the growth of e-market operations.

In 2005, challenges were much the same with an emphasis on slow uptake of electronic exchanges. Company E folded business due a lack of interest from steel buyers trading online. New business models with an emphasis on value rather than price is an important consideration.

V. Conclusion

From this research it is apparent that technology opportunities gave birth to a new type of business, the intermediary services. It shows that the internet offers opportunities to buyers and suppliers in the B2B e-space to automate transactions, expand offerings to business partners, launch catalogues, e-procurement sites, auctions and communication. Some intermediaries service only vertical industries and some provide services horizontally. All emphasise on the efficiency to reach out to and be gained by bringing together buyers and sellers in an electronic marketplace.

Business models of e-markets are predominantly neutral third parties operating in the horizontal, vertical or both horizontal and vertical markets. However, the need to move from buyer-oriented, buyer-seller oriented and seller oriented to mega-marketplaces offering combined products and services, a transport network, communications hub and markets where products can be changed across manufacturers are being considered for next generation business to business exchange services.

Despite technical challenges e-markets are faced with the challenges of buyer and seller participation and changes to their sourcing systems. It is a very competitive business which is indicative of the need for new, innovative and integrated services and business strategies for revenue expansion and future survival.

An evaluation of the e-markets shows that although they are now more experienced and capable of offering better services, becoming industry specific or diversifying services is the new trend for capturing value.

It also highlights the fourth wave, which is merges and consolidation with new and diversified services. New

revenue and business models are also evolving.

Abstract: In the modern business world, the IT advances accelerate the world's commercial development with the help of Internet technology in supporting variety of activities. As a result, e-commerce play a significant role in almost every industry. Hotel industry is one of those which are fully beneficial from the e-commerce, which fulfills the customer's needs. This research is conducted to study the character of the hotel e-commerce and the measurement of performance of the hotel e-commerce in Thailand in all perspectives of Balanced Scorecard.

In the research, the researcher uses the reasoning approach to describe the relationship between the variables of causes and effects whose directions are precisely specified. The samples of the research are the hotels in the Bangkok metropolitans and vicinity areas. The researcher uses questionnaires to measure the customer satisfaction of business operations according to the Balanced Scorecard. Then, the initial collective information is analyzed to categorize those samples in percentage. Next, the result of the satisfaction based on Balanced Scorecard measurement is tested for the relationship of all variables by using the statistic of interrelation and chi-square values.

The result of the research provides us the character of operating of the hotel industries and the sufficiency of operating e-commerce of hotel industries in Thailand. In addition, it can be used as a guideline in hotel business development which enhances the capabilities of performance and competition.

Keywords: e-Commerce, Performance, Balanced Scorecard.

I. Introduction

Tourism industry can make incomes to many countries and

enormously pull foreign currencies into the country. Consequently, tourism market has speedily grown. World Tourism Organization estimates that in the year 2020 over 1.5 billion tourists would take international journeys. Europe would still be the most popular tourist place. Second to Europe, Asia Pacific would welcome up to 397 million tourists. The growth rate is average as 6.5% per year [1].

Tourism industry shows a satisfactory growth rate. Anyway, what follows is a highly competitive situation. As known, tourism can bring foreign currencies to the nation's economy at a quite fast time so many developing countries have turned to give an importance to tourism by emphasizing on tourism development as the initial issue in the National Social and Development Plan. Developed countries have also developed their tourism. In the Asian Pacific region, Thailand is one of the tourist destinations due to the natural uniqueness and prominence. Market share of tourism in Thailand is expected to be growing up. In 2020, there would be around 37 million tourists, or 63% increase, to visit Thailand. To respond to such situation, we should develop our tourism industry in all perspectives in order to be internationally competitive.

Currently, hotel business introduces e-commerce to various kinds of work such as internet booking, self-plan tour, hotel information providing in terms of location, type, room price and facilitations, e-mail correspondence, raw material purchase to supplies via internet and online payment. All these facilitate more effective operation. Nevertheless, the business has not evaluated the application of e-commerce to business. So, to be the approach for the evaluation, the objectives of this research are to study the feature of e-commerce in hotel business in Thailand and to develop the effectiveness indicator of e-commerce as to the principle of balanced scorecard. Indicators will be considered from work systems of hotel in four perspectives: financial, customer, organization internal, knowledge and development and will be set up from factors internally and

externally affected. It would be quite beneficial to introduce balanced scorecard to hotel business for performance evaluation and more effective development and improvement of operation.

II. Related Research

II.1 E-Commerce Principle

E-Commerce means any economic activities between at least two persons or businesses conducted on electronic network such as booking, purchasing, negotiating, bidding, paying, advertising, service providing and transactions in other forms, which may occur within a company such as designing, product manufacturing, coordinating, payment transaction. This can be conducted by business to business, business to customer, customer to customer or business to government sector or other kinds, which may late define by the development of e-commerce [2].

From the research of Somnuek Kirito and Phumsak Smutkhup conducted a study on the approach of the development of e-commerce indicator progress in Thailand [4]. From the research, it was found that firstly, the definition and concept of e-commerce should be clear for simple understanding and good survey. If there was no standard definition, the survey would lack reliability and accuracy and would not bring the result to compare in the international level.

E-Commerce Division [2] conducted a study on the evaluation of e-commerce in Thailand as to the principle of Balanced Scorecard such as. The samplings were the entrepreneurs who registered their websites with the Ministry of Commerce. There are 4 main perspectives of Balanced scorecard 1.customer, 2. knowledge and development, 3. internal process and 4. financial were referred for the analysis. Moreover, other perspectives as marketing and information technology and e-commerce were evaluated. From the study, it was found that, in financial perspective, most companies started the business from their own capital so they were small and bore no many expenses. This was good to e-commerce. However, the disadvantage was they were not much considered. For customer perspective, the business gave an importance to customer service by creating relationship and good impression to customers. What was found was that the increasing numbers of customer was rather low. For internal process perspective, most businesses tried to introduce e-commerce and technology to improve the quality of service. For the knowledge and development perspective, most business had growth potential because the entrepreneurs and executives had good education and moderately understand e-commerce features but lacked e-commerce marketing training to their staff and lacked marketing survey so the long-term problem would be faced because of no suitable product development for the market.

II.2 Balanced Scorecard Concept

Balanced Scorecard has been generated by Professor Robert Kaplan and Dr. David Norton who conducted a study on the cause of the US stock market difficulties. This was due to the most use of financial indicator so they thought of other 4 perspectives to evaluate an organization, namely, financial perspective which reflected the financial performance, customer perspective which reflected customer satisfaction, internal process perspective which was the improvement of internal process to respond to financial purpose, knowledge and development perspective which reflected the satisfaction of staff and how to maintain staff with the organization [6].

Wim Van Grambergen and Isabell Amelinckx [7] conducted a research on "Measuring and managing e-business projects through the Balanced Scorecard". They studied the e-business management evaluation by balanced scorecard and found that for the investment in former e-business, ROI, NPV, IRR, PB were considered and these were only the financial result because the executives saw that decision making on investment had to rely on financial perspective. This overlooked other relevant points. BSC helped the executives to consider other perspectives because BSC allowed periodic monitoring and report to the executives so that they could know BSC problem and could adjust to more effective indicators.

II.3 E-Commerce in Hotel Business

The past adjustment of hotel to technology still relied on wholesale partner. Anyway, when internet played an important role, new customer group occurs. Each hotel advertisement was rather troublesome and spent many budgets. After internet introduction, hotel can create their website, design and input details with tiny expenses and is available for new-generation tourists from all over the world, who enjoy searching details and new lodgment from websites.

Sansakon Phikunkheha [3] conducted a feasibility study on e-commerce investment in hotel operation: case study: Chiang Mai Orchid Hotel on 4 perspectives: techniques introduction of e-commerce to hotel operation technology could highly facilitate the hotel operation, marketing the higher the competitive situation was, the higher the customer's bargain power would be, management the information providing in e-commerce in hotel business was not high but the reservation and payment through internet system was rather risky. Hotel should have readiness of specialists, financial – NPV should be at 2.6 years and IRR should equal to 64.97%. From this, it is possible to introduce e-commerce into hotel business.

III. Research Methodology

In the research, the researcher uses the causal research to describe the relationship between the variables of causes and effects whose directions are precisely specified. The samples of the research are the hotels in The Bangkok metropolitans and vicinity areas which standardized by Hotel Standard and Tourism Authority of Thailand and Association of Thai

Travel Agents. The researcher collects information by tool such as questionnaires. The first questionnaire asks the questionnaire of his or her profile to analyze his or her qualification by the measurement of mean and percentage. The second part asks the opinions of the four parts according to the Balance Scorecard to analyze the satisfaction using the statistics of Correlation Coefficient and Chi Square. This tests the relationship between the variables of causes and effects. And the third one is to investigate suggestions after applying business into e-commerce.

IV. Preliminary Results

The study shows that some groups of hotels industries understand that the e-commerce are e-mail, online reservation, and Web sites. Here are some examples of statistics. 18.2% of them purchases goods and services via Web sites, 12.7% use internet banking, 10.6% pays bills through Web sites and takes distance learning, and 8.5% experiences online auction respectively 5.2%.

In terms of monetary measurement, the study finds that the average monetary efficiency as a whole is in a higher position after adopting e-commerce. It increases the revenue from foreign customers and sales also crease during the promotion. After adopting the e-commerce, hotels also gain better images. customers recognize their images, services, and activities. Hotels that accept e-commerce gain more new customers each year.

In terms of interior operation measurement, the research finds that the interior operation efficiency average is in a better position after adopting the e-commerce because it accelerates communications with customers. This enables a better customer service and better reservation management during the high season. It also provides a sufficient communication with customers due to a more sufficient planning.

In terms of learning and growing, the study finds that learning and growing is in a medium level. After adopting e-commerce, hotels are ready for TI since they invest more in technology and employees learn more about their organization and have a better view of the organization. Hotels of e-commerce also provide computers as tools which enhance the employees' skills.

In conclusion, according to the four perspectives of Balanced Scorecard, the operation is involved with e-commerce efficiency.

V. Conclusion

To use e-commerce in business sufficiently, hotels should measure the operation after adopting the e-commerce from time to time to observe the business growth. This will make it clear that e-commerce investment is beneficial to their business. Research shows that e-commerce improves the

operation and enable the business to grow. For a better result, organizations should train employees about the new technology so they can get the best out of it. In addition, the government should improve the law about the e-commerce to ensure the credibility among the service providers and customers of their Web sites since the confidence of e-commerce in Thailand remains unreliable. This is one of the significant steps for hotel industries whose growing customers are mostly foreigners.

Abstract: From the point of view of cost-reduction and benefit-improvement, this paper puts up with a new E-Commerce mode for the medical industry—E-Commerce based on supply chain management (SCM). At the same time, this paper qualitatively analyzes the risks of the mode, including risk of management, risk of technology, risk of human resource and risk of the mode itself. At last, the paper puts forward a set of risk management models for this E-Commerce mode according to the basic principles of project management.

Keywords: E-commerce; Risk analysis; Medical industry; Management; Model.

I. Introduction

The medical industry is a traditional basic industry with very wide development prospect and it is also one of the industries of the national economy with the fastest developing speed. China has already become the big medical country of the world.^[1] The medical industry of China has already built up comparatively perfect industrial system and circulating network. The output and kinds of the medicine stand on the top of the world. The medical industry is now breaking the yoke of long-term planning economy and the property right structure is being developed in the pluralistic directions.^[1] Furthermore, the opening of medical industry has made great achievement. At present, the most important thing for the development of medical industry lies in how to utilize the modern information technology means to tackle the opportunity and challenge of joining the World Trade Organization (WTO).^[1]

The medical industry E-Commerce refers to the medical trade platform that the network members include the medical organizations, pharmaceuticals, banks, medicines manufacturers, medicinal information service providers and insurance companies.^[1] And it offers a safe, reliable, open and medicinal trade platform for users that is easy to maintain.

II. Medical Industry E-Commerce Based on Supply Chain Management (SCM)

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 299 - 303.

II.1 Basic Principles of E-Commerce Based on SCM

The basic principles of E-Commerce based on SCM lies in "Greatly lower costs by reducing intermediate links of medicine supply chain utilizing the basic principle of supply chain management, which can really show the advantages of E-Commerce over traditional trade". The supply chain here means the concept that "the third party supply chain management service". It is a very creative mode and its service range is showed as the figure below.^[1]

II.2 the Make Up Of E-Commerce Based On SCM

The center of E-Commerce based on SCM lies not in technological solution, but technology is the supporting platform of this mode to launch supply chain management service. From the view of technology, E-Commerce based on SCM can summarize as "three system, building databases on two levels". The three systems so-called include an E-Commerce website, a regional home-delivery center website and the chain drugstore management system. "Building databases on two levels" means regional medicinal database and national medicinal database.^[1]

The above-mentioned content constitutes the basic support of forming the E-Commerce based on SCM. This can show as figure 2.

In E-Commerce based on SCM, the main functions of all the components should be as follows:

- 1) **E-Commerce website:** it is a window for the E-Commerce platform for the mode. It collects key data in all areas in the country, and it is responsible for analyzing the industry and issuing information.
- 2) **Virtual local delivery center:** It's the operational center of the mode, which takes charge of the supply chain management for local area and it also corresponds to information service. The center adopts organizational form of "virtual enterprise", which is organized according to the requirements of "three kinds of companies, two kinds of supporting systems" for the third party supply chain management service. Essentially, it is a virtual delivery center based on Internet. What is called "three kinds of companies" is used to indicate the three parties of "virtual enterprise". The three parties are companies that provide the third party supply chain management service, medicinal wholesale companies (the companies of low reaches)

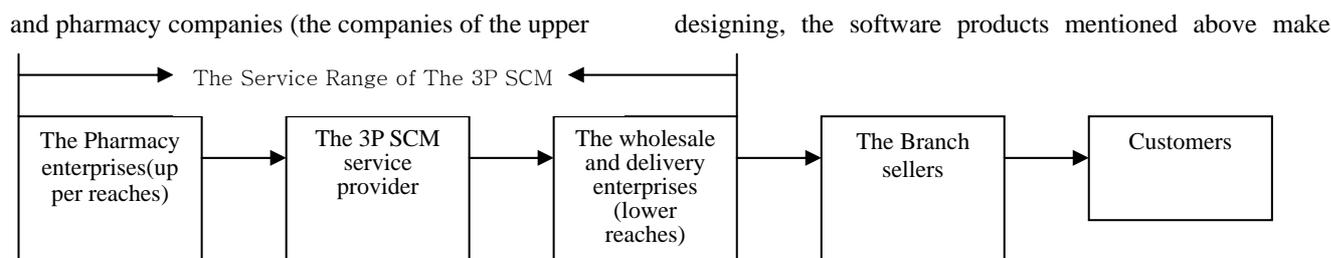

Figure 1: The Service Range of the 3P SCM

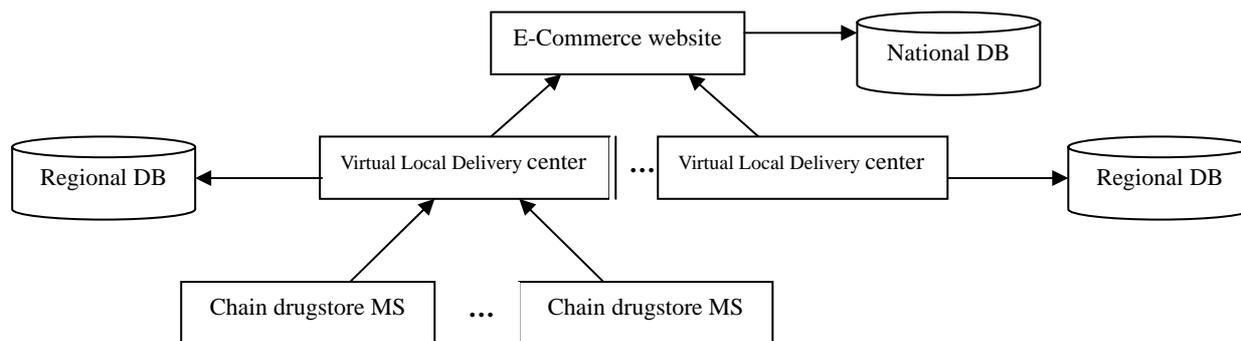

Figure 2: Support Platform for E-Commerce Based On SCM

reaches). The two supporting systems refer to regional delivery center websites, which orientate to medicinal trade services in certain area and logistic delivery system.

- 3) **The chain drugstore management system:** It is the supplementary part for operations of the mode, it aims at medicinal chain enterprises and it offers the internal informatization solutions for enterprises. It mainly acts as “a stepping-stone to success” among the whole E-Commerce mode system. The chain drugstore management system is mostly used to collect sales data of each drugstore and upload them to regional database.

III. Risks of E-Commerce Based on SCM

Risk refers to the possibility of loss or injury.^[2] To analyze the risk of this E-Commerce based on SCM, this paper defines the risks from several points of view.

1) **Risk of human resource:** this kind of risk refers to the condition under which senior employees who carry this mode for a corporation quit, The design of service product, management decisions and organization will all be influenced. If important technical staffers leave the company, software technology will lose. This means the decline of research ability in the company and accordingly the mode will probably be lost. If the relevant employees of marketing department leave, the customers of this mode will be influenced.

2) **Risks of technology:** E-Commerce website, regional home-delivery center website and chain drugstore management system are main technical support platform for the mode to be realized. Though during the course of

every effort to keep being in the lead. With the progress of science and technology, there will be more advanced technology, especially in the industry of the computer. The speed of renewal of knowledge will be very fast. This forms the risk of technology, which will result in backwardness of developed software performance and suitability and then lose already existing market competitive abilities.

3) **Risk of management:** Managing risk mainly comes from reliance on main administrators and the management and administration integration capability of administrators. Companies implementing this mode must have better cohesiveness. If the main administrators left the company because of various kinds of reasons, this mode is difficult to operate according to the established route successfully. In addition, if administrators have inadequate experience on management and inaccurate knowledge to realize what market demand, all these will cause risks, such as marketing insufficient, new product lacking of suitability and managing enterprise improperly, thus they enable expecting benefit discounted.

4) **Internal risk:** the characteristics of this mode lie in that it offers the third party supply chain management service. From the analysis above we can

IV. Risk Management Model for E-Commerce Based on SCM

What is most important for risk analysis is how to manage the risks and avoid loss. Therefore, basing on the qualitative analysis of the risks of this kind of E-Commerce mode, this paper will put forward a set of risk management models that

is based on the principle of project management for E-Commerce based on SCM, including risk identification model, risk assessment model and risk monitoring model.

IV. 1 The Six Processes of Risk Management

In the book "IT Project Management" written by Kathy Schwalbe, the author made a summary of the processes of risk management. The major processes involved in risk management include:^[2]

Risk management planning, Risk identification, Qualitative risk analysis, Quantitative risk analysis, Risk response planning and Risk monitoring and control. The six processes above could be described as the follow figure3. This is the basic principle for the risk management model put forward in this paper.

IV. 2 Risk Management Models for E-Commerce Based On SCM

IV. 2. 1 Risk Identification Model--Fault Tree Method

This paper considers that it is a good way to identify the risk of the E-Commerce mode with the fault tree method. This method uses a graphic way to divide a large risk into several kinds of small risks. Or analyze the reasons for the risks. This is an advantageous tool for risk identification. In analyzing the risks of the E-Commerce mode, this method uses a tree-shaped figure to describe the risks of the E-Commerce mode with a way of from roughness to details and arrange according to different levels. It is easier to find all the risk elements because of the definitive relationship among them. The principle of fault tree method shows as the figure 4 below.

IV. 2. 2 Risk Assessment Model--Risk Assessment Table

There are many methods for risk assessment. In this paper, the method "risk assessment table method" would be adopted. During the procedure of risk analysis, a four-dimension array would be built.

$$Array=[R_i, L_i, X_i, Y_i]$$

In this array:

R_i --Risk;

L_i —the possibility of the risk;

X_i —the loss of risk;

Y_i —the expectation of risk

To most of the IT project like the medical industry E-Commerce based on SCM in this paper, the risk factors including the cost of development, cost for human resource, technological support, the performance of the web platform constitute a typical frame of reference for risks. That is to say that there exists an average at which would lead to the termination of the project if one of the following situations exists: the development cost exceeds, difficult to technological support, cost of human recourse exceeds and so on.

In the analysis of the risk for the E-Commerce mode, if one or more factors exceed the average, the project would have to be stop.

If the risk of the E-Commerce mode reaches the critical point, then it could be judged from the performance analysis, cost analysis and quality analysis to decide whether the project should be terminated or not. This paper takes the software (web platform) and the development cost as an example. Showed as figure 5 below.

In reality, the reference point usually forms a easily changeable section but not the smooth curve showed on the figure 5. Therefore, this paper considers that when assessing the risk for the E-Commerce mode, the following steps should be followed.

- 1) Define a risk average reference value;
- 2) Find the relationship between each array of [R_i , L_i , X_i , Y_i] and its risk average reference value;
- 3) Assess an array of critical point for the termination section of the E-Commerce mode;
- 4) Assess how the risk assemble influences the risk average reference value. That is the extent to which the project should be terminated.

The following table1 is a risk assessment table, which is made up of risk, possibility of loss, loss and the expectation by using the platform performance and cost of development as frame of reference.

Table 1: Risk Assessment Table

Risk R_i	Loss possibility L_i	Loss X_i (US\$)	Expectation Y_i (US\$)
Not support multi-users	30%	5000	1500
Sloe database connection	20%	4000	800
difficult to re-development	50%	25000	12500
Difficult to update or maintain the database	30%	12500	4000
not friendly user interface	20%-30%	2500	1500-2000

In table 1, the persons who are familiar with the platform should confirm the loss possibility. For Example, using the Delphi Method. Each person assesses the every risk independently, and discusses the reasonability of each assessment round by round until the final decision reached.

IV. 2. 3 Risk Monitoring Model

Since it is difficult to determine the influence of time on the E-Commerce mode, therefore, risk monitoring becomes an important job for implementation of the E-Commerce mode. Risk monitoring refers to monitoring the products (here mainly refers to the platform and the management system for chain medicine stores) , the progress of the project and the change of environment. Under most condition, the information will increase with the time, the uncertainties would descend and the risk-monitoring job would be more and more complex. Risk monitoring for the E-Commerce

mode here is mainly executed by experienced management staff. It adopts the prototype method in project management,

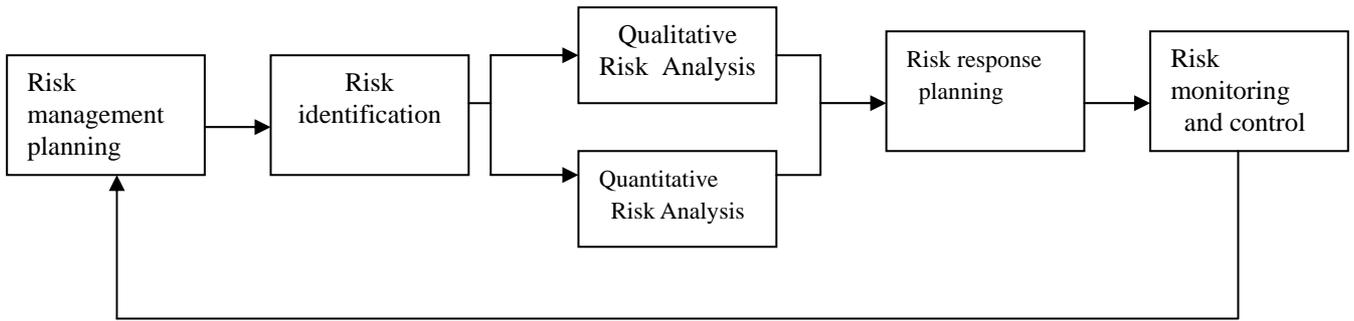

Figure3: Six Processes of Risk Management

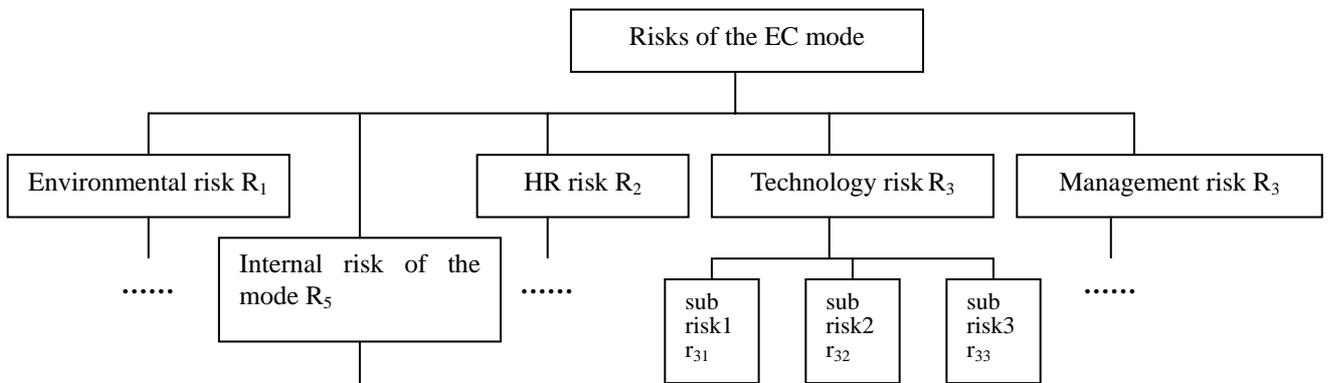

Figure 4: Principle of Fault Tree Method

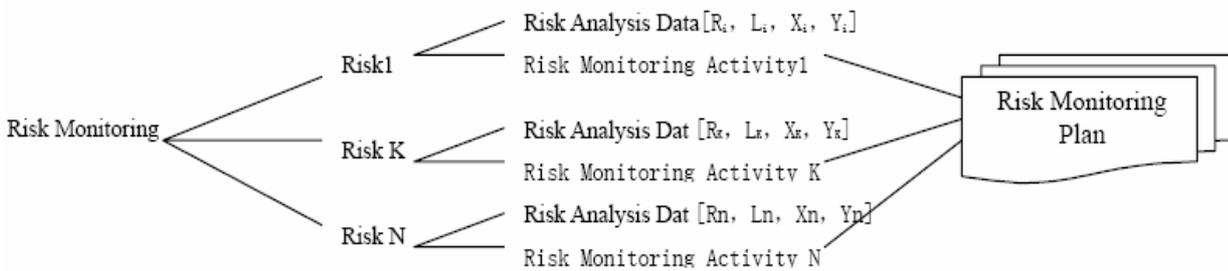

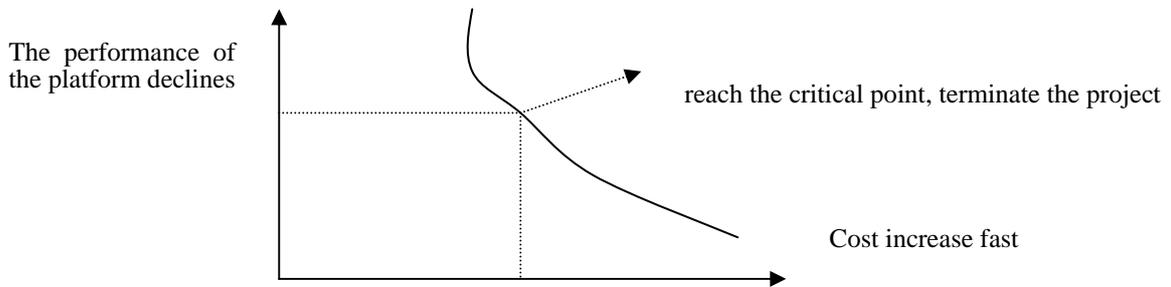

Figure 6 : Risk Monitoring Activities

software psychology and so on to avoid and transfer risks. This risk monitoring activities could be showed as figure 6. That is risk monitoring activity, in this paper, the method "ten risk events listing table" is adopted as the best efficient tool for risk monitoring. It is a tool that could keep a sense of risk through the whole life cycle of IT project, so as for the E-Commerce mode here. The listing table includes: the rank at present, the rank of last, the number of occurrence on the table in a special period and the avoiding progress for the risk. Table 2 is an example for the E-Commerce mode risks event list. The project manager checks the table every week and re-considers the risk events and pays more attention to the changes happen.

Table 2 Ten Risk Events Listing Table

Risk Event	Rank of this month	Rank of last month	Number of occurrence	Risk avoiding progress
difficult to re-develop	1	2	3	redesign the database
bad design	2	4	2	design according to the norms
could not submit the developing tools on time	3	5	5	the purchasing department has regarded it as the highest priority
not well planning	4	1	2	modify the whole plan
...

V Conclusion

Medical industry E-Commerce develops very fast in China as well as all over the world. And its development would take place in a more and more complex and dynamic environment that included high levels of uncertainty and risk.

In this mode for the medical industry E-Commerce, investment risk would be most highly concerned since the revenue would be low at the beginning of the project. As a result of fact, legal measures would have to adopted to preventing the investor from withdrawing his or her investment. Moreover, human resource risk is also an important concern. It is a new project for the study of risk of E-Commerce development, here this paper could not describe every aspect in detail. And this paper only provides a set of theoretical methods for risk management of E-commerce development both for medical industry and other industries; it should be penetrated into further research.

Acknowledgements

The authors are grateful for the constructive comments of the referees. And thanks for all the people whose workings are referred to in the paper. For those who are not referred but included their workings (papers or publications), the authors would feel deeply appreciated.

Analyzing the Role of Interorganizational Systems on Coordination Cost between Firms

Geng Zhang, Zhenyu Liu

Department of Management Science, Xiamen University, Xiamen, P.R.China, 361005
zhanggeng001@126.com, zhenyliu@xmu.edu.cn

Abstract: It is believed that the adoption of Interorganizational systems (IOS) can enable organization to use the information processing capabilities to reduce coordination costs and improve performance. However, the past researches have shown mixed results about the impact of IOS on coordination costs. While drawing on transaction cost analysis, this paper suggests that analyzing the association of IOS use and coordination costs of interorganizations should consider different levels of asset specificity. To illustrate the explanatory power of this analysis, this paper presents a case study from China. The findings from the case study show that, when asset specificity is high, IOS use can reduce coordination costs for monitoring or cooperative purpose. While under a condition of low asset specificity, the association between IOS use and coordination costs is negative.

Keywords: E-commerce management, Interorganizational system, Coordination cost.

I. Introduction

The recent increased interests focused on cooperative relationships across organizational boundaries have put great emphasis on interorganizational system (IOS) issues. IOS is firstly defined by Cash and Konsynski [5] as “an automated information system shared by two or more companies”. These kinds of systems are different from intra-organizational and distributed information systems by exchanging information across organizational boundaries. Although a number of researchers have demonstrated that in an interorganizational relationship, the adoption of IOS could enable organization to use the information processing capabilities to decrease costs and strengthen relationships among participating organizations and as thus improve performance [17], the past researches have also shown mixed results about the impact of IOS on the performance of participating organizations. For instance, Hengst and Sol [11] have introduced transaction cost theory to study the impact of information and communication technology (ICT) on coordinate activities among organizations. They argue that using of ICT can lower coordination costs and they assert there exists a positive relationship between benefits gained from coordination and the level of ICT applied. But on the other hand, they acknowledge that using of ICT will

also increase the complexity of coordination, such as inducing more communication activities and more information processing.

Such problem implies that we should analyze the impact of information system in coordinating activities among organizations under different conditions. This paper addresses this problem by analyzing how the use of IOS affects coordination costs under different levels of asset specificity. Based on our analyzing method, this article presents a case study about IOS using of a manufacturing firm from China. From this case study, we try to investigate the attitude of firms towards the effect of IOS use under different environments.

This paper, in the next section, reviews the primary contributions and arguments of transaction cost analysis in the context of interorganizational relationships. In the subsequent section, we present hypotheses to discuss possible directions to the impact of IOS use on coordination costs among firms under different conditions. Next, we describe the case study from perspectives of managers to explain the power of this framework. This paper ends with conclusions and directions for future research.

II. Implications of Transaction Cost Analysis

Transaction cost analysis (TCA) has focused on the appropriation concerns in interorganizational relationships, which are originated from pervasive behavior uncertainty and contracting problems. The basic assumption underlying the TCA perspective is that the specific governance form is based on an economizing on transaction costs. Williamson [18] argues that the total costs of an organization are consisted of production costs and coordination costs. An organization should choose a proper governance form according to a trade-off between the advantage of low coordination costs in the case of hierarchies and low production costs in the case of markets.

Asset specificity and environmental uncertainty are the key dimensions of TCA that are used to predict the boundaries of a given firm. The concept of environmental uncertainty plays a major role in TCA which is referred to circumstance surrounding an exchange cannot be specified *ex ante*. Considering environmental uncertainty is beyond the control of an organization, we take environmental uncertainty being substantial as the premise of our analysis.

Asset specificity refers to physical assets, production facilities, tools and knowledge tailored to a specific relationship that cannot be re-deployed for other purposes without the sacrifice of productive value. When entering an

interorganizational relationship, participants usually have to invest on assets with specific use only in this relationship. As regarding the manufacturing industry, a firm should, which is looking for appropriate supplier, make great effort on searching and evaluating the potential partners. This may consume a lot of capital, labors and time to establish and maintain the cooperative relationship. Besides, the participants might take the risk to be locked-in by special production equipment, computer technology and related interorganizational systems that link the buyer's and supplier's scheduling and production activities. As asset specificity becomes substantial, interdependency is deepened and coordination is needed for safeguarding the appropriation concerns.

Past researches have studied the association of coordination costs and asset specificity under substantial environmental uncertainty [2][4][9]. Their findings suggested that substantial asset specificity would create bilateral dependence and reduce the firm's control over its business partner. Therefore, the firm's coordination costs might increase [2][8][9]. For example, in the study of buyer-supplier alliance, Anderson and Buvik [1] have confirmed that the association between buyer's asset specificity and buyer's coordination costs was positive. Figure 1 illustrates the association between coordination cost and asset specificity.

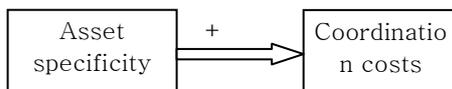

FIGURE 1: Association between coordination cost and asset specificity

III. Analysis of IOS and Coordination Cost

With the rapid development and diffusion of computers and telecommunications in the past decades, organizations can be able to extend the range of cooperation with other organizations based on information systems. Initially, the adoption of Interorganizational systems enables participating organizations to use the information processing capabilities to improve performance and to strengthen relationships with other organizations sharing the IOS. Therefore, IOS are widely adopted in industries such as airlines, banking and transport [17]. Nowadays, it is realized that cooperation and interdependence with other organizations are vital and information technology is an important enabler to such interorganizational activities. To address the influence of IOS, some researchers have investigated the efficiency advantages in transactions gained by IOS. Malone et al [14], Gurbaxani and Whang [10], Clemens et al [6] point out that using of IOS has a positive impact on the cost to coordinate activities between organizations and leads to competitive advantages. At the same time, other researchers have

identified disadvantageous effects of using IOS, such as the risks of becoming locked in with system and relationship specific investments and the issues of changes in bargaining power between firms [3][6][13].

We argue that the mixed findings about the effect of IOS on interorganizational coordination cost relate to the influence of asset specificity and interdependency. Therefore, the analysis of impact of IOS should be discussed under different conditions.

There are different forces of information system to influence the coordinative activities between firms. Gallivan and Depledge [7] classified them as monitoring effect and collaborative effect. The monitoring use of IOS is to ensure trading partners will act as expected to avoid opportunism and moral hazards. While the collaborative use of IOS is contributed to facilitate knowledge transfer and information share among partners. Based on such category of effect of IOS, we establish our analytical framework below.

When analyzing the impact of IOS use on interorganizational coordination cost, it must be realized that investments on IOS should enhance the level of total asset specificity [12][16]. Because IOS is built with interface and information exchange procedure which is proprietary to a particular group of firms, therefore, firms wishing to join the network often need to invest in the special hardware and software for the system. Besides, any trading partner should put into effort to train its personnel to operate such system which is perhaps unique to others [13]. Support for this argument has been provided by Nidumolu [15]. His findings manifest that specific investments of IOS will bring about great switching costs among firms involved in a buyer-seller relationship. The result leads to increasing bargaining power for the firm initiating the IOS which is against other business partners' favor.

According to TCA, when organization is confronted with external uncertainty, the introduction of interorganizational relationships may conflict with the safeguarding problem incurred by substantial investments in specific assets [4]. Consequently, under conditions of substantial asset specificity, IOS may be used to monitor and control over other party's behavior to avoid them taking advantage upon the situation or exercising opportunistic behavior. Therefore, gains by use of IOS are predicted to be much more dominant than the negative influence of additional asset specificity added by the investment of IOS.

On the other conditions of low asset specificity, analysis of impact from IOS using is somewhat complexity. In accordance with TCA, low asset specificity induces no substantial safeguarding problem and interorganizational coordination is an appropriate adaptation response to environmental uncertainty. As a result, IOS is introduced to facilitate the coordination among business partners. However, under this circumstance, using of IOS may bring about great risks to both initiators and participants of systems. On the one hand, investment on system should increase asset specificity of initiators which means that they

are facing a risk to suffer from the anticipated opportunistic behavior of other organizations. While for participants, owing to have no control on the operation over system, they would be locked-in by this system and might face the possibility to be impropriated by the initiators. Therefore, to alleviate the conflict originated from IOS, all the organizations should put into more efforts to coordinate with each other to achieve their common interests. Based on this reasoning, we hypothesize:

H1: Under conditions of high asset specificity, the association between investment in IOS and interorganizational coordination costs is negative.

H2: Under conditions of low asset specificity, there is a positive association between investment in IOS and coordination costs among trading partners.

Our hypothesized relationships between IOS use and interorganizational coordination costs are summarized in figure 2.

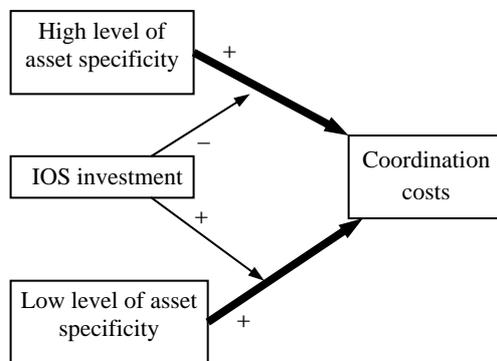

FIGURE 2: Impact of IOS use on coordination cost under different level of asset specificity

IV. A Case Study of Manufacturing Firm in China

To examine our research analysis, firstly we make a survey to investigate the using of IOS in Chinese manufacturing industry. Under the pressure of global competence, more and more firms have formed IOS-based inter-firm relationships to achieve competitive advantage. Our survey shows that more than 70% of firms have participated in certain kind of interorganizational system with their business partners. Most informants recognize they are motivated by the potential ability of systems to access greater quantity of better quality information. Nevertheless, they have different opinions on the decreasing effect of coordination cost by virtue of IOS. To illustrate our analytic method, here we select a firm located at Xiamen, a coastal city of China, for case study.

Amoi Electronic Corporation is a multinational electronic enterprise, which highly focuses on developing

and manufacturing products from telecommunication, digital video and audio to IT industry. Nowadays Amoi has become an internationally well-known leading manufacturer and supplier of mobile phones in China. In 2003, this firm has employed about 20,000 persons and the total sales reached 850 millions US dollar.

This firm has established its own interorganizational information system which has designed interface with its intra-organizational information systems. Participants of this IOS include Amoi's primary suppliers and distributors. For instance, Tianma Microelectronics Corporation (TMC) is an important supplier who provides mobile phone used liquid crystal display (LCD) for Amoi.

Since its business partners are mostly located in other cities all over China, managers of Amoi claim the operation of IOS has a crucial role on reducing communication costs and saving time of transaction. Nevertheless, considering the ability of reducing total interorganizational coordination costs by IOS, the situation is somewhat complexity according to different trading partners.

When considering its supplier, Amoi recognizes TMC as one of its most important business partners. The reason is that mobile phone is Amoi's most profitable kind of production and cutting costs is just the fundamental aspect to win competent advantage over drastic telecommunication product market. Another reason is that the supply of screen for mobile phone demands high degree of customization. Therefore, Amoi has spent a huge time, labors and capital to certify and adapt its designing and manufacturing processes for selected LCD. That means Amoi has invested high level of specific asset with TMC. If the supplier has any changes on R&D or output of LCD, and if Amoi cannot collect such information in time, that would bring about enormous damage to the producing arrangement of Amoi. To avoid contingency happening, or even being misappropriated, Amoi uses IOS to monitor this supplier's plan of R&D and throughput. On the side of TMC, it also benefit from using of this system. Because they can get the right demands from Amoi beforehand, that would be useful for them to arrange their manufacturing program. As a result, managers of Amoi acknowledge that they have experienced savings of coordination cost with TMC through IOS.

As for relationships with its distributors, both Amoi and distributors have no need to invest substantial specific asset to hold the bilateral cooperative relationships. Under such circumstance, Amoi faces a dilemma situation. On one hand, Amoi depends on distributors to occupy market. So this information system can assist Amoi to monitor sale activities of distributors' in time. On the other hand, distributors sell not only products of Amoi, but also the same kind products of others. Therefore, all the two parties have some extent of doubt. Amoi has a worry about secret leakage when using this system. And from distributors' perspective, they want to keep control of their business and remain independent from manufacturer. This leads to low level of interdependent relationships among them. Consequently, managers of Amoi claim that they cannot perceive significant reduction of

coordination cost with distributors from using of IOS.

V. Conclusion and Future Research

It is pervasively believed that interorganizational systems can play an important role in coordinating activities between organizations. Accordingly, it is reasonable to expect that the adoption of IOS can enable organization to use the information processing capabilities to reduce coordination costs and improve performance. However, the past researches show mixed results about the impact of IOS on the coordination costs. Some researches provide favorable evidences to this suggestion [10][14], while other results give no significant support to it [3][13]. This paper focuses on the possible conditions under which IOS use can positively affect coordination of activities between firms.

According to transaction cost analysis, under external uncertainty environment, asset specificity becomes the primary issues to influence coordinative patterns between business partners. From the perspective of technology, IOS may be used as a collaborative platform to share knowledge and facilitate knowledge transfer between firms [7]. Moreover, organizations usually use IOS as a control mechanism to monitor the business partners. In general, the monitoring use of information system is applied to alleviate risks induced by investment on specific asset, while the cooperative use of information system is to strengthen bilateral cooperative relationships. On the other hand, investment on system should increase asset specificity of initiators which means that they are facing a risk to suffer from the anticipated opportunistic behavior of other organizations.

This paper discusses impact of IOS use on interorganizational cost under two situations of asset specificity. If a high level of asset specificity exists, organizations have to put more coordinative efforts to maintain the cooperative relationships. Upon that, gains by use of IOS are predicted to be much more dominant than the negative influence of additional asset specificity added by the investment of IOS. However, on the conditions of low asset specificity, investment on system should increase asset specificity. As a result, IOS use has a potential to increase interorganizational coordination cost.

At last, a case study is presented here to investigate IOS use in manufacturing industry from China in accordance with our framework. The findings from the case study demonstrate researching direction of our method.

Though the findings of this study provide valuable insights, there are still a lot of works need for further research. For instance, considering the shortage of case study method, it is essential to require quantitatively methods examining large number of IOS use from a wide

extent. Second, because of diversified goals, abundant development and operation of IOS, association of information technology use and coordination cost under economic conditions needs to be examined in a much broader context incorporating more types of IOS.

Abstract: This research sets out to determine factors that influence consumers' adoption of B2C E-commerce in Macao. While prior research has shown that there are many factors that influence E-commerce adoption, this research hypothesized that two variables – namely, trust and willingness to use credit cards for online transactions – influence E-commerce adoption in Macao. This research further hypothesized that trust and willingness to use credit card interact to influence adoption. Using data collected from a questionnaire survey, the results of this study found that the two hypothesized variables are positively related to intention to adopt E-commerce. The results also support the interaction effect. The nature of interaction showed that trust is related to E-commerce adoption only when willingness to use credit card for online transaction is high. Also, willingness to use credit card for online transaction is related to E-commerce adoption only when the level of trust is high. These results provide a richer understanding of the relationship between the hypothesized variables and E-commerce adoption. This study also collected interview data related to Internet users' adoption of E-commerce. The interview data provide a better understanding on why Macao people are afraid of using credit card for online transactions. The researchers gathered more information about interviewees' credit card usage and habits, their attitudes toward credit card security, and their thoughts regarding identity theft. The interviews also uncovered other factors that may influence E-commerce adoption.

Keywords: E-Commerce Management; E-Commerce adoption.

I. Introduction

The internet has played an increasingly important role in people's daily life. One important feature provided by the Internet is that it creates an innovative channel called the electronic commerce that enables people to do business through the network. E-commerce is currently revolutionizing the way people work. Many commercial establishments as well as researchers are keen to determine the factors that influence people to engage in E-commerce. Although numerous studies have been conducted, they were carried out mostly in a western setting. Few studies exist on E-commerce in less developed places, such as Macao, a special administrative region of China. The researchers, being residents in Macao, are interested to determine the

factors that influence consumers' adoption of E-commerce in Macao.

There are few statistics on the popularity of E-commerce in Macao. A study by Cheung and Wang (2004) has found that about 57 percent of household in Macau has Internet connections. This figure suggests a potential pool of E-commerce users exists. This study, therefore, focused on B2C E-commerce in Macao and it sought to determine the factors that influence consumers' adoption.

A literature review on EC adoption has found that trust is a variable that is extensively emphasized in prior research. Even though the literature stressed the importance of trust in E-commerce, empirical research has found there was only a small variance between trust and adoption of E-commerce. Bhattacharjee (2002) has pointed out that trust explained only 13 percent of the users' willingness to transact online. This result is surprising. No explanations have been provided for the low variance. One motivation for this research, therefore, arises from the curiosity to further examine this relationship.

Given that the context of this research is in Macao, the researchers are interested to know if consumers' willingness to use credit card for online transactions would affect adoption of E-commerce. In Macao, credit card facilities are reasonably accessible from financial institutions. People in Macao, however, may not be easily persuaded to use credit cards online because of some inherent fear they have regarding its usage. The willingness to use credit card for Internet transactions, therefore, is chosen as a variable that warrants closer attention in this research.

This study develops and tests a model that determines the factors that underlie people's adoption of E-commerce in Macao. Specifically, this study hypothesizes and tests the relationship of two independent variables that influence the adoption of E-commerce. The two independent variables are perception of trust in E-commerce and willingness to use credit card in electronic transactions. The dependent variable is the adoption of E-commerce. Besides linear relationships between the independent and dependent variables, this research also tests the presence of an interaction effect created by the two independent variables. Prior research has not examined or explored the interaction effect.

It should be noted that even though there may be many factors that could influence the adoption of E-commerce, this research has chosen to focus on two salient variables – namely, trust and willing to use credit card for online transactions. Technical dimensions of E-commerce are not included in this research.

II. Factors influencing usage of E-commerce

Chang et al. (2004) have done a thorough review of the literature on factors that influence usage of B2C E-commerce. Their review found that many variables influence usage. They include security, risk, trust, willingness to use credit card in electronic transactions and others. The following sections review these variables.

II.1 Security in E-commerce

Internet security is very important to E-commerce users. As the internet is a public network, it is possible for hackers to steal passwords and personal information. Hackers can also impersonate users and perform illegal transactions over the internet. For example, there are hackers who use other people's name and password to perform illegal financial transactions to obtain money or goods.

Although academics and industry have known about the security problems (Bhatnagar et al., 2000; Suh and Han, 2003), these problems have been accommodated rather than corrected. As a result, there have been more and more cases of wide-scale security infractions throughout the network over the last few years. For example, there have been reports that credit card information has been stolen due to breaches in security (Bergstein, 2005).

II.2 Risk in E-commerce

E-commerce users need to take more risks compared to traditional commerce users (Martinsons, 2002). For example, E-commerce users may receive services or products that are below their expectations and they have minimal recourse because the legal protection for E-commerce users varies from country to country. Web retailers may also take advantage of the distant and impersonal characteristic of E-commerce to mislead consumers (Pavlou, 2003). Some of the risks that E-commerce users face include economic risk (lost of money), personal risk (safety of the goods or services), seller performance risk (careless control of the buying process) and privacy risk (revealing consumers' private information).

II.3 Trust in E-commerce

Rotter (1971) has pointed out that trust is the expectation that commitments undertaken by another person or organization will be fulfilled. Trust also involves a person's willingness to be vulnerable to the actions of another person or people (Mayer et al., 1995). That is, the parties will protect the right of the other party involved. Trust is very important in many social and business activities.

Suh and Han (2003) have pointed out that trust is important because there are uncertainties and risks involved in E-commerce. Gefen (2002) has also emphasized the importance of trust in E-commerce because of the less verifiable and less controllable business environment in the Internet. Kim and Prabhakar (2004) argued that consumers'

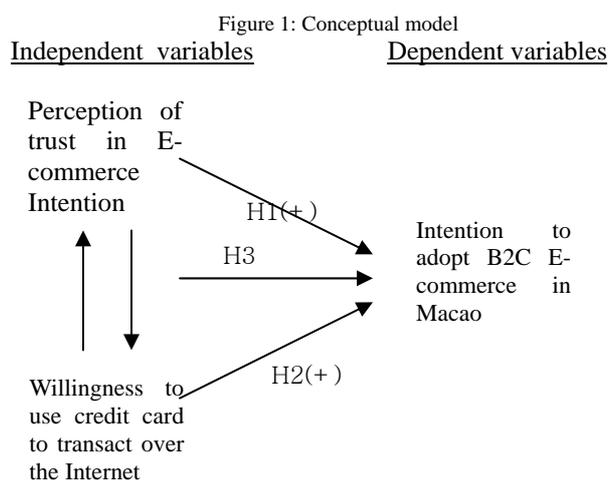

lack of trust in the electronic channel is a possible reason for the delayed acceptance of the Internet as a retail distribution channel. Indeed, prior studies have found that there is a significant positive impact on overall trust affecting people's usage of online shopping. (Bhattacharjee, 2002; Gefen, 2000; Gefen et al., 2003; Yoon, 2002).

II.4 Willingness to use credit card in E-commerce

Suh and Han (2003) pointed out that even though the number of Internet users has increased dramatically, many are not willing to use credit card over the internet because people do not have confidence in E-commerce security. Based on volume, credit cards and charge cards were the most common payment methods used in the U.S. (Sienkiewicz and Bochicchio, 2002). In some countries outside of America, using credit card for online transactions may not be popular. Many Internet users are afraid of security issues when they send credit card information over the Internet. When their personal information is sent through the Internet, they are exposed to hackers who may be able to intercept their information.

III. Hypothesis development

In this study, the researchers selected two of the more compelling variables that may impact E-commerce adoption in Macao. The intention is to develop a parsimonious model. Figure 1 shows the model. As shown in the figure, the dependent variable is the intention to adopt E-commerce. The two independent variables are (i) the perception of trust in electronic transactions and (ii) willingness to use credit card in electronic transactions. The following paragraphs describe the variables as well as the hypotheses developed for the research.

- Intention to adopt E-commerce in Macao

Intention to adopt E-commerce is used as a proxy for adoption of E-commerce. Longitudinal data are required to measure adoption of E-commerce. As this study used cross

sectional data, intention to adopt E-commerce is used as a proxy. According to prior research, intention is the best predictor of behaviour (Ajzen, and Fishbein, 1980). Prior research has used intention to adopt E-commerce as a proxy for E-commerce adoption (Cao and Mokhtarian, 2005).

- Perception of trust in electronic transaction

Traditional commerce is the main channel for doing business in Macao. Macao has a small geographic area of about 26 square kilometres. Shopping for most products and services is easy and convenient. Furthermore, Hong Kong, which is considered a shopping paradise, is just an hour's ferry ride away. People will avoid using E-commerce unless they have trust in it. Macao is a Chinese and Portuguese society. If people want to buy things from foreign countries' websites, the buyers frequently need to have good knowledge of English in order to complete the transaction. When people want to use electronic transaction and they do not have a clear understanding of the terms and conditions, they become vulnerable. Trust, therefore, plays a very important part in E-commerce. Even though prior research had shown that there is a positive relationship between trust and E-commerce adoption, this study seeks to affirm that the relationship holds true in the Macao business environment. Hypothesis 1, therefore, is as follows:

H (1): When people have a higher perception of trust in E-commerce, their intention to adopt E-commerce will be higher.

- Willingness to use credit card in E-commerce

Most E-commerce transactions are carried out using credit cards. When people use credit card in E-commerce, they need to provide their credit card number and personal information to the other party. After the other party receives the money from the buyer's credit card account, the goods or services will be delivered to the buyer. It is simple and convenient to use credit card payment in E-commerce transactions. Some people feel, however, it may not be safe to transmit credit card information over the Internet because the Internet is a public network and as such, information provided in the transaction may be stolen. Also people fear that information related to the E-Commerce transactions may be abused.

Human nature is such that we always need a sense of security. We need to protect our personal information. E-commerce is still a new mode of doing business compared to traditional commerce. People need to bear certain risk when using the credit card for E-commerce transactions. Their personal data may be stolen. For these reasons, people may hesitate when they shop online. Hence the following hypothesis:

H (2): When people have a higher willingness of using credit card in E-commerce, their intention to adopt E-commerce will be higher.

- Interaction effect

As mentioned previously, prior empirical research has found only a small variance between trust and adoption of E-commerce. This is surprising, given that trust has been emphasized extensively in the literature. It is possible that trust interacts with another variable to influence E-commerce adoption. Figure 2 shows it is possible that when there is low willingness to use credit card for electronic transactions, trust does not have any relationship with intention to adopt E-commerce. Similarly, figure 3 shows that when there is low trust in E-commerce, willingness to use credit card does not have any relationship with intention to adopt E-commerce.

Based on the hypothesized interactive effect, a set of topology is proposed for the various groups of E-commerce adopters. Figure 4 shows the topology. The figure shows that people with low trust in E-commerce and low willingness to use credit card in E-commerce are classified as non-adopters. People with high trust in E-commerce and low willingness to use credit card in E-commerce are classified as ready but afraid category. People with low trust in E-commerce and high willingness to use credit card in E-commerce are classified as not ready but willing category. People with high trust in E-commerce and high willingness to use credit card in E-commerce are classified as adopters.

Figure 2: Trust and adoption of E-commerce

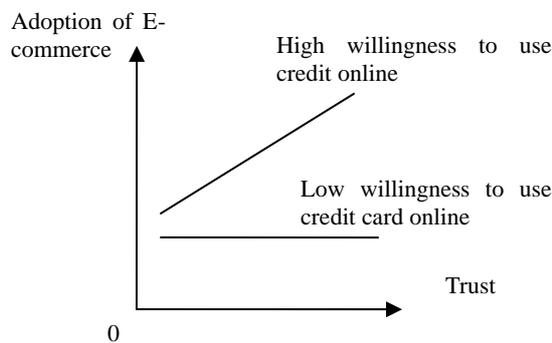

Figure 3: Willingness to use credit card and adoption of E-commerce

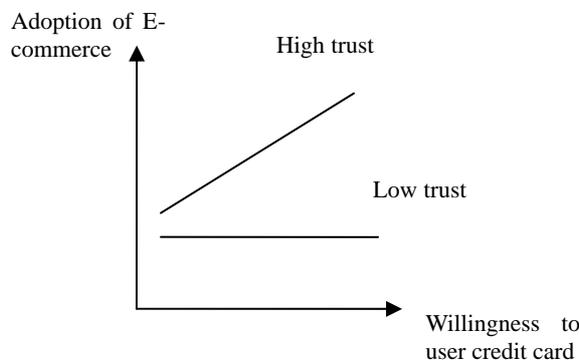

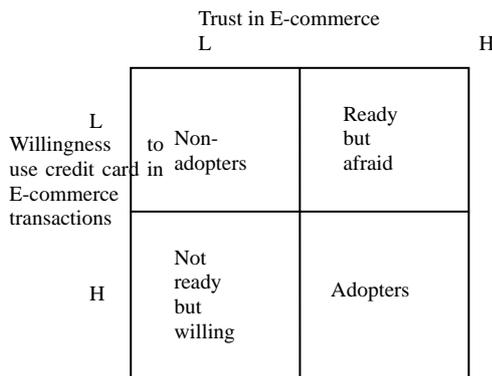

Figure 4: Topology of E-commerce adopters

Based on the above discussion, the following hypothesis is developed for this study:

H(3): Trust and willingness to use credit card interact to influence intention to adopt E-commerce.

III. 1 Research method

Quantitative and qualitative approaches were used to conduct the study. The following sections discuss these approaches.

III. 2 Quantitative approach

The quantitative aspect of this research made use of data that have been collected from a E-commerce questionnaire survey. The respondents for the survey were Internet and E-commerce users in Macao. The questionnaires were distributed to 250 Internet and E-commerce users. They comprised colleagues, office workers, and postgraduate students studying at the University of Macao. Respondents participated in the questionnaire survey voluntarily. The respondents were assured that the information gathered in the survey will be kept confidential. The questionnaire did not require respondents to identify themselves.

The questionnaire items were in English. As most respondents read Chinese, a Chinese translation was provided. To minimize translation errors, the draft Chinese version of the questionnaire was translated back to the English version to ensure translation errors were minimized.

From the data collected, the researcher made use of data for two global measures. They were (i) perception of trust in electronic transaction and (ii) willingness to use credit card in electronic transactions. Data for two items measuring intention to adopt E-commerce were also used in this research. All measures used in the research are shown in Table I. The data were based on a seven-point Likert-type scale.

Demographic data were also collected during the survey. These include gender, age, occupation, income, education level, experience using the Internet, and online habits of the respondents. The software named SPSS (Statistical Package for Social Science) version 12 was used for data

analysis. Moderated multiple regression was used to analyse the data.

Table I: Measurement

Measurement items *	Variables to be measured
a. I am not willing to use my credit card in online transactions	Willingness to use credit card in electronic transaction
b. E-commerce is not trustworthy	Perception of trust in electronic transaction
c. I will try my best to avoid using E-commerce	Intention to adopt E-commerce
d. In the coming future, I would not use E-commerce	Intention to adopt E-commerce

* items were reverse coded.

III. 3 Qualitative approach

This study also conducted semi-structured interviews to collect qualitative data. The purpose of the interviews was to obtain a richer understanding about B2C E-commerce adoption in Macao. Specifically, the interviews were motivated because it is possible that there are some underlying reasons for the Internet users' perceptions regarding trust in E-commerce and their willingness to use credit card for online transactions. The interviewees were chosen based on the researchers' contacts. The interviews were conducted in company premises such as meeting rooms or at a quiet place where the interviews were free from disturbances. The third author conducted separate interviews for seven interviewees. Each interview lasted about 20 minutes. A set of questions was prepared to guide the interviews. Before the interviews, the researcher asked permission to record the interviews. The interview data were then transcribed and analyzed.

IV Data analyses

To analyze the data collected, the survey responses were first coded and input into the SPSS data sheet. The following sections describe the survey respondents and the results of analyses for the survey data. They also describe the analyses of qualitative data.

IV. 1 Descriptive statistics for survey data

Among the 250 questionnaires distributed, 178 were answered completely. Thirty four were incomplete and 38 did not return the questionnaires. The response rate, therefore, was 71.2%. Table II shows the demographic characteristics of the survey respondents. The table shows that majority of the respondents are between 21 to 30 years of age. Their educational level was mostly college and above and they had more than 5 years experience in using the Internet. About 67% spent between 28 to 42 hours online per week.

Table III shows the descriptive statistics. As shown in the

table, the mean score for the three variables in the table are below 4. Given that the scale for measuring the variables ranges from 1 to 7, where 1 represents “strongly disagree” and 7 represents “strongly agree” with the statement presented, and 4 is the neutral value, the mean score shows that respondents generally have low trust for electronic transactions, low willingness to use credit card in electronic transactions, and low intention to adopt B2C E-commerce.

The Pearson Correlations in Table III show that the two independent variables – perception of trust in electronic transaction and willingness to use credit card in electronic transaction – are positively correlated to intention to adopt E-commerce. There is also a positive correlation between willingness to use credit card in electronic transaction and perception of trust in electronic transactions.

IV. 2 Hypotheses testing

The hypotheses were tested using regression analyzes. The tests used three regression models. Each model corresponds to the hypothesis to be tested. For example, Model 1 has one independent variable and one dependent variable. The independent variable is the perception of trust in electronic transaction and the dependent variable is the intention to adopt E-commerce. After Model 1 has been tested, a second independent variable – which is the willingness to use credit card in electronic transactions – is added to the regression. Model 2, therefore, comprises two independent variables and one dependent variable. Hypothesis 2 is tested using Model 2. After testing Model 2, an interaction variable – which is created by the multiplication of the first two independent variables based on their centered scores – is added into the regression model. The new model, which is model 3, is used to test hypothesis 3.

Table II: Demographic characteristics of respondents (N=178)

		Freq	Percentage
Gender	Male	102	57.3
	Female	76	42.7
Age	21-30	128	71.9
	31-40	50	28.1
Occupation	Student	14	7.9
	Employee	123	69.1
	Official	9	5.1
	Businessman	10	5.6
	Others	22	12.4
Monthly Income	Below \$5,000	8	4.5
	\$5,000-\$8,000	66	37.1
	\$8,001-\$12,000	39	21.9
	\$12,001-\$20,000	58	32.6
	\$20,000 or above	7	3.9
Education level	Secondary	17	9.6
	College or above	161	90.4

	above		
Experience in using Internet	3 years to 5 years	17	9.6
	Above 5 years	161	90.4
Online habit	14 to 28 hours	49	27.5
	28 to 42 hours	119	66.9
	Above 42 hours	10	5.6

Table III: Descriptive Statistics

Variables	N	Mean	Std Dev	Correlations*	
				T	W
Perception of trust in electronic transaction (T)	178	2.97	1.61	-	-
Willingness to use credit card in electronic transaction (W)	178	3.41	2.09	0.456	-
Intention to adopt E-commerce (A)	178	3.35	1.16	0.418	0.363

*All correlations are significant at $p < 0.01$

Table IV summarizes the results of regression analyses. The table shows that in Model 1, the beta for the independent variable is positive and significant. Hence, hypothesis 1, which states that when people have a higher perception of trust in E-commerce, the more they will adopt the use of E-commerce, is supported.

Table IV also indicates that there is a significant increase in R-squared when Model 1 progressed to Model 2. The increase indicates that the addition of the second independent variable – willingness to use credit card in online transactions – provides additional explanatory power to the regression model. Note that the betas for the two independent variables are significant. Hence, hypothesis 2, which states that when people have a higher willingness of using credit card in E-commerce, the more people will adopt the use of E-commerce, is supported.

Table IV: Results of regression analyses

Variables in model	Model 1	Model 2	Model 3
Constant	2.456**	2.256**	2.357**
Perception of trust	0.302**	0.230**	0.188**
Willingness to use credit card	-	0.121**	0.106**
W x T	-	-	0.163**
R2	0.175	0.212	0.236
Change in R2	-	0.037**	0.024**

** $p < 0.01$

The centered scores of the two independent variables were used to calculate the interaction term in model 3. This was done to mitigate the problems of multicollinearity (Aiken and West, 1991). The results of the regression analyses show that there is a significant increase in R-squared when the interaction variable is added to Model 2. This result indicates that the interaction variable provided significant explanatory power to Model 3. Note that the coefficient of the interaction variable is significant. The value of the VIF for the interaction term is 1.239, which is within the limit that indicates multicollinearity is not a concern. The results, therefore, supports hypothesis 3, which states that trust and willingness to use credit card interact to influence usage of E-commerce.

Given that there is a significant interaction effect, the researcher proceeded to examine the nature of the interaction effect. First, the researcher divided the respondents into two groups – those with low and high willingness to use credit card in electronic transactions. Respondents who have W less than or equal to 3 were grouped as people who have low willingness to use credit card in electronic transaction. There are 108 respondents in this group. Respondents with W greater than or equal to 5 were grouped as having high willingness to use credit card in electronic transactions. There are 53 respondents in this group. Regression analyses were carried out to determine how trust and intention to adopt E-commerce relate to each other in these two groups.

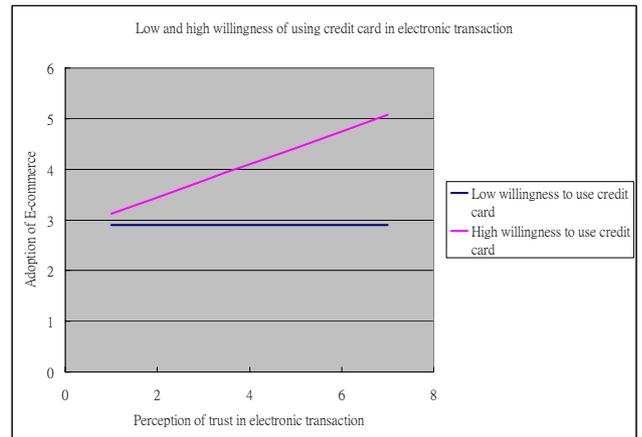

Table V summarizes the results of the regression for the groups with low and high willingness to use credit cards for online transactions. Figure 5 provides a graphical representation of the results shown in Table V. The graph in Figure 5 shows that when people have low willingness to use credit card in electronic transactions, the level of trust is not related to intention to adopt E-commerce. This is unlike the case when there is high willingness to use credit card in electronic transactions. In this case, the level of trust is positively related to intention to adopt E-commerce.

Table V: Regression analysis of low and high willingness to use credit cards

Variables in model	Low willingness to use credit card	High willingness to use credit card
Constant	2.905**	2.798**
Perception of trust in electronic transaction (T)	0.072	0.325**
R2	0.009	0.278

** p<0.01

Figure 5: Graphical representation of low and high willingness to use credit cards

The study also divided the respondents into those with low and high perception of trust in electronic transactions. For respondents with T less than or equal to 3, they are grouped as people who have low perception of trust in electronic transaction. For respondents who have T greater than or equal to 5, they are grouped as having high perception of trust in electronic transaction.

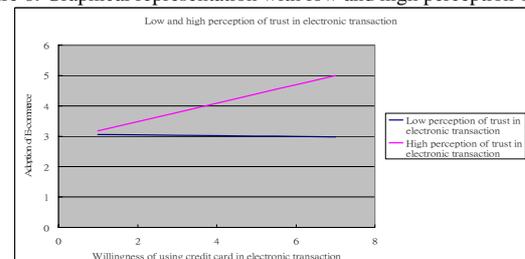

Table VI summarizes the results of the regression for the groups with low and high trust in E-commerce. Figure 6 provides a graphical representation of the results shown in Table VI. The graph in Figure 6 shows that when people have low trust in E-commerce, the level of willingness to use credit card for electronic transactions is not related to intention to adopt E-commerce. This is unlike the case when there is high trust in E-commerce. When there is high trust, the willingness to use credit card for E-commerce transaction is positively related to intention to adopt E-commerce.

Table VI: Regression analysis with low and high perception of trust

Variables in model	Low Trust in E-commerce	High trust in E-commerce
Constant	3.075**	2.880**
Willingness to use credit card in electronic transaction	-0.014	0.303**
R2	0.000	0.360

** p<0.01

Figure 6: Graphical representation with low and high perception of trust

IV. 3 Results of qualitative analysis

This study conducted separate interviews with 7 Internet users. The interviewees unanimously agreed that trust is “very important” in E-commerce. The interviewees said that in E-commerce, trading is performed without the physical interaction between the trading parties. Consumers, therefore, must trust each other completely when they are involved in E-commerce.

With regards to credit cards, the interviews found that they are very popular with the interviewees. The interviewees, however, used their cards mostly offline. Not many used their cards online. They felt that there is a difference in using credit cards online and offline. One interviewee, who used her credit “10 to 20 times a month” used her credit card for online transactions only twice. She said, “When I used it (credit card) online, it makes me a bit worried.” Another interviewee said she used her card “several times a month”, but she had not used her card for E-commerce. She went on to say, “The law protection for E-commerce is not enough in Macao. ... I think E-commerce is too new in Macao. ... At this time, I think I will not use E-commerce unless it has a great improvement on protection to the user.” Another interviewee shared the same feeling. She said the reason she was not willing to use her credit card online was because she thought that the security for E-commerce is not mature.

Despite the interviewees’ worries about using credit cards online, they generally think that E-commerce is advantageous because it is convenient. They think that western countries are large and people there cannot buy things easily. Westerners, therefore, are more willing to use credit card to do online transactions. Some interviewees felt that there was no need to use E-commerce in Macao because Macao is a small place and people can buy things easily.

The interviewees felt that they have no choice but to use credit card as the payment method if they decide to use E-commerce. Some interviewees said that digital signature can help to improve security. Another interviewee suggested that government can set up a central clearing house for every E-commerce transaction.

Besides trust and willingness to use credit card online, some interviewees have alluded that factors such as price, uniqueness and convenience are factors that may influence people to use E-commerce. People will choose E-commerce when it can offer a lower price than traditional commerce. Uniqueness will attract people to use E-commerce because people will use E-commerce once they cannot find the products they want in traditional commerce. According to the interviewees, people may only use E-commerce as a substitute to traditional commerce.

A number of interviewees also said that it is easy to disguise one’s identity over the Internet, even though it required some technical skills to avoid being detected by others. Most of the interviewees agreed, however, it is difficult to detect identity theft. Due to the fear of identity

theft, many interviewees ended up not using E-commerce.

V Discussion and Conclusion

This study has obtained three significant sets of results. The first showed that Internet users in Macao generally have low trust in E-commerce, low willingness to use credit card for E-commerce transactions, and low intention to adopt E-Commerce. The second showed that Internet users’ perception of trust in electronic transaction and their willingness to use credit card in electronic transactions are both positively related to intention to adopt E-commerce. These relationships are consistent with those found in prior research. The third set of results showed that there exists an interaction effect between trust in electronic transaction and willingness to use credit card in electronic transaction on intention to adopt E-commerce. This interaction effect provides a significant contribution to knowledge as it helps to shed light on why prior research has found only a small variance between trust and adoption of E-commerce. Prior research could have obtained a higher explanatory power on the relationship between trust and adoption of E-commerce if it had taken into consideration the willingness to use credit card in E-commerce transactions.

V. 1 Managerial implications

The results obtained from this study suggest a few areas the Macao E-commerce industry should focus in order to expand the industry. First, the results showed that trust is very important. To increase adoption of E-commerce, it is important that customers be provided with a trustworthy environment. Among the many ways that might help to develop trust, E-commerce companies should consider upgrading their computer hardware and software so that with the advantage of new technologies, the companies can increase the security of the transaction environment. It will make more people trust E-commerce once the environment becomes more secure. Trust may also be developed through other means such as building a good reputation or having a good company image. Companies should think of ways that can help to develop their reputation and image so that there will be more E-commerce customers.

The results obtained from this research also imply that willingness to use credit card in electronic transaction could influence adoption of E-commerce positively. It is important, therefore, to increase willingness to use credit card in electronic transaction. Most of the Internet users interviewed said they were reluctant to use credit card over the Internet because of their concern regarding security of the Internet. It is important, therefore, to address this issue. The industry should consider using newer technologies to innovate and improve on internet security. The industry should also develop payment methods to complement or substitute credit card payment. While credit card is currently the primary method used for payment in E-commerce transactions, other methods of payment could also be developed.

V. 2 Limitations

The results obtained from this research are subject to a number of limitations. First, the results should be interpreted in the context of the research setting. The research was carried out in Macao, and as such, the results are applicable only to E-commerce in Macao. The results may not be generalizable to E-commerce in other countries. Second, the selection of respondents and interviewees for this research was based mostly on the researchers' contacts. Most participants were from similar sectors of the society, that is, they are mostly white-collar workers. Nevertheless, the researcher has found that the demographic characteristics (in terms of age and educational level) of the respondents in this study are similar to those of another study on the Internet users in Macao (Cheung and Wang, 2004).

VI. II Direction for future research

While this study has found that trust and willingness to use credit card for online transactions are variables that influence intention to adopt E-commerce, future research should explore other factors that may also influence E-commerce adoption among Internet users in Macao. For example, advertisements, government regulations, pricing strategies and after sales services may be possible factors that are related to consumers' adoption of E-commerce in Macao. Future studies may help to shed light on these factors. As suggested by the interviewees, future research may also focus on developing safer payment methods for E-commerce transactions.

Abstract: Business-to-Employee (B2E) portals represent a customised, personalised, ever-changing mix of news, resources, applications, and e-commerce options that become the desktop destination for everyone in a business. They have the potential to improve corporate communication with employees and enhance their productivity and loyalty. Attracted by this potential, many organisations are now investing in B2E portal technologies. Little is however reported about the experience of businesses in adopting these portals. This paper presents the staff portal adoption experience of a large Australian university and reports on the findings about the motives of the university for adopting the portal, the features included in the portal, the approach used in its introduction and the key factors that influenced the decision of the university to invest in it. The findings identified an important factor that was not cited in the portal literature. The implications are discussed.

Keywords: e-commerce management, portal, B2E portal, staff portal, adoption, portal adoption, Australia, case study.

I. Introduction

Today's businesses are characterised by the presence of a distributed workforce that is required to stay in touch with corporate offices and access relevant contents and applications in order to make decisions [3]. However, the dynamic business environment within which the distributed workforce functions often leads to a lack of communication, and consequently, company loyalty. To maintain communication with their employees, to encourage them to share knowledge, and to build a sense of community, businesses are challenged to develop a good delivery system for their workforce [13]. Corporate intranets which were developed by many businesses for delivering services to their dispersed employees are often fragmented and lack customisation features [2]. Fortunately, business-to-employee (B2E) portals have recently emerged that embrace e-business approaches and internet technologies and are able to provide a comprehensive set of services to employees [21]. These portals, which are also known as employee or staff portals, represent the next step beyond the current generation of corporate intranets [7]. They provide not only

corporate information tailored to the needs of employees but also useful applications for assisting them in performing their routine tasks [19] and serve as a single point of business contact with employees [15].

The use of employee portals is growing steadily. Merrill Lynch Capital Markets envisage portals to become a US\$14 billion business outnumbering the growth rates of other hot enterprise applications markets [7]. According to Banks [4], the number of organisations implementing B2E portals is also increasing in Australia. However, very little research is reported about the adoption of these portals which is not surprising given that it is an emerging technology. Moreover, academic literature had traditionally been slow to follow up the fast-moving trends of e-business in general [12]. As a result, little is known about why businesses adopt B2E portals, how they introduce these portals, what portal features are offered, and what factors influence their decisions to adopt B2E portals. This paper addresses these key research concerns by focusing on a large Australian university that has introduced a staff portal in recent years. The findings from the university are significant because they illuminate the influence of a set of success factors useful to the senior management of the potential adopter organisations intending to introduce B2E portals. The paper also contributes in building a rich empirical foundation for B2E portals.

The paper is organised as follows. First, the existing literature on the adoption of B2E portals is briefly reviewed and a preliminary model is developed explaining how key factors affect the decision of business to adopt B2E portals. Second, the research approach is described. Third, the background of the participating case organisation is presented. Fourth, empirical evidence from the case organisation relating to the research concerns is presented. Fifth, the case study findings are then discussed in the light of the existing literature and the proposed model. Finally, the contributions of the research are highlighted and areas of possible further investigations are mentioned.

II. Related B2E Portal Literature

Business Motives for B2E Portal Adoption

Generally, being motivated by the intent to gain economic benefits businesses adopt B2E portals. These portals are expected to offer customised contents and applications to employees which in turn empower them in making decisions,

improve their efficiency and enhance their satisfaction with their business [7, 11].

Features of B2E portals

A range of attractive features are included in B2E portals in order to enable the dispersed workforce to access customised services through the portal. These features can be grouped into three broad categories [5]: core capabilities, supportive capabilities and web services. Core capabilities refer to the ability of portals to create contents and inclusion of documents in many formats (called publishing), search capability to enable employees to locate relevant documents, personalisation facility allowing employees to modify their own interfaces, and on-line collaboration capabilities. Supportive capabilities include those tools that are necessary for the well-function of portals, and consist of: security to access resources and profiling aimed at sending information to employees based on data obtained from human resources department. In contrast, web services include those services that provide employees with an access to e-marketplace where a company offers employees discounts on products or services.

B2E Portal Adoption Approach

Sparse scholarly literature is available that addresses how businesses should introduce B2E portals. This view is consistent with that of Tojib et al. [20] who acknowledge that inadequate attention has been paid in the portal literature concerning the adoption approach of B2E portals. However, trade magazines provide useful suggestions concerning the introduction of employee portals in business settings. For example, Meuse [14] offers a multi-step guideline concerning the introduction of successful employee portals: a) determining employees' want, b) making content compelling, c) reviewing popular websites to determine how employee access portals, d) establishing a single point of entry, e) creating useful services, f) branding employee portals and g) choosing a competent provider. On the matter of in-house B2E portal development, Tojib et al. [20] have recently proposed a framework in which they have recommended prototyping and incremental approach as the most suitable development strategy. In addition, the use of pilot project was also emphasised.

B2E Portals Adoption: A Preliminary Model

A brief review of the existing B2E portal literature indicates a sheer lack of studies investigating the factors affecting the adoption initiatives of portals. Hence, the information technology and e-business literature was consulted to develop a preliminary model (shown in Figure 1) that includes the following most frequently cited factors: (a) management support, (b) IT expertise, (c) complexity with B2E portals, (d) cost of introducing B2E portals, and (e) vendor pressure. A brief justification for including these factors is provided below.

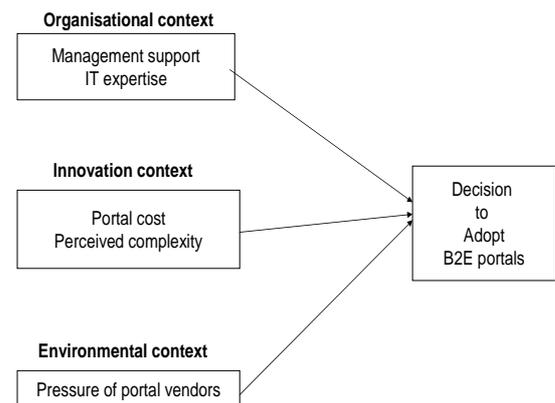

Figure 1: A conceptual model of B2E portal adoption

Management support refers to not only the articulation and symbolic championing of a new undertaking by the senior management but also the commitment of resources [16]. Many studies in IT have shown that management support is absolutely necessary for successfully adopting an innovative application [17, 18]. In the context of B2E portals, it is important to secure commitment from senior management because employees represent a key asset for the survival and progress of business. Management must recognise that availability of on-line resources through portals has the ability to significantly improve the performance of employees. The integration of on-line resources with portals however requires considerable investment which cannot be obtained without strong management support. Moreover, training, which helps the smooth completion of B2E portals on schedule involves financial commitment for which management commitment is further necessary. Hence, the following proposition is suggested:

P1: Management support is positively related to B2E portals adoption decisions

A lack of technical knowledge has long been identified as an important factor that may negatively affect the introduction of an IT project [9]. Unlike many other IT applications, B2E portal projects are more complex due to the need for establishing seamless integration with many other applications (that may possibly run on different platforms). Therefore, adequate IT expertise must be available before deciding to introduce B2E portals. Considerable expertise is also needed for building a B2E portal from scratch. Moreover, when B2E portals are acquired from external vendors, expertise must be available on how to tailor the product to suite the needs of business. Therefore, an organisation is likely to adopt B2E portal when it has relevant IT expertise. Hence, the following

proposition is suggested:

P2: The IT expertise of organisations is positively related to B2E portals adoption decisions

Cost is an important factor for any IT application and is usually assumed to negatively affect the adoption of the application [8]. This view is supported by Benbya [5] who argued cost effectiveness of portals as a major factor affecting its adoption by organisations. In relation to B2E portals, costs include hardware costs, software license costs, software development costs, design costs, system integration costs and maintenance. Such costs play even a greater role because commercially available portal products are very expensive which quite often run into millions. This is supported by Gartner group which estimated that portals featuring full workplace integration would cost between US\$1 million to US\$3 million [1]. Therefore, the following proposition is developed:

P3: The perceived cost is negatively related to B2E portals adoption decisions

Complexity generally refers to whether a technology is difficult to understand and use [6]. In the context of B2E portals, it is argued that complexity is likely to be greater than other forms of IT-systems because of the need to integrate portals with disparate application systems that exist in organisations. The perceived complexity may thus deter the introduction of B2E portals in organisations. Hence, the following proposition is suggested:

P4: The perceived complexity is negatively related to B2E portals adoption decisions

Today's organisations, of all sizes, operate in a highly dynamic business environment which is characterised by pressure arising from influential external bodies. The adoption of B2E portals by rival organisations may encourage businesses to adopt these systems to remain competitive. Furthermore, IT vendors position portals as a compelling way of integrating business processes that spans across multiple applications [2]. Hence, driven largely by vendor hype and promises, businesses are also likely to introduce B2E portal solutions. As such, the following proposition is suggested:

P5: The perceived vendor pressure is positively related to the B2E adoption decisions.

III. Research Approach

B2E portal adoption is a contemporary phenomenon which needs to be examined in its natural settings. Moreover, the complex interplay of actions between academic and administrative staff and the distribution of power among different faculties and administrative units within an university environment are also likely to increase the complexity of B2E portal adoption. Hence, it is critical to capture the experiences of the relevant people and the

context of their actions to understand B2E portal adoption practice. As such, a case study approach which is suitable for understanding phenomena within their organisational context was chosen [22]. A large university was selected as a revelatory case site because it successfully introduced staff portals in recent years and was willing to share its rich experience with the researchers. In-depth interviews were sought from three senior executives: head of the IT function, IT applications manager and a senior manager responsible for flexible learning and teaching (FLT) environment. The interviewees granted access to university reports relating to the introduction and structure of staff portals, flexible learning and teaching environment, and conference papers that they had presented on staff portals. This helped the researchers to corroborate the information provided during the interviews. The interviews were tape recorded which were subsequently transcribed and were sent to the interviewees for review. Data collected from the interviews were analysed using the pattern matching logic [22].

IV. Description of Case

The participating case is a large university located in a capital city, Australia. It has more than 50,000 students from over 100 countries and 5000 staff who are spread over several campuses. The university is recognised for its excellence in teaching, learning, research and graduate outcomes. In the year, 2004 the university had a revenue of about A\$800 millions. Its IT department consists of about 100 employees and has employed a wide range of IT enabled applications in support of major business processes supporting the core functionalities of the university.

V. Case Study Findings

This section presents empirical findings concerning: a) the motives of the university for adopting staff portal, b) the features and services offered by the portal, c) the portal development approach, and d) the factors that had an effect on the university's decision to adopt staff portals.

Staff Portal Adoption Motives

The motivation to adopt portals was conceived internally. In the year 1997, the senior management of the participating university recognised that its teaching practices require significant changes in order to retain and expand its current market. Consequently, a university-wide master plan was developed in the year 1998 that provided a new direction for the university. As a part of the master plan, the 'Flexible Learning and Teaching Plan' was released that suggested the university to embark on a program to deliver a student-centered flexible learning and teaching practices based on a suitable IT infrastructure. More specifically, the plan identified the need for a homogeneous and integrated IT-enabled environment to allow staff and students alike to access and manage online resources. The integrated

environment should serve as a means to coalesce, summarise and personalise online resources into a manageable stream of highly relevant information for both staff and students.

Members of the senior management were contemplating how best they could address the vision of the flexible learning and teaching plan. By consulting the head of the IT function, the senior management then expressed the need to introduce an internet-based solution in which all of the teaching and learning resources, services and functions could be made available in one place. The head of the IT function then consulted those senior IT staff who had expertise in the development of web-based applications for delivering services. After carefully analysing the university's needs to support the flexible learning and teaching plan, the senior IT staff and the head of IT function then recommended the introduction of a web-based portal as a solution to implement the directions provided by the plan.

The senior management accepted the views expressed by the senior IT staff and advised them to prepare a project proposal. The senior IT staff then looked at the commercially available portal offerings (e.g. 'Domino', 'Latest Domino') that were available in the market at that time. The team soon realised that most of the existing products were immature and very expensive. This prompted them to consider an in-house development option.

The primary motivation for the university to introduce the portal was to help positioning itself in a highly competitive education market. Portals were chosen a vehicle to create a flexible learning and teaching environment that would set the university apart from other educational institutions. The university currently prides itself as being the leader in introducing portals. This sentiment is reflected when the IT manager made the following remarks:

"We are the leader among Australian universities in relation to portals. Whenever any other university develops any portal-related applications they usually come to us and check on our applications and systems, they try to follow us as we are successful."

This view is also shared by the manager of the FLT team as he made the following comments:

"Our portal has always been the premier portal in Australia, so we are the leader in this field"

Features and Services Offered through the Staff Portal

Several dozen services are currently offered through the portal. However, the most popularly used services include: a) e-mail, b) employee self-services, c) class booking, d) research grant administration, e) handbook printing, and f) online advertisement via marketplace. E-mail service is heavily used by the university staff particularly when they are off-campus. The portal has also integration with employee self services and enables staff to view their pay-slips and leave status. There is a class booking system available on the portal and hence if any staff wants to do a library class or one of the expert research classes then they

may book it through the portal. The portal has links with research grant administration systems (which is in SAP) and it allows administration staff to look at financial snapshots. Staff are able to view all their research projects and grants. Staff can also access a system called Cupid which records information relating to printing of materials and handbooks of all courses run by the university. There is also an online marketplace where both staff and students can buy and sell things. However, only advertisement is handled and actual payment is not supported by the marketplace. Currently, the portal neither offers any functionality for online procurement nor it supports staff travel. Hence, staff cannot book and purchase tickets.

The university staff generally use a web browser (Netscape) to access the portal. They authenticate using their credentials recorded in the LDAP directory services which is the central backbone of the university's IT infrastructure. It provides a single, authoritative source for identification, authentication and profile information, such as department, role of systems access. Once authentication is successful, staff are able to view their pay-slips and leave information through the ESS (which is in SAP ERP), update a course on the courseware system, view the status of a call in the HelpDesk system or review summary information from other web resources. All these information are homogenised by the staff portal into a set of information and services that is meaningful to staff. In summary, staff can quickly log in, find what they need, change it if required, and log out again from anywhere on or off campus. A workflow model of the portal is shown in Figure 2.

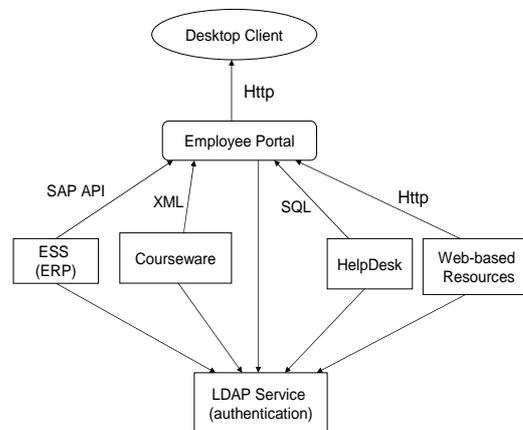

Figure 2: A workflow model of the staff portal

Portal Development Approach

The FLT group was established in the year 1999 which is responsible for developing the portal and integrating the services (discussed in the previous section) through the portal. The group consists of about fifteen people chosen from four functional areas: learning and teaching, research, administration support and information technology services.

At the initial stage, about five IT staff joined the FLT group and constructed the core of the portal. However, once the portal became operational more IT people joined the FLT group for providing on-going maintenance and training of portals.

The portal was built with an open source toolkit called 'Html mason' which is in PERL language. PERL was chosen because of its rich collection of open source library functions. The development team used about 100 library functions to offer functions like discussion groups, your directory and e-mail and many others through the portal. The development team felt the need for powerful servers to support the operations of the portal and hence several 18K domain hardware servers were acquired.

The FLT group adopted an incremental developmental process for constructing the portal. At the initial stage, a prototype was developed which was demonstrated to the senior management and many other staff chosen from several functional areas of the university. Based on their feedback, the portal was further enhanced. The first pilot trial of the portal took place in March, 2000. Based on the feedback received from the participants of the trial, several aspects (most notably interface and performance) of the portal were further improved. Eventually, the portal was officially launched in July, 2000. The FLT group is still enhancing the functionalities offered by the portal. According to the manager of the FLT team:

"We never stopped developing, we are still developing it's an incremental developmental approach. We were doing prototyping, what the people want, let's find that thing, lets build that thing and then release it."

Critical Factors Affecting Portal Adoption

A discussion with the participating executives confirmed the existence of a strong management support for the adoption of staff portal in the university. The senior management understood and appreciated the role of portal in implementing the flexible learning and teaching environment within the university, and hence offered full support for the project both in terms of providing requisite resources and academic credibility. This is reflected in the following remarks of the head of the IT function:

"The senior management was the driving force of the project. They actually provided the project with the academic credibility and the value; they could see the academic value of what we were doing and they then became closely associated with the project and their involvement was absolutely critical."

This view is also shared by the manager of the FLT team who commented:

"... Senior management support was certainly there. The portal project was not under funded, it started well."

The university had some bright IT staff members who were innovative and supportive to the needs of

implementing staff portals. These members had the right mind set, understood the meaning of portals (as very little was known about portal technologies at that time), and had the ability to train themselves about the open source technologies to be used in building staff portals. These members exploited the available set of open source tools based on the Perl programming language and created a working prototype which was demonstrated to the senior management. The prototype convinced the senior management about the ability of the in-house IT staff in implementing staff portals. Therefore, the availability of in-house IT expertise was a major factor that persuaded the senior management to introduce staff portal. According to the head of the IT function:

"Two of our most innovative staff members responded to my request to participate in staff portals. They took advantage of the available technology and knowledge to create a very prototype portal. This prototype was subsequently formed the basis to obtain an approval by the senior management."

The portal project was conceived as a direct result of the existence of a strong need for the university to provide on-line services to staff and students alike in support of the flexible learning and teaching environment. Without such an expressed need, it would have been impossible for the IT department to push the idea of establishing a staff portal for the university. According to the Head of the IT function:

"There was an established need within the university to provide on-line services to staff and students through the Internet."

The manager of the FLT team supported this view as he made the following remarks:

"They (the senior management) were thinking how they could fulfil the university's need for delivering on-line services to facilitate flexible teaching and learning objectives. They were really saying like, we want a Harvard Quality Learning and Teaching activity so that all of the resources and all of the services and functions will be in one place. This sounded like a portal to us."

The university did not invest heavily in the staff portal project and therefore did not consider the project to be an expensive undertaking. The portal was built within the existing university budget. Necessary human resources in terms of IT application developers were pulled from other projects; they were brought together to form a team. Furthermore, as the team used free open source code for developing the portal little cost was incurred for acquiring necessary software. Hence, the actual cost of development was perceived to be very low. Therefore, cost of the project was not considered to be a major factor affecting the decision of the senior management to introduce staff portals. According to the Head of the IT function:

"Yes, the portal was developed within existing budget. I

had the kind of resources/budget for various areas and I decided how to actually get a start together and activate it."

The university did not experience any pressure from the portal vendors to introduce staff portals. The head of the IT function and the IT applications manager both confirmed this view. According to the IT applications manager:

"At that time, the portal solutions offered by the vendors were not mature and there was no pressure from them on us to introduce their products".

VI. Discussion

The university neither looked at the staff portal as a means to receive direct visible economic gains nor introduced the portal in response to frustrations expressed by unsatisfied employees who had difficulties in locating university resources from off-campus. The initiative was directed at addressing the strategic vision of the university to promote itself as a distinguished educational institution by creating a flexible learning and teaching environment.

A description of the features and services offered by the staff portal (presented earlier) reveals that the portal possesses all the three broad groupings of features identified by Benbya et al. [5]. The portal allows the inclusion of documents in multiple formats and enables employees to use the search engine for locating the relevant information. The contents of the portal are customised based on the needs of each faculty. The portal however lacks tools to support on-line collaboration among employees. The staff portal has also incorporated security mechanisms and each employee is required to authenticate using a password. However, the portal does not offer any features that allow employees to customise their own interfaces or contents. Interestingly, the portal does provide employees with an access to weather information and a university operated on-line marketplace in which employees and students alike can place advertisements.

The question of whether to build a portal from scratch or purchase commercial components was critical to the university. It recognised that the commercial products offered by the IT vendors were not only immature at that time but were also found to be inadequate to meet their unique needs to implement the flexible teaching and learning environment. Consequently, the university made a concise decision to build the staff portal from scratch. The experience of the university is consistent with the views expressed by Brooks [7] who encountered difficulties in recommending a suitable employee portal for a large company. She evaluated four major portals and discovered that each one of them was targeted in a direction that really did not address the needs of the company.

The portal development team had followed an incremental approach and used prototypes to establish employee requirements and obtain approval from the senior management which according to Brooks [7], Gruhn et al. [10]

and Tojib et al. [20] is a useful strategy for developing successful e-commerce portals.

Out of the five key factors shown in the conceptual model of B2E portal adoption (Figure 1), only two factors (i.e. management support and IT expertise) have received strong support in relation to the adoption of staff portal in the university. In contrast, cost of portal and pressure from portal vendors were not found to have any influence on the decision of the university to adopt staff portals which is not surprising given that the portal development team had used free open source code for developing portal and the immaturity of the commercial available products at that time for which vendors could not press hard on the university to acquire their solutions. However, the factor that was found to have strongest influence on the university's decision to introduce staff portal is its explicit need for an appropriate technology to support the flexible teaching and learning environment. In other words, the existence of an explicit business need encouraged the university to actively seek a portal solution.

VII. Conclusion

This paper has addressed four key concerns relating to the adoption of B2E portals in the education industry. A large Australian university which has introduced staff portals in recent years provided the empirical context in which to better understand the research concerns. The initiative of the university to adopt a staff portal was found to have originated in-house and was aimed at improving its flexible teaching and learning environment and thus to set the university apart from other tertiary educational institutions. The portal was found to have included a range of features that were explained in terms of the taxonomy suggested by Benbya et al. [5]. Finally, the proposed conceptual model of B2E portal adoption has also received some support. However, the evidence from the university suggests the presence of a strong business need to be an important determinant of the decision to adopt staff portals. This particular aspect is not promoted by the portal vendors.

The findings of this study are important because, as the B2E discipline is very new and still immature, useful guidelines and success factors are not yet available compared to those of the B2B and B2C aspects of e-business. Furthermore, as the risk of B2E portal failure represents a significant financial loss for business, an important task of the e-business researchers is to contribute to the knowledge to support the business community to successfully adopt and diffuse portals. This paper contributes to this aim by investigating the factors that potentially affect the decisions of business to successfully introduce B2E portals.

The paper does not address the challenges presented by the portal or examines the success of portals from the viewpoint of employees. Thus, further studies are required to investigate these issues and to determine whether cultural factors have a significant influence on business decisions to adopt portals.

Abstract: The web design for international e-commerce sites is becoming an increasingly important issue. This paper addresses issues about cultural differences in web design and designers' views. The summary of research work includes understanding of designers' attitudes and approaches in designing web sites for different countries. Some suggestions about important aspect of localized design are made from case studies conducted during this research.

I. Introduction

Web design for international customers is one of growing issues in web based e-commerce. This research focused on issues in the design web pages for customers in different countries, particularly in business-to-customer (BtoC) e-commerce, including an understanding of designers' approaches in different countries. This paper begins with an overview of current approaches in the global e-commerce design, and follow on to present a case study about comparisons between Singaporean and Australian web design practices. This study investigation attempts to search for an understanding of the barriers in designing e-commerce on a global level.

Web design and user interaction are increasingly important for e-commerce for information presentation to the customer, and a high-quality web design increases customers' interests and interactivity [1-3]. However web design is only on a small part of e-commerce service function provided to the customer. Most likely, cultural differences reflect in user-service provider relationships, communication channels and user expectation levels of information service functions. E-commerce service providers including web designers are stepping up their use of new technology to achieve their goals, i.e. customers get products and services that they desire and the providers provide these with efficiency. The web developers have realized the importance of providing right information for target customers so that e-commerce companies can succeed in conducting business through the Internet. There are great opportunities in different countries for niche products and services to become a part of the multinational e-commerce. It is expected that such an expansion in electronic business will support economies of several nations and create new opportunities in and around their physical locations. The

issues of suitable web design for international customers are significant factors in global business implementation. Hence the need to study web-site design practices for international appeal in electronic commerce.

II. Web Design Issues and Challenges

II.1 Current e-commerce Service and Design

E-commerce services and design, like any other product, are not only conveyed with web providers' perspectives but also with customers' perception of choices through the communication channel of the Internet. To be precise, information on the web relies on both groups forming a common perception. In a global context, most web interfaces do not support effective usage due to use of unsuitable tool for conveying information in a global context, as most of the information is presented on the web by icons, metaphors, shapes, colors of text and background, frame/text locations on screen, etc. which may be relevant to the culture of origin but may be misinterpreted by the global audience.

Normally, web design features are directly translated into different languages at most and distributed to users internationally. In an international context, the web content features employed makes a somewhat lesser impact in the variety of contexts it is supposed to be effective in, although they may be clear to a minor proportion of the population. Thus a consideration of human factors in the design of web for an international user base is an important factor in promoting effective usage of information presentation.

Challenges of web design are how to provide appropriate information to satisfy users, and give benefits to business providers. From the designer's view, providing a good interface possibly start with an understanding of customers' interests. The following two sections describe two aspects of web design that are important for customers.

II.2 Information on the Web

Generally, customers are interested in information, representing style and interaction with web usage, depending on the quality of information. Sometimes, the amount of graphical components supports customers' understanding. Visual information on the web is increasingly important to support information as well as interaction between customers and business providers. Visual information promotes customer understanding, acceptance and determination to purchase products from the web. In global

markets, users are sensitive to interaction with product information on the e-commerce sites.

Del Galdo and Nielson [4] demonstrated that color and web page design directions have different psychological and social associations in different cultures. More importantly, different users have different concepts of web page usage. Design of web sites normally need to consider Latin-based screen design starting from the top left-hand corner or a Chinese language style starting from top right-hand to bottom left-hand. In such difference in script writing concepts, it is very difficult to provide localized screen designs if they are not included in the original design. Resources are currently available for web designers who wish to maximize the usability of a web site including usability guidelines. Collections of human factor references, web sites intended as a gateway to human factors resources and companies offering web-focused human factors consultancy. Also Human Computer Interaction (HCI) theories, methods, techniques and tools may be applied to the study of computer-mediated communication (CMC) in general, and web sites in particular [5] [6].

III. Web Design and National Cultural Characteristics

Web design is concerned with what a web site will look like and how it will communicate with the customer [5]. The issue for Information Technology professionals and researchers, business developers is to develop sufficient theories and models to describe behavior of humans who use information systems, with the aim of designing systems more effectively. Cultural factors in information systems are likely to impact on effectiveness through web design. This study brings up web design issues in two different countries, but could be easily extended to a much broader scope. There is some literature on national culture that provides different perspectives in successful business practices or best practices, but lack depth of perspectives for e-commerce. One of the most widely used set of national cultural characteristics in business is a study by Hofstede [7]. Hofstede found that national cultures differ in five dimensions: individualism vs. collectivism, femininity vs. masculinity, long term vs. short term orientation in life, power distance, and uncertainty avoidance[7]. The dimension of individualism vs. collectivism is a suitable aspect to explore the differences between Asian and Australian web designers' attitudes. Some selected key differences between individualist and collectivist countries are described in table 1.

Individualist	Collectivist
Everyone grows up to look after him/herself and his/her immediate family only	People are born into extended families or other in groups which continue to protect them in exchange for loyalty

Identity is based in the individual	Identity is based in the social network to which one belongs
low-context communication	high-context communication
employee-employer relationship is a contract supposed to be based on mutual advantage	employee-employer relationship is received in moral term, like a family link
management is management of individuals	management is management of groups

Table1. Differences between individualist and collectivist (source from Hofstede's study [7])

Australia belongs to a high individualistic group, whereas Singapore belongs to a collectivistic group. From this fact, the study of web designers' approach and their attitudes can be a basis for comparison that might help e-commerce practitioners in developing successful applications. Particularly it will help in creating a basis for designers' preferences and attitudes that cater to the requirements for web design in different cultures.

In general, a good web interface provides user satisfaction and conveys trust, such that a user can easily find general bearings of the information presentation scheme and retrieve the information they need. Design of web sites for effective performance is a complex and highly creative process. It combines intuition, experience, and careful consideration of numerous technical issues and investigations [8]. Moreover without proper consideration of cultural factors in design, the impact of culture is undermined and certainly does not position as an important issue. Culture influences certain methods of performing tasks, even common tasks in certain ways. Practices result from life long training of human and set rules and circumstances. Hence, localized e-commerce site deal with how differences between people from different cultures impact their behavior in specific circumstances. History and values can also impact on user's perception. E-commerce advocates have substantial claims made for the web's effectiveness as a tool in the sales process to customers. However, little real research has addressed these factors that will make customers buy, when in electronic shopping malls. Findings from cultural factors research for e-commerce could be beneficial for web developers catering for a domestic customer base, as well as for an international market with the specific understanding of their culture and the human behavior it promotes. Particularly, understanding of designers' aspects from different countries through this study may add more value to web design in e-commerce sites for the benefit of providers as well as customers.

IV. THE CASE STUDY

IV.1 Study objective and Approach

The objective of this research was to find out web designers'

preferences when they design web sites, and determine their approach in different countries. Generally, web designers apply their knowledge and ideas while designing web sites, negotiating the final content with businesses so that both have a common understanding of the information being offered to the community. In this paper we investigated designers based in two different countries, Australia and Singapore to study their approach to web design for e-commerce. There are many ways that culture can be reflected in the web design and this influences their way of presenting information on the web. This research seeks differences in designers' aspects through cases, such that the outcome may provide some benefits to web providers and global e-commerce companies.

The research method that was used in this study was exploratory case study. The case study approach was utilized as outlined by Yin (1994). The qualitative research method was used to answer questions about the people's behavior towards effective web design. Yin (1994) defines case studies as "an empirical enquiry that investigates a contemporary phenomenon within its real life context, especially when the boundaries between a phenomenon and context are not clearly evident". Case studies are especially effective for studying the subtle nuances of attitudes and behaviors, and for examining the web design processes and implementation. The case study was the preferred method used in this research, since what this research sought to obtain was the depth of understanding of the designer's attitude and behavior within a particular setting or context.

The process involved interviews of participants and also studying the web sites developed by these participants. This meant that more than one research method had to be used for data collection. However this approach was beneficial to confirm the generalizations and to test the impact of cultural differences on web design. This research attempted to formulate more precise objectives for further research.

The research approach used a qualitative approach, which involved the use of interviews, documents and participant observation to understand the social and cultural phenomena. For this research, although cultural generalizations needed to be confirmed, it was realised that cultural differences cannot be revealed directly. The research method that was used in this study was exploratory case study [9]. The process involved interviewing participants and also studying the web sites developed by the participants. This meant that more than one research method had to be used for data collection. However this approach was beneficial to confirm the generalizations and to test the impact of cultural differences on interface design. This study attempted to formulate more precise ideas for further research.

There was a study based on the Hofstede's dimensions (1997) of collectivism and individualism on web design by del Galdo and Nielson (1996), comparing Japan and the United States. They mentioned that collectivist-type users would like to have common behaviour as a group at an organizational level, and under individualist users want to

have control over their surrounding environment. Singapore and Australia are similar to the example presented by del Galdo and Nielson's comparison of Japan and the United States, Singapore being the collectivist culture and Australia being the individualist culture. Hence these characteristics can be reflected in typical attitudes used in e-commerce. Singapore is a collectivist society as identified by Hofstede (1997), while Australia has an individualistic culture. Based on Hofstede's findings, we decided to select companies from two countries; Singapore as for a collectivist society, and Australia as for an individualistic society. Ten cases were reviewed with over ten web designers/developers from five companies each in Australia and Singapore. These case studies were conducted through a combination of face-to-face interview, email and on-line interview. The data were used from selected participants to draw conclusions about the impact of cultural differences on the interface design. The case study used interviewing as a primary method for gathering data from each of the cases. An informal, semi structured, interview style was used. This style of interview allowed participants to express their own views freely and allow participants to feel comfortable during the interviews. The interviewer conducted the interviews using a set of open-ended questions, and built up the case.

The focus on data analysis was on findings patterns and regularities within the data. The analysis included data reduction, display and verification. The data were used from selected participants to draw conclusions about the impact of cultural differences on the interface design. In this research, web design components were divided into six attributes of display colors, image representations, symbols, animations, pictures and functionality (see table 2). Then web designers' preferences and attitudes were observed in creating new web page designs.

Web design components
Use of display colors
Image representation
Use of symbols
Use of animations
Use of pictures
Functionality of the web site

Table 2: Web design components divided into attributes

V Findings

In general, Australian designers preferred to have more functional websites such as ordering and search options. In contrast Singaporean designers preferred to display information on images rather than focus on text information. Singapore designers maintain and change information on web site more frequently than Australian. Australian customers preferred more direct and open communications, content oriented web sites and did not importance on picture

information. For instance, Australian web developers and companies had no particular preference of colours, animations, pictures and symbols. However company prestige was considered to be more important than image, and mainly used text based information. Australian designers feel that they have right to contribute own opinions to build up a web site. Also customer reaction was considered as the major influence on design, so that, they provided information with images, animations and company logos as per companies' requirements. Australian companies did not perceive signs and symbols to convey meaning. Australians believe in doing things to build trust.

Those interviewed Australian web designers mentioned that web sites could be created not only depending on clients' requirements but also generating their own ideas. Web designers emphasized that web design was a collaborative processes between clients and designers. Company managers were a part of the web design team. A new application was used only when it integrated into the design and they felt comfortable with using the concept. Some findings are summarized in Table 3.

Table 3: Web designers' preferences in two countries

Singaporean Designers	Australian Designers
-Use particular color scheme (depends on companies preference)	-No color preference from companies
-Company logo is important	-Company prestige is more important than image
-Not prefer any particular symbol	-Not prefer any particular symbol
-Prefer to put many animations	-Consider to use animations but not many
-Large and many numbers of pictures	-Not to put pictures, and prefer to put text-based information
-Customers are not main consideration	-Customer reactions are major influence on design

In case of web site maintenance and changes designers were able to manage or easily update public information if designers thought it was appropriate, another reflection of individualism. Australian designers applied more individual opinions, and were less sensitive to the use of graphic images on web sites compared to Singaporean designers. Besides the above case study, we examined ten selected IT global sites based in USA. Apparently there were no different web design features for different countries in international Electronic Business. Most of international e-commerce sites from an additional investigation concluded that sites use similar image design for international users as for home-based users. This indicates that international market providers (mainly USA based) use the same pattern

of colors, symbols, and images on the web in different countries.

VI Discussion

The study result demonstrates that, designers from different countries have different approaches, and provide different web features. Also visual-information is an important source of communication between business providers and customers on the web. Designers and developers need to be aware of their customers in different countries. Currently there are many different approaches to dealing with cultural issues, as applied to the problem of how to support customer goals using the e-commerce site; two dominant approaches are discussed below.

Cultural aspects

Cultural aspects' impact on globalization of web design in web-based E-Commerce is essential. Web developers need to consider that the users are located in different geographical locations and belong to different culture backgrounds. The significance of web design is usually directed to the management while leaving the user out of consideration, unless specific problems arise and are addressed. Turk and Trees [10] mentioned that global Information Systems on the web should be developed in such way as to localize information and design for different culture background users. Web applications could be adopted for local users rather than be internationalized to produce a cultural relevant user interface. Information presentation on the web needs to be considered in localized web design context with globalized information.

VI.1 Working relationships

The result indicates that designers and company managers are also from different culture backgrounds in terms of belonging to sub-cultures, and may have different goals to provide information presentation on the web. Their relationship is critical to provide the right information presentation to customers at the right time. Web design in approach should be a collaborative process, where establishment of a working relationship between companies and web designers is a major starting point in the design process. This promotes a common perspective to information presentation for the customers and further if target customer's cultural dimension is taken into consideration then it is likely to promote business objectives of trust and effective information delivery.

VI.2 Conclusion

The case studies as described in the previous sections, although the cultural background of customers and designers that is very important for web design, current design practice takes minor account of cultural issues. Many global business web sites have been designed and developed with absence of understanding of customers and their cultural differences on the global scale. Customers' expectations are not taken into

consideration in designing the functionality of web sites in global business companies. Apparently Australian web designers are more customer-oriented in web design, in comparison to general global business web designers though they appear to be less sensitive to the use of graphics on the web. The web sites of leading Information Technology companies studied in this research did not have their interface to account for different user cultures. This research found that designers' approach from the two different countries were dissimilar for web design in electronic business applications. This study also concluded that there is a need for localized web interface design to transmit the meaning of a business concept on web sites in various locations.

In addition, there is increasing attention to investigate ways to develop e-commerce sites for different countries. Future Electronic Business technologies will definitely introduce more attractive and convenient tools for the customers from different countries. Moreover, web image components are better suited to be used in certain ways to improve web based e-commerce. Not surprisingly web

images are being used a lot to attract customers and increase company's presence in the global e-commerce.

Abstract: This paper identifies and examines evidence of e-commerce failure in small and large businesses, focusing specifically on their Internet branding strategies, the impact of management actions and how those actions contribute to e-commerce success. This paper argues that as we move to a more interactive mode of working with customers and competitors using Internet technology, the role of marketing is critical; within marketing, brand management is seen as a particularly important activity.

The work reported here assembles evidence that brand management is indeed important, and that there is a lack of theories to guide brand management activities in an Internet context. Internet-related partnering opportunities with large firms remain a concern for smaller firms. It also reveals that much Internet research has taken a technical viewpoint although some experts have begun to make connections between Internet success and brand management.

I. Introduction

This paper presents an analysis of a retail company in South Africa. Though it seems too early to generalise about e-commerce failure or success in business, and in particular businesses in the developing African countries, it is hoped that the e-commerce experience of the company reported here could lay a solid foundation for others that set out to explore the many opportunity of modern technology. Businesses have made huge investments in Internet technology, often with little or no benefits. Yet, the Internet remains an important and viable communication channel for all kinds of businesses, particularly small businesses with scarce (financial, managerial and technological) resources. This research aims to provide evidence of e-commerce success factors and a categorisation scheme for small businesses.

According to [1] the Internet is important because it allows small businesses to gain access to information about

larger businesses, making it a cost-effective source of market intelligence. Yet for many, the benefit is perceived to be only basic communication such as is provided by email.

Nevertheless, the Internet has transformed – and continues to transform – the way many people live, work and play, according to Bray [2]. This transformation has important consequences for the management of national economies and business activities. The unrealised commercial potential of Internet technology is significant and continues to attract substantial investment. One should endeavour to make sure that these investments are effective, especially where they affect small businesses. The question therefore arises: what should a business do to ensure success, and what in particular does a *small* business have to do to avoid wasting precious money and resources?

One of the key consequences of the Internet for today's business is the emergence of e-commerce. The unique interactive feature of Internet technologies provides businesses with numerous potential benefits [3]. These benefits help businesses to meet their promotional needs and manage their customers' changing expectations – all critical components of what is generally termed “brand management”. For small businesses, this is not a quick fix. How should small businesses manage business relationships using Internet branding strategies? The Internet offers rich synchronous and asynchronous communications potential that is impossible using traditional technology such as telephone and facsimile. The multimedia and data transferability of the Internet (according to [4]) makes it easy to interact with different communities such as staff, business partners and customers. It is noted further that management enthusiasm and support for “remote relationship management” through the Internet is consistent and continuous.

The need for this study

This paper describes a study of the ways in which businesses can successfully develop and manage Internet brand equity within their overall marketing communications strategy. The intention is specifically to help SMMEs understand the

importance of the Internet, because they are especially vulnerable and must understand not just the importance and potential of the Internet, but also the good management practices that will deliver success.

Sources of difficulty

Brand management has been identified as an area of special significance, but it is not the only potential problem area. There are other areas in business such as project management, human resource management and financial management, any one of which might impede the success of an Internet investment. Any one of these, badly executed, will stifle e-commerce initiatives; small businesses will be particularly susceptible as there may be just one person trying to implement all elements of an initiative at the same time. The problems of a small business may well emanate from an inability to recognise and manage new business processes, arising from the use of the Internet, that then fail to link the e-commerce investment with the strategic benefits of well managed brand equity.

Though other areas of management activities might be significant, this paper argues that the question of branding is sufficiently important to provide the initial focus; other problem areas can be noted and investigated as they prove to be significant.

First, there is a brief review of relevant literature. Then, a conceptual model is described that relates some of the critical issues that must be managed and that provides a basis for a research design. Finally, a case study is presented and discussed in the light of that conceptual model.

II. Background

The existence of the Internet adds a new *communication channel* between a business and its customers, suppliers and partners. This has the potential to support brand management efforts, but equally it has the potential to confuse it. It is argued by experts that with multiple brands and multiple communication channels, branding activities can fall short of ensuring business success unless continuously improved brand equity is used as the strategic driver of the marketing communications effort [5].

A brand (according to [6]) is "...a distinguishing name and/or symbol (such as a logo, trademark, or package design) intended to identify the goods or services of either one seller or a group of sellers, and to differentiate those goods or services from those of competitors." The author notes further that brand equity is the total sum of: brand assets and liabilities, the brand name, and symbols that add to or subtract from customers' perceived value of the brand.

Others take a different view, seeing brand equity as the outcome of a process that is aimed at creating customer-based brand equity. The value of a brand is based on customers' assessments of the brand. This assessment is achieved through links to secondary associations that the customer can easily identify with.

The complexities of brand management become apparent

as one reflects on these definitions, and the challenges to a small business will clearly be severe. Establishing good brand management practice that will minimise the risks and maximise the benefits of Internet investments will clearly be helpful.

E-commerce and small business

It is pertinent to recognise that business practice in a large firm is different from that in a small firm [7], and that the e-commerce needs of a small firm are understood through an exploration of the unique aspects of small business and their practices. For example, large businesses are often presumed to have the resources to achieve difficult things, and yet it is possible for a small business to be much more "professional" than a large business – a large business is frequently hampered by cumbersome processes of debate and decision, a small business can move quickly and more easily assess the impact on customers and other partners.

These realisations, and the fact that little reported work seems to be available concerning these things, led directly to the initiation of this research.

The importance of business partners

E-commerce is not an activity that concerns only one business. In all cases, by definition, e-commerce involves more than one party: a business and its customers, or a business and its partners; possibly a business and a government agency or regulatory authority. It follows that research can not be confined to one organisation, the views of the other party must also be understood. It is therefore important that the collective interest of small businesses *and* their e-commerce partners is established, because in e-commerce more than one party is always involved. A business does not do business with itself (or, if it does it is comprised of *different business units* – unlikely in the case of small businesses). The views of all stakeholders involved in SMME-related business processes need to be elicited, as all involved parties must benefit from an e-commerce enterprise for it to be entirely successful [8] (except perhaps the involved party that comprises "the competition").

Branding and the Internet

As has been noted, the impact of the Internet can cause the introduction of new kinds of business activity. Where a business is unwilling to undertake significant change, then the benefits of e-commerce investments might be severely limited. The adaptation of business processes can now be so radical that the overall effect (on business *communication* processes in particular) now extends far beyond what we have become used to in traditional business practice [9]. The Internet has become the agent of change in organisations, seen through new access to new information and new societal processes that would be unthinkable without the Internet, creating new forms of business and consumer interaction [10]. Achieving the benefits of this new interaction depends on key factors such as communications and general management [11]. Overcoming communications

barriers (possibly involving differences in cultural background and different languages and vocabularies) will allow managers to deal successfully with many Internet-related problems.

The Internet has opened up new business opportunities, in particular access to new markets arising from the extended "reach" that comes with the Internet. This means that approaching new markets, possibly in remote places, requires that managing *brand* will be important and that there will be a necessary increase in *branding activities*. Marketing is the means to address the needs of new markets, and the brand is the thing that must be established for the market to be persuaded to respond. That is why the Internet and Internet branding are important.

There are other concerns about the contribution of e-commerce to business success [12] that will require changes in management strategy, but there is not sufficient available information to establish the facts about e-commerce success, and again the need for this research is emphasised.

The linking of computers to different networks through the Internet allows data to be transferred between two otherwise incompatible machines; a level of data communication becomes possible that would have been unthinkable just a few years ago [13]. The transferability of data through the Internet creates an opportunity for development and management of cost effective business relations, through the interpretation and management of data as the *information* that facilitates the transacting of business between partners.

A review of communications management in the Internet-dominated environment is necessary, to understand the potentially negative impact it may have on Internet investment benefits for small businesses.

III. The Strategic Importance of the Internet

The emergence of the Internet has created a situation of strategic uncertainty. As a consequence of this, the strategic importance of the Internet to business has come to the fore. For small businesses entering this environment, a management strategy that defines and manages the firm as a brand could be helpful.

Angehrn [14] argues that Internet activities can be categorised into three stages: (1) Internet presence, (2) interaction and, (3) full e-commerce. At what stage of the Internet activities do we need to involve branding? Angehrn's framework helps us to understand this.

Stage one

At stage one, a business typically mounts a web page or two in order to disseminate product and service information to customers and potential customers alike, and to provide contact information in the form of telephone numbers and email addresses. At this stage the medium is new, as is the management intent, and there are basic lessons to be learned. Therefore, a lack of insight into the critical strategic issues of brand management will already reveal itself. To deliver

true and consistent product and service value to customers the whole organisation and all its activities should be managed as a brand [15]. The change in communication medium (using the Internet) introduces changes in the relationship between perceived organisational values and perceived customer values, that must all be satisfied to establish internal and external satisfaction. Even a few web pages that establish a presence (no transactional capability, no e-commerce) can convey the wrong messages and undermine efforts to establish a consistent and coherent brand identity.

Stage two

Stage two provides transactional interactivity through a web browser, for example using forms and scripted program code at the server (ASP, PHP or similar). Waterman [16] argues that stage two in the Angehrn model has the potential for two-way communication, including transactional and messaging capability within the web- and browser-based system. Although this two way exchange is possible using other traditional means, such as telephone and fax, clearly we are interested in the advantages that might arise from use of the Internet and this research is therefore focused on the use of the Internet and its advantages.

At this second stage, a lack of trust on the part of the customer and lack of strategic overhaul of management philosophy threatens to inhibit the customer relationship management effort. Businesses depend on personal networks and social interaction as a way of building trust and managing customer relationship. The implication is that the trust that is so important to relationship management and so traditionally dependent on face-to-face interaction, cannot be developed in a context like the Internet [17,18,19]. More research is required in the area of remote relationship management and the building of online trust, separate from or in parallel with face-to-face relationship management.

Stage three

This third stage of Internet maturation includes more dynamic features such as bulletin boards and chat rooms, as well as the use of audio and video facilities to improve the richness of the Internet-based interaction. Again, an evolved management philosophy is needed to develop and deploy creative brand management tools for effective and efficient customer relationship management at this level.

Summary of strategic importance

Brand management typically (but not always) starts at the first stage and progresses with increasing intensity to stage three, where more and more interaction with external stakeholders is committed to the Internet, making it more and more important strategically. Internet brand equity increases with this intensity and the risk of conflict with other branding that is delivered in conventional ways increases; full implementation of e-commerce implies full implementation of branding and brand management on all channels, not just on the Internet alone.

Hence, branding activities must increase once web-sites have become full e-commerce sites. Experts argue that Internet branding is beyond the general focus of day-by-day business attention [20, 21, 22]; it is of course necessary to view *all* management actions holistically, and to understand their overall ability to contribute to brand equity as well as to the other domains of business activity. Therein lies the challenge to all businesses adopting the Internet, especially resource-starved small businesses.

IV. Brand Management

One important attribute of brand management is the ability to react to changes in society and market dynamics, so that good communication of brand essence is established and sustained. Key factors militating against easy brand management include rapid changes in the business environment (market complexities, competitive pressures, global forces) and the challenges of information management (with the advent of advanced information technologies that allow information to be abused as easily as it is mis-managed). Establishing *online* brand recognition that complements the *offline* brand will reduce the risk of failure.

Small businesses are likely to fail in the Internet environment if they do not realise that some Internet solutions are designed for large businesses, and do not particularly fit the needs of small businesses. Information management that is crucial for building online brand and managing customers' relationship on the Internet could not support small business e-commerce initiative. Ward and Lee argue that unlimited information access on the Internet supports the need for building online brand to save customers' time and search cost [23]. Though too much information on the Internet can be problematic to customers, small businesses need more information (rather than too little) in order to develop and deploy successful branding strategies.

A small business that is already uniquely established knows its product and service offering, as well as its target market. With the information provided by the Internet, managing the expansion of these target markets nationally and internationally will be more easy and cost effective than without the Internet. In a highly competitive virtual environment small businesses armed with sufficient competitors' and customers' information could create brand association to locate and respond effectively to each target market. According to Varian [24] the information management ability of small businesses will remain relevant despite the changes that will be introduced by the Internet. Varian argues that unique brand strategy and up-to-date customer information accentuates the brand management effort of small businesses. For significant profit potential and customer conversion, the brand management competency of

small businesses should improve customers' product-association level, (customer benefit) as a differentiation strategy.

Internet technology has changed the traditional (brick and mortar) cycle of product development, distribution and retailing to what is sometimes referred to as "brick and click"; the difference with information flows enabled by the Internet is that customers' tastes and needs can be observed, tested and analysed throughout the product development cycle [25] – what the market needs can be far more easily seen, at all points in the chain of supply. This visibility provides opportunities for changes in management philosophy, seeking simplicity and pragmatism in business operations where there was once chaos and confusion. For example, Dell's made-to-order computers, Dunhill's customised software and Google are a few examples that illustrate how technology has been used profitably to satisfy customers' needs [26].

If investments in Internet technology have not been successful, we have to realise that it might not be a consequence of poor technology. Rather, it might be the result of inadequate business competencies, such as a failure to develop a viable business strategy properly based on brand management and linked to Internet implementation issues. A holistic approach is needed to improve business-to-business, business-to-consumer and business-to-employee relations, all of which stand to benefit from good brand management.

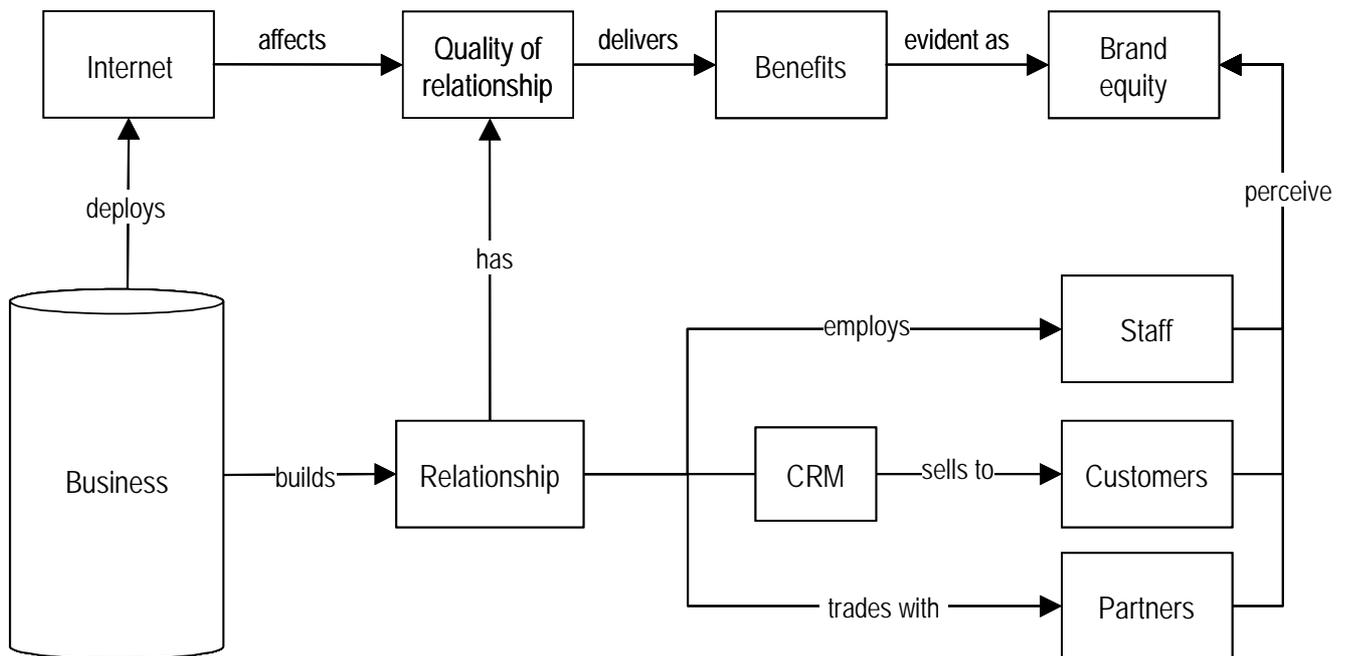

V. Methodology

This review of the literature has found that it is necessary to examine the relationship between Internet investments and business success, as seen through management competencies such as (indeed centred on) brand management. Whilst there are many success factors described in the literature, brand management issues recur and the adoption of brand management perspective shows some promise in establishing the elusive holistic view that experts consider necessary.

This study sets out to assess the importance of brand management in achieving Internet success. At this stage, the experiences of a single large business are used to establish the viability of the conceptual model. Further work will apply deploy it in the analysis of other kinds of business, including small ones and business partnerships, and thereby refine it so as to develop an improved understanding of how adoption of the Internet can be made to work successfully.

According to Poon and Swatman [27] such an understanding will help us to understand current issues and the future activities needed to provide improved quality of business relations; branding strategies are a means to achieve this objective.

Figure 1: Conceptual model of the research domain

Use of case studies

Benbasat, Goldstein and Mead [28] state that in the field of information systems, the case study method is particularly useful to investigate these types of problem: where research and theory are at their early stages and where practice-based examples reveal important factors, and where the context of actors' experiences and actions are critical to understand.

In the fullness of time multiple case studies will be used, so as to yield a variety of results that would not emanate from a single case study, but only a single case study is reported here. The merits of single and multiple case studies suggest that multiple case studies should be regarded in the same way as multiple experiments – the rationale being that multiple case studies are desirable when the research objective is to build and test models and theories [29, 30]. One case study cannot be used to draw a generalised conclusion: Yin [32] states that findings cannot be applied in general term using one case study, and this project is intended to deliver results that can be generalised. However, the intention at this stage is simply to assess the model through deployment in a single case.

Research into Internet branding strategies is a relatively new idea and therefore challenging, especially in the specific area of small businesses and their customer relationship management. The case study is therefore considered to be the most suitable in this particular research, because, as argued by Myers [31] it is the most common qualitative research method used in describing information systems and

their relationship with real life. Myers argues that the case study ensures continuous interplay between collection and analysis of data, and is especially useful in the field of information systems where attention has moved from technical matters to organisational issues of success. That is precisely the situation here, where there is clearly much published research into the technical aspects of the Internet, but relatively little into the soft issues.

The case study method allows the simultaneous collection and analysis of empirical data, hence another reason for adopting this method is to ensure that the findings are relevant to a wider segments of small businesses through continuous improvement in the understanding.

Conceptual model

The model above (Figure 1) depicts the research domain, drawn from the literature as it is seen at this stage. It can be described as follows:

Practically, a business undertakes to build different kinds of relationship with their stakeholders – principally *customers*, *staff* and business *partners*.

Dealing with the relationship with customers is often referred to as “customer relationship management” or CRM. No doubt the relationship with partners and employees is the subject of similar thinking on the part of the specialists concerned.

Brand equity is seen as the sum of all the perceptions of these key stakeholders (and other related things).

This deals with the lower part of the conceptual model,

which can be argued to represent “conventional thinking”, that is, before the introduction of the Internet. This is shown in the upper part of the model.

The Internet is an investment in technology and systems that should enhance the quality of the relationship with stakeholders.

Quality in the relationship leads to real benefits, judged not by the “IT department” but by the stakeholders themselves.

The manifestation of these benefits is seen as increased or enhanced brand equity.

In this way, brand equity is not just a feature of good marketing, it is seen as an indicator of success arising from the introduction of new technology. The detailed examination of brand management and its contribution to Internet success in small businesses will be designed around this model.

The case analysis of Woolworths, a South African retail company, is presented below.

VI. Case Study: Woolworths

History

Woolworths was established in 1931 and is generally perceived to have built a reputation for innovation, quality, value and professional integrity over 74 years of operation. The company sells a wide range of food products, clothing and homeware in two hundred stores nationally. One of the most important assets of the company is said to be its employees: they “*protect the brand in everything they do by upholding the highest standards of business practice and corporate governance in all areas of the business*”. The company strives to ensure that it acts responsibly to all stakeholders including customers, suppliers, employees and shareholders.

The introduction of e-commerce

In 1998, Woolworths (Pty) Limited set up a project team to investigate the opportunities of online retail service offering. Collin Hall, former CEO of Wooltru played a vital role in this initiative, that drew for implementation on the expertise of an IT company known as *definitive-logic*. In 2000, an operating company known as *Inthebag* emerged, following the sale of Woolthru assets to Woolworths. At that time, the investment in the e-commerce project had already consumed a reported R30,000,000; newspaper reports some three years later reported steady, but not remarkable, growth, and therefore there is an air of caution in the air. Perhaps the potential benefits of e-commerce have been very much overstated?

The situation today

Inthebag (Pty) Limited is now responsible for providing commercial e-commerce services to Woolworths and manages the online contract with customers for selected Woolworths merchandise.

The e-commerce operation of Woolworths in South Africa today is under the leadership of Keith Scott (general manager, e-commerce operations) at the head office in Cape Town, South Africa.

He explains that all core activities of the company are divided into three categories: operational management; process management and brand management. The brand management function runs through other management activities including the online services that support operations. All these function are separated organisationally, but tightly aligned to one another for consistency and coherence.

There is a history to brand management at Woolworths. With 74 years in business, the Woolworths brand has developed and established strong relationships with many customers. Extending this relationship to the online (remote) environment requires a great deal of trust between the customer and the brand, Scott considers. He understands that they rely on this trust to drive the e-commerce operation forwards and break through the barriers that they still face in the online environment. He affirms that the truly innovative challenge is how to continuously extend and replicate this trust that derives from their history of retailing, into a versatile online environment. This is clearly a challenge that they are still willing to pursue.

Benefits of e-commerce

According to Scott, benefits are slow in coming. Inthebag is still seen as a new business channel that the company will continue to develop, even though there is no immediate benefit. The e-commerce operation is seen as providing a strategic opportunity to extend additional service offerings that will help to retain existing customers. Customer retention is a huge strategic challenge that Woolworths wants to address, and e-commerce is one way to achieve this, through continuous and consistent delivery of service value that is innovative, professional and convenient for customers.

However, the present scenerio of high cost and low volume is worrisome, but Scott considers that the company cannot renege on its commitment to ensuring customer retention with good Internet-enabled customer relationship management for that segment of the market that does actually value Internet-based services. He believes that effective customer relationship management will ultimately lead to improved brand equity.

Achievement of benefits

To achieve this objective of successful customer relationship management, the business continuously mines customer personal information using e-commerce technology. They use the resulting information to analyse customer needs and package products and services that satisfy those needs. The result has been an increase in market share and profit for the Woolworths brand, although it is not clear what portion of the customer relationship management success is attributable specifically to Internet based e-commerce operations.

Strategic significance of the Internet and brand management at Woolworths

Scott is clearly committed to further use of the Internet and he recognises the pros and cons of extending brand management to enhance customer relationships.

Others in the management team include Anthony Dean (brand manager), Sean Smith (customer relationship management), and Phila Ndarana (e-commerce manager). When asked, they all stressed that online customer relationship management is a crucial managerial function and they believe that only a professional, innovative and progressive company can work to overcome the trust barriers that might prevent e-commerce success.

This common commitment suggests a high level of strategic awareness of both the opportunities and the risks of e-commerce. Trust is clearly in their collective consciousness; they consider that a growing increase in online trust, arising from their strategies, has created an atmosphere of confidence in the whole e-commerce operation. Out of the 90,000 registered online customers, 17,000 are active online shoppers (very similar figures to those reported by other comparable retailers such as Pick 'n Pay). This represent 19% of the prospective online customers, and with various ongoing innovation, they intend that more customers will be converted and committed to active online shopping and – just as important – retained as online shoppers in the coming years.

Assessment of the conceptual model

One business is revealed to be committed to the use of the Internet, and there is no hesitation in their belief that this can contribute to the improvement of the quality of relationships. However, the respondents in this initial study refer only to relationships with the customer, and apart from the fact that they themselves have a high level of unanimity in their commitment to e-commerce and brand management strategies, there seems to be little consciousness of the importance of staff and business partner relationships (or the unimportance of them). This requires further investigation and might be revealed when more managers from other internal functions are interviewed.

With this exception, that a more complex range of relationships might be affected by the introduction of the Internet and e-commerce, this case study fully justifies the focus on marketing and brand management as an important, even critical, feature of successful e-commerce implementation. Having said that, actual e-commerce success and hard evidence of brand equity is not necessarily apparent, so in a sense it is actually shown that even five years after initiation of e-commerce at Woolworths, the “jury is still out” and there is much more work to be done before we can draw confident conclusions.

VII. Conclusion

The fundamental principles of branding and brand

management will probably remain unchanged, despite the radical changes associated with doing business on the Internet. This paper has found that business opportunities created through the Internet are seen as potentially beneficial, provided that adequate attention is given to the implementation of branding strategies that recognise the dynamics and characteristics of the Internet, and even though it is clearly still early days, and the patterns of management activity and action that will ensure success are by no means clear.

Large businesses like Woolworths are sometimes dependent on small businesses. Where this study has focused on customer-side e-commerce (the side of the consumer, in this case), it is possible that e-commerce on the supply side will be equally if not more interesting. As businesses like Woolworths struggle to achieve the customer side benefits, perhaps they will be drawn to review the merits of e-commerce on the supply side, where (it is important to note) they have far more influence over whether their partners will join in; customers can choose to shop elsewhere and frequently do so – suppliers are far more interested in doing what the buyer would like them to do.

Customer-side or supplier-side, the evidence indicates that the benefits of e-commerce investments will have a lot to do with branding strategies and brand management.

Because of the evident difficulties revealed by this case study, the availability of fully developed and tested models such as that presented here will enhance the prospects for success through good branding and good customer relationship management, especially in those challenging situations related to the introduction of the Internet and e-commerce.

The Effect of Online Feedback Mechanisms in Electronic Markets: A Field Study Perspective

Her-Sen Doong Ching-Kuang Hsieh
National Chiayi University

hsdoong@mail.ncyu.edu.tw s0931308@mail.ncyu.edu.tw

Abstract: Online feedback mechanism, best known right now for building trust and reputation in electronic markets, are regarded as a major player in the success of many online trading communities. It can reduce sellers' anonymities, mitigate the buyers' risks, and affect the price premiums. In this paper, we investigate the relationship between feedback mechanisms and price premiums by the analysis of field data. An intelligent agent is build to collect actual data from Yahoo Auction. The research results will also allow us to better understand whether positive/negative rating has different effects. It may also clarify mediating effects of product characteristics on the relationship between reputation systems and price premiums.

Keywords: Feedback Mechanisms, Reputation, Online Auction, Trust.

I. Introduction

In the past several years market exchanges have been done in ways that were not possible before. This is due to the development of technology online business activities rapid increase. People can now perform commercial activities without meeting their trading partners (Xu & Yadav, 2003). Online auctions, as a new form of E-Commerce, provide new opportunities for people to exchange products efficiently and conveniently. According to the report of Yahoo Auction in Taiwan, transaction amount reached 10 billion NT dollars in 2003. Many sellers have even started to consider online action transactions as full-time jobs; thus raising the importance of understanding factors that impact online auctions.

Nevertheless, online trading is regarded as risky because trading parties may never have met. Traders have little knowledge about the identities of their trading partners and the real conditions and qualities of products (Xu & Yadav, 2003). According to the report announced by Internet Fraud Watch in February 2005, online auction is counted for 51% to rank first in consumers' complaints in 2004, which is about 765 dollars that each consumer loses. Here trust becomes an important issue in the online transaction environment, especially in the online auction market. It is essential for both buyers and sellers to identify the others' trustworthiness.

Online feedback mechanism, best known today as a mechanism for building trust and reputation in electronic

markets, are regarded as a crucial role in the success of many online trading communities. They are large scale online word-of-mouth communities in which individuals share opinions on a wide range of topics, including products, services, and companies (Dellarocas, 2003). The feedback mechanisms can reduce the sellers' anonymity and mitigate the buyers' risks (Gefen et al., 2003). While one would expect the feedback mechanisms to benefit only the buyers, the sellers benefit as well. Strader and Ramaswami (2002) investigated the level of importance of factors affecting online buyers' decision making process. Their research result shows that trust, using feedback profiles as a proxy, significantly affects price premiums, which decreases as the transaction value increases. Ba and Pavlou (2002) also indicate that higher positive rating increases the trust of buyers and makes price premiums.

That being the case, however; it is important to note that these studies primarily depend on surveys of individuals' perceptions or observations of subjects in a controlled experimental setting. They do not account the effects of online feedback mechanisms from an actual behavior perspective. In this paper, we investigate the relationship between feedback mechanisms and price premiums by the analysis of field data. An actual behavior data illustrates the relationship between feedback mechanisms and price premiums. The research results will also allow us to have a better understanding of whether or not positive/negative rating has different effect. It may also clarify mediating effect of product characteristics on the relationship between reputation systems and price premiums.

II. Conceptual Model

Figure 1 presents the research framework for the study. Feedback profiles with both positive and negative rating affect price premiums. It is moderated by product characteristics.

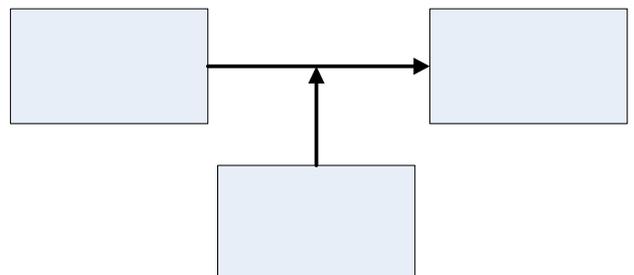

Figure 1. Research Framework

Trust

Following Ba and Pavlou (2002), trust is defined as the subjective assessment of one party that another party will perform a particular transaction according to his or her confident expectations, in an environment characterized by uncertainty. There are three sources of trust that can be distinguished in E-Commerce (Gefen et al., 2003): calculative-based trust, institutional trust, and familiarity. Familiarity through repeated interaction are not possible in most online transactions (Xu & Yadav, 2003); because institutional structures in the online world are not yet well-developed (Fung & Lee, 1999). The most prevalent source of trust in non-repeated transaction environment is probably calculative-based trust, which means that it is not worthwhile for the opposite party to engage in opportunistic behaviors (Doney et al., 1998).

Trust is an essential component of online transaction behaviors. It reduces perceived risk and increases willingness to buy (Xu & Yadav, 2003). Pavlou and Gefen (2004) indicate that trust in the community of sellers has positive effect on transaction intentions, but significant negative effect on perceived risk of the seller community. Because buyers realize the effect of perceived risk, they are willing to compensate reputable sellers with price premiums in order to assure safe transactions. According to the definition of Ba and Pavlou (2002), price premium is the monetary amount above the average price received by multiple sellers for a certain matching product. They also find that trust of sellers has a positive effect on price premiums.

Feedback Mechanisms

Feedback mechanisms are used widely in online auction markets. They provide a place where users are able to leave comments about their buying and selling experiences and their evaluations of the buyers and sellers whom they perform the transaction with (Ba & Pavlou, 2002). They rank as positive ratings, neutral ratings, and negative ratings. Each rating equals a paired buyer-seller transaction. This mechanism allows buyers and sellers to rate each other following transactions and makes the history of a trader's past ratings public to the entire community (Dellarocas, 2003). Feedback mechanisms can be viewed as a reputation system or word-of-mouth network. It also encourages traders to behave well if they want long-run plays.

Prior researches have also shown that feedback mechanisms affect trust in Community of sellers (Pavlou & Gefen, 2004), and that trust in sellers has positive effects on price premiums (Ba & Pavlou, 2002). Strader and Ramaswami (2002) also indicated reputation of the seller as the most important factor in trust that affects online sellers' choices. Although we can't directly measure the effects of trust in the field data experiment of this research, prior study have suggested feedback mechanism as a proxy of trust. According to these researches, we can assume the effects of

feedback profiles and form the following hypothesis:

H1: Sellers with better feedback gain higher price premiums compared to sellers with worse feedback.

Product Characteristics

There are a big number of product items that are investigated by online auction researches. Resnick et al. (2002) summarizes 14 previous studies of product items, as shown in Table 1. Strader and Ramaswami (2002) chose baseball cards as their product sample. This does not, however, answer the question of whether or not different products result in different outcomes of research. Ba and Pavlou (2002) investigated the moderate effects of product price. They found that the relationship between trust and price premium is stronger in expensive products. It is unknown if there exist any other characteristics of product affect trust and price premiums. For example, previous researches focus on the search goods rather than experienced goods. By categorizing the product we realize there might be different in price premiums.

There are many ways to categorize the product. Nelson (1974) defined two types of goods:

- A good is a "search good" when full information for dominant product attributes can be known prior to purchase.
- A good is an "experience good" when either condition holds:
 1. Full information on "dominant" attributes cannot be known without direct experience.
 2. Information search for "dominant" attributes is more costly/difficult than direct product experience.

Table 1. Summary of previous researches (Resnick et al., 2002)

Citation	Item sold
Ba and Pavlou (2002)	Music, software, electronics
Bajari and Hortacsu (2003)	Coins
Dewan and Hsu (2002)	Stamps
Eaton (2002)	Electric guitars

Figueiredo (2000) argued that the ability to judge the quality of a product is the biggest differentiator among product categories on the Web. He classified the product into four categories: commodity products, quasi-commodity products, "look and feel" goods, and "look and feel" goods with variable quality; however, look and feel goods with variable, like original art or used cars, is difficult to use to analyze the effect in online auction environments. We choose two types of goods as our product categories and investigate whether or not there are different outcomes between search goods and experienced goods.

H2: The relationship between trust and price premium is moderated by product characteristics.

III. Proposed Research Methodology

This study builds an intelligent agent to collect actual behavior data from Yahoo Auction. We choose Yahoo Auction as our sample due to that it is 16 times larger than the Taiwan eBay auction market.

Figure 2 illustrates the architecture of the agent system. We implemented the intelligent agent with Asp.net and Microsoft SQL Server 2000. As depicted in figure 2, the agent can respond for parsing required data gathered from the web page of Yahoo Auction website and then filter and store it in database for future analysis. We will employ multiple regression analysis to examine the relationship between feedback mechanisms and price premiums. Independent variables are the logarithm of the number of positive and negative ratings, and the dependent variable is the price premium developed by subtracting the mean price from the final price of each product divided by its mean price. It is expressed in equation (1).

$$\text{Price Premiums} = \beta_0 + \beta_1 \cdot \text{Log(PositiveRating)} + \beta_2 \cdot \text{Log(NegativeRating)} + \varepsilon \quad (1)$$

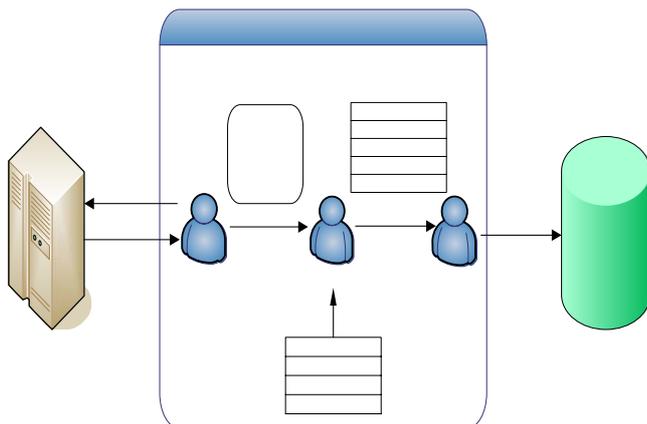

Figure 2. The System Architecture of Intelligent Agent

IV. Current State of Research

At present, the field data of Yahoo Auction bidders' behaviors is being collected. We will employ linear procedures in SPSS to approximate all parameters. By the time of the conference, we expect that the relationship between feedback mechanisms and price premiums will be fully explored. The fitness of equation and mediating effects of product characteristics will also be presented at the same time.

Abstract: Online readiness self-assessments are widely used in universities providing distant education, and they can help prospective students to understand the requirements and their readiness to study in these universities. Most of the self-assessment systems are Web-based static questionnaires. In this paper, a novel adaptive online self-assessment system AM I READY is introduced. The system is based on knowledge models, including static and dynamic user model, counseling model and self-assessment process model. It can dynamically filter questions to be asked to a specific user and adjust the contents of webpage dialog between the user and the system according to knowledge models and the user's responses. The system is more effective and helpful than the usual ones.

Keywords: E-Learning & Innovations in Teaching, Knowledge Modeling, Self-Assessment

I. Introduction

Online readiness self-assessments are widely used in universities that provide distant education service. The purpose is to help potential students to know the leaning style and requirement of studying as a distant learning student, and decide if the distant learning is the right choice for them. Most current readiness self-assessment tools are online questionnaires. By doing the questionnaires, potential students read some information and may get a final score related to their answers to these questions. The high score means high degree of their readiness. This kind of model is relatively simpler and needs to be upgraded in several aspects.

Actually, in this paper, we treat readiness self-assessment as a kind of counseling process. By doing so, we can analyze the counseling process to understand what should be done to upgrade the current model. The self-assessment system is functionally like a counselor, who needs to know the background information of his/her client (the user of the system) as early as possible and ask necessary questions to get more required information of the client until the counselor finally form an assessment about the client. During the counseling process, the counselor may also pick and/or skip some questions of all possible or potential questions according to the needs to logically understand the client by his/her answers to previous questions, and form a

more and more specific figure of the client and finally the assessment to the client about his/her readiness.

This paper describes our work to attempt fulfilling this upgrade based on this thought. As most of current systems adopted in other universities, the previous system of Am I Ready for Athabasca University is a self-assessment questionnaire: Am I ready for Athabasca University? It involves several self-test groups, including Goals, Preparation, Supports and Commitment, which are content-fixed or static (i.e. tests that do not adapt to the user's responses). Each of these groups is a Web-based questionnaire. The user can choose one of several options (Yes or No) for each question and finally get a score. The score reflects the total number of Yes and No answers, but is not objectively correlated with any measure of readiness for distance education. The students can get some information from the assessment according to the score and the meaning of Yes or No for each question. A lot of "No" answers may indicate the user needs to think more seriously about their decision before they begin their studies. The shortcoming of this system is that it does not help the prospective students very much to find out what are needed to succeed and how to get those needs met. Also, it can't dynamically alter the sequencing of questions according to user's answers in order to assess the student's readiness more precisely.

The new version of AM I READY for Athabasca University (AM I READY) is an adaptive online self-assessment tool for prospective students of Athabasca University. It is based on knowledge models of counseling process, including User Model, Counseling Model, Process Model and Assessment Model. It can choose and present most necessary questions to users by enabling, disabling and changing priority of questions according to those models, and produce dynamic question-answers dialog to a specific user. It involves better understanding of a user and effective self-assessment process with a smaller necessary question set. It can provide real time information to conduct users and show related resources to users to help them with more information. It can also find the contradictory answers of a user and give assessment according to all of the user's answers.

In the rest of this paper, the related work is reviewed right after the introduction, including adaptive questionnaires or assessments. The knowledge modeling of AM I READY system is proposed in the third section. Some details of User Model, Counseling Model, Process Model and Assessment Model are described there. In section four, the design and realization of AM I READY is

introduced. The last part of this paper is about the conclusion and future work.

II. Related Works

There are some related works about the adaptive questionnaire or self-assessment, and knowledge modeling currently. An adaptive Web-based questionnaire for course survey is developed and evaluated by Chou et al in [1]. It uses the answers to certain questions, which are called Adaptive Questions, to determine the next series of questions and to skip unrelated questions. Only few questions are Adaptive Questions in their question set. Unlike other questions, they only show one by one on individual Web page for the convenience to immediately decide and lead to other related question groups in the following page. This restriction does not exist in our AM I READY system, in which all kinds of questions are combined together and priorities are used to order or control the proper presentation of following related questions. Web-based online questionnaire can also acts as an online pupil consultation system according to Milne et al [2]. Three adaptive algorithms, including Skipping, Branching and Relevance Weighting Algorithms are analyzed and compared, and Branching Algorithm is finally used in the work to make it more effective and easier to use. An interface is designed for teachers to construct the questions, response and possible path of those questions. However, it is hard to define all possible paths if there is a larger question set and relations between those questions. Nokelainen et al [3] designed an adaptive questionnaire based on Bayesian Modeling. In their paper, Bayesian statistical techniques are used to create an individual learner’s profile (in Profile Creation Phase) and optimize the number of questions presented to each user (in Query Phase). It is very suitable for such surveys or test applications that we only know few about their results and categories. But it is not fit for AM I READY project, where all possible relations between questions are coded and put to the knowledge base, because it needs more controllable and user specific self-assessment process. There are also many works about knowledge modeling recently. One of them, which is related to user-adaptive interface, proposed by Rosis et al, is a visual formalism and an evaluation tool, XDM, context-sensitive dialogue modeling, to model user-adapted interface based on extended Petri nets [6]. As to other application of self-assessment, it can also act as a self-learning system according to Gayo-Avello [4]. Another related field is Adaptive Testing [5], in which testing is adapted interactively to match the ability level of the examinee by means of a statistical method called “Item Response Theory”.

III. Knowledge Modeling

Let’s have a look at a real counseling process first. There are two roles involved: a counselor, who is the expert of the specific counseling field and the controller of the current

counseling process, and a client, who has his/her own needs and background information that the counselor needs to know during (and maybe before) the counseling process. The more information the counselor knows about the client, the fewer questions he needs to ask while trying to understand the client and then give an assessment to him/her. Respectively, there are several models built to support the adaptive self-assessment of AM I READY, namely, User Model, Counseling Model, Process Model and Assessment Model. User Model is the knowledge about the client, including static (produced before or at the beginning of the counseling process) and dynamic ones (produced during the process). We model the counselor by Counseling Model (related to field knowledge), Process Model (knowledge about the counseling process) and Assessment Model (knowledge about the assessment). All these models are showed in Figure 1.

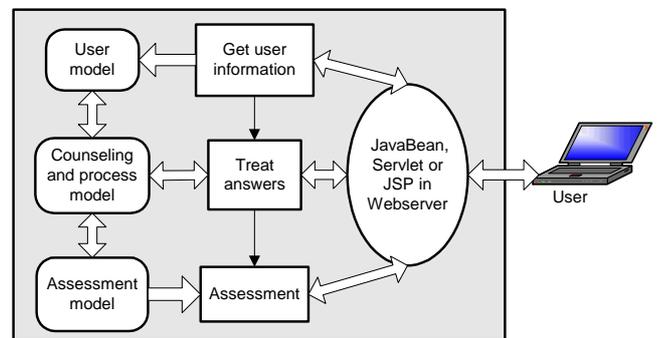

Figure 1. Knowledge Models and Architecture

User Model

There is lots of information about a user. However, we only need those that mostly affect the readiness self-assessment of the user. For this purpose, we chose several items about a user as the User Model parameters, namely:

- Highest level of education
- Work status
- Financial capability
- Computer skills
- Favorite questions groups

Users can make their choices at the very beginning of their self-assessment by clicking the options of these parameters. Figure 2 shows the Web page for building user model. The values of those model parameters directly affect the questions the system is going to ask later. For example, if a user tells the system that he/she has graduated from college or above, the system is not going to ask any questions to assess his/her readiness of basic writing skills. Two kinds of relations have been built into the model about what *questions* or *fields* are “Disabled”, “Enabled” or “Plus”

priority by a specific value of a parameter. This is the *static* user model – they are not going to change during the assessment after they have been set. The inner representations are the parameters and their relations in the form of *Facts* and *Rules*.

The *dynamic* user model is essentially about the records of the user's choice history along the assessment, which is always changing during the assessment. The main items include the answer of each question, records of questions that are disabled, enabled, and have high priority. The increasing records will continue affecting the questions of the next page asked to users according to the same rules mentioned above.

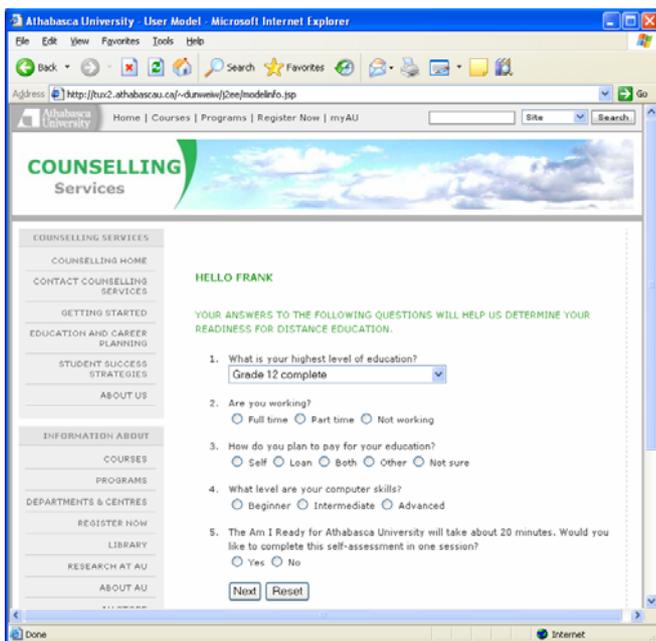

Figure 2. Static user model Web page

Counseling Model, Process Model and Assessment Model

Needless to say, counseling knowledge is always different in contents, forms and styles according to different domains and processes. However, we can still try to model the general level of the counseling knowledge, like the methods of counseling knowledge representation and resolution. In this part, we have captured five kinds of knowledge for AM I READY, which forms Counseling Model (*Questions, Relations, and Instant Information*), Process Model (*Process*) and Assessment Model (*Assessment*).

Questions are the knowledge sets about all questions of a system, its fields and sub-fields and predefined answer types. All questions are divided into eight groups (or fields) in AM I READY, e.g. Educational & Career, Financial Readiness, Academic Preparation, Course/Program Awareness, Commitment & Motivation, Computer Readiness and so on. Each field may have some sub-fields. Like that Financial Readiness includes four sub-fields, namely, General Information, Family Support, Loans and Awards. Each

question belongs to a sub-field and each sub-field belongs to a field, which forms a standard hierarchical tree structure. All questions are in plain text and can have predefined different kinds of answers. Currently, AM I READY has (1) Yes and No, (2) Yes, No and Not Clear, (3) Grade and (4) Multi-Checks. The last one can have multi-choices answers. Questions and related answer options can be seen in Figure 3. Users can choose their answers to those question by click related radio buttons. Even questions of Multi-Checks type can be represented by multi radio button pairs.

Instant Information is the additional information related to answers of certain questions. Users can see the instant information immediately after he/she click an answer button, as showed in Figure 3. The main purpose of instant information is to give users immediate response, and provide related resources (links or emails) and guidance to follow self-assessment process.

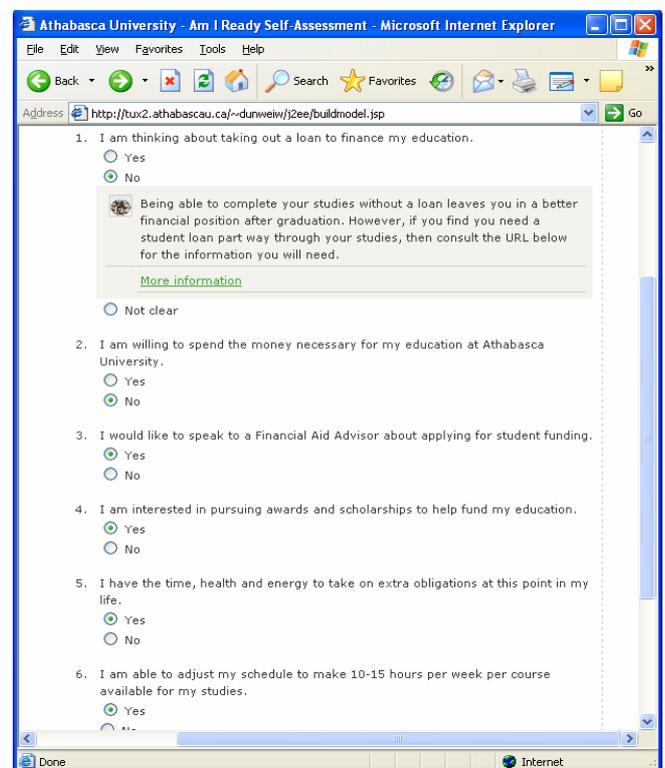

Figure 3. A self-assessment Web page

Relations include all relations between questions. We also regard them as rules. In AM I READY, relations can be question to question(s), question to sub-field(s), and the latter can finally become question to all questions belonging to the sub-field(s). So the relations are always one-many relations. There are four types of relations as briefly mentioned above, which are *Enable*, *Disable*, *Plus* and *Contradictory*. The first three relations are in this form:

(**Enable** (Answer(i) of question(j), (1)
 (question list)
 (sub-field list)))

It means that an answer of a question will enable some questions or other questions belonging to some sub-fields if they have been disabled before. *Disable* relation can disable some questions that are no longer needed to ask the user according the user’s current answer. *Plus* means to enable some questions and add the priority of those questions, which can cause those questions to be asked soon. The order to show questions is made by sorting those questions according to their priority. *Contradictory* means that some answers to certain questions are contradict:

(**Contradict** (Answer(i) of question(j), (2)
 (list of answers of some questions)))

Process is the knowledge of how to control the counseling process. To improve the effectiveness of a self-assessment, modeling the counseling process in a suitable way is very helpful. And it is also useful for AM I READY system to understand the process and make suitable or nature “dialog” between users and the system. To do this, we need to combine the process with other knowledge like user model and other counseling models. Just as what a real counselor is going to do, there are two critical methods: (1) *Adopting models* mentioned above, including user model and counseling model, (2) *Changing Priority* in real time and *Sort Questions* by their priority. By adopting user model and counseling model, AM I READY can filter, skip, gather questions, and by the help of priority handling, AM I READY can ask more related questions together, which is more natural to use and more friendly to interact. For example, after the user choosing Yes or Not Clear to the first financial question: “I am thinking about taking out a loan to finance my education.” All detailed questions about the loan are going to show on the next Web page (see Figure 4). Not like [1], in AM I READY, every question can be an “Adaptive Question” and questions on next Web page are always most related to current answers. It gives the system great flexibility and produces a kind of flexible or dynamic “Webpage-Dialog”. With the flexible filtering and skipping functions, AM I READY is more effective and suitable for applications with large set of question. On the other hand, by the help of these mechanisms, we don’t need to be too serious about the questions set, if only we can tell and capture the relations of those questions.

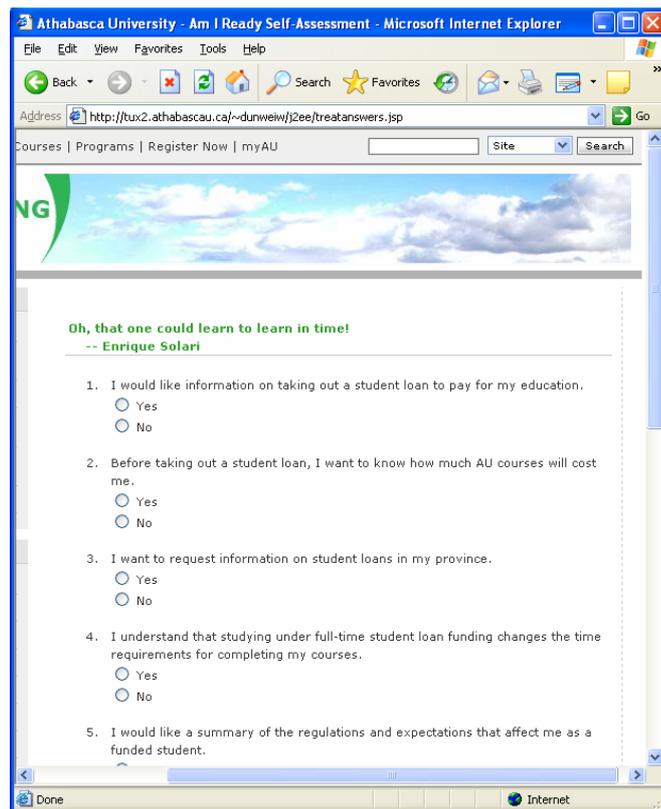

Figure 4. A dialogic Web page after Figure 3.

Assessment is information about the assessment sentences, which are going to show at the last page of the self-assessment. As mentioned in introduction section, we don’t use a single score to assess the readiness of a user. Actually, some assessment information plus remedial suggestion are more useful to users, which can help them to understand how to make it happen if he/she is not so readiness in some aspects. We’ve designed two kinds of assessment information: *Question Related* and *Question Group Related*. The latter has more than one conditions coming from different fields and questions:

(Assessment (i) (3)
 ←
 (answer(i) of question(j),
))

The final assessment information is in Figure 5. Users can browser, download and print the assessment information in AM I READY system.

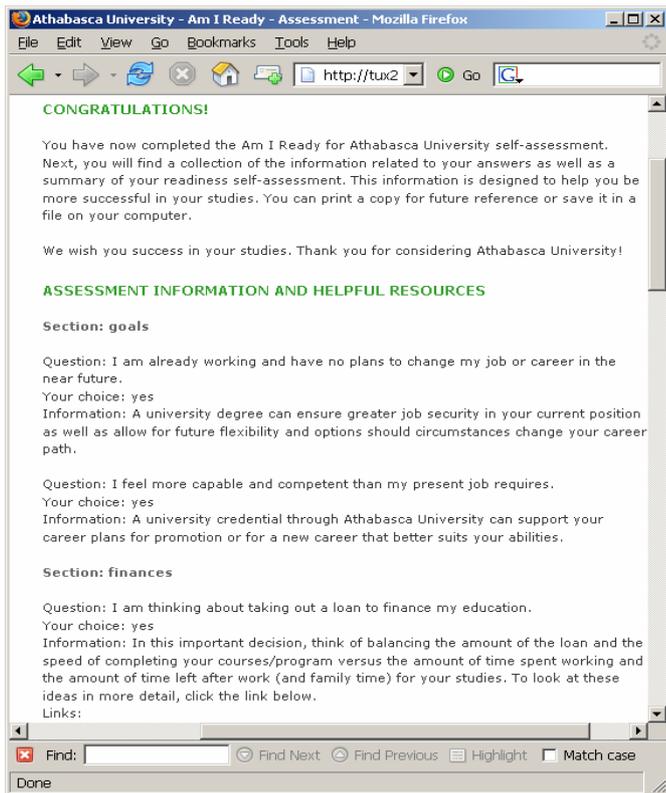

Figure 5. Assessment information

IV. System Structure And Realization

As mentioned above, AM I READY is a knowledge intensive system. We have modeled different knowledge with different representation. We can then use different expert or reasoning tools and methods to realize the self-assessment process. As it should be a stable and sustainable system serving to online users, and should be compatible with current information infrastructure of Athabasca University, we've tried to put the knowledge, including rules, relations, facts and text information, into PostgreSQL database, and to reason the questions to ask next by SQL and Java/JSP. The system structure is depicted in Figure 6, and the overall counseling or self-assessment process is depicted in Figure 7.

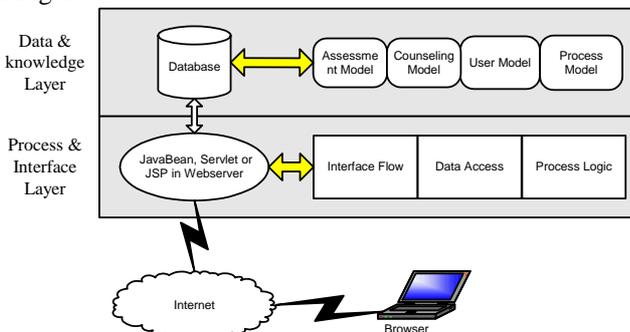

Figure 6. System structure

The system can be functionally divided into two layers: Data & Knowledge Layer, and Process & Interface Layer. All the data and knowledge are stored in the first layer with the help of database and SQL reasoning, while Java/JSP on the second layer handles the interface and interaction between the system and users. Users can online access the system by the Internet.

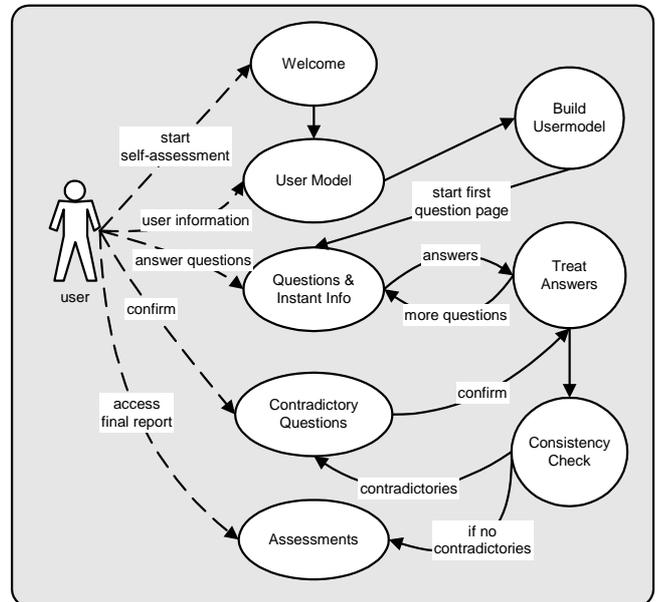

Figure 7. Information interactions among components

As you can see in Figure 7, a user can input user information at the beginning of the self-assessment. The system then builds the user model according to the inputted information. Based on the first filtered or arranged question sets, the system starts to ask questions and the user starts to answer those questions in turn. The system can ask new questions to the user after it accepts the user's answers and selects questions to ask by reasoning and sorting all currently available questions which are always changing to follow the direction to "model" or "understand" or "assess" the user. If there are no more questions to ask, the system is going to check answers to see if there are some contradictions among them. If yes, related questions are going to be sent back to the user for double check. After the contradictory questions has successfully confirmed, the final assessment information displays on the last page.

V. Conclusion and Future Works

Knowledge modeling in AM I READY project has captured different kinds of counseling knowledge and several models of self-assessment process, and has brought new features to traditional self-assessment online questionnaire system. Those features include flexible questions designing, user oriented or user specific questioning, dynamic and adaptive self-assessment process. Knowledge modeling, representation and reasoning have been proposed and implemented

in this project. Functionally, it provides a more effective and natural process to understand and assess its users. It can also provide real time guidance and remedial information to the users, which can be very helpful for the prospective students not only get to know their readiness, but also know how to improve the readiness.

The system is currently running and providing online services. However, we still have some work to do in the future. A knowledge editor is needed to improve the knowledge modeling and modification. A new change for improving the final representation of users' readiness by statistical information is on the way. A Formal knowledge description and a SQL based reasoning method for AM I READY are going to be reported in another paper. Data mining can also be done to analyze the questions and their relations and provide some information to improve the knowledge base. Readiness self-assessment is only the rudimentary step to a general counseling system, which we expect to intake more Psychology and Artificial Intelligence technologies to pursue the research and development on it.

Acknowledement

This work is a part of the E-Learning Accelerator project of Athabasca University, Funded by Alberta Learning Access

Fund Fast Track 2003 One-Time Grants. We would like to thank the project team, Athabasca University, Alberta Advanced Education and National Science & Engineering Research Council (NSERC) of Canada for sponsoring this work.

Assessing E-Learning Effectiveness: Developing Strategies for Pedagogy, Resources and Delivery

Indrit Troshani, Sally Rao
School of Commerce
The University of Adelaide
233 North Terrace, Adelaide, SA 5005
Australia

Email: {indrit.troshani, sally.rao}@adelaide.edu.au

Abstract: Although e-learning is spreading quickly across the globe in both educational and non-educational institutions there are problems and misconceptions related to e-learning. Thus, the aim of this paper is to review existing literature, particularly previous research pertaining to the three dimensions on the basis of which online courses should be designed and assessed. Essentially, we argue that e-learning should take a systematic approach and the checklist we have developed can be used to assess online teaching and learning sites and to develop strategies for pedagogy, resources and delivery in e-learning. It is hoped that introducing measurability of online course assessment will help quantify the usefulness of online course.

Keywords: E-Learning & Innovations in Teaching

I. Introduction

The aim of this paper is to review existing literature, particularly previous research pertaining to the three dimensions on the basis of which online courses should be designed and assessed. These dimensions include pedagogy, resources and delivery [20]. This is important because there is significant evidence in literature suggesting that although that e-learning is spreading quickly across the globe in both educational and non-educational institutions there are problems and misconceptions related to e-learning [12,13,15].

As a result, the identified factors can be of significant help to educators who design online courses and who are involved in online teaching and learning. The identified factors are summarised as components of a checklist, which can be used to assess online teaching and learning sites. A method to validate the proposed checklist is then presented. Finally, limitations of the checklist and a future research directions to improve the checklists further are also identified.

II. Pedagogy Strategy and E-Learning

Pedagogy refers to the activities which underpin a learning environment [20]. There are three aspects to any pedagogy

namely, dependant/independent, structured/unstructured, and guided/open-ended, where each choice is independent of the other [47]. No single pedagogy suits all students and all courses. Consequently, educators may use more than one pedagogy in a course to provide variety in order to cater to the needs and abilities of different students.

Recent theory supports the notion that learners learn best in environments that are created from an approach that advocates situated learning which immerses them in an authentic, problem based, goal oriented, open ended learning environment and actively engages them, and uses collaboration in its constitution. In the case of online learning, this approach provides support from the lecturer in the form of coaching and scaffolding to facilitate knowledge construction and self regulated learning.

The use of the social constructivist approach is well documented as the preferred approach to online learning [18,20,28,35,43]. There are seven pedagogical goals that designers of constructivist learning environments should take into consideration [14]:

1. Experience with the knowledge construction process
2. Experience in and appreciation for multiple perspectives
3. Embed learning in realistic and relevant contexts
4. Encourage ownership and voice in the learning process
5. Embed the learning in social experience
6. Encourage the use of multiple modes of representation
7. Encourage self-awareness of the knowledge construction process

Through a constructivist approach, learners can create their own interpretations of the events around them and use existing knowledge and understandings, and construct their own new understandings from these interpretations [28]. As an extension of this, Social Constructivism [44] emphasises that the interaction of learners with others leads to cognitive development and supports collaborative construction of knowledge through social negotiation. There is agreement in the literature that that knowledge building results when learners interact with their peers, challenge their thoughts, beliefs, perceptions and existing knowledge by collaborating, discussing their positions, forming arguments, reevaluating their initial positions, and negotiating meaning [3,22]. The Internet in general and the World Wide Web support many different forms of communication that facilitates collaboration (e.g. online discussion boards, etc.) and should

be used in the online learning environment in a meaningful way relevant to the set tasks. Therefore, teaching and learning activities should be designed such that a smooth progression from socialisation through to information sharing and to knowledge construction can be made [5].

Expert advice can be provided to online students in many different ways, such as, feedback on work submitted, asking challenging questions, correcting misconceptions and through inviting practitioners and other experts to participate in online discussions. By participating in weekly discussions, commenting on students' contributions, adding comments and references that relate to the weekly topic tutors can both feed the discussion environment and guide their students playing a vital role in promoting consistent and relevant interaction between students and tutors [8,43].

Therefore, educators play a vital role in promoting consistent and relevant interaction with students. Their role as facilitator, virtual or online is crucial to the development of skills required for students to move from dependency on the e-moderator to self-directed learning. However, the educator should not be seen as an authoritarian figure, but rather as a coach and refrain from imposing (their) views on the discussion but carefully guide the students in exploring an issue through multiple perspectives [43]. By providing multiple perspectives or interpretations of reality knowledge can be further integrated into the learners' existing schemata. Thus, a variety of learning activities should be provided to accommodate different learning styles and life experiences of the learner [2,8,21].

Constructivists perceive that students construct different cognitive structures based upon their previous knowledge and interests. Consequently, learning tasks and activities should be centred around problems that have personal relevance to students [42,46]. Moreover, the way in which problems are introduced to the students is critical to the amount of buy-in by the students. The problem presentation needs to be interesting, appealing and engaging and simulates the problem in a context in which it is normally and naturally encountered as the context defines and structures the problem [36]. Problems that are situated in authentic, real world scenarios that are linked to the students own experiences provide an open-ended learning environment that is goal-oriented and often complex by nature. They arouse curiosity, engage the student, and encourage active participation [24-26]. Authentic learning is

active learning. It involves real life situations and problems that have context, depth, complexity and duration. They involve cooperative situations and shared consequences, are worth solving and can provide benefits when solved. They are comprised of a single sustainable complex task that provides the opportunity to look at different perspectives, promote reflection to enable abstractions to be formed and promote articulation to enable tacit knowledge to be made explicit. By providing relevant, problem-based, real life scenarios the learning is situated in the problems that are being solved.

An online learning environment should provide opportunities where the student can actively manipulate available functionality in order to facilitate learning and reflecting [24-26,34,45,46]. This metacognitive process should be facilitated by the teacher who should provide guidance and support in the knowledge construction process with the provision of flexible scaffolding where the instructional design and teaching tactics surround, but do not fill in, the learning by students [20]. This support should be provided in the initial stages and it should be gradually removed as students increase responsibility for their own learning and become more self-directed. Nevertheless, interactions with the lecturer should always be the centrepiece of education, no matter what the medium [27].

The identification and articulation of aims and objective in e-learning is important as it provides the foundation for the instructional design, development, delivery, and assessment of an educational event [19]. These aims and objectives should form part of the teaching and learning plan as they predetermine what is to be taught and learned. Consequently, it can be expected that e-learning activities will equip students with the necessary skills, knowledge, and experience to meet the aims and objectives of the course.

In addition, assessment points throughout the course should reflect the educational growth of the students. Continuous assessment is important for both teachers and students because it provides information on the progress made, it helps measure the accomplishments of learning objectives, while also providing students with benchmarks for monitoring their progress and means of adjusting their learning tactics. Therefore, assessment and measurement strategies should be integral parts of the learning process.

To summarise, we propose the following pedagogy strategy checklist for e-learning:

Authentic tasks:

- | | | |
|---|-----|----|
| • Tasks have a clear purpose | Yes | No |
| • Activities are problem based using real world scenarios [situated learning] | Yes | No |
| • Activities are authentic to the environment in which they are used | Yes | No |

Opportunities for collaboration

- | | | |
|---|-----|----|
| • Activities create opportunities for learners to interact meaningfully | Yes | No |
| • There are opportunities for interaction between student and tutor | Yes | No |
| • Guidance is provided to ensure collaboration is meaningful and relevant to the set tasks. | Yes | No |
| • The tutor promotes consistent interaction | Yes | No |

• Activities support peer tuition and/or assessment	Yes	No
• Activities make provision for industry mentors	Yes	No
Learner-centred environments		
• Activities actively engage the learner	Yes	No
• Problems are complex	Yes	No
• Problems are encourage active participation	Yes	No
• Tutor provides guidance or scaffolding where appropriate	Yes	No
• Learning is based on inquiry or problem-based tasks	Yes	No
• Instructional activities should encourage and required students to actively participate in the acquisition and processing of educational content.	Yes	No
• Activities support and develop students metacognitive skills	Yes	No
• A variety of learning activities are provided to accommodate different learning styles and life experiences of learners.	Yes	No
Engaging		
• Activities and assessments are linked to learners own experiences	Yes	No
• Activities arouse curiosity and are interesting	Yes	No
• Problems are contextualised and complex	Yes	No
Meaningful Assessments		
• Evaluation of performance is directed toward the measurement and assessment of the predefined learning goals and objectives.	Yes	No
• A variety of "low-stakes" assessment and measurement strategies are provided to enable students to gauge their progress without impacting on course grade or performance measurement	Yes	No
• Automated systems (e.g. on-line quiz tools) are provided for immediate feedback, relevant suggestions, and guided support in response to learners' performance.	Yes	No
• Asynchronous technologies such as electronic mail, bulletin boards and/or other technologies support the assessment and measurement activities.	Yes	No
• Opportunities for students to provide feedback regarding the instructional design of the program.	Yes	No

III. Resource Strategy and E-Learning

One of the important aspects that the educational design of an online unit needs to take into consideration includes the resources that are provided to the learners [20].

Accessibility. Firstly, accessibility is an indication of the ease with which learners are able to locate and access information resources provided by the online unit [38]. Accessibility of online resources by people with disabilities is similar to the accessibility of online resources by non-disabled people that browse in non-standard conditions, such as outdoors, on-the-move, or through devices with limited capabilities [31-33,39].

One of the accessibility rules is the separation of unit contents from the sites appearance. This means that online learning sites should provide users with the capability to override defaults styles with user-preferred styles [1,39]. This should reflected in site design principle that sites should allow for customisation based on user preference. That is, the site should allow for versatility of the way information is presented (e.g. display changes, timing events, etc.).

Another rule is the provision of text alternatives for visual components (images and multimedia features). This

rule is important to accommodate access for learners who cannot afford suitable browsers or Internet connections [39] which can be accomplished by developing sites that are compatible with assistive technologies (ATs) and complete keyboard access.

The contents of the resources provided to the learner should also be given the due attention (Vrasidas & McIsaac 1999). The content structure of an online unit should be sufficiently detailed and meaningful in order to modularise the contents into small manageable chunks [43]. The level of detail and modularisation, however, should not interfere with the organisational logic, clarity and intuition of the provided information. Moreover, users should be allowed to easily navigate through the site hierarchy to retrieve what they require. Therefore site maps and advanced search capabilities, context and orientation information, navigation aids, etc. may be provided to assist easy navigation [1,31,33].

Standardisation. A related issue is learning content standardisation (Hodgins & Conner 2002) which should be based on accredited content libraries or learning management systems with the goal to reuse, transfer or have interoperability between learning systems. It is claimed that learning content standardisation will help answer questions like:

- How will one mix and match content from multiple sources?
- How will one develop interchangeable content that can be reused, assembled and disassembled quickly and easily?
- How can one ensure that one is not trapped by vendor’s proprietary learning technology?

Examples of standards to help answer questions like the above include the IEEE Learning Technology Standard Committee, Advanced Distributed Learning Initiative, Instructional Management System (IMS) Global Learning Consortium, Education and Training in European Society (PROMETEUS), etc [1,21,31,33,38,40].

In this context, online sites need to provide content management tools, like authoring tools for course development and revision (Belyk, Schubert, & Baggaley 2002). They also should contain student management tools like password-protected logins, registration and withdrawal procedures, and other general student tracking functions. These functions will increase the flexibility, extensibility, interoperability, multicultural and multilingual support, etc. with which the provided resources are managed [4,17,31,33,38].

Useability. Useability is not only based on a set of best practice principles developed by Jakob Nielsen but also comprises a new principle according to which the content of an online learning web site should be matched to its audience [40]. This means that the target audience should be the determinant factor to define the communication style of the website. Specifically, Smulders (2001) argues that e-learning websites should steer from jargon and culture-specific perspectives. This, however, appears to be at odds with Herrington et al.’s (2001) guideline of resource inclusivity which suggest that resources should include a variety of cultural perspectives, where possible [17,31,33,38,43].

Another aspect of Smulders’ (2001) useability notion includes content organization adherence to consistency and observance of tried-and-true standards. The rationale behind this is to systematically standardise website look and feel by making learning sites more predictable environments in order to allow learners to know what to expect. This aspect of Smulders’ (2001) useability appears to be supported in [23,31,33,38] too.

To summarise, we propose the following resource strategy checklist for e-learning:

Accessibility of Resources

- | | | |
|--|-----|----|
| • The online site separates unit contents from the sites appearance | Yes | No |
| • The online site offers text alternatives for visual components (images and multimedia features). | Yes | No |
| • The online site offers auditory contents alternatives for visual components (images and multimedia features). | Yes | No |
| • The online site offers keyboard access options to all features. | Yes | No |
| • The content structure of the online unit is sufficiently detailed. | Yes | No |
| • The content structure of the online unit is sufficiently meaningful. | Yes | No |
| • The content structure of the online unit is logically organised. | Yes | No |
| • The content structure of the online unit is clear and unambiguous. | Yes | No |
| • The content structure of the online unit is intuitive and easy to follow. | Yes | No |
| • The contents structure of the online unit is based on tried and true standards. | Yes | No |
| • The resource have the learning content metadata feature in order to allow quick and advanced search capabilities of material provided. | Yes | No |

Standardisation of Resources

- | | | |
|--|-----|----|
| • The learning content is sufficiently standardised to allow to easily mix and match from multiple sources. | Yes | No |
| • The learning content is sufficiently standardised to allow one to develop interchangeable content that can be reused easily and quickly. | Yes | No |
| • The learning content is sufficiently standardised to allow that users are not trapped by vendor’s proprietary technology. | Yes | No |
| • | Yes | No |

Modifiability of Resources

- | | | |
|---|-----|----|
| • The online learning site contains contents management tools allowing contents changes to be flexibility. , extensibility, interoperability, multicultural and multilingual support, | Yes | No |
| • The online learning site contains contents management tools allowing contents changes to be extensible. | Yes | No |
| • The online learning site contains contents management tools allowing contents changes to be provide for multicultural and multilingual support. | Yes | No |

<i>Inclusivity of Resources</i>	Yes	No
• The resource in the online learning web site are matched to all possible audiences, or provisions for different audiences are made.	Yes	No
•	Yes	No
<i>Richness</i>		
• The subject matter resources provide for multiple views on the subject matter.	Yes	No
• The subject matter resources encourage critical appraisal of what is available.	Yes	No
• The subject matter resources encourage empirical evaluation, where possible.	Yes	No
• The subject matter resources encourage creative thinking based on existing works.	Yes	No
<i>Currency</i>		
• The resources contain seminal works on the subject matter.	Yes	No
• The resources contain recent developments in the subject matter.	Yes	No

IV. Delivery Strategy and E-Learning

The ways in which an online course is delivered to students need to be anticipated in its design to ensure its quality [20]. As students come with a variety of backgrounds and technology experience, an online course needs to cater to these differences to ensure each student becomes involved in the learning experience in their own terms. The site should be reliable and have a robust interface that provides the student with a sense of adventure while being motivating, a confidence in tackling the technology, and support their efforts for knowledge acquisition without any barriers.

Online courses, should not be restricted to one delivery platform and should be flexible and easily customisable based on the following characteristics:

- use of software that is readily available;
- use code that can be customised easily and the use of development software for more sophisticated usage (eg Flash) for components that will not change;
- the development of resources that can be used in various delivery platforms;
- site structure that allows a student to progress through the learning material in a variety of pathways;
- site can be extendable and scalable.

The technology should be transparent to the student (Herrington et al (2001)). The layout and navigation should be clear and follow one's common sense. Therefore, sufficient technical instructions should be provided to assist students in the use of the site or details of how to obtain, support and assistance, e.g. technical help desk, student administration and other support services. An online learning site should be created with students in mind. Assumptions should be made that students do not have a high degree of technical expertise.

Influences affecting interface design that should be considered include: usability testing to gauge user

comfort/connectedness; user control/user centredness so that users can control their learning pathway and the activities are linked to their learning requirements; the interface design is consistent with the content structure; and the interface design supports the learning approach; and the interface provides for the students' individualised needs [37].

Online learning sites should provide students with clear goals, directions and learning plans and relationships should exist between learning outcomes, resources, activities and assessments (Herrington et al (2001)). The literature is consistent that the following should be unambiguously displayed in an online learning site:

- a unit outline that provides students with the aims, objectives, learning outcomes and learning approach used;
- the interaction required – details and times ;
- assessment – criteria, quality elements, length and weighting;
- texts (where the purchase and costs), references and websites – include textbook chapters, articles to consult, supplementary readings;
- suggested study schedule;
- links to student support material – eg institution handbook, student portal, learning centre, technical helpdesk;
- information written in greater detail so that the student can proceed independently or with need for little clarification by teaching staff;
- contact details (email, phone and fax) – teaching staff as well as student support areas.

As indicated earlier in the paper, knowledge building occurs through interaction with other students. Consequently, in an online environment, opportunities need to be provided for students to communicate with each other and their teacher. A variety of way can be used to accomplish this: asynchronous interaction, synchronous interaction and email. Asynchronous interaction enables students and teachers to participate in online forums where the entire learning community can partake in scholarly exchanges of mutual

benefit [9]. Synchronous interaction enables students to participate in real time interchanges that provide students with an immediate response to questions or comments. Email communication is useful for interchanges between the student and their teacher such as the student requesting assistance of a personal nature. Alternatively, email can also be used when the teacher advises feedback and grades, administration issues etc. (Chellman & Duchastel; 2000). Therefore, the learning channels should be open to all students, and encourage collaborative learning and knowledge construction.

When delivering e-learning bandwidth considerations should also be made. Bandwidth is defined in the literature as the amount of data that can be carried in the unit of time. Bandwidth considerations are important because they affect download times which also depend on connection speed for file size. Different students might have access to different types of network or Internet connections, therefore, the delivery of the online materials is likely to be affected [31,33]. For example, narrowband internet connections would be limited to [6]:

- Provision of materials – text, stills, limited low quality video
- Interaction with materials – text, stills, low quality video
- Interaction with teacher – email, chat, online discussion, low quality streaming
- Interaction between students – email, chat, online discussion, low quality streaming

Whilst broadband internet connections would offer [6]:

- Provision of materials – text, stills, video streamed from server (quality dependent on bandwidth)

- Interaction with materials – text, stills, high quality video
- Interaction with teacher – email, chat, online discussion, streaming (depending on bandwidth)
- Interaction between students – email, chat, online discussion, streaming (depending on bandwidth)

Students undertaking online learning should also be provided with recommended requirements for undertaking the online course. These requirements include minimum hardware and software specifications, internet connection, additional plug-ins as well as the details of how such plug-ins should be obtained. Online learning materials which are too large for downloading over the internet should be delivered to students via alternative means (e.g. CD-ROM mail-outs etc.)

An online learning site should also ensure equitable access by vision and hearing impaired students. Therefore, the design of the websites should comply with W3C Web Content Accessibility Guidelines 1.0 (<http://www.w3.org/TR/1999/WAI-WEBCONTENT-19990505/#Guidelines>). Designers of online learning sites should also ensure that local standards are met. For example, in Australia, online learning sites should comply with EdNA (Education Network Australia). Metadata standards should “support interoperability across all sectors of education and training in Australia in the area of online resource discovery and management” (<http://standards.edna.edu.au/metadata/>). In addition, copyright materials that are made available online for educational purposes must comply with the Copyright Act 1968, which imposes obligations regarding the electronic communication of Copyright material. To summarise, we propose the following delivery strategy checklist for e-learning:

Reliable and robust interface:

- | | | |
|--|-----|----|
| • Content can be created using software that is readily available. | Yes | No |
| • Content can be used with other delivery platforms. | Yes | No |
| • Site is flexible and can be updated for currency/changed easily. | Yes | No |
| • The use of html code can be customised easily. | Yes | No |
| • The use of development software for more sophisticated usage (eg Flash) for components that will not change. | Yes | No |
| • The site structure allows a student to progress through the learning material in a variety of pathways. | Yes | No |
| • Layout and navigation is clear . | Yes | No |
| • Site has been created with students with little technical experience in mind. | Yes | No |
| • Useability testing has been undertaken. | Yes | No |
| • The interface supports the learning approach taken for this unit. | Yes | No |
| • The interface is consistent with the structure of the unit. | Yes | No |
| • The interface enables the students to complete their learning requirements. | Yes | No |
| • The site provides access or details about support and assistance available to students. | Yes | No |

Clear goals, directions and learning plans:

- | | | |
|--|-----|----|
| • Unit outline is available that provides student with aims, objectives, learning outcomes and learning approach used. | Yes | No |
|--|-----|----|

• Details are provided about interaction required of students.	Yes	No
• Details are provided about assessment including criteria, quality elements, length and weighting.	Yes	No
• Details are provided about texts, references, websites and other sources of information.	Yes	No
• A suggested study schedule is provided.	Yes	No
• Links to student support material are provided (eg administration, helpdesk, learning centre etc.).	Yes	No
• Information provided for the online student has been written in greater detail.	Yes	No
• Contact details have been provided for teaching staff as well as student support areas.	Yes	No
• Students have choices in the resources they use from the site.	Yes	No
• The site is not wholly based on content as a resource for learning.	Yes	No
• The site provides facilities for the student to interact with their learning.	Yes	No
Communication:		
• Communication is used to encourage active and collaborative learning and knowledge building.	Yes	No
• Provision is made for students to interact with the teaching staff and other students.	Yes	No
• Students are provided with email facilities or email addresses of teaching staff and other students.	Yes	No
• Students are provided with asynchronous discussion facilities.	Yes	No
• Students are provided with synchronous discussion facilities. (<i>Optional</i>)	Yes	No
Technical issues:		
• Technical instructions/support are readily available.	Yes	No
• Site can be assessed via an internet connection using a 28Kkbp modem.	Yes	No
• The site does not use large files for streaming video, online simulations and multimedia that distract or hamper the learning experience.	Yes	No
• The site can be viewed using a standard internet browser.	Yes	No
• Access or details about additional plug-ins the student may require has been provided.	Yes	No
• Details have been provided to students about the recommended requirements for undertaking the online unit (eg. minimum hardware and software requirements).	Yes	No
• Students have access to offline content (eg CD-Rom with large video or audio files; hard copy print based reader). (<i>Optional</i>)	Yes	No
Equity, accessibility and legal requirements		
• Unit materials and activities are available and are accessible by all students especially disabled students.		
• Site complies with the W3C Web Content Accessibility Guidelines.	Yes	No
• Site has been put through the Bobby tool to ensure web accessibility guidelines have been met.	Yes	No
• Site complies with EdNA (Education Network Australia) Metadata Standards.	Yes	No
• Site complies with the Copyright Act 1968.	Yes	No

V. Proposed Methodology

In the previous sections checklists assessing the effectiveness of online learning sites were proposed. In their current form, these checklists are based on current e-learning literature alone. For them to have practical value, empirical validation is required. We propose that validation should be carried out in two stages. In the first stage popular online learning sites will be reviewed in an attempt to enrich the

current checklists or identify items which are not supported. With the second stage, we believe that focus groups with students and educators are appropriate as a means of further validation. Focus groups allow for group interaction and have the potential to generate synergistic effects and, therefore, can produce data and insights which would otherwise be less accessible [7,10,11,16,29,30,41]. This, we believe, will enhance the quality of the data.

VI. Conclusions and Future Research

The checklists recommended above constitute an attempt to comprehensively and effectively assess online course for teaching and learning. As online teaching and learning becomes more popular and is used for teaching various fields of knowledge there is a growing need to standardise pedagogies, resources and delivery strategies which constitute the three most important components of online learning. In addition, with an increasing number of course delivered online less ambiguous assessment is required. In this paper, we have developed checklists which assess the three components of online learning.

Further research needs to be conducted in order to determine the relative importance of the proposed checklist items. This is important because the current checklists weigh all items equally. The reviewed literature indicates that certain checklist items may be more important than others. In addition their importance may vary for online courses of different fields of knowledge. Once determined, the relative importance of the checklist items may be quantified in terms of weights. The assessors of online course may then rate each checklist item depending on the assigned weight, to obtain a final score. Different online courses may then be compared on the basis of the calculated score. It is hoped that introducing measurability of online course assessment will help quantify the usefulness of online course.

Abstract: The purpose of this study is to call attention to the consensus of stakeholders of corporate e-Learning system regarding success. We identified the critical success factors (contents, technical features, management, and organizational support) as major components of corporate e-Learning systems and questioned whether stakeholders' consensus on the importance of these components facilitates the implementation of these components to achieve good quality or well. We also questioned whether the influence of these components on user satisfaction could be moderated by contextual factors. Based on empirical testing of 18 e-Learning user companies, we verified that the consensus of stakeholders regarding the importance of content, technological features, and organizational support has a positive influence on the perceived quality of these factors in their e-Learning systems, which in turn is positively related to user satisfaction. The learning subjects and learning style did significantly moderate the influences of these perceived qualities on user satisfaction.

Keywords: e-Learning system stakeholders, consensus of stakeholders, e-Learning user satisfaction.

I. Introduction

Online education systems (or e-Learning systems) have presented possible solutions for many problems arising from off-line-based education and training, such as temporal and spatial limits, and the distinctive benefits unavailable from traditional education systems such as agile updates of content, personalization, interactivity, and timeliness[5]. However, opinion is getting stronger among scholars and practitioners in the human resources development field that we need to be more clearly aware of the diverse views of stakeholders on education and training that can cause either chaos or consistency in the overall structure and efforts of education and training systems [22]. Thus, this study poses the following research questions:

-Who are the stakeholders that render substantial influences on the quality of corporate e-Learning systems?

-What kinds of factors influence the end users' satisfaction with corporate e-Learning systems? Also, are their influences stable or subject to contextual factors?

-What is the role of stakeholder consensus on the quality of such influential factors?

To answer these questions, first we reviewed how previous studies in management approached and investigated the issues regarding stakeholders and then identified three different groups of stakeholders who render substantial influence on corporate e-Learning systems. Second, we explored diverse literature on traditional learning, e-Learning system, and information system (IS) implementation to come up with a list of the influential factors pertaining to end-user satisfaction with e-Learning systems. Third, we developed measurement scales to assess the degree of consensus of the stakeholders regarding the importance of these influential factors and empirically tested how such consensus relates to the quality of implementation of the factors and eventually end-user satisfaction with e-Learning systems.

Further, this study presumes that the effects of these influential factors are susceptible to moderating variables instead of being steady and stable across diverse learning contexts. This study investigates whether the learning subjects and learning style moderate the effects of various influential factors on end-user satisfaction regarding corporate e-Learning systems.

II. Theoretical Framework

II. 1 Stakeholders of e-Learning Systems and Their Consensus

Freeman (1984) [11] defined stakeholders as individuals or organizations that make influences on or are influenced by a company to achieve its goals. Because stakeholders can influence organizational behaviors, decision-making, policies, and goals, companies need to divide the stakeholders into small groups with the same interests and deal with individual idiosyncrasies and demands with each stakeholder group [11]. Recognizing and reflecting the diverse perspectives of stakeholders must be a working strategy to increase cooperative attitudes among stakeholders, reduce risks stemming from stakeholders'

power abuse, and thus predict and control stakeholders' behaviors. Such lessons to relate to cooperative relationship with stakeholders have substantial significance on company education activities: i.e., recognizing all the diverse perspectives of stakeholders in education and training clearly [22]. Although researchers have diverse opinions about the components and stakeholders of e-Learning systems, practitioners and academia in Korea have agreed to classify the stakeholders of corporate e-Learning systems into **learners, e-Learning service providers, and human resource departments in charge of corporate education**. This study focuses on corporate e-Learning systems.

As previous studies on corporate e-Learning stakeholders are not abounding, we conducted in-depth interviews with e-Learning content developers, producers, service providers, and human resources development officers as well as individual users of e-Learning user companies, and asked all groupings whether the above three categories of stakeholders of e-Learning systems were valid. Through their agreement in this study, we come to confirm the three groups of stakeholders for corporate e-Learning systems.

This study is interested in the role of the prior consensus of stakeholders on the important factors that apply to their corporate e-Learning systems. Our posture is that high consensus among stakeholders on the importance and value of critical success factors of e-Learning systems facilitates actual implementation of those factors in good quality, which in turn leads to user satisfaction. Each stakeholder can also have unique critical issues that are not relevant to other stakeholders (for example, market share of e-Learning system products may matter only for the e-Learning service provider). However, the objective variable of this study is end user satisfaction, and therefore, the influential factors in the study are all limited by their relevancy to end-user satisfaction with e-Learning systems.

Our inference about the role of stakeholders' consensus on the ultimate qualities of e-Learning systems is based on the previous studies that have attributed the success or failure of organizational activities to a consistency and consensus in values, opinions, and significance of organizational stakeholders [24]. The importance of stakeholders' consensus has been highlighted by the theory of "group mind" for the last ten years. Several terms have been used to explain the process in which individuals form a collective sense for their teams, organizations, and environments, and emphasize the importance of agreement or consensus among group members. Particularly, the shared mental model is one of the most widely used terms [18]. The shareness of individual mental models is desirable for team performances because team members can form similar predictions for tasks, acquire the necessary information to complete them, and better adapt to the requests and issues of other teammates [4]. These previous studies insinuate that consensus of stakeholders regarding the importance and value of critical success factors for e-Learning systems can improve the possibility of implementation of those factors

and their qualities as well. Thus, what aspects of corporate e-Learning systems do the stakeholders need to appreciate and acknowledge in common to achieve this goal?

II. 2 Influential Factors for the Success of e-Learning System

We examined diverse literature of information systems and education engineering as it regards corporate education, e-Learning, and e-Learning systems in order to identify the influential factors for corporate e-Learning systems. More attention was needed for information systems because new technical features are being continually imported to e-Learning systems, such as Internet, graphics, animations, sounds, images, and color videos. Through the literature review, we agreed on the following four categories of influential factors that produced the success of corporate e-Learning systems: Content, technical features, management (of service providers), and (end-user) organizational support.

Keegan (1986) [15] emphasized the importance of lecture **content** in education. Keegan (1986) [15] and other constructivists proved that the content of multi-media education systems should be valid [17], well-structured [25], and clear and straightforward [23] for good performance and results. Thus, the learning experience can be varied according to how the different learning content is selected, structured, and expressed.

Howell & Silvey (1996) [12] indicated that the performance of multi-media training is deeply related to its **technical characteristics**. The representative metrics include the robustness and trend updates of technical features [21], convenience of system usage [7], and the speed and accessibility of the network [9].

Motivation and interaction are in the realm of e-Learning **management** of education and training service providers that support, encourage, and facilitate learners to continue learning [1]. Keller (1984) [16], who developed the ARCS (Attention, Relevance, Confidence, Satisfaction) Model for motivation development, contended that motivation and feedback are two major factors to obtain effective information system-based education.

Organizational support can be psychological (such as encouragement, recognition, and positive expectations of colleagues, bosses, and management) or materialistic (such as compensation and rewards based on performance of the learners) [1]. Doll (1985) [10] compared the organizational support between successful and failure IS-based education systems and found that successful systems are accompanied by substantial support from top management.

II. 3 Moderators of e-Learning Systems

Through intensive interviews with numerous e-Learning stakeholders, we sensed that e-Learning service providers and human resource departments consider the characteristics of learning subjects in preparing e-Learning programs. They determined different requirements of course load and prerequisites for learners and different caliber levels and

qualifications for instructors. In addition, structuralism in education has mandated that the diverse learning styles of learners possess different preferences, requirements, and priorities for different learning systems.

The **subjects** of organizational education can be classified into hard and soft skills [20]. Hard skills relate to such issues as information technology, software operations, product knowledge, and task operations, all of which need to be well defined, structured, and closely related to current tasks. Soft skills denote knowledge that cannot be easily articulated or explained, such as personal relationships, courtesy and manners, interview tactics, ethics, and leadership. So far in Korea, e-Learning programs of most companies have been focused on hard skill contents; however, soft skill subjects are steadily increasing. Therefore, this study examines whether the learning subjects moderate the effects of those influential factors mentioned above on user satisfaction with corporate e-Learning systems.

Studies have identified that individual attributes, such as cognitive ability, experience, motivation, attitude, values, and expectation, are deeply involved with the overall effectiveness of traditional corporate educations [19]. Such attributes also exert significant influence on information system-based learning systems [8]. Particularly, we examined individual **learning styles** that possessed the preferences and requirements to complete each course. Due to this innate foundation, we need to identify the role of learning styles on learning and education performance. We propose that e-Learning style correspond to the usage type of decision support systems developed by Inmon et al. (1999) [14] because e-Learning systems require similar interactions to DSS in terms of cognitive challenge and purpose of use. We came up with a binary category for learning style: Exemplary type and whimsical type. These two respectively correspond to the farmer type and the explorer type of Inmon et al. (1999) [14] DSS usage categories of learning type. The exemplary type regularly uses e-Learning systems, clearly recognizes the goals of study, and focuses on the contents delivered through the system. The whimsical type does not regularly access the e-Learning system, is not conscious of the study goals, and searches for more information beyond the course contents whenever they desired or required.

III. Research Model and Hypotheses

We have produced the following four groups of hypotheses. The first group relates to the role of stakeholder consensus regarding the importance and value of the four categories of critical success factors. Critical success factors need to constitute corporate e-Learning systems for desirable performances, so are called e-Learning system components in this study. The second group of hypotheses relates to the relationship among these factors, and we supposed the hierarchical relationship in this regard. The third group of hypotheses reflects the theoretically induced influences of

those factors (i.e., e-Learning system components) on the effectiveness of corporate e-Learning systems (i.e., user satisfaction). Finally, the fourth group of hypotheses anticipates the moderating role of the learning subject and the learning style in regards to the effects of those factors.

H 1. The consensus of stakeholders on the importance and value of critical success factors for corporate e-Learning systems positively influences the implementation quality of these factors.

- 1-1. The consensus of stakeholders on the importance and value of contents positively influences the perceived content quality (PCQ).
- 1-2. The consensus of stakeholders on the importance and value of technical features positively influences the perceived technical quality (PTQ).
- 1-3. The consensus of stakeholders on the importance and value of management positively influences the perceived management quality (PMQ).
- 1-4. The consensus of stakeholders on the importance and value of organizational support positively influences the perceived organizational support quality (POQ).

H 2. The perceived qualities of e-Learning system components are in a hierarchical relationship.

The ultimate quality of e-Learning systems depends on content, and content is the major object to be delivered to organizational members. Therefore, we put PCQ at the high point of the hierarchical relationship. PMQ and PTQ are two direct supporting activities that help learners understand and apply the content, which is the main *raison-d'être* for any e-Learning system. POQ sets up the organizational mindset, attitude, and direction regarding e-Learning systems, which then buttresses all relevant activities. Therefore, we present the hierarchical relationship among these factors as follows.

- 2-1. POQ positively influences PTQ.
- 2-2. POQ positively influences PMQ.
- 2-3. PTQ positively influences PCQ.
- 2-4. PMQ positively influences PCQ.

H 3. The perceived qualities of e-Learning system components positively influence the performance of e-Learning systems.

- 3-1. PCQ positively influences the user's satisfaction with e-Learning systems.
- 3-2. PTQ positively influences the user's satisfaction with e-Learning systems.
- 3-3. PMQ positively influences the user's satisfaction with e-Learning systems.
- 3-4. POQ positively influences the user's satisfaction with e-Learning systems.

H 4. The learning subject and learning style moderate

the effects of perceived qualities of e-Learning system components.

- 4-1. The learning subjects moderate the effects of PCQ regarding user's satisfaction.
- 4-2. The learning subjects moderate the effects of PTQ regarding user's satisfaction.
- 4-3. The learning subjects moderate the effects of PMQ regarding user's satisfaction.
- 4-4. The learning subjects moderate the effects of POQ regarding user's satisfaction.
- 4-5. The learning style moderates the effects of PCQ regarding user's satisfaction.
- 4-6. The learning style moderates the effects of PTQ regarding user's satisfaction.
- 4-7. The learning style moderates the effects of PMQ regarding user's satisfaction.
- 4-8. The learning style moderates the effects of POQ regarding user's satisfaction.

IV. Research Methodology

IV.1 Definitions and Operationalization of Variables

Most measurement items were adopted from previous studies and modified to our research context. Two critical issues on the measurement of the consensus of stakeholders were the objects and the degree of consensus. As mentioned already, the objects of consensus are the influential factors for user satisfaction with e-Learning systems. As for the degree of consensus, we adopted the phenomenological approach that puts emphasis on the belief of organizational members regarding the degree of shareness of mental models among themselves and then calculated the Euclid distance among respondent's beliefs about this shareness of mental models.

It was quite challenging to choose the objective measure for the performance of e-Learning systems. User satisfaction and system use are especially popular because direct benefits and costs are associated with many delicate issues, such as time lag, control of exogenous factors, and representation. However, when information systems are in obligatory use due to regulatory or conventional reasons, user satisfaction is more appropriate than system use as the surrogate measure of information system success [2]. Therefore, we adopt user satisfaction because corporate e-Learning systems are compulsory in many organizations.

IV.2 Samples and Data Collection

We first contacted the top three e-Learning service companies in Korea and requested their client list. To avoid sampling bias, we selected companies in various industries and of diverse size. We asked our first contact person of the e-Learning service provider to introduce staffs who had worked for more than two years, and then surveyed the inductees. Then, we contacted the human resource department staff of this client company list, who was in charge of corporate education or e-Learning programs. We

asked the first contact person to introduce more of the corporate education staffs who had been in the same job for more than two years, and then asked these staff persons to cooperate with our research by participating in our interviews, surveys, and introducing the e-Learning system users (learners). Finally, we contacted e-Learning system users who had taken more than two courses in their current organization. The consensus on each CSF was calculated by the Euclidean distance among the perceptions of the user, his/her organization's HR department, and his/her e-Learning service provider regarding the importance of the same e-Learning components. User perceptions on the qualities of these components and user satisfaction were the subsequent indigenous variables of this exogenous variable (i.e., consensus).

We distributed total 500 questionnaires to 3 e-Learning service providers and 18 client companies of these e-Learning service providers. In three weeks, 426 surveys were replied (return rate was 85.2%), and 398 surveys were judged appropriate for further statistical analysis excluding 28 invalid replies. There were 311 end-users (learners), 36 human resource department staffs, and 51 service provider staffs.

V. Data Analysis and Hypothesis Test

V.1 Qualities of Instruments: Reliability and Validity

Reliability of each first-order construct measurement was assessed by Cronbach's alpha. The Cronbach's alpha of 'system quality' in PTQ was 0.58 below the general criterion of 0.6. However, we decided not to exclude this construct because it is one of the major components in PTQ of our research model, and exhibited acceptable reliability scores in other studies.

To investigate whether the questionnaire items measured the constructs as they were supposed to, we tested the construct validity of four, second-order latent variables by examining convergent and discriminant validity. Our convergent validity analysis demonstrated that all the *t*-values of CFA loadings were significant except for system quality and interaction. However, these constructs were not excluded from further analysis because it was important to retain as many original items as possible to preserve the original research design and then compare the results with other studies that used the same scales. The discriminant validity of constructs was assessed by criteria similar to multi-trait/multi-method analysis. To assess discriminant validity, we compared the measures of Average Variance Extracted (AVE) with the correlation values in the corresponding rows and columns. Discriminant validity would be secured if the diagonals exceeded 0.5 and the off-diagonals in the corresponding rows and columns [6]. Discriminant validity was secured for all the second-order constructs.

V.2 Analysis

V.2.1 Goodness-of-Fit Determined by Comparing with

Alternative Competing Models

We constructed two competing models, C1 and C2. When compared to our research model (C3), Model C1 excluded the hierarchical structure among e-Learning system components. Meanwhile, Model C2 admitted the hierarchical relationship among PCQ, PMQ, PTQ and POQ, but assumed that PMQ and PTQ take up only the mediating role between POQ and PCQ without direct influence on user satisfaction with corporate e-Learning systems.

We used RMSEA (Root-Mean Square Error of Approximation) and TLI (Tucker Lewis Index) as goodness-of-fit indexes. RMSEA evaluates the discrepancy between model and data per degree of freedom and simultaneously considers both errors and parsimony of a research model. TLI addresses the enhancement of a research model compared to the null model. RMSEA needed to be less than 0.05 for excellent fit and range between 0.05 and 0.08 for acceptable models [3].

The criterion for TLI used to be 0.9-0.95 [13]. Our model demonstrated 0.066 for RMSEA and 0.94 for TLI, both of which satisfied the acceptable criteria.

However, it is not fair to consider only the goodness-of-fit indexes of research between models without considering complexity (degree of freedom). Therefore, we calculated the trade-off between goodness-of-fit (chi-square value) and parsimony (degree of freedom) among the competing models and concluded that our research model (C3) maintains a better fit than the competing models. C2 was more complicated than C1, thus having less chi-square value ($\Delta \chi^2 = 253.082$) and less degree of freedom ($\Delta \text{Degree of Freedom}=2$). This improvement was significant, so C2 and C3 were compared next. C3 had less chi-square value than C2 due to model complexity ($\Delta \chi^2 = 10.913$) with the loss of

degree of freedom by 2. This improvement was also significant.

V. 2. 2 Hypothesis Test

Figure 1 presents the result of SEM (Structural Equation Modeling) analysis by AMOS 4.0. Because our model was judged to fit our data, we refer to this model and test our hypotheses.

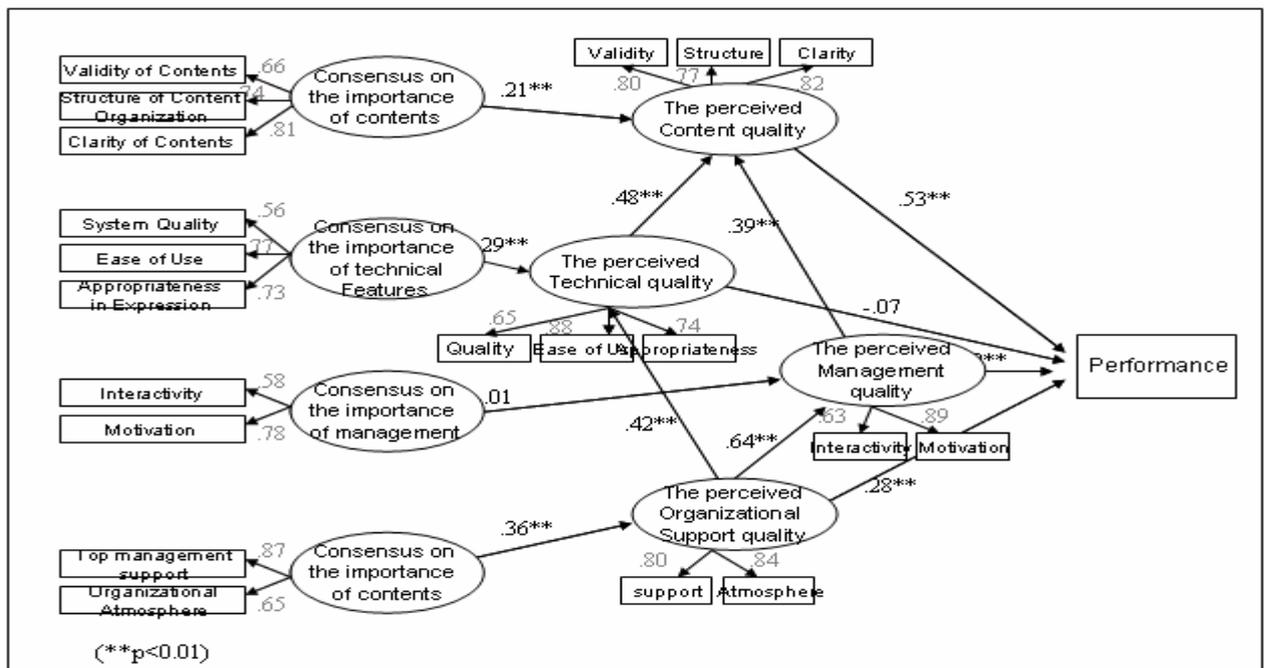

Hypothesis 1 stated that the consensus of stakeholders regarding the importance and value of critical success factors for corporate e-Learning systems positively influences the implementation quality of these factors. The analysis shows that all the path coefficients between stakeholder consensus and quality of critical success factors are significant except for the path to PMQ (Hypothesis 1.3).

Hypothesis 2 stated that the perceived qualities of e-Learning system components are in hierarchical relationships. Our analysis indicates that all the path coefficients are significant ($p<0.00$) as we assumed.

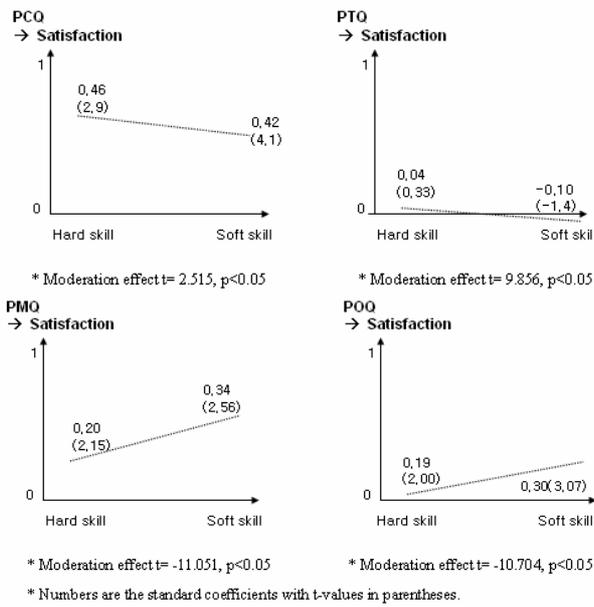

Hypothesis 3 stated that the perceived qualities of e-Learning system components positively influence the performance of e-Learning systems (user satisfaction). Our analysis shows that all the path coefficients between the perceived qualities of e-Learning system components and user satisfaction are significant except for the path from PTQ (Hypothesis 3.2).

Hypotheses 4.1 - 4.4 concern the moderating roles of learning subject between the perceived qualities of e-Learning system components and user satisfaction. Figure 2 demonstrates that the learning subject clearly moderates the effects of the perceived qualities of all the e-Learning system components on user satisfaction.

[Figure 1] Analysis Results

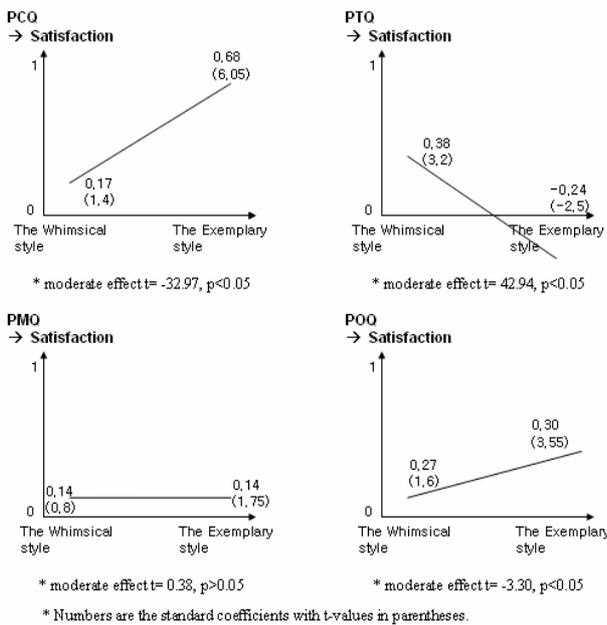

[Figure 2] Moderation Effect of Learning Subjects

Hypotheses 4.5 - 4.8 concern the moderating role of learning style between the perceived qualities of e-Learning system components and user satisfaction. Figure 3 illustrates that learning style significantly moderates the effects of perceived qualities of e-Learning system components on user satisfaction except for PMQ (Hypothesis 4.7).

[Figure 3] Moderation Effect of Learning Style

VI. Discussion and Conclusion

The primary purpose of this study was to recognize who has stakes for corporate e-Learning systems and how their consensus on the importance of e-Learning system

components works on the implementation qualities of these components to eventually influence user satisfaction. In addition, we tested whether the influences of qualities of e-Learning system components change at different contexts, an issue that relates to when we can achieve the maximal value of e-Learning systems. Learning subject and learning style were found to significantly moderate the effects of critical success factors. Our findings can be summarized as follows.

First, stakeholder consensus on the importance of e-Learning system components helps implement most of these components in good quality except for management quality. In other words, stakeholder consensus on the importance of content, technical features, and organizational support for corporate e-Learning systems leads to the implementation of these three components in good quality, respectively. Even though many management services are embedded or cared for by automatic systems, we found that learner perception regarding the quality of e-Learning service provider management is substantially influenced by the personal characteristics (attitude, mission, personality, etc.) of staffs in charge of e-Learning rather than being facilitated by the consensus of related stakeholders. For example, in the case of examination or report submission, learners confessed that they are more thankful for personal calls, emails, or consultation with staff than mechanic or blunt notification from systems because they can talk about their personal problems or negotiate schedules.

Second, in regards to the hierarchical relationship among e-Learning system components, we found that organizational support quality buttresses the quality levels of all the other components. It influenced the qualities of technical features and management, both of which in turn facilitated the realization of content in good quality. Our finding that technical quality leads to content quality implies that learner perception regarding content quality can be improved if the e-Learning system uses more advanced technical features, such as multimedia functions. The influence of management on content quality signifies that the quality of content is not only related to text materials, but also to the interaction with instructors and operators. E-Learning service provider management and technical features are the instruments of the content to be delivered and internalized by learners. The value of such facilities is appreciated much more if user organizations (especially, human resource departments in charge of corporate education) demonstrate strong support for e-Learning programs. Therefore, our study reveals that organizations should establish and demonstrate a strong culture and intent for corporate e-Learning systems more than any other effort.

Third, all the components except for the technical quality, had a positive influence on user satisfaction with e-Learning systems. The reason for the lackluster influence of technical features could be traced to the more recent development of information technologies and a default embedment of such features into most e-Learning systems in Korea. In the past when there was substantial variance in IT features of e-

Learning systems, such features did matter for user satisfaction with e-Learning systems. Such phenomena have recently dissipated because IT features have become quite standardized among e-Learning systems in Korea, so that most e-Learning systems are not differentiated from each other in terms of technical features.

Fourth, we verified that the learning subject and learning style moderated the influences of these e-Learning system components regarding user satisfaction. Particularly, the learning style addressed the more dramatic moderating role. The whimsical style appreciated the qualities of content and organizational support, whereas the exemplary style did not. The exemplary style acknowledged the quality of technical features, while the whimsical style did not.

Our study has the following limitations that need to be overcome by future studies. It seems appropriate to include the role and influence of instructor as another stakeholder as long as the content can be regarded as the core component of e-Learning systems. In our study, the issues of instructor were submerged into content. Future studies can distinguish the issues of instructor from content and analyze the independent influences of instructors on user satisfaction.

MIS studies have been successful in identifying and verifying **what** are the critical success factors for implementation of various types of information systems. Our question was basically related to **how** we can implement these factors and attend to the consensus among stakeholders that facilitate the implementation of those factors. We wish more future studies to elucidate the processes and conditions regarding how we can implement those important factors better for successful information systems.

Abstract: The expansion of education beyond national boundaries has created a new market for the education industry. Many universities have formed partnerships with organisations in other countries in order to expand their programs. Several implementation models have been identified including distance education via E-Learning, study abroad programs, the establishment of a university campus in a foreign country and the travel of faculty lecturers to foreign countries for full or partial curriculum delivery. There has been dramatic growth in the development of electronic interactive learning systems and their application via E-Learning to higher education in the international market. The curriculum associated with Information Systems and in particular the teaching of Enterprise Resource Planning (ERP) systems is particularly suited to the application of E-Learning technologies. Victoria University has extended its offshore programs by offering ERP education in the Asian region and has applied E-learning technologies blending synchronous and asynchronous content to assist this expansion. A number of technologies facilitate teaching: application service provision (ASP), web-CT, computer-based training and virtual classroom technology. This approach provides an innovative and efficient means to deliver higher education internationally in terms of flexibility in subject delivery and increased learning outcomes.

Keywords: E-learning, Innovations in Teaching, Synchronous E-learning, Asynchronous E-learning, E-Learning Technology.

I. Introduction

The expansion of global education has created a new market for the education industry. Aoki (2004) has identified four trading service modes defined within the framework of the General Agreement on Trade in Services (GATS) and applied these to the education market:

Mode 1 – Cross-over supply: E-Learning in which the education provider and student do not relocate.

Mode 2 – Consumption Abroad: Study programs where the student travels to a foreign country.

Mode 3 – Commercial Presence: The establishment of

programs in another country.

Mode 4 – Presence of Natural Persons: Educators travel to another country to present program.

Aoki (2004) asserts that E-Learning allows educational services to cross over national boundaries. Demand for education is particularly strong in developing countries where education is seen as an important ingredient to economic prosperity. Many universities have introduced distance learning programs and are trialling E-Learning tools to support their expansion into the international education market. Several have formed partnerships with other institutions to enter the international education market taking advantages of new developments in E-Learning technologies. Aoki (2004) describes four well-known international consortia: U21global, Global University Alliance (GUA), World Alliance in Distance Education (WADE), and Cardean University.

Many studies have been carried out on the effects of E-Learning on a university's education strategy. Chan and Welebir (2003) describe the effects of the Internet and online distance education on a university's overall strategy. They present a strategic agenda that traditional universities can follow to develop E-Learning programs including the suggestion of forming a strategic alliance to enter the e-education market and expand globally. Gibson (2001) suggests that the virtual classroom will eventually replace the traditional classroom. His study explores methods to enhance the distance learning experience and create a competitive advantage.

II. ERP Curriculum

Curriculum associated with the teaching of Enterprise Resource Planning (ERP) systems is more suited to the use of E-Learning tools than many other areas especially where the curriculum is expanded beyond the traditional boundaries of universities (Hawking and McCarthy, 2001). ERP systems are modular application software that helps businesses increase the productivity of such mission-critical components as human resources, finance, parts purchasing, inventory control, supply chain and customer relationship management. ERP systems are enterprise-wide and claim to incorporate best business practice that replaces legacy systems and current business processes. The leading ERP vendor is SAP. SAP maintains about 35% of the worldwide ERP market (Gilbert, 2000) and its ERP product is called

SAP R/3.

An increasing number of universities are investigating strategic alliances with ERP system vendors to provide the support for incorporating ERP knowledge into their curriculum (Hawking, 1998). The ERP vendor benefits from these alliances by increasing the supply of skilled graduates that can support their product thereby enhancing its marketability. Chan and Welebir (2003) highlight the competitive advantages universities can gain by forming alliances, particularly their benefit in leveraging into the global e-education market.

The SAP University Alliance Program in Australia is an example of a strategic alliance between a number of universities and an ERP vendor. As part of the alliance, SAP provides approximately \$2.5 million worth of its product and technical and professional support for the integration of SAP R/3 into the curriculum. However it is still the responsibility of individual academics to develop the necessary curriculum and the university to provide the necessary infrastructure to support the system.

III. International Education

The Faculty of Business and Law on behalf of Victoria University joined the University Alliance Program in 1998 and has developed a Graduate Certificate, Graduate Diploma and Master of Business in Enterprise Resource Planning Systems as well as incorporating SAP R/3 into several undergraduate subjects. Currently we have 15 staff teaching more than 20 subjects at both the undergraduate and postgraduate levels to approximately 700 students.

Many higher education institutions are making plans to globalise their courses. Victoria University is no exception and offers a broad range of academic programs throughout the Asian region. The international programs involve over 3500 students from Malaysia, Singapore, Thailand, People's Republic of China and Bangladesh. Many of these universities have indicated that they wish to include ERP related subjects in their courses. While there have been indications that the high growth rates in the ERP market of recent years have somewhat dwindled, good growth has been maintained in many Asian markets with the expectation of continued growth in the foreseeable future (Pinaroc, 2000). SAP has established a University Alliance Program in many Asian countries to assist with provision of appropriately educated consultants to support this increased market. However even though these alliances have been established many of the universities have had difficulties in developing curriculum due to lack of skilled staff and available resources. Increasingly Asian universities are forming partnerships with foreign universities in an endeavour to broaden their curriculum offerings and add value to their students. Clearly there are advantages to be gained by both parties in setting up a partnership to teach different aspects of ERP systems. The provider is able to derive income to recoup some of the cost of developing curricula and maintaining systems while the receiver obtains

the benefits of their students acquiring ERP education without the need to invest in hardware, staff training and curriculum development.

In 2002 Victoria University commenced the Master of Business in ERP Systems at Sumbershire Business School, Singapore. In February 2005 the ERP masters program commenced at the Beijing Jiaotong University, P.R. of China. We are currently negotiating the introduction of ERP studies with institutions in Malaysia, Thailand and Tanzania.

IV. The Application of E-Learning Technology

Many E-Learning models have been developed and trials conducted in recent years. Neubauer and Lobel (Neubauer and Lobel, 2003) describe a highly structured synchronous model for teaching and doing research on medium to large sized groups over the Internet. Arnone (2002) reports on the technical standards being developed to allow colleges in the US to customise distance-learning programs by blending online-learning software from several vendors. Ehrmann and Collins (Ehrmann and Collins, 2001) describe examples of virtual classrooms that use the Internet to create new kinds of collaboration and learning. Tansley and Bryson (2000) evaluate the implications of replacing traditional modes of small group teaching with "virtual seminars".

Victoria University uses E-Learning technologies to facilitate the teaching of ERP systems in our offshore programs. The E-Learning technologies blend synchronous and asynchronous content. Asynchronous E-Learning does not involve the presence of the teacher. Typically the learning content is located on a web server that students can access using the Internet. The content can be interactive but the presence of the teacher is not required. Typically asynchronous E-Learning is implemented by Web-based training (WBT) and may include online forums, threaded discussions and download materials. Synchronous E-Learning requires the learner and teacher to be present in the event at the same time. It is a real-time, instructor-led online learning event in which all participants are available at the same time and can communicate directly with each other.

To support offshore teaching a model for ERP E-Learning has been developed and has been applied in Singapore since 2002 and China in 2005. It is also used in a limited way in an offshore program in Hong Kong. The model blends synchronous and asynchronous content and integrates four major technologies which provide a comprehensive medium for online learning.

The technologies are:

Application Service Provision

Application Service Provision (ASP) is responsible for providing the necessary technological infrastructure and support to host a particular software product. This enables the clients of the ASP to remotely access the software via the Internet. One of the barriers to ERP education mentioned earlier was gaining access to the ERP system and providing the necessary infrastructure. The ASP model provides a

solution to overcoming this barrier.

Victoria University has configured one of its SAP servers to support the role of an ASP to its partnering universities in Asia. Students from these universities can access the SAP software at Victoria University via the Internet once they have installed the SAPgui software on their local PC's. Students can access the SAP software from anywhere in the world as if they were sitting in front of a PC at Victoria University.

The control and administration of the ERP system is still the responsibility of Victoria University and allows our Asian partners to access SAP R/3 without the need to purchase an expensive computer server and employ the necessary support staff. Through the use of clients in the SAP R/3 the system can be individually configured to suit the learning objectives of each offshore institution.

Web-CT

Web-CT is a web based tool which acts a repository of learning materials to assist students with their ERP education. Web-CT has tools for storing and delivering course materials including text, graphics, audio and video. Material can be released according to various criteria, such as date and student name.

Web-CT also has tools for organising and enhancing course material, communication tools so that chat, "internal" mail, discussion groups and whiteboards can be made available for use by students and instructors and tools for monitoring student progress and providing feedback.

In terms of ERP delivery the Web-CT site allows students to view and download subject outlines, assignments, past examination material and lectures in various formats. Students can submit assignments via the site and then view their results once the assignments have been marked. Chat facilities can be enabled to allow students to discuss set tutorial questions and discuss issues they have encountered. This interaction may occur between students within their tutorial, university, other Asian universities, or Victoria University.

Web-CT is used as the foundation to deliver the asynchronous E-Learning content in the ERP offshore program.

SAPTutor

This tool is used for developing interactive tutorials in a simulated SAP environment. It enables the lecturer to record an action or transaction within the SAP environment and capture the screens involved to form the basis of a tutorial. After recording the tutorial, the SAPtutor Editor is used to edit the structure of the tutorial, define alternative paths (branching), edit instructional texts and create additional supplementary descriptive texts. This facility allows educational concepts to be inserted into tutorials using tools such as PowerPoint. The computer-based tutorials enable students to combine ERP theoretical concepts with the appropriate SAP screens and actions. Students can replay the tutorial as many times as necessary to understand the

concepts.

The SAPtutor tool enables staff in the Asian location to have access to a repository of ERP educational materials overcoming the lack of resources barrier identified earlier. The Virtual Classroom technology is used for plenary sessions to reinforce the concepts covered and answer any questions coming out of the SAPtutor tutorials.

This tool has the added benefit of capturing and storing a lecturer's knowledge that can then be reused by others at a later stage either in a different subject or to assist if the lecturer is no longer available.

Virtual Classroom

There is a growing trend amongst academics to use the Internet to increase access to educational materials in a variety of ways to support the learning process (Pather and Erwin, 2000). The ASP enables access to the ERP system while the Virtual Classroom technology provides access to the curriculum.

The virtual classroom tool enables synchronous E-Learning whereby the learner and teacher are present in the event at the same time. It is a real-time, instructor-led online learning event in which all participants are available at the same time and can communicate directly with each other. This virtual classroom capability is facilitated by the Centra Corporation virtual classroom software, Central Symposium, which provides the capability to deliver live, instructor-led classes direct to student desktops using fully integrated voice-over-IP technology. This is used to present theoretic concepts related to ERP Systems and practical demonstrations related to SAP software. Lesson delivery includes integrated full-duplex audio, interactive whiteboards, application sharing, breakout rooms and online surveys and evaluations. The technology allows lessons to be recorded for editing and playback. Centra Symposium is very powerful as it integrates many interactive tools that can be used in the live delivery. Of particular note is the "Application Sharing" tool that allows an application stored on the presenter's PC to be viewed on the students PCs. The presenter can demonstrate features of the application to students in the session and also give control of the application to individual students and allow them to utilise and manipulate the application. This is a very powerful feature and quite unique.

If a student has a query, they can "summon" the lecturer via the Virtual Classroom and the lecturer can then appropriately respond to the query. This two-way communication facilitates the interaction between the lecturer and student thus enhancing the learning process. This has been lacking in many of the online solutions up-to-date.

V. Conclusion

The application of E-Learning technology can provide opportunities for universities to expand their education services beyond national borders. Many universities have

formed partnerships with other institutions to expand their programs offshore; many of these are using E-Learning technology. The four E-Learning technologies used to deliver ERP education in the Asian region provide an efficient means to deliver higher education internationally in terms of flexibility in subject delivery and increased learning outcomes. The application of E-Learning technology will become increasingly relevant in the light of the growing demand for education services by developing countries.

Abstract: This paper describes a method of domain knowledge modeling for program planning and scheduling in intelligent e-Learning advising systems, focusing on the modeling and representation of precedence relations among course learning objects encoded in model curricular and the representation of domain experts' knowledge using Petri nets formalism and a XML-based markup language. We developed a Web-based program model editor.

Keywords: E-Learning & innovations in teaching, knowledge modeling and representation, program planning, Petri nets.

I. Introduction

Curriculum planning for student advising is an interactive decision-making process, which assist learners in the development of meaningful learning plans which are compatible with their career/life goals maximize educational potential through communication and information exchanges with an educator. An intelligent e-learning planning agent is a knowledge-based system able to assist e-learners to generate a personalized curriculum best suitable for them. The abilities of such a system hinge on possessing knowledge about the domain and program structure, learners, and pedagogy.

One of the important tasks in developing intelligent program planning systems is to model and represent the program model in the context so that the scheduling agents can use it to generate learning plans flexibly and adaptively. Due to the complex pre-requisite relationships among the course learning objects, this task is not trivial. This paper presents a Petri nets based model of program structure knowledge modeling and XML-based representation for dynamic program planning. We develop a knowledge editor for constructing and maintaining curriculum models.

To demonstrate the feasibility of the model, we developed an intelligent advisor able to generate personalized curriculum and generating a schedule for the courses selection according to students' temporal constraints, and course availability.

This paper mainly describes the method of domain knowledge modeling and representation for program planning and scheduling in e-Learning, focusing on the representation of precedence relations among course

learning objects encoded in model curricular and the representation of domain experts' knowledge.

We proposed an extended Petri nets model to represent the logical relationships among courses in a curriculum. We developed a Web-based knowledge editor providing straightforward modification to accommodate addition or deletion of courses, prerequisites, co-requisites, and rules.

To demonstrate the feasibility of the model and the editor, we show a real-world example of Petri nets represented course-flow for MSc IS program of Athabasca University of Canada.

II. Literature Review

The literature records several efforts to employ computers to reduce the tedium, and improve the consistency, in student advising [1-7]. These systems exploit AI, expert systems or knowledge-based systems to provide some of the functions of a faculty advisor to students. Several of them provide students with a prioritized list of suggested courses and check prerequisites and sequencing. Most of them were designed to run on mainframes environments or standalone PCs. Gunadhi, et al., (1995) presented a framework for an intelligent advisory system for college students that combine object-oriented and knowledge-based paradigms [3]. They did not address how to acquire and incorporate "real-life" expertise and how to interface to other systems in the university such as online registration system, academic and student databases.

Flow diagrams, narrative descriptions, and time-line analysis are useful for a variety of modeling problems. Those tools however make it difficult or impossible to expose critical time-dependencies, task concurrencies, and event-driven behavior. Petri nets are a useful and powerful modeling tool and overcome the aforementioned shortcomings [8].

In curriculum modeling, an important task is representing the complex logical relationships among the prerequisites. Both state machines and graphs do not have capability to model curricular. State machines with the property that each transition has exactly one incoming and one outgoing arc or flow relation. They are a subclass of P/T nets [8]. State machines allow us to model choice or decision. Because each place may have multiple output transitions, they do not allow modeling of synchronization or concurrent activities, which are common in a curriculum. Concurrent activities require that several transitions be enabled concurrently [9]. In a marked graph, each place has

only one incoming and one outgoing flow relation; thus, marked graphs do not allow modeling of choice while choices are important in course-choosing.

Knowledge modeling using Petri nets and its extensions in AI applications has received much attention. Net related models have been proposed for validating knowledge bases [10]; diagnostic knowledge representation and reasoning [11], determining requirements [12], and representing knowledge in discrete event systems [13].

K. Lee and M. Y. Jung (1994) presented a method for flexible operation planning using the Petri net approach [14]. A Petri net is used as a unified framework for both operation planning and plan representation.

III. Curriculum Petri Nets

Before describing the proposed Petri nets model, let us review the ordinary Place-Transition Nets.

III.1 Place-Transition Nets (P/T nets)

Place-Transition nets (P/T nets) are the basic type of Petri nets from which all other types are derived. They consist of four elements [8]:

(1) **Places:** places model conditions or objects such as program variables. They are represented by circles.

(2) **Tokens:** tokens are represented by black dots. These are contained within places and represent the specific value of the condition or object which that place represents. The initial arrangement of tokens on places is known as the *initial marking* of the Petri net.

(3) **Transitions:** transitions are represented by hollow rectangles and model activities which change the values of conditions and objects.

(4) **Arcs:** arcs are represented by lines connecting places and transitions. These indicate which objects are changed by which activities. As Place-Transition nets are bipartite, arcs may only connect places to transitions or transitions to places, but not places to places or transitions to transitions. An arc may have a *weight*, which specifies how many tokens are created or destroyed when a transition to which it is attached is fired.

A P/T net can be defined formally using functional notation:

Definition 3.1: (P/T nets)

A Place-Transition net is a 5-tuple

$$PN = (P, T, I_-, I_+, M_0)$$

where

$P = \{p_1, \dots, p_n\} (n > 0)$ is a finite and non-empty set of places;

$T = \{t_1, \dots, t_m\} (m > 0)$ is a finite and non-empty set of transitions, $P \cap T = \Phi$;

$F \subseteq (P \times T) \cup (T \times P)$ is a set of directed arcs, called flow relations;

$I_-, I_+ : P \times T \rightarrow N_0$ are the backward and forward

incidence functions respectively; If $I_-(p, t) > 0$, an arc leads from place p to transition t , whilst if $I_+(p, t) > 0$ then an arc leads from transition t to place p ; $M_0 : P \rightarrow N_0$ is the initial marking.

The dynamic behavior of a P/T net is determined by rules concerning the enabling and firing of transitions. When the arcs connecting a transition to its input places have a weight of one, the transition is enabled if all of its input places are marked with at least one token. Only an enabled transition may fire. When it does, one token on each of its input places is removed and one token is created on each of its output places. It is possible, however, for an arc to have a weight greater than one. In this case, if the arc is an input arc then the transition is only enabled if the number of tokens on the place to which it is connected is equal to or greater than its weight. When then transition is fired, the number of tokens removed on the place is equal to the arc's weight. If it is an output arc, firing the transition creates the number of tokens on the output place equivalent to the arc's weight. The numerical values of each of the I_- and I_+ functions correspond to the weights of the arcs connecting places and transitions. By convention arc weights of 1 are not shown explicitly.

The rules for the enabling and firing of transitions can be formalized thus:

Definition 3.2: (Firing rules of P/T nets)

If $PN = (P, T, I_-, I_+, M_0)$ is a P/T net. A marking of a P/T net is a function $M : P \rightarrow N_0$, where $M(p)$ is the number of tokens on place p , $N_0 = \{0, 1, \dots\}$;

A set $P_1 \subseteq P$ is marked at marking M , only and if only (iff) $\exists p \in P_1 : M(p) > 0$; otherwise P_1 is unmarked or empty at M ; A transition $t \in T$ is enabled at M , denoted by $M[t >]$, iff $M(p) \geq I_-(p, t), \forall p \in P$; A transition $t \in T$, enabled at marking M , may fire yielding a new marking M' where

$$M'(p) = M(p) - I_-(p, t) + I_+(p, t), \forall p \in P,$$

denoted by $M[t > M']$. In this case M' is directly reachable from M and we write $M \rightarrow M'$. Let \rightarrow^* be the reflexive and transitive closure of \rightarrow . A marking M' is reachable from M , iff $M \rightarrow^* M'$; A firing sequence of PN is a finite sequence of transitions $\sigma = t_1 \dots t_n \quad n \geq 0$ such that there are markings M_1, \dots, M_{n+1} satisfying $M_i[t_i > M_{i+1}], \forall i = 1, \dots, n$. A shorthand notation for this case is $M_1[\sigma >]$ and $M_1[\sigma > M_{n+1}]$, respectively. The empty firing sequence denoted by ϵ and $M[\epsilon > M]$ always holds.

The firing of a transition when the P/T net has one marking creates a new marking. The set of all markings

which are reachable from M_0 is known as the *reachability set* of the net and the connections between the markings in this set are represented by the reachability graph.

We extended P/T nets to model concurrent course taking activities, complex course dependency relations (e.g. prerequisites, co-requisites), preferences (priorities), and exclusion.

III.2 Curriculum P/T Nets

Course-taking process for an e-learner can be viewed as a process of changing the states of knowledge of the e-learner. To take a course, a learner's state of knowledge must meet the prerequisite requirement. After completing a course, the learner's state of knowledge is changed. The process of taking courses is then represented by a nondeterministic firing and passing the markers. The state of knowledge of a learner is thus denoted by the markup of the Petri net.

Definition 3.3 (Curriculum P/T nets):

A Curriculum P/T net

$$PN = (P, T, I_-, I_+, M_0)$$

is an extended P/T net,

$$PN = (P, T, I_-, I_+, M_0)$$

defined in **Definition 3.1** and **Definition 3.2** with the following extensions.

(1) **Transitions T :** Learning a course is mapped as a transition in a curriculum Petri Net, called course transition.

(2) **Places P :** We use places of P/T nets to indicate three types of the states in a program-perusing process.

(a) **Done Places:** There is only one output place for each course transition. That output place is named as Done Place. For example, the output place for course transition "Java Programming" is done place p_2 in Figure 1.

(b) **Ready Places:** We use an input place to represent the readiness of a prerequisite course of a course transition. There may be zero, one or many input places for a course transition. If a course has no prerequisite course, we still add an input place for that transition. That input places are names as Ready Places. If a done place of a course transition may be a ready place of another course transition. For example, course "Object-Oriented Programming (COMP501)" has no prerequisite courses in the program; its input place is Ready place p_1 ; p_2 is also a Ready place of course transition "Distributed Systems (COMP689)" as shown in Figure 1.

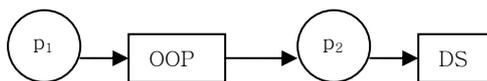

Figure 1: Example for Ready Places, Done places, and course transition.

(c) **Choice places:** we use a special place as a common input place of a set of course transitions to represent a situation of multiple choices in a curriculum. For example,

an MSc IS student at Athabasca University can take only either "IS integration essay" or "IS Integration Project", once the student completes the IS Foundation Courses and Core Courses. So, we set a Choice place p_3 to represent the case of exclusion (see Figure 2).

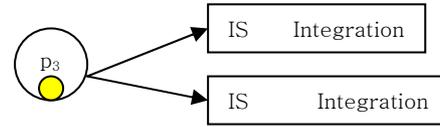

Figure 2: Example for choice places

(3) **Markings M :** The markings in an input place p of a course transition t represent the readiness of the prerequisite course t_0 in which the place p is its output place. If there is a token in an output place of a course transition, then the student already finishes the course.

(4) **Incidence functions I_+, I_- :** Considering one course can be the prerequisites of many courses, and it is hard to predict how many succeed courses of course t will be selected by a learner pursuing a program. Also, a learner may re-take a course to get a better mark. To keep the status that this course has been completed during the process of the program completion, we use a special incidence functions for all places in curriculum P/T nets:

- Once course t is done, one token will be created in its Done place p , i.e. $I_+(p, t) = 1$;
- No token in a Ready place p will be destroyed when its course transition t is fired, i.e. $I_-(p, t) = 0$;
- For a Choice place, one token will be removed from it when its course transition is fired, i.e. $I_-(p, t) = 1$.

(5) **Firing rules:** We extend the ordinary P/T nets by assigning a new firing rule:

A transition t in T is enabled at M , denoted by $M[t >, \text{iff}$ the condition predicate $pre(t)$ holds: predicate $pre(t)$ is formed by using the Boolean operators (AND, OR, NOT) over the place set $\{M(p): I_-(p, t) > 0, p \in P\}$.

The predicate only contains Boolean operators OR, AND, and NOT, and does not contain XOR operator, because the case of exclusion is represented by *Choice* places.

We classify the all possible pre-requisites into four categories:

Basic type:

- (1) AND: $C_1 \wedge C_2 \wedge \dots \wedge C_n$;
- (2) OR: $C_1 \vee C_2 \vee \dots \vee C_m$;
- (3) n OUT of m : $\{n, C_1 \vee C_2 \vee \dots \vee C_m\}$;

More generally, complex type:

- (4) $G_1 \wedge G_2 \wedge \dots \wedge G_i$,

$G_i (i = 1, 2, \dots, m)$ is a condition expression of 'n OUT OF

m' type.

For example, one of the most commonly-used prerequisite conditions is "to take course C, learners must take X course out of Y courses, some are mandatory". The condition represents that a student must take X prerequisite courses of course C, from Y courses to enable the course transition P. some of them are mandatory, Then the $pre(t)$ can be described as follows:

(1) $\forall p \in P$, if the course transition which uses p as a Done place is a necessary course (the inscription of Arc connecting the input place and the transition is MANDATORY) then $M(p) > 0$; and

(2) $(\sum_p M(p) \times I_-(p, t)) \geq X$.

IV. Petri Net Markup Language

Petri Net Markup Language (PNML) is an XML based standard format for the interchange of Petri nets. The main elements in the PNML file for a curriculum are Transition, Place, and Arc. These three elements represent the three kinds of basic elements in a Curriculum Petri Net. Each of those elements has its sub-elements. To represent curriculum Petri nets using PNML, we do not have any element for the firing rules in the PNML, because we do not use a standard firing rule to fire the course Petri nets automatically. Instead, we set up a special business rule that implemented to fire the transitions of curriculum Petri nets.

In order to illustrate the PNML format, Figure 3 shows a very simple sub-net of a curriculum Petri net shown in Figure 1 and its corresponding PNML description. In between the `<place id="p1">` and `</place>` tags, everything about that place is described. The value of its initial marking is contained between the tags of that name. The transitions are similarly described, whilst the arcs record their starts and ends as the nodes which they connect.

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<pnml>
  <net id="n1" type="BlackTokenNet">
    <name> An Example of Curriculum Petri Net </name>
    <place id="READYCOMP501">
      <marking> <value>1</value> </marking>
      <name>
        <value>READYCOMP501</value>
      </name>
    </place>
    <initialMarking><value>1</value></initialMarking>
    ... ..
    <arc id="a1" source="READYCOMP501"
      target="COMP501">
      <inscription>
        <requirement>MANDATORY</requirement>
```

```
<direction>input</direction>
  <value>0</value>
</inscription>
</arc>
... ..
<transition id="COMP501">
  <name>
    <value>1</value>
  </name>
</transition>
</net>
</pnml>
```

Figure 3: An example of PNML-represented curriculum Petri nets.

To represent the complex relation of prerequisite courses in the `<value>` in transition node of the PNML, we use a special expression

```
<value>
  m1, course1, course 2, ..., course n1;
  m2, course1, course 2, ..., course n2;
  ...
  ml, course 1, course 2, ..., course nl
</value>
```

($l > 0, m_i < n_i, i = 1, 2, \dots, l$). Here symbol ';' separates course groups. l is the number of the groups. m_i is the number of the required courses and n_i is the number of the courses to be selected.

For example, the value element in the transition node of the PNML for COMP696 is:

```
<value>
  4,COMP501, COMP503, COMP504, COMP601,;
  5,COMP603,COMP604,COMP605,COMP607,
  COMP610, COMP695,COMP617,;
</value>
```

Here symbol ';' separates course groups. So, COMP696 has two course groups as its prerequisite courses. In the first course group, there are four courses, and four courses are required to be taken in that course group. It actually means every course is MANDATORY. In the second course group, there are seven courses, and five courses are required to be taken in that course group.

In this value string, we can't tell which course is MANDATORY or OPTIONAL. We can get that information from the inscription of Arc connecting the input place and the transition. In this example, among all these prerequisite courses in the second course group, only COMP695 is MANDATORY.

V. Web-Based Program Knowledge Editor

We developed a Petri nets based knowledge editor by using an extended PNK [15] which is a Java-based Petri Net

Kernel (PNK) providing an infrastructure for bringing ideas for analyzing, for simulating, or for verifying Petri Nets into action. Petri nets can be loaded and saved in PNML [16], a language for the description of Petri nets based on XML. This Web-based knowledge editor provides administrators with a convenient tool for the construction and maintenance of program models by adding, updating, or deleting courses, prerequisites, co-requisites, and rules. Figure 4 and 5 show the four steps to adding a course into course dependency database using the developed Web-based program knowledge editor.

The screenshot shows a web interface titled "Add a Course into Course Dependency Database". It is divided into two steps:

- Step 1 of 4:** "Please input the course name" with a text input field containing "COMP617" and a submit button.
- Step 2 of 4:** "Please input a prerequisite course name" with a text input field containing "COMP635" and an "Add to list" button. Below this is a "Prerequisite courses list:" containing a scrollable list of course IDs: COMP602, COMP603, COMP604, COMP605, COMP607, COMP610, and COMP635. A "Delete from list" button is at the bottom right of the list.

Figure 4: Step 1 and step 2 of adding a course into course dependency database using the Web-based program knowledge editor.

The screenshot shows the continuation of the web interface:

- Step 3 of 4:** "If the number of the prerequisite courses shown above is more than one, Please indicate the relationship between the prerequisite courses". It offers four radio button options: (1) AND, (2) OR, (3) X OUT OF Y, and (4) X OUT OF Y, SOME ARE MANDATORY. Option (4) is selected.
- Step 4 of 4:** "Please indicate among all the prerequisite courses, Students have to take at least how many courses : 5" with a text input field containing "5". Below this is the instruction "If some of prerequisite courses are mandatory, please choose them".

At the bottom, there are two scrollable lists: "Prerequisite courses list:" (containing COMP602 through COMP635) and "Mandatory courses list:" (containing COMP635). Both lists have "Add to Mandatory" and "Delete from Mandatory" buttons.

Figure 5: Step 3 and step 4 of adding a course into course dependency using Web-based program knowledge editor.

We applied the ontology-driven software development methodology for Web services and agents for the Semantic Web to develop a program planning agent --- e-Advisor [17]. Maximizing openness and choice can lead to learners making poor choices, thus flexible systems need to be accompanied by strong advice, monitoring and support systems [18]. Our continuing challenge is to maximize the quality and, availability of this support while continually reducing its cost. Given the wide number of courses choices or paths through the curriculum, it is important that each student be assigned an academic advisor who is a

faculty member of the School of Computing and Information Systems. To be effective, advisors and faculty need to understand each individual student's educational and career objectives, their time and financial constraints, and their progress through the program. These can then be matched against degree requirements, course start dates, course availability, and prerequisites in order to generate a personalized course path. The provision of effective program advice for the average of 30 graduate students per faculty member is a time consuming task. In order to meet the students' needs and to reduce the workload of the advisors, we are developing an intelligent agent able to provide the students with an automated MSc IS Graduate program scheduling service (GPSS). On behalf of the students' advisors, the agent will assist them in generating *up-to-date*, *personalized*, and *optimal* study plans by constantly monitoring and utilizing related information resources.

The plan generation is executed by the Petri net program in the MSc IS ontology as a constraint-solving process. To communicate with Web services, the scheduling agent has to wrap its messages as SOAP messages. We are using Axis (<http://ws.apache.org/axis/>) and Java to build and deploy all Web services.

VI. Conclusions

The curriculum P/T net model proposed in this paper is able to represent accurately and dynamically the course-taking procedure for a given curriculum, provide a graphic tool for knowledge representation of the type of precedence relations constraints, provide a powerful simulation tool for program planning, give all possible solutions/study plans by simulation tracing or reachability analysis.

We are working on the verification (model-checking) module of curriculum Petri nets based program models and Web Services for Accessing PNML-represented program models. We are also exploring how to apply this approach to modeling concept ontology for developing intelligent e-learning systems.

Acknowledement

We would like to thank National Science & Engineering Research Council (NSERC) of Canada and Athabasca University for sponsoring this research project.

Diffusion of Innovation: An Investigation of e-Procurement Assimilation in the Australian Public Sector

Kishor Vaidya (PhD Candidate)

kishor@turing.une.edu.au

School of Mathematics, Statistics and Computer Science, University of New England,
Armidale, NSW 2351, Australia

Abstract: As part of a larger research project whose objective was to determine the antecedent condition for e-Procurement assimilation, this paper assesses the diffusion of e-Procurement in the Australian public sector. With the help of an extensive literature review and pilot study, e-Procurement diffusion attributes were identified, a research model was developed and hypotheses were formulated. Based on the Diffusion of Innovation theory, it is hypothesized that perceived benefits and compatibility impact positively whereas the perceived complexities negatively impact the transactional and strategic assimilation of e-Procurement. A nationwide web-based survey of Procurement/e-Procurement professionals in the Australian public sector is in the final stage of completion at the time of writing of this paper and analysis of the complete set of data will be presented in the camera-ready version of the paper.

Keywords: Electronic Procurement, Diffusion, Assimilation, Procurement

I. Introduction

Procurement innovation such as Electronic procurement (e-Procurement) is breaking new ground within the public sector of the advanced as well emerging economies by providing the governments with a wealth of supply chain information via the Internet. E-procurement has been on the political agenda in a number of countries [15]. As such, the past few years have seen the greater popularity of e-Procurement technologies in that the governments in the advanced economies including Australia, the USA, and the UK as well as the governments in the emerging economies including China, India, the Philippines, Mexico, Brazil, and Korea are implementing e-Procurement initiatives as part of their Electronic Government (e-Government) agenda. However, just implementing an e-Procurement system is no guarantee to improved procurement performance. It is important that the contextual interrelations between the organisation and management, practices and processes and systems and technology be examined, understood and documented before deciding that e-Procurement might improve procurement performance [29]. The authors advocate such hybrid model for studying e-Procurement implementation processes, particularly for understanding the

implementation events that occur and the antecedent conditions that promote or inhibit implementation outcomes.

The potential benefits of an e-Procurement system commonly include more effective inventory control, reduced purchasing agent overhead, reduced lead times, and competitive pricing [32]. Despite the potential benefits, organizations differ in the speed with which they assimilate e-Procurement and in the level of actual benefits achieved among the organizations that have implemented. The popularity of e-Procurement, at the same time, has raised several research questions that deserve answering in relation to its assimilation. What are the antecedent conditions that could lead towards diffusion of e-Procurement? Which theory can best explain the prevalence of such condition? What would be the impact of such conditions on transactional and strategic assimilation of e-Procurement? This paper attempts to address these questions. As such, following the definition and scope of e-Procurement, this paper conceptualizes the dependent variable for this study – the intensity of organizational assimilation of e-Procurement in the third section. The theoretical support for this study has been provided by the Diffusion of Innovation theory, which has been discussed in the fourth section. The fifth section presents the research model and hypotheses and the sixth section discusses the research methodology adopted. Following the results of the data analysis in the seventh section, this paper concludes with the discussion of limitations of this research and its implications to academics and practitioner in the eighth section.

II. E-Procurement Assimilation: A Literature Review and Development of Hypotheses

This paper regards e-Procurement as the innovation in procurement, as part of e-Government, defined as internet-based applications between two or more companies. An important innovation attribute is the degree to which an innovation creates changes in the structure and functioning of the organization, which requires aggressive technological policy [30]. Damanpour [5] terms this sort of innovation as the “radical” innovation and argues that radical innovations produce fundamental changes in the activities of an organization while routine innovations result in little departure from existing practices. It is important to note that e-procurement is not only the example of radical innovation but also the process innovation. This is emphasized by Sheng, [26], in [5]) that e-Procurement should not only be considered as the re-engineering of old

manual processes but as the re-engineering of the process itself.

The extant literature on technological innovations and electronic commerce has contributed significantly to our understanding of e-Procurement assimilation. However, this literature has limited applicability for investigating the extent of organizational assimilation in the public sector. This is because the technological and transactional characteristics of the Internet differ significantly from other technologies (e.g. EDI) examined in the prior literature. E-procurement assimilation within the same public sector agency may differ between the two phases of assimilation, i.e., e-Procurement use may be high in transactional phase but not in strategic phase, or vice-versa. Furthermore, e-Procurement use may vary extensively across organizations. A comprehensive investigation of this widespread variation necessitates that we conceptualize and examine the organizational assimilation of e-Procurement in both transactional and strategic phases.

Given the definition and scope of e-Procurement in the above section, the intensity of e-Procurement assimilation can be further defined as the degree of adoption, implementation and utilization of e-Procurement technologies across the transactional and strategic procurement process. Although the literature gives account of the various steps or stages in the procurement process, this paper will use the nine important steps of the procurement process namely information search, requisition request, approval, purchase order, delivery receiving (tracking) and payment, and identifying sourcing opportunities, negotiate, and contract [12]. As e-Procurement comes in various forms, assessing the intensity of e-Procurement can help identify what the public sector agencies are doing with e-Procurement, what steps of the procurement process have been automated with e-Procurement technologies and how intensively each step of the purchasing process has been "e-enabled". Furthermore, it is important to various e-Procurement adoption practices as public sector agencies may have different emphases for different steps of the procurement process that need to be automated with e-Procurement technologies. By differentiating the intensity of e-Procurement assimilation across the procurement process, it can be possible to link each domain of assimilation with its resulting dimension of procurement performance. This sort of approach can help the procurement organisation to better assess the impact of antecedent conditions that influence e-Procurement assimilation on the procurement performance.

The intensity of e-Procurement assimilation is the main dependent variable that is the aggregate measure of e-Procurement technologies implemented in the organisation for the conduct of procurement and the assimilation stages. This research has considered a number of technologies utilized including e-Procurement system (third party or in-house), electronic catalogues, electronic marketplace, electronic auction/reverse auction and, electronic tendering. The intensity of e-Procurement assimilation also captures

the concept of assimilation stage [8] for each e-Procurement technology. Furthermore, the intensity of e-Procurement assimilation also quantifies the penetration of each of the e-Procurement technologies to determine the level of support for the transactional and strategic procurement functions. It is important to aggregate these measures to determine the intensity of e-Procurement assimilation in terms of the number of e-Procurement technologies, the extent of their usage and their support for each transactional and strategic procurement activities of the organisation.

The assimilation process that includes adoption, implementation and routinization [19], [22] has been modeled as containing the six stages: i) Intention to implement; ii) Evaluation or Pilot use; iii) Commitment iv); Limited deployment; v) Generalized deployment [8]; and vi) Rejection [23]. The sixth stage can be justified by the authors' arguments that the implementation of an innovation can not be considered successful even if it survives through the deployment stage, as the innovation may ultimately be rejected by its users [23]. Together, these three dimensions provide an e-Procurement intensity index that signifies how many e-Procurement technologies are being used in an organization, to what extent these technologies are being used, and in which stage of the procurement process. In particular, a thorough understanding of e-Procurement assimilation necessitates that the assimilation be examined in both transactional and strategic activities, but the prior literature largely ignores strategic activities and does not examine several transactional aspects (e.g., delivery receiving). The transactional procurement activities included information search, requisition request, approval, purchase order, delivery receiving (tracking) and payment whereas the strategic procurement activities included identifying sourcing opportunities, negotiate, and contract [12].

An aggregate strategy has been chosen to represent these three dimension in order for the findings to be more robust and generalizable [9]. The following six conditions as identified by Fichman [9] that favor aggregation of technologies in the context of this paper are: i) our main interest is to develop a model that generalizes to the e-Procurement class, as opposed to a specific e-Procurement technology such as e-Marketplace; ii) antecedents are posited to have an effects in the same direction in the assimilation stages of a number of e-Procurement technologies ; iii) characteristics of organizations can be treated as constant across the e-Procurement initiatives within the Australian public sector; iv) e-Procurement characteristics cannot be treated as constant across the Australian public sector agencies; v) the innovation in this study (i.e., e-Procurement) can include substitutes or moderate complements and; vi) sources of noise in the measurement of the procurement performance because of e-Procurement may be present.

II. 1 Diffusion of Innovation

A substantial literature exists that investigates Inter-organizational information systems (IOS), and IT adoption,

diffusion and use (e.g., [1]; [13]; [21]; [14]; [10]). As discussed above, the assimilation of e-Procurement initiative can be an issue of technology diffusion and adoption of innovation. Obviously, innovation diffusion theory [24, 25] can be used to understand e-Procurement assimilation as the theory has also been extensively used recently as a fundamental theoretical base of innovation adoption research in the field of IS/IOS. As the adoption of e-Procurement as an innovation generates uncertainty, the procurement organization must be aware of the relative advantage and risk of implementing such innovation. Although the attributes suggested by IDT include relative advantage, compatibility, complexity, trialability, and observability [24, 25], only two variables – relative advantage (i.e. degree to which an innovation is perceived as being better than the idea it supersedes) and compatibility (of an innovation with existing practices and values) have been consistently found to be positively related and only variable – complexity (i.e. degree to which an innovation is perceived as relatively difficult to understand and use) has been consistently found to be negatively related to adoption of innovation [28]. As the different public sector agencies with different adoption intensity can perceive the characteristics of an innovation differently, Downs and Mohr [7] suggest taking perception-based characteristics of innovation into account rather than the inherent characteristics of the technology that do not vary across settings and organizations. Figure 1 below presents the research model.

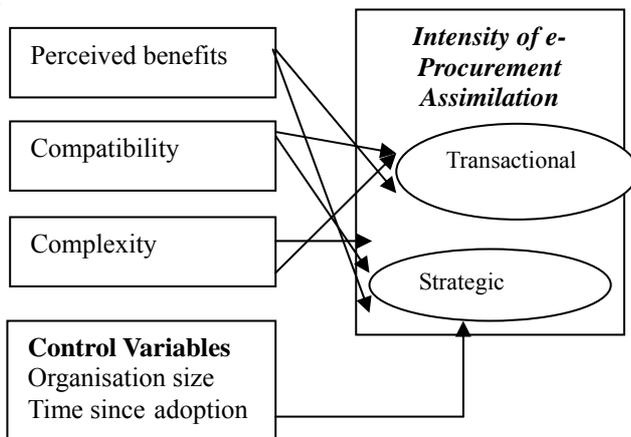

Figure 1: The Research Model

II. 2 Perceived Benefits

Perceived benefits refer to the anticipated advantages that an innovation can provide to the organisation. A number of studies have found that perceived benefits significantly impact IT adoption (e.g., [5], [2], [21], [16]). As organizations are motivated by the perceived benefits from the adoption of an innovation [16], they realize the need to use the technology fully and integrate it with existing applications [21]. Once the organizations are convinced of the relative advantages, they tend to allocate the managerial, financial and technological resources necessary for adoption

[2]. The availability of the necessary resources including the technical infrastructure also facilitates higher technical knowledge, which in turn increases the use of assimilation [5].

Relative advantage is apparent in the form of increased efficiency [24]. While Kalling and Cadeerskold [18] argue that e-procurement does not replace an existing system (but is rather a complement to existing ones, i.e. binary), the practitioner literature has reported the relative advantage of e-Procurement in various contexts. For example, according to the recent e-Procurement Benchmark report by the Aberdeen Group [20], organizations have been able to reduce off-contract spending by 64%, requisition-to-order cycles by 66% and requisition-to-order costs by 58%. The use of the Internet, the open standard, and the web technologies are such strengths of e-Procurement technology that contribute to interoperability. Interoperability promotes integration, however, also poses risk and security threats when organizations integrate e-Procurement systems with other internal information systems. Hence it can be hypothesized that:

H1a: Greater the extent of benefits of e-Procurement, greater will be the intensity of its transactional assimilation in the organization.

H1b: Greater the extent of benefits of e-Procurement, greater will be the intensity of its strategic assimilation in the organization.

II. 3 Compatibility

Compatibility of an innovation can be thought of as the organizational fit of the system introduced [19]. It is the degree to which the innovation is perceived as being consistent with existing financial and accounting systems, procurement practices and the e-Procurement implementation strategy and procurement policies and guidelines of the organization. This approach provides us with an opportunity to identify the different types of compatibility – technological and organizational. E-Procurement might require changes in the existing stages of the procurement processes and practices and might introduce new or reduced stages to complete the purchase-to-pay cycle. According to Premkumar and Ramamurthy [21], compatibility of the new system with existing work procedures increases the likelihood of adoption and this is also true in the case of e-Procurement. Hence it can be hypothesized that:

H2a: Greater the extent of compatibility of e-Procurement, greater will be the intensity of its transactional assimilation in the organization.

H2b: Greater the extent of compatibility of e-Procurement, greater will be the intensity of its strategic assimilation in the organization.

II. 4 Perceived Complexity

Rogers [25] has defined perceived complexity as the degree to which an innovation is perceived as relatively complex to

understand and use. As the assimilation of e-Procurement as an innovation generates uncertainty, the procurement organization must be aware of the relative advantage as well as the risk of implementing such innovation. As the assimilation progresses, Teo et al. [27] note that the heightened knowledge gap between the current requirements and the current resources creates a higher sense of uncertainty about the innovation for the organization. Based on Zaltman et al.'s [31] classification, two levels of complexity can be identified. First e-Procurement implementation may contain complex ideas, i.e., e-Procurement may be difficult to understand from a business as well as technical perspectives. Second, using e-Procurement may be difficult to understand and visualize the whole process of procurement-to-pay (P2P). It is also important to note that ease of use is an important indicator of information systems success [6]. Hence it can be hypothesized that:

H3a: Greater the extent of perceived complexity of e-Procurement, lower will be the intensity of its transactional assimilation in the organization.

H3b: Greater the extent of perceived complexity of e-Procurement, lower will be the intensity of its strategic assimilation in the organization.

III. Research Methodology

Initial feedback on the survey instrument was sought from ten academic experts at the Australian, UK and US universities. The initial structured questionnaire was generated based on the pilot study with Procurement/e-Procurement managers involved in the implementation of e-Procurement, and academic and practitioner-oriented (government reports) literature. A total of 40 professionals from the five states of Australia including the agencies that are actively involved in the implementation of e-Procurement such as Centrelink, Australian Government Information and Management Office, Standards Australia, SmartBuy (NSW), Australian Antarctic Division (AAD), CSIRO etc. participated in the study. The comments were sought on the length, completeness and readability of the survey and each item was reviewed for content, scope and purpose. Results of the pilot study were used to assess the content validity of the measures. Although the participants indicated no major modifications with regards to the conceptual model and the antecedent conditions for e-Procurement assimilation, however, a number of important comments were incorporated in the instrument development and wording/consistency of the questionnaire items.

A five-point Likert scale was used to collect the response. The preliminary version of the questionnaire was pre-tested during the qualitative pilot study (email communication, informal interviews). Iterative refinements were made to the preliminary version and the final version of the questionnaire consisted of nine items for the two constructs. Since the time period was still early in the early stages of e-Procurement in organizations, the public sector agencies

were chosen opportunistically – that is, the researcher sought the agencies that have implemented or were beginning to implement e-Procurement, rather than to seek a representative set firms who were both adopters and non-adopters of the technology.

Respondents were asked to indicate the extent of their organisation's level of e-Procurement use in terms of overall procurement transaction on the scale of "No intention to implement", "Intention to implement", "Evaluation or Pilot use", "Commitment", "Limited deployment", "Generalised deployment" and "Rejection". Respondents were also asked to indicate the predominant e-Procurement technology among the e-Procurement technologies through which their organisation uses (or plans to use) to conduct procurement in terms of overall procurement transactions. In order to assess whether the e-Procurement assimilation was transactional or strategic, respondents were asked to indicate the procurement activities that are supported by e-Procurement in their organizations. The transactional procurement activities included information search, requisition request, approval, purchase order, delivery receiving (tracking) and payment whereas the strategic procurement activities included identifying sourcing opportunities, negotiate, and contract [12]. Control variables included the size of the organisation - measured in terms of organisation's annual direct and indirect procurement expenditure for the last financial year, and assimilation gap which was measured by asking the respondents when their organizations first adopted e-Procurement.

Overall navigation of the survey website was designed to be linear, as simplified as possible. Respondents were required to indicate the name of their organizations or divisions/units. Following the suggestions of Couper et al. [4] to avoid checkboxes in academic web-based research, radio buttons were used instead. A federal government agency, the Australian Procurement and Construction Council (APCC) agreed to endorse and administer the survey, which is supposed to generate a greater response rate. Also, as with any survey research, response bias is always a concern, however, given the arrangements in regards to the administration of the survey, it can be anticipated that misleading responses will not be submitted by the professionals of the government agencies (members) who are usually aware of the accountability and ethical issues.

IV. Data Analysis and Results

Given the cross-sectional nature of this research, correlation and regression analyses [3] will be completed using the statistical software package SPSS 13. While the correlational analyses will be used to support (or reject) the hypotheses, consistency will be ensured by taking into account the regression analyses that regression results can categorically reject such support. Furthermore, testing the measurement model will involve examining the internal consistency (Cronbach's α), convergent validity (factor loading), and discriminant validity (correlations) of the constructs. It has

not been possible present the analysis of complete set of data as only 70 responses have been received at the time of writing of this paper, however, we will come up with the results of this research when submitting the camera-ready version of the paper.

V. Conclusions

This paper has both academic and practitioner implications. Academically, this paper has proposed an e-Procurement assimilation model which draws its insights from both the literature on diffusion of innovation adoption as well as from e-Procurement research on organizational assimilation. Such a model can be hoped to explain the interplay among organizational context variables, attributes of managers' implementation strategies, and other characteristics that, in aggregate, shape assimilation process and outcomes of e-Procurement initiatives in the public sector. By developing a clearer connection between existing theory and apparent most relevant factors, a richer, more generalizable understanding of the antecedent conditions influencing the e-Procurement assimilation and its impact on the procurement performance is likely to emerge. By dividing procurement activities into transactional and strategic phases, we are able to distinguish the impacts of antecedent factors on different phases. Such an approach also enables us to evaluate if the same e-Procurement antecedents impact procurement performance in the organizations differently in the two phases. From the practitioner point of view, since the phenomenon under investigation is still in early stages, our research has considerable practical implications for procurement professionals and e-Procurement project managers. This study presents the critical antecedent conditions that influence the extent of e-Procurement assimilation. It can be expected that the procurement professionals and e-Procurement project managers in the public sector can influence and manage the e-Procurement assimilation in light of these antecedent conditions.

While the Diffusion of Innovation Theory is still relevant for the study of e-Procurement adoption and implementation, Gallivan [11] suggests that these theories only focus on the individual level adoption of innovation and neglect the realities of implementing technologies in the organizational level. Similarly, Jenkins-Smith & Sabatier [17] maintain that stage models operate without a causal motor, i.e. they lack identifiable forces that drive the policy process from one stage to another. Given these limitations, it is necessary to study the subject of e-Procurement assimilation and our future research in this regard will be focused on using other theoretical bases such as institutional theory and resource-based theory in order to identify further antecedent conditions that may influence e-Procurement assimilation. Another limitation is that this study represents a "snapshot" view of this phenomenon. A longitudinal study would provide more insight. Also, expanding the study

to other industries would provide a more generalizable and robust examination of the hypotheses.

Abstract: This paper aims to contribute to the development of a process based conceptual model of electronic procurement. Model is based on three basic e-procurement processes – strategic, tactical and operational e-procurement. Processes are divided into phases which are supported by applications (i.e. software programmes). Apart from applications supporting basic procurement activities there is a currently fast growing group of ADM (Analytical - Decision support - Management) applications, which brings business benefits especially in complex procurement environments. The basic view is that of ICT's (Information and Communication Technologies - namely Internet, Internet technologies, Internet standards, Internet applications) support of procurement activities. Paper presents integrated e-procurement applications and also various integration requirements of e-procurement applications. Model may perhaps help enterprises, which are new to e-procurement, e.g. SMEs, to gain basic understanding of which applications may be used for implementation of e-procurement processes.

Keywords: e-procurement, e-auction, e-tendering.

I. Introduction

Procurement refers to the processes used by buying party in locating, purchasing and moving materials from suppliers to the buyer's point of need [19]

Procurement (of direct materials) is also an important part of SCM (Supply Chain Management). SCOR (Supply Chain Operation Reference) model, i.e. system of process definitions for SCM, consists of four elementary process types – plan, source (i.e. procurement), make, deliver [20], [7].

Procurement concerns two types of materials

- direct (production) materials i.e. raw materials, components, production-oriented services, products, which become parts of finished product/service or are further sold to company's customers
- indirect (non-production) materials i.e. materials which are not part of product/service, which is produced and sold by the company. Typically MRO (Maintenance

Repair and Operating) supplies – laboratory equipment for research, computer HW and SW, leased cars, office equipment, food for catering, cleaning - and non-production services

Both material types have different characteristics, as seen from table 1 (modified [6], [10]). These characteristics influence the e-procurement (EP) solutions for direct and indirect materials.

Several definitions of e-procurement (EP) have been presented e.g. [16], [18]. Our definition is the following:

E-procurement is implementation of procurement functionality for direct as well as for indirect materials/services using application software (applications). In modern e-procurement, which is subject of our paper, Internet, Internet-related standards, Internet (web) applications or services are used.

As in many other application areas, also in e-procurement ICT are used for electronic processing (as opposed to manual processing), process automation, as stimulator of process modifications, means of communication, information sharing and coordination among all participants as well as for internal as well as for external integration [19].

Implementation of e-procurement is influenced by many factors and developments in ICT/IS area. The basic ones are the following

- use of Internet (for business support) – global communication network, environment for internet-applications
- applications architecture – from monolithic via client/server to Web-enabled client/server to SOA (Service Oriented Architecture)
- ERP developments – in functionality, internal architecture, integration means, means of user communication with ERP
- e-marketplaces developments – functionality, ownership [8], [12]
- integration solutions – namely data and application integration, inter and intra-enterprise integration, modern integration technologies SOA (Web service) oriented [9].

II. Process-Based E-Procurement Conceptual Model

II.1 Introduction

There is a large body of literature describing in various extent e-procurement processes, mostly tactical and operational EP. Various references use different phases of processes, different terminology and different “width” of description – processes are typically used as basis for analysis of different EP attributes. Boer [5], whose main aim is to assess the impact of e-procurement, presents six “forms” of e-procurement. Knudsen [11] presents process descriptions based on seven steps of business procurement life cycle by Archer and Yuan [3], as well as on e-procurement applications based on Boer’s “forms”. Davilla [4] presents e-procurement “models”, which are basically the e-procurement technologies in our view and discusses also barriers to their utilization. Both Turban [21] and Puschmann and Alt [17] present a short view of e-procurement processes, as basis for their further analysis of other aspects of EP. Weele [22] presents comprehensive description of procurement processes, with different process phases than our EP model. Aberdeen Group [1], [2] has been for many years active in e-procurement research, analysis and methodologies. Based also on references mentioned above the aim of this paper is to contribute to the development of EP process based conceptual model.

Our process-oriented conceptual model (framework) of e-procurement is oriented at buyer-executed activities. From institutional point of view the buyer may be

- enterprise (business) – because of specifics from the EP point of view often SMEs and “non-SMEs”, i.e. larger enterprises, are distinguished
- public administration
- In this paper we take the enterprise’s point of view.

Two basic ways of procurement (buying), from buyer’s perspective are

- contract – based (systematic) buying, based on long-period contract – which is the basis for partial deliveries (transactions) i.e. repeated execution of operational EP process. This way is subject of our paper
- spot buying without a priori contract. Includes one delivery (transaction) i.e. only one execution of operational EP process. With ICT support this way may be implemented
 - in case of fixed prices by e-catalogues located at supplier site or at 3rd party sell-side vertical procurement portal
 - in case of variable prices by direct Internet auctions at B2B auction sites or B2C auction sites (for some indirect materials)

Presented conceptual model, see fig 1, consists of three hierarchical levels of e-procurement processes. Process position in the hierarchy is determined by the strategic importance of activities implemented in the process. The processes are the following

- strategic EP process
- tactical EP process

- operational EP process

Dotted lines in fig.1 depict conceptual business strategic impact.

All EP processes are supported by ICT, especially by Internet, internet applications and internet technologies. Processes are divided into phases, which are further divided into steps. Functionality of individual steps is implemented by applications, i.e. software products/programmes) in relation to organizational, personal and other aspects. The application may concern, i.e. to implement processes of, several steps and also more applications may concern, i.e. to implement processes of, only one step of EP. Most EP applications are web-based client/server applications with light client i.e. web browser. At strategic and tactical level the ICT-supported processes, presented in this paper, are not considered to be substitutes for other (i.e. non ICT) activities as personal dealings, use of traditional information sources etc, but rather as enhancement of EP activities.

Strategic EP process is sub-divided into following phases

S1 – EP strategy formulation

S2 – EP strategy update

Tactical EP process is sub-divided into following phases

T1 - Requirement specification

T2 - Determination of the way of requirement solution

T3 - Suppliers identification and selection

T4 - Contracting

Operational EP process is sub-divided into following phases

O1 – Ordering

O2 – Delivery acceptance and payment

Operational EP process is executed for every partial delivery (transaction), in the scope of valid contract negotiated between buyer and seller in tactical EP process (i.e. systematic buying) or is executed only once for spot buying.

Typical EP scenario, i.e. systematic buying, which is considered to be typical for EP, is the following: in tactical EP process contract for given material with (the most convenient) supplier is signed. By repeated purchases (i.e. repeated instances of operational EP process), the partial purchases (transactions) are realized – in scope of signed contract.

Tactical and operational EP processes are event-initiated (apart from typical events given below there may be a big scope of specific events)

- tactical EP process – initiated typically by determination, at enterprise level, of long-term need for material, for which there is no supplier selected and no contract signed
- operational EP process – initiated typically by determination of immediate need for material, for which there is contract signed with selected supplier, i.e. partial deliveries in the scope of this (long-term) contract
Initiating event may be

- employee (end-user) needs material, typically indirect material e.g. MRO – mobile phone, and requires it by DPS (Desktop Procurement System) [15]
- need of direct material is determined by production planning application, which is a part of ERP system (i.e. MRP Material Resource Planning) or by SCM (Supply Chain Management) application. Operational EP process is initialized, which may be (in the case of direct material) executed by (preferably web-enabled) ERP applications or by SCM application

Our conceptual model does not include some phases, included by other sources i.e. quality control [21] or product consumption, maintenance and disposal [3].

Several steps of tactical and operational EP include means for EP coordination and collaboration, typically based on message transfer and (in some cases) on mutual access to information (databases). Coordination [19] involves the sharing and exchange of relevant information both internally as well as externally i.e. between enterprise and its business partners. Issues of coordination and collaboration are not detailed in our model.

Unified terminology in procurement and especially in e-procurement area is far away at the moment with various subjects, i.e. consultants, analytical corporations, users, solution providers, using different synonyms. „Tactical EP process“ is often called „sourcing process“ or „e-sourcing“, „operational EP process“ is often called „purchasing process“ or „e-procurement“. „E-sourcing“ sometimes include only the phase of selecting potential suppliers

Integration is an important issue of EP. Application integration is mostly used as well as data integration (typically for analytics, see 2.5.). In EP there are various ways of application integration, namely

- EP applications with inter-enterprise applications related closely to procurement processes (i.e. with some ERP applications and other inter-enterprise applications)
- (between) Individual EP applications, creating “integrated EP applications”
- EP applications (or users) with external applications, as with
 - Applications/IS of suppliers
 - Applications of intermediaries, which implement some steps of EP processes e.g. e-marketplace
 - Applications of ASP, which implement one or more phases of EP processes as service

For given EP implementation the degree of integration, measured basically by number and also by business scope of integrated application, may be

- null, i.e. only isolated EP applications is used, e.g. real-time Internet auction
- significant, i.e. several EP applications are integrated into “integrated EP application”. Typical examples
 - DPS (Desktop Purchasing System) application -

integrating basically all functionality of operational EP for indirect materials,

- e-RFx-based application – integrating e-tendering (including RFX creation), e-auctions (typically Internet online reverse auction) including supplier selection, which is one of modern EP integrated applications

SRM (Supplier Relationship Management) application – integrating most of inter-enterprise functionality for tactical and operational EP.

II. 2 Strategic EP Process

This process, oriented towards formulation, control and modifications of EP strategy, consists of two phases

S1. EP strategy formulation

Result from this phase is EP strategy, which is a part of enterprise’s procurement strategy. It is based on enterprise’s current level of procurement and on current level of ICT use. Based on enterprise’s procurement strategy and with the aim to support enterprise business goals, EP strategy specifies especially

- which EP processes/applications are used, e.g. to support procurement of various materials (or groups of materials)
- strategic criteria used in EP processes e.g. criteria for supplier selection
- ICT participation in analytical, decision supporting and corresponding management activities
- which EP applications are hosted by enterprise and which are hosted by 3rd party (i.e. outsourced)

S2. EP strategy update (modification).

Is process of EP strategy modification, executed according to significant changes in business or IT environment as well as according to EP results so far.

II. 3 Tactical EP Process

In this process applications executing procurement functionality as well as AMD applications (see 2.5) and supporting services are used. AMD applications’ functionality goes well beyond automated tactical procurement and brings additional benefits. Process phases and their steps are the following

T1 - Requirement specification

Result from this phase is specification of requirement, typically log-term, for given product. This specification includes [22]

- functional a detailed technical specification
- quality specification
- logistic specification (e.g. delivery period)
- delivery volume (e.g. in pieces), target budget
- some other specifications, depending on industry

For direct materials this specification is included in product specification, based on BOM (Bill Of Materials), for indirect materials is set up by procurement officer.

T2 - Determination of the way of requirement solution

In this phase the tactical solution, which is in accord with EP strategy, is selected for fulfilment of requirement specified in phase T1. Two points of view are taken into consideration

- business – i.e. which benefit is expected (e.g. lower cost, short delivery period), way of delivery solution – spot buying, long-term contract, expected length of contract, specific criteria for supplier selection (e.g. if strategic supplier is being selected), whether one of current suppliers or new supplier should be selected etc.
- technological (ICT) – which ICT means (applications, their integration, communication environment etc.) in which EP processes will be used for requirement fulfilment.

T3 – Suppliers identification and selection

Result from this phase is selection of one (i.e. most favourable) supplier for fulfilment of the requirement. Contract with this supplier is signed in the following phase T4. Steps in this phase are not executed sequentially; particular steps are selected by buyer.

In this phase electronic request for information (RFI), request for proposal (RFP) and request for quote (RFQ) – commonly called e-RFx, as well as online reverse auctions and other applications, e.g. AMD applications as advanced bid analytics, are often used. RFP and online reverse auctions represent widespread online negotiation methods.

This phase is divided into two sub-phases

- suppliers identification – is the process of identification of potential suppliers (for given material or group of materials),
- supplier selection - is the process of evaluation of potential suppliers according to buyer specified criteria/requirements and selection of (typically) one supplier. Under specific circumstances more suppliers may be used for given material. For simplicity reasons we don't consider this situation

Sub-phase: suppliers identification

Step: information gathering

Is the process of market research, used for identification of potential suppliers, based on information gathering mostly from external sources, in significant part using Internet technologies.

The following sources/applications are used

- web-sites of potential suppliers
- internet search engines, internet portals
- internet supplier catalogues – at internet portals, e-marketplaces, specialized internet suppliers catalogues
- 3rd party services (“sourcing services”), accessible by Internet - for recommendation of possible potential suppliers. 3rd party with significant supply category expertise and know-how of given vertical market (and possibly own thorough evaluation of potential suppliers)

may recommend potential suppliers for given category/material. In some cases the service may include also hosting and consulting of all remaining steps of phase T3, resulting in selection of one (final) supplier.

Step: contacting suppliers

Is the process of contacting suppliers in order to get more info needed for their basic evaluation. Buyer asks suppliers to fill standard electronic RFI (Request For Information- eRFI) sent by e-mail or published on buyer web-site, which is evaluated in the next step.

Step: suppliers review

Is the process of performing general evaluation of potential suppliers, based on available information, by buyer qualification criteria e.g. financial stability, references, manufacturing facilities, material characteristics etc. Suppliers references may be verified by contacting supplier's customers and product samples may be tested by buyer. Result of this step is a list of potential suppliers, used in the next sub-phase. Internet is used often as communication media and information source

The following sources/applications are used

- suppliers web-sites (annual reports etc.), internet news servers (news, analysis), vertical information/procurement portals
- 3rd party services, accessible by Internet - for verification of supplier credibility, economic strength etc, (e.g. Dunn&Bredstreet)

Sub-phase: supplier selection

Step: e-tendering

Is the process of supplier selection in case of dynamic prices. It is executed in the following steps

- buyer publishes on Internet his requirements for bid (offer) for material delivery from potential supplier in the form of standard electronic RFP (Request For Proposal) or RFQ (Request Of Quote). Often buyer reduces access to RFP/RFQ to pre-selected (in previous sub-phase) potential suppliers.
- Interested potential suppliers submit, till the given date, their electronic bids (offers) in structure specified by buyer by Internet (e.g. to buyer web-site or by e-mail)
- this step often includes also bids analysis, comparison and assessment. Bids are typically in electronic standard structure, may be in XML format. Therefore semi-automatic multi-criteria supplier selection may be implemented. Criteria specified in RFP, price in bid and other criteria are used. The result of this step is either selection of one supplier, which satisfies best the given criteria, or selection of several “good” suppliers, from which the best is selected in the next step e.g. online reverse auction.

Step: e-auctions

Is the process of supplier selection in case of dynamic prices by use of internet auctions. From EP point of view the internet auctions are classified according to two criteria

- (algorithm) mechanism of auction criteria determination
 - o direct auction – during auction process the auction criteria (typically price) is increased
 - o reverse auction – during auction process the auction criteria (typically price) is decreased
- length of time of auction execution
 - o “standard” auction – executed during several days or several weeks
 - o real-time (on-line) auction – executed during few hours. During this time period all potential suppliers participate in auction process (are on-line connected over Internet or react by e-mail). All participants are “pre-selected” (e.g. by e-tendering), so that they satisfy all buyer’s requirements.

Reverse real-time Internet-based auctions, which are often used in EP, may be classified

- by type of materials bought
 - o single material auctions
 - o multiple materials auctions
- by number of attributes included into auction evaluation
 - o single attribute auction (typically price)
 - o multi-attribute auction, including also other attributes than price

As the (final) supplier, the one who satisfies best given criteria is selected.

Internet auction may be implemented on

- buyer web-site
- e-marketplace, supporting this functionality
- 3rd party web-site, supporting e-auctions. For spot buying typically direct auction at B2B auction sites, or (for SMEs also) at B2C auction sites
- 3rd party web-site, which is used only for real-time auctions, typically reverse auctions for systematic buying

Step: e-aggregation

Is the process of supplier selection based on aggregation of (partial) demands of various buyers into aggregated demand, which is then published (on Internet) for potential suppliers as electronic RFP, RFQ. By demand aggregation typically the lower price can be reached. This process is used only to limited extend, mostly for commodities.

E-aggregation is implemented on

- e-marketplace, supporting this functionality, typically consortia e-marketplace. There is a limited number of e-marketplaces supporting aggregation.
- 3rd party web-site, with specialisation at aggregation

Step: e-negotiation

Is the process of buyer negotiation with potential suppliers with the aim to reach the agreement on the contract between buyer and supplier under complicated conditions, when above mentioned approaches (i.e. e-auctions, e-tendering), which often include supplier’s a priori agreement with important contract conditions proposed by buyer, cannot be used.

Process is based on Internet use as communication media and often on use of DSS applications for support of negotiation management and evaluation of results. These applications are relatively new, used in limited extent.

Final signing of contract is not part of this step.

T4 – Contracting

The result of this phase is contract signed by two parties – buyer and supplier, which is also a basis of partial demands/deliveries (transactions) executed in operational EP process.

This phase is supported by CMS (Contract Management System) application (see section 2.5.) and typically by buyer specific ADM applications, often Excel-based.

II. 4 Operational EP Process

This process is started by recognition of immediate need for material for which (typically) contract was already signed (i.e. systematic buying). Process consists of two phases which are executed sequentially.

Applications supporting both phases of operational EP are typically integrated into one integrated application, supporting whole process of operational EP. Basic differences between procurement and operational processes for direct and indirect materials appear in table 1.

	Direct materials	Indirect materials
Order size	Large lots	Often small
Percentage of total spend (typical)	80%	20%
Percentage of total numbers of purchase orders (typical)	20%	80%
Scheduled by	Production runs	Not scheduled, ad hoc
Locus of operation	Professional buyer’s desktop	employee desktop
Driven by	Design specification	Catalog-employee selection
Approval	Not required	Required
Degree of automation	High	Low (often no automation)

Table 1: Procurement of direct versus non direct materials.

On these differences the differences between integrated applications for direct and indirect materials are based. Integrated application for indirect materials provides functionality, i.e. requirement generation by end-user, material selection from catalogue, requirement approval, which is not required for direct materials. This is the main reason for separated solutions (applications) of operational EP for direct materials and operational EP for indirect materials

- operational EP for indirect materials – provided by integrated application DPS
- operational EP for direct materials – provided by integrated application Web-ERP (i.e. ERP with web-browser interface) including integrated ERP applications e.g. MRP for operational procurement planning, eventually with integration of SCM application (especially for strategic and tactical EP planning)

Operational EP process for indirect materials is described below.

O1 – e-ordering

This phase is divided into two steps

Step: requisition creation

Requisitions for direct materials are typically automatically generated by MRP or APS application, including order generation and it's sending to supplier by agreed upon communication channel (Internet, EDI etc.)

Requisitions for indirect materials are generated by end-user (employee) using multi-supplier e-catalogue for materials selection, by means of web-browser. Only materials already contracted with all suppliers are listed in catalogue. The result of this step is electronic requisition for material, which is automatically passed to next step.

The catalogue should always contain complete and actual information. Therefore its content management and its location are of importance.

Buyer may use the following catalogue organization and location

- integrated multi-supplier catalogue, located at buyer IS (web-site)
- integrated multi-supplier catalogue, created and maintained in 3rd party system (e.g. e-marketplace), i.e. outsourcing from buyer's point of view
- partial catalogues located in systems (sell-side web-applications) of individual suppliers and accessible by Internet

Step: requisition approval, order generation, sending an order to supplier

Electronic requisition, created in previous step, is automatically passed to proper managers for approval. By definition of requisition rules (and financial limits for employees) the number of approval steps can be limited or excluded at all. These activities are executed by (application)

workflow management system. Standard purchase order is automatically created from requisition, including integration with corresponding ERP applications (e.g. purchasing, accounts payable). The result of this step is electronic purchase order, sent to supplier by some communication/integration technology as e-mail, fax, EDI, XML message.

O2 – Delivery acceptance and payment

This phase is divided into three steps

Step: delivery monitoring (by buyer)

By use of ICT buyer can monitor the state of delivery i.e. if it is being completed, if it has been expedited already etc. Immediate state of delivery can be monitored at supplier web-site or at logistic firm's web-site in case the logistic operations has been outsourced by supplier.

Step: acceptance of delivery and of supplier's invoice

Material is delivered to buyer, who executes the corresponding activities in corresponding applications, typically in ERP applications e.g. accounting, inventory. Invoice is then sent to buyer. Supplier may use ICT for electronic invoicing (e-invoicing). Electronic invoicing is the transmission and storage of invoices by electronic means, without the delivery of paper documents. For electronic invoice integrity and authenticity have to be provided (e.g. by EDI, electronic signature). This step executes buyer's activities following invoice acceptance, provides comparison of invoice with accounts payable and approval of invoice discharge by automatic workflow. The result of this step, which is executed in significant degree automatically, is authored payment order.

Step: e-payment

Based on payment order the payment by electronic means, typically through a bank, is executed in this step. EDI, electronic banking is used. Other progressive means to limited extent. For increased process efficiency buyer's electronic self-billing can be used.

II. 5 EP ADM Applications

These ADM (Analysis-Decision support-Management) integrated applications enhance EP functionality (mentioned above) in one or in more steps of EP processes. Some applications, e.g. TCM, go far beyond the scope of procurement. In these applications analytical functionality is typically closely integrated with EP decision support and EP management functionality. Data are extracted from various, mainly internal procurement related (typically operational EP related) sources. Advanced analytical methods are used, known as well as "Business Intelligence" e.g. data mining, neural networks, as well as various optimisation methods, valuable especially in situations with multiple variables. Partial applications support above mentioned EP processes as well as new specific processes e.g. analytical processes.

These applications are offered under various names

(“labels”), accenting analytical or management functionality. It is in this area of EP applications where is the greatest pace of new developments at present. Forrester’s forecast of worldwide revenues for EP related software [14] predicts bright future especially for spend analysis (management) and also for contract life-cycle management applications.

ADM applications are event-initiated and may be executed either periodically or on as need basis. They support execution of tactical and strategic e-procurement processes.

Typical ADM applications are the following

Bid analysis

Application is used for simultaneous negotiations and evaluation of complex bids. Optimisation may be used for solution of multiple variable problems within given constraints. Application is used typically in phase T3.

Contract Management System

This integrated application includes applications (tools) and processes for contract life cycle management – contract formulation, contract execution/use, contract termination. Analytics applications – analysis of supplier performance, analysis of contract compliance (which is an important instrument for enterprise to fully implement savings negotiated in contract) – are often integrated into this application. Application of DMS (Document Management System) is used for creation and management of archive of all documents created during contract life-cycle. Data for contract compliance (by buyer) are extracted also from related applications e.g. ERP. Analysis of contract compliance by buyer is typically executed, while contract compliance by supplier is typically part of supplier analysis integrated application (see below). CMS is used in EP tactical process, typically for support of step T4.

Spend analysis (and management)

This integrated application is oriented towards

- extraction of procurement related data from various sources (ERP, EP applications)
- classification of this data, using various BI analytical methods, into typical categories - material category, division, supplier, employee
- automated data analysis from different perspectives related to various EP processes and supporting applications – tactical EP, contract compliance management, supplier management, EP strategy and procurement strategy. Use of this application provides measurable benefits in all these areas.

Basic aim of this application is to provide in-depth quantitative view of how the company spends procurement money, typically on global company basis.

Category spend analysis (and management)

This application is basically a subset of “Spend analysis”, oriented towards one product category.

Supplier performance analysis (and management)

Application is used for analysis of supplier performance against his contractual obligations, based on standardized metrics. Results as typically used for supplier management e.g. in negotiations with suppliers e.g. contract renovation and for possible modification of procurement and EP strategy in area of supplier selection.

Total cost management (TCM)

TCM is managerial approach, supported by applications, of managing TCO (Total Costs of Ownership) of all enterprise supply-related costs. In TCO all costs related to materials, supply infrastructure, supply –oriented process execution, supply performance exceptions are included. For purpose of TCO enterprise organization, processes, knowledge and technologies are aligned. For effective execution of TCM-related activities proper technology infrastructure (ICT supported) as well as central data repository, containing all related enterprise-wide data, is needed. From applications point of view TCM is an “umbrella” integrated application, using most of EP functional as well as ADM applications. Included in TCM are tactical EP, operational EP, as well as ADM applications spend analysis, contract management, supplier performance measurement [1].

III. Conclusion

Numerous benefits of e-procurement have been cited in [4], [5], [10], [11], [15], [16]. Although various reasons have been cited for using EP by buyer, the main reason is typically costs reduction. The reason being that costs reduction goes directly into bottom line. Wyld [23] reports that almost half of all American companies use e-procurement applications. 30% of companies surveyed use e-procurement for RFQ, 25% use on-line auctions, 33% use e-marketplaces. Most companies use only one EP application. Use of integrated EP applications or several isolated EP applications hosted by company itself has been mostly limited to large (often multinational) companies, where the benefits e.g. costs reduction in complex environment of many suppliers and many items purchased, are significant. However Forrester [13] reports growing interest in outsourced, i.e. 3rd party hosted, EP applications and services. Because of lower front-up costs, outsourcing of EP application may be viable alternative even for smaller companies.

As seen from previous sections, possibilities of ICT support of procurement activities are quite numerous and taking into account it’s benefits we may expect continuous adoption of EP in the future.

Perhaps the presented conceptual model may help companies in getting systematic view of EP and its possibilities, taken primarily from EP’s support by ICT point of view.

Analysis of Functionalities of Commercial Websites Used for Procurement: Implications on Design and Operations

Younes Benslimane, Zijiang Yang
York University, Toronto, Canada

Abstract: This research analyzes the functionalities of commercial websites used for electronic procurement and links them with the benefits as perceived by users and with relevant operations. Findings from a Data Envelopment Analysis (DEA) used on data collected from 88 corporate buyers working in a wide range of industries and using the World Wide Web to support the procurement process show that adding advanced functionalities to informational websites can reduce their efficiency, which suggest that commercial websites are more often used to reduce buyers' search costs than their processing costs. Possible explanations and implications of such findings on the design of commercial websites used for business-to-business transactions and on operations for both vendors and buyers are discussed.

Keywords: Operation strategy for e-commerce – DEA.

I. Theoretical Background

The World Wide Web has emerged as a promising medium for electronic commerce and thousands of "dot.com" and "brick and mortar" organizations have set up commercial websites to do business over the Internet [6] [14] [15]. The commercial websites hence deployed have the potential to support supply chain operations in general and procurement in particular [8]. Today, business-to-business transactions account for the largest proportion of the transactions conducted over the Internet.

Generally speaking, commercial websites can have four functionalities that support the procurement process [4] [13]. The identification functionality of commercial websites allows buyers to spot potential vendors of a given input. The selection functionality gives buyers an online access to pricing and other relevant information that allow them to compare different offerings and select a supplier for the pondered input. The execution functionality allows buyers to check the availability of a given input, place orders and make payments. Finally, the post-sale functionality allows buyers to track the status of their orders and of their shipments online.

Previous work has considered these functionalities as different stages of a growth model for commercial websites [16] [17]. Although their degree of integration to backend systems varies from one vendor to another, transactional websites can be considered as the last stage of development for a commercial website. The cost of developing and mai-

ntaining commercial websites increases as advanced functionalities are added, running anywhere between the tens and the hundreds of thousand dollars for a static website and anywhere between the hundreds of thousand dollars to millions of dollars for a transactional website [17] [19]. Typically, websites that only support the identification phase have the lowest cost whereas transactional websites are the most complex and the most expensive to develop.

The value of commercial websites can be assessed from the perspective of vendors who deploy such systems or of buyers who use them to support their procurement process. In general, advantages of electronic business-to-business transactions include operational and strategic benefits for both vendors and buyers [18]. In the specific case of electronic procurement, the identification and the selection functionalities of commercial websites can help reduce buyers' search costs as it becomes easier and faster for users to contact more potential suppliers and decide on the "best" one [2] [3]. The execution and the post sale functionalities can help users reduce processing costs for their transactions by eliminating paperwork, reducing data re-entry, improving information accuracy and reducing lead times [11] [18].

Depending on their functionalities, commercial websites can support, in whole or in part, electronic transactions. As a result, the availability and usage of such functionalities have different repercussions on vendors' and buyers' business processes hence supported and shaped. Business process redesign (BPR) refers to an information technology-enabled fundamental rethinking of business processes that helps achieve dramatic improvements in performance [5] [9] [10]. Electronic commerce (on vendors' side) and electronic procurement (on buyers' side) offer the opportunity to redesign business processes. El Sawy [7] has provided eleven principles that can be used as guidelines for BPR efforts in the context of World Wide Web-based electronic commerce. The eleven principles can be grouped in four categories: the first one focuses on streamlining a business process and removing valueless activities, the second on restructuring it to allow for a faster and a flexible execution of that process, the third on capturing, "moving" and generating information around a process, and the fourth on creating and managing knowledge around a process. Commercial websites typically include electronic catalogs, shopping carts, payment systems and order tracking systems that can support the redesign of vendors' order fulfillment and/or buyers' procurement processes through the implementation of the BPR principles related to the first three categories presented above. Other systems can be developed to build repositories and further analyze data, allowing for the management of knowledge around the

transactions commercial websites can support.

The objective of this paper is to analyze how functionalities of commercial websites deployed by vendors are used in the context of electronic procurement and how such usage affects operations of both buyers and vendors. Such investigation is based on a Data Envelopment Analysis (DEA) model that identifies the minimum functionalities that create the maximum value for buyers. The rest of the paper is organized as follows. Section 2 presents the basics of DEA, Section 3 the research model and Section 4 the methodology. Findings are presented in Section 5. The discussion and the implications of this research conclude this paper.

II. DEA Basics

DEA is used to establish a best practice group amongst a set of observed units and to identify the units that are inefficient when compared to the best practice group. DEA also indicates the magnitude of the inefficiencies and improvements possible for the inefficient units. Consider n Decision Making Units (DMUs) to be evaluated, DMU_j ($j=1,2,\dots,n$) that consumes the amounts $X_j = \{x_{ij}\}$ of m different of inputs ($i=1, 2, \dots, m$) and produces the amounts $Y_j = \{y_{rj}\}$ of r outputs ($r=1, \dots, s$). The input oriented efficiency of a particular DMU_0 under the assumption of variable returns to scale (VRS) can be obtained from the following linear programs (input-oriented VRS mode):

$$\begin{aligned} \min_{\theta, \lambda, s^+, s^-} \quad & z_0 = \theta - \varepsilon \cdot \bar{1} s^+ - \varepsilon \cdot \bar{1} s^- \quad (1) \\ \text{s.t.} \quad & Y\lambda - s^+ = Y_0 \\ & \theta X_0 - X\lambda - s^- = 0 \\ & \bar{1}\lambda = 1 \\ & \lambda, s^+, s^- \geq 0 \end{aligned}$$

where s^+ and s^- are the slacks in the system.

Performing a DEA analysis requires the solution of n linear programming problems of the above form, one for each DMU. The optimal value of the variable θ indicates the proportional reduction of all inputs for DMU_0 that will move it onto the frontier which is the envelopment surface defined by the efficient DMUs in the sample. A DMU is termed efficient if and only if the optimal value θ^* is equal to 1 and all the slack variables are zero. This model allows variable returns to scale. The dual program of the above formulation is illustrated by:

$$\begin{aligned} \max_{\mu, v} \quad & w_0 = \mu^T Y_0 + u_0 \quad (2) \\ \text{s.t.} \quad & v^T X_0 = 1 \\ & \mu^T Y - v^T X + u_0 \bar{1} \leq 0 \\ & -\mu^T \leq -\varepsilon \cdot \bar{1} \\ & -v^T \leq -\varepsilon \cdot \bar{1} \\ & u_0 \text{ free} \end{aligned}$$

If the convexity constraint ($\bar{1}\lambda = 1$) in (1) and the variable u_0 in (2) are removed, the feasible region is enlarged, which results in the reduction in the number of efficient DMUs, and all DMUs are operating at constant returns to scale (CRS). The resulting model is referred to as the CRS model.

In summary, each DEA model seeks to determine which of the n DMUs define an envelopment surface that represents best practice, referred to as the empirical production function or the efficient frontier. Units that lie on the surface are deemed efficient in DEA while those units that do not, are termed inefficient. DEA provides a comprehensive analysis of relative efficiencies for multiple input-multiple output situations by evaluating each DMU and measuring its performance relative to an envelopment surface composed of other DMUs. Those DMUs forming the efficient reference set are known as the peer group for the inefficient units. As the inefficient units are projected onto the envelopment surface, the efficient units closest to the projection and whose linear combination comprises this virtual unit form the peer group for that particular DMU. The targets defined by the efficient projections give an indication of how this DMU can improve to be efficient.

III. Research Model

From vendors' perspective, the cost of developing and maintaining commercial websites increases as features supporting the selection and the transactional (i.e., the execution and the tracking) phases of the procurement process are added to informational websites [17] [19]. This research analyzes how functionalities of commercial websites are used to support the procurement process and to link them to benefits buyers report. A DEA model using websites' functionalities as inputs and websites' usefulness, reduced search costs and reduced processing costs as outputs was created accordingly. The proposed model can provide vendors with guidelines on how to design efficient commercial websites based on ratings from buyers who use them to carry out their procurement tasks. In this context, the proposed DEA model can minimize the functionalities (and therefore the cost) of commercial websites and maximize the benefits as perceived by buyers.

Figure 1 presents the model used for this research. The inputs and outputs were measured from the perspective of buyers using the deployed commercial websites. A survey of corporate buyers helped collect data related to the

functionalities and the benefits of the general commercial websites they interact with when carrying out their procurement tasks. From this perspective, each rating related to the functionalities and benefits of commercial websites respondents generally access is considered as a DMU.

FIGURE 1 HERE

Input orientation was selected for the DEA model in this research as vendors deploying commercial websites would be more interested in minimizing the cost subject to attaining the desired output levels. Both types of envelopment surfaces, BCC and CCR will be used and scale efficiency issues will be examined.

IV. Methodology

To collect data used in this research, a questionnaire was sent to all the 988 corporate buyers members of the "Corporation des Approvisionneurs" in the province of Quebec, an organization affiliated to the Purchasing Management Association of Canada. Respondents were surveyed about their general perspectives regarding the functionalities and the usefulness of the commercial websites they generally access to carry out their procurement tasks. Respondents were also surveyed about the perceived performance improvements related to such usage. Among the 114 corporate buyers who returned a usable questionnaire, 88 reported accessing commercial websites to carry out their procurement tasks. The sample spanned corporate buyers working for over 80 different organizations doing business in a wide range of industries.

Seven-point Likert (1=Strongly disagree, 7= Strongly agree) scales were used to measure the inputs (or functionalities of commercial websites) and outputs (i.e., usefulness of commercial websites, reduced search costs and reduced processing costs) of the DEA model. Whenever possible, pre-existing instruments were used because normally they have been tested for reliability and validity properties: the measure of the functionalities was based on Leenders et al. [13]; usefulness was measured using a four item-scale by Karahanna et al. [12]; the assessment of reduced search costs was based on Bakos [2] and Barua et al. [3] whereas the measurement of reduced processing costs was based on Jones and Beatty [11].

After the survey, the validity of the instrument was assessed using a factor analysis. The well-known criterion of eigenvalue greater than one was applied. A factor loading greater than .50 with the theoretically correct sign was required for the assignment of an item to a factor. The principal components method with Varimax rotation was used to extract the factors. The reliability of the instrument was assessed using the Cronbach's alpha. Findings from the factor analysis show support for the validity of the scale. The Cronbach's alpha varied from .67 to .93 showing acceptable level of reliability of the scales. No item significantly deflated alpha, so all items were kept for

analysis. The score for each of the five factors retained equaled the mean score of its retained items and was used as inputs and output scores in the model. Table 1 summarizes the validity and the reliability analyses performed is presented.

TABLE 1 HERE

V. Findings

Descriptive statistics based on a seven-point scale show that respondents use commercial websites to support to a greater extent their identification (Mean = 6.1) and their selection (Mean = 4.1) tasks and to a lesser extent their execution (Mean = 2.5) and their post-sale tasks (Mean = 3.4). Furthermore, respondents consider accessing commercial websites to be useful (Mean = 5.3) for the procurement process and report on average a greater improvement in search costs (Mean = 5.3) than in processing costs (Mean = 3.3).

DEA findings are first used to analyze the link between the functionalities commonly used and the benefits for buyers. The DEA results summarized in Table 2 show that the model identifies 92% technical efficiency. Scale efficiency can be calculated as the ratio of the CCR and BCC scores. If the frontiers of the CCR and the BCC models are very close, one can conclude that the DMUs operate at constant returns to scale. Otherwise, there is significant scale inefficiency. Comparison of the BCC scores with CCR scores shows that most of the units are operating under constant returns to scale since the scale efficiency is very close to 1. Thus, the CCR efficiency score will be used in the following analysis unless otherwise stated.

TABLE 2 HERE

It is observed that most of the ratings are efficient; however, results show that buyers can use a reduced number of functionalities without reducing the level of benefits they report.

DEA results are further used to analyze the effect of different functionalities on the efficiency of users' ratings. The DEA model divided the data set into efficient and inefficient groups. Table 3 presents the average rating on each functionality for the efficient and the inefficient group. Findings show that the two groups have different input mixes and that the inefficient group of ratings reports a higher level of usage of the functionalities that support the execution and the post-sale activities. This indicates that reducing the level of access to these functionalities can lead to a greater efficiency in ratings. Results show however that a higher level of usage of functionalities that support the identification and selection activities is critical for the benefits reported. Results from Mann-Whitney tests at the confidence level of .95 confirmed the significant differences in functionalities usage between the two groups of ratings.

TABLE 3 HERE

Overall, findings suggest that the identification and selection functionalities are the most important factors affecting the benefits buyers get from accessing commercial websites to carry out their procurement tasks. Further analyses examined the non-response bias and the possible confounding factors. Findings showed support for the representativeness of the sample and for the independence between respondents' profile and DMUs' efficiency.

VI. Discussion and Implications

Findings from this study suggest that buyers logging onto commercial websites to carry out their procurement tasks tend to use them essentially for the identification and the selection of suppliers. They suggest also that more advanced functionalities of commercial websites such as the online ordering system, the online payment systems or the online tracking system does not add much benefit as perceived by users of such systems. As a result, buyers accessing vendors' websites tend to report more important reductions in search costs than in processing costs.

Possible explanations as to why using the transactional functionalities of commercial websites present less interest for corporate buyers include the perceived lack of security regarding web-based transactions and a personal preference for more traditional ways (phone calls, on-site visits, paper-based) to do business with suppliers.

Findings from this study have implications for both vendors deploying commercial websites and buyers using them. Vendors who are interested in new channels to sell their products and services must balance their business strategy and operations between "pure play" electronic commerce and "brick and mortar". The "bricks and clicks" in the middle of such continuum requires that vendors provide both channels and synchronize the "physical" and the "digital" business processes [1] [7]. However, findings from this research suggest that vendors may experience a somewhat reduced volume of transactions executed through their websites, hence limiting the effect online order fulfillment systems can have on the redesign of front-office operations and their integration to back-office operations. From the perspective of El Sawy's [7] set of BPR principles, informational websites and electronic catalogs only help implement two of the eleven principles identified (namely streamlining and losing wait) allowing for a limited streamlining and a very limited restructuring of front-office operations but not allowing for any management of the information and of the knowledge around such processes. Moreover, vendors concerned with balancing the cost of developing and maintaining their companies' commercial websites and the benefits of such systems as perceived by potential buyers can opt for websites that just support the identification and the selection phase of the procurement

process. Such websites may offer the maximum usefulness given their limited functionalities and therefore, given the costs they involve.

The implication of our findings on buyers' side is that, although commercial websites have the potential to support the entire procurement process, they are essentially used to establish communication channels with suppliers. In this context, commercial websites help reduce the time and effort (the so-called search costs) needed to identify and select a supplier for a given transaction. Findings from this study show however that commercial websites are rarely used to order inputs, pay for them or to check the status of such orders. Corporate buyers tend to opt for other means (probably more traditional means) to execute their transactions, which limits any improvement in processing costs and any dramatic redesign of the procurement process.

The objective of this research was to investigate the range (and the extent to which each) of functionalities of commercial websites buyers use to support the procurement process. The implications of our findings on related business operations and on the design of such websites were discussed. Future research can investigate such relationships for specific commercial websites in specific industries. Future work should measure the inputs from the perspective of organizations that deploy commercial websites and take into account several outputs related to the benefits of commercial websites' functionalities for organizations that implement them and for customers who use them.

Why Do People Share Music Files in the P2P Environment: An Ethical Decision Perspective

Rong-An Shang, Yu-Chen Chen, Pin-Cheng Chen

Abstract: Digitalized information and the Internet have brought great impacts on the music and movies industries. This study tested the ethical decision model of Hunt-Vitell to understand why and how people share unauthorized music files with others in the P2P network. Four scenarios of using P2P system and four norms related to them were proposed in the study. The results indicate that the deontological norm of anti-piracy, whether is theft of intellectual property or not, is not the main factors affecting P2P users' ethical consideration regarding sharing music with others. The results also suggest the music companies should care more about how to realize the benefits of the digital and network technology to increase the consumers' welfare instead of just declare the intellectual property they owned and resist the innovations caused by the new technologies.

Keywords: P2P computing in e commerce, Ethical Decision Model, Computer Ethics, Music industry, Consumer ethics

I. Introduction

Information technology has changed the economics of production and distribution of information products. Because the cost of reproduce a copy of digitalized information is low and the quality of the copies is almost the same as the original one, piracy has been recognized as a major ethical issue in the information age (Mason, 1986). Most of the previous studies of piracy focused on the unauthorized software copying or soft-lifting of students or IT professions. Probably due to that most people perceive softlifting causing little harms to the faceless, billion-dollar company, software piracy may not be perceived as an unethical behavior (Logsdon et al., 1994). Researchers suggest introducing ethical consideration and code of conduct in the education as solutions for the problem. However, there are still arguments for and against unauthorized copying of software (Siponen and Vartianine, 2004).

The technologies of peer-to-peer (P2P) architectures, in which users directly connect to the others to share and download files, further speeds up the propagation of digital resources. Although, under the present laws, act of exchanging copyrighted file is probably an invasion of

intellectual property (Lessig, 2002; Von Lohmann, 2003), people still now exchange a huge amount of digital music or movie in the P2P network. File sharing using P2P networks has been called the "killer application" in the Internet (Krishnan et al., 2003), or the disruptive innovation for the music industry (Spitz and Hunter, 2003). The norms of using the P2P network are still emerging (Spitz and Hunter, 2003), and thus it raises the needs for understanding people's ethical perception of sharing copyrighted files in the P2P network. The users' motives and concerns for downloading or sharing music files in the P2P environment are not the same as the motives and concerns for softlifting. Factors affecting ethical decisions of people in the P2P environment are still unclear.

User's unauthorized copy of music files is a problem of consumer ethics. Previous studies of consumer ethics often use Hunt and Vitell's (1986) model to describe the ethical decision making processes of consumers (Vitell, 2003; Vitell et al., 2001). This model has also been shown useful for understanding the decision processes of softlifting (Tong and Yap, 1998). However, people using P2P network may face dilemmas caused by the conflicts among different norms. This fact was rarely investigated by previous studies. This study proposed and tested a simplified model derived from Hunt-Vitell's model to describe people's ethical decision processes about sharing unauthorized music files in the P2P network. We also extended Hunt-Vitell's model to test and investigate the impacts of the beliefs of the norm of anti-piracy, the ideology of free software, the norm of reciprocity, and the ideology of consumer right on the deontological evaluation of sharing music files in the P2P environment.

II. Theoretical Background

The Hunt-Vitell model is grounded on the deontological and teleological theories of moral philosophy to describe the decision-making process for situations involving a marketing ethical problem (Hunt and Vitell, 1986). Deontological theories focus on the specific actions or behaviors of an individual while teleological theories focus on the consequences of those actions. The model suggests the ethical decision-making process is initiated by the individual's perception of an ethical problem in a situation, and then the perception of various possible alternatives that might be used to solve the problem. The ethical judgments in this situation are determined by both the deontological and teleological evaluation of the subject. The former

involves a comparison of the various alternatives with a set of predetermined deontological norms that represent the individual's personal values. Teleological evaluation is a function of the perceived consequences of each alternative for various stakeholders, the probability that each consequence will occur to each stakeholder group, the desirability of each consequence, and the importance of each stakeholder.

The model proposes that ethical judgments impact people's behavior through the mediation of their intention. However, moral intention will differ from ethical judgments because the teleological evaluation also independently affects moral intention. Behavior will also differ from moral intention resulted from the situational constraints. The model also suggests cultural, industrial, and organizational environment, and personal experiences as four external constructs that affect the ethical decision processes. After the conduct of behavior, an evaluation of the actual consequences of the chosen alternative will affect an individual's experience, forming an iterative loop of learning in the model.

For the Hunt-Vitell model presents the various philosophical theories that explain a decision maker's ethical judgments and the details of the individual decision-making process, it is widely used in the researches of ethical decision making in marketing (Vitell and Ho, 1997). Vitell et al. (2001) and Vitell (2003) have also suggested that by eliminating the constructs of professional, organizational and industrial environments, the Hunt-Vitell model is the most appropriate model for testing the research questions involving consumer ethics. Consumers' copying or buying unauthorized software is also a major issue in consumer ethics. Previous researches have shown the Hunt-Vitell model can adequately describe the ethical decision-making process involving software piracy (Thong and Yap, 1998). However, researches also found that, probably due to that most people perceive softlifting as causing not much harms to anyone, and the "victims", i.e., the individual software developers or companies, are perceived as far removed from and impersonal to the softlifters (Logsdon et al., 1994; Simpson et al., 1994, Vitell et al., 2001), unauthorized copying of intellectual properties such as software, tapes or movies was not perceived as even being unethical at all (Vitell, 2003).

III. Research Framework

Because the Hunt-Vitell model is complex, empirical studies usually simplify and test only part of the model (Vitell and Ho, 1997). The deontological norms in the model could range from general beliefs about such things as honesty, stealing, cheating and treating people fairly to issue-specific beliefs about such things as deceptive advertising, product safety, sales "kickbacks," confidentiality of data respondent anonymity and interviewer dishonesty (Hunt and Vitell, 1986). However, prior studies usually simplify the model by including only one set of deontological norms as the

determinant of deontological evaluation. For examples, studies about the information system ethics could use the professional code of conduct such as the ACM as the deontological norms (Thong and Yap, 1998). Therefore, the ethical dilemmas of the conflicts among different norms were not shown in the previous studies, and it implicates the dilemmas of the ethical decision in these studies were primarily caused by the conflict between the deontological evaluation and the teleological one.

But people using a P2P system to share music files with others may face the dilemmas caused by the different norms (Spitz and Hunter, 2003). Siponen and Vartiainen (2004) proposed several approaches for and against the unauthorized copying of software and shows that there are still arguments about this issue. Because most of the music files shared in the P2P networks are copyrighted, sharing them with, or providing them to or even downloading files from others in the P2P network, is very likely a piracy and against the law of intellectual property right (Von Lohmann, 2003). Therefore, for the using of the P2P network to share copyrighted music files with the others, we propose that:

H1 : *Deontological Evaluation is negatively related to the subject's belief in the norm of anti-piracy.*

On the other hand, there are also some arguments for the sharing of music files in the P2P network. First, the culture of freeware ideology is popular among users of Internet in its early age. Stallman (1995) argues for the importance of freeware in the information age and indicates that enforcing copyright is harming society as a whole. Raymmod (2000) further promotes the open source software and suggests the social status in the age of abundance is determined not by what you control but by what you give away. Gift giving is a way of creating and maintaining relationships of power, and then transforms these relationships to interdependencies based on the idea of reputation (Bergquist and Ljungberg, 2001). The spread of the open source software companies that earn profits by providing services has suggested the feasibility of the open source business model. Information technology should bring the similar revolutionary change in the music industry as well. Instead of selling the compact discs of the music, the musicians and the music companies can earn profits by providing the service of performance and the complementary products based on the reputations they earned (Liebowitz, 2002). Therefore, we define the belief that digital information should be free in the Internet era to maximize the social benefits as the ideology of freeware and propose that:

H2 : *Deontological Evaluation is positively related to the subject's belief in the ideology of freeware.*

The success of the P2P network lies in its users' being willing to share files with the others. Resources in the P2P environment are analogous to the public goods, and the problem of "free-riding" might prohibit users' intention to share resources with others (Asvanund et al., 2004; Krishnan et al., 2004; Shneidman & Parkes, 2003). The social

exchange theory suggests the norm of reciprocity is probably the prerequisite for users in a P2P network to emerge into a cooperative community to solve the free-riding problem. Blau (1964) stated that the starting mechanism of social interaction and group structure is the need to reciprocate for benefits received in order to keep receiving them. The participant in a P2P network is motivated to contribute valuable resources to the community because of a pre-existing expectation that he/she will receive something

useful in return (Tiwana & Bush, 2000). Nissenbaum (1995) also justifies user's copying software as an act of generosity or kindness to satisfy the need of his/her friend. Providing files to the community may be perceived as necessary and ethical for members in the P2P community. Therefore, we proposed that:

H3 : *Deontological Evaluation is positively related to the subject's belief in the norm of reciprocity.*

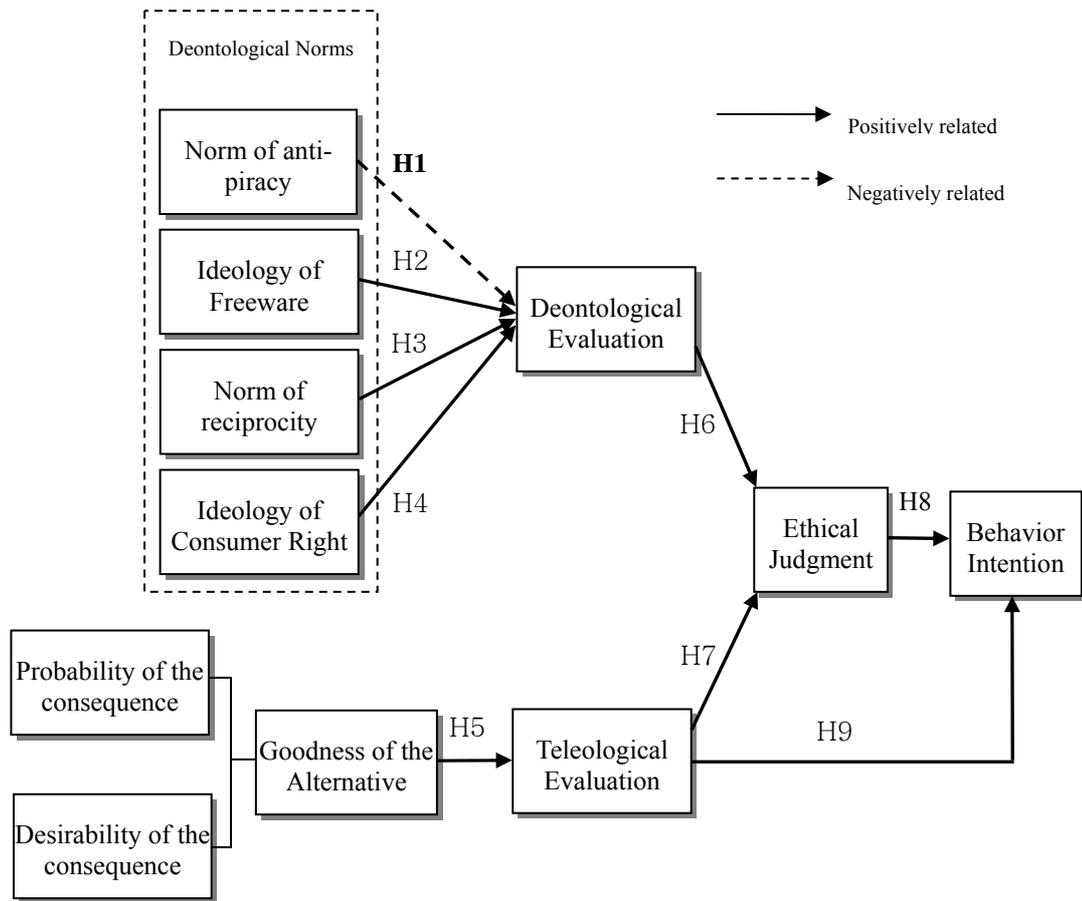

Figure I Research framework

The big music companies today may have earned extra revenue from their nearly oligopoly control of the distribution channel of music. As file sharing using P2P networks has been perceived as the disruptive innovation to the music industry (Krishnan et al., 2003; Spitz and Hunter, 2003), the new technology will changed the distribution channel of music, the structure of the music industry, and even the distribution of revenues of this industry (Clemons

et al., 2002). Consumers can access to the music they like in the Internet instead of buying music CD under the control of the music companies. For example, consumers should have the right to buy just the music they like, instead of having to buy twelve music songs or so bundled in a CD. The musicians can also earn more without the control of the music companies. Besides, because the music is experienced goods, consumers may have to have listened to the music before they can make the decision to buy it. As a result, the distribution of music files in the P2P network may attract

more people to access to and then buy the music (Spitz and Hunter, 2003). The big music companies may, through their oligopoly power, try to defer the diffusion of the new technologies and the emergence of an innovative business model, and hurt the benefits of consumers and even musicians. We defined the ideology of consumer right as a belief about the basic requirements of consumers that have to be satisfied in a fair transaction, and we proposed the hypothesis that:

H4 : *Deontological Evaluation is positively related to the subject's belief in the ideology of consumer right.*

Previous studies usually simplify the teleological evaluation process in the empirical test of the Hunt-Vitell model. We also simplified the determinants of teleological evaluation by dropping the importance of stakeholders and incorporated the evaluation of stakeholders into the other components. We defined the perceived goodness of an alternative as the summation of the multiplications of the probability of the consequence and the desirability of the consequence for each possible consequences of the alternative. Therefore, we proposed that:

H5 : *Teleological evaluation is positively related to the subject's perceived goodness of the alternative.*

Finally, the Hunt-Vitell model suggests four core hypotheses that ethical judgment is determined by both the deontological evaluation and teleological evaluation, and moral intention of the behavior is determined by the ethical judgment and teleological evaluation. The hypotheses and research model of this study is shown in figure 1, and these four hypotheses are listed as followed:

H6 : *Ethical judgment is positively related to the deontological evaluation.*

H7 : *Ethical judgment is positively related to the teleological evaluation.*

H8 : *Behavioral intention is positively related to the ethical judgment.*

H9 : *Behavioral intention is positively related to the teleological evaluation.*

IV. Research Method

The research model was tested by a scenario survey as suggested by Hunt and Vitell (1986). Because using P2P system to share music files with others is popular among teenagers, High school and university students were selected as the subjects for the study. The design of the scenario questionnaire is similar to the one used in the previous study (Thong and Yap, 1998). To evaluate whether or not the scenario and the items are understandable to the specified subjects, and the appropriateness of the alternatives and consequences, a pretest was conducted on 34 first-year

junior high school students. Some items and consequences of alternatives were revised according to the interviews with the subjects. Then, a pilot-study was conducted with a convenient sample of 73 junior high school students to evaluate the validity and reliability of the measurements. 62 valid responses were acquired and the measurements of the ideology of freeware and the ideology of consumer right were revised to increase the validity and reliability. The design of the finalized questionnaire was as followed:

Deontological norms. The questionnaire begins with the items measure the four deontological norms. Norms of anti-piracy were measured by six items revised from the items used to measure the deontological norms related to softlifting in Thong and Yap (1998). Some items were revised because these items were used to measure the piracy of music instead of software. Scales to measure the ideology of freeware, norm of reciprocity, and the ideology of consumer right were developed in this study by asking the subject if he/she agree with statements related to the norms. All the items mentioned above were measured on a seven-point Likert-type scale. Items measure deontological norms are listed in the appendix A.

Scenario. After the items measuring the deontological norms, paragraphs illustrated the details of a popular mode of P2P system were presented. The scenario describe a system of monthly pay of NT\$99 to search for and download files from the other users on this system. Once upon a user installs the software, the system will automatically build a shared folder in his/her hard disk. Files downloaded from the other users will be saved in this shared folder. While connecting to the system, a list of the files stored in this shared folder will be sent automatically to the server, and the other users in the network will be allowed to download files from this shared folder. There is a huge number of music files on the system now.

Alternatives. We presented four alternatives for the scenario. First of all, because users may concern about the legal issue of providing copyrighted files to the others in the Internet, they may just download files they like from the network but will not provide files to others. Secondly, some users may feel dutiful to provide the downloaded files to others under the norm of reciprocity, so will keep the downloaded files in the shared folder. Thirdly, except for the second kind of behavior, it is curious that where the original copy of the music files came from. Probably caused by the ideology of freeware on the Internet, some users may copy the music files from elsewhere, or even convert the music from the other format, into the P2P network. Finally, if the users don't care about the piracy, it would be strange why they would pay for using the P2P system. Therefore, we proposed some users might try to use the other free P2P systems or use other people's account such that they don't have to pay for it. As we intended to compare the impacts among different norms, the alternative of not using the system was not included in the study. The alternatives in this study is listed below:

Alternative 1. *I would pay to use the P2P software to download the music files from the others, but I would move the file from the shared folder once it is downloaded.*

Alternative 2. *I would pay to use the P2P software to download the music files from the others, and I would keep the downloaded files in the shared folder so the others could download the files from my computer.*

Alternative 3. *I would pay to use the P2P software to download the music files from the others and keep the downloaded files in the shared folder. Besides, I would also copy the other music files I have into the shared folder to let the others download these files from my computer.*

Alternative 4. **I would use the other free P2P system to share music files with the others.**

Deontological Evaluation. As in the previous study (Thong and Yap, 1998), deontological evaluations of each alternative were measured by two 7-point Likert scales that asking the subjects if they agree that “Based on my own values, without considering any possible consequences, I think Alternative (1) is very ethical,” and “Based ..., I think Alternative (1) is ethically acceptable.”

Consequences. The positive and negative consequences to the stakeholders, including the user him/herself, the music company, the artists, and the other users in the P2P system, under each alternative were identified. Consequence of each alternative were listed in the appendix B. We first measured the subjects’ evaluation of the probability of the consequences for each alternative by asking them to identify the probability on a 11-point scale, from the probability equals to 0 to the probability to 1, 0.1 per interval. After that, we asked the subjects to evaluate how much they desire for each consequence, from very dislike to very like on a 7-point scale.

Teleological Evaluation and Ethical Judgment. The measurement of teleological evaluation and ethical judgment were also followed the study of Thong and Yap (1998) by

asking “Based on the possible consequences, I think that Alternative (1) is very ethical,” and “Based ..., I think that Alternative (1) is ethically acceptable” for teleological evaluation, and “Considering both the possible consequences and my own values, I think that Alternative (1) is very ethical,” and “Considering ..., I think that Alternative (1) is ethically acceptable” for ethical judgment. All the measures were in a 7-point Likert scale.

Behavior Intention. Behavior intention of each alternative was also measured on a 7-point Likert scale that asking “In the above scenario, Alternative (1) would definitely not be the alternative I would choose,” as was used in Thong and Yap (1998). Finally, we asked the subjects if they feel hard to make decision in the situation, also on a 7-point Likert scale, to measure if the subject perceived he/she were in an ethical dilemma situation.

The actual surveys were conducted in the class of a convenient sample of high school and college students. The subjects were asked to follow the sequences of the questionnaire to answer the questions. Although the subjects were told it’s all right if they don’t want to take part in the study, they still may not be truly voluntary. Therefore, we used an item in the desirability of consequences as a criterion for the valid sample. Respondents with the answer that they would like to be sued for the piracy were judged as invalid. Totally 674 questionnaire were submitted and excluding the incomplete and invalid ones, 453 valid samples were acquired. 253 respondents among the sample had used a P2P system before. 163, 101, and 189 samples were respectively senior high school, junior high school, and university students.

V. Results

Table 1 shows the results of the deontological evaluation, teleological evaluation, ethical judgment, and behavior intention of each alternative.

Table 1. Descriptions of the results

	Mid ^a	Alternative 1		Alternative 2		Alternative 3		Alternative 4	
		Mean	SD ^b	Mean	SD	Mean	SD	Mean	SD
Deontological evaluation	8	9.07	3.16	9.00	2.95	8.66	3.08	8.85	3.33
Teleological evaluation	8	8.54	2.96	8.55	2.66	8.36	2.87	8.43	3.11
Ethical judgment	8	8.60	2.98	8.55	2.67	8.30	2.87	8.29	3.05
Behavior intention	4	4.29	1.65	4.31	1.60	4.27	1.44	4.28	1.46

^a: Mid value of the scale.

^b: Standard deviation

All of the means of these variables were a little higher than the middle value of the scale, suggests the subjects may present a neutral but somewhat positive attitude toward these alternatives. Table 1 also shows there were no significant differences of these variables among alternatives.

A principal components analysis with orthogonal rotation by varimax method was conducted to test the construct validity. Table 2 presents the factor structure for the variables of deontological norms. Four factors with eigenvalues larger than one were extracted and the result

shows the data fit well with the predicted factor structure. Table 2 also shows all the Cronbach’s α of the four deontological norms were larger than 0.7, suggests the reliability of these variables were acceptable. Table 3 presents the Cronbach’s α of the three variables in the ethical decision processes of each alternative. The results also indicate good reliabilities of these variables.

We used the structure equation modeling with observed variables to test the path structure in this research. Item scores of each construct were summarized to calculate the

observed score of the variable. Table 4 shows the results of the path analysis and hypothesis testing for each alternative. The ideology of consumer right had a significantly positive effect on deontological evaluation of all the alternatives. Hypothesis 4 was supported in this study. On the other hands, the norm of reciprocity didn't influence the deontological evaluation of any alternative. Hypothesis 3 was not supported. People interact with each other to exchange resources in the P2P network. Although there are usually some forums functioned as the space of interaction for the P2P systems (Spitz and Hunter, 2003), the anonymity of computer-mediated-communication may reduce the impacts of the norms of P2P community because the anonymity would decrease the social presence (Short et al., 1976), or reduce the social cues conveyed in the social interaction (Kiesler et al., 1984; Rutter, 1984).

The impacts of the norm of anti-piracy and the ideology of freeware were different among alternatives. The ideology of freeware significantly affected the deontological evaluation in alternative 3. This result suggests the ideology of freeware could explain where the original copy of the files came from and why there was some people copying files from elsewhere or transferring files from the other format. The ideology of freeware also affected the deontological evaluation in alternative 4, indicates that people with the ideology of freeware would try to use a free P2P system. However, it is interesting to note that the norm of anti-piracy affected deontological evaluation only in the alternative 4. In other words, people who had paid for using the system seem to care less about the piracy issue. This is probably due to that they suppose that, since they have paid for the benefits they get, piracy is only a problem between the P2P and the music companies. This may explain why although there are some free or opensource P2P systems, the systems with charge are still popular among users.

The hypothesis 5, 6, and 7 were all supported in the study. The subject's perceived goodness of the alternative measured by the proposed had a significantly positive influence on the teleological evaluation. The ethical judgment was affected both by the deontological and teleological evaluation. However, the impacts of the teleological evaluation were larger than the impacts of the deontological evaluation in all of the four alternatives. Finally, this study found that the subjects' intention to download files but not provide files to the others, and the intention to use free P2P systems were primarily influenced by the teleological evaluation but not the ethical judgment. On the other hand, the subjects' intention to provide the files they downloaded from the P2P network to the others was influenced by the ethical judgment, and the intention to look for or transfer files from elsewhere was influenced by both the ethical judgment and teleological evaluation.

VI. Conclusion

Copying and distribution of digital files in the Internet have brought great threats to the music industry. This study tested

the Hunt-Vitell model to understand users' ethical decision about copying unauthorized music files in the P2P network. The results show that the deontological evaluations are influenced by the ideology of consumer right for all alternatives, and by the ideology of freeware and the norms of anti-piracy for some alternatives, but are not affected by the norms of reciprocity. However, results of this study should be explained carefully. The Hunt-Vitell model does not describe well the way that people in the real world make ethical judgments (Cole et al., 2000). The model suggests that when behavior and intentions are inconsistent with ethical judgments, one of the consequences will be the feel of guilt (Hunt and Vitell, 1986).

But the work of Strutton et al. (1994) indicates that even normally ethical consumers can easily rationalize unethical behaviors by appealing to the techniques of neutralization (Vitell, 2003). The impacts of the deontological norms found in the study may be just the rationalized attribution after the decision has been made, instead of the factors affect the decision processes.

The above findings have implications for the music companies. Since consumers can easily rationalize their behavior by the norms such as the ideology of consumer and the ideology of freeware to reduce the feeling of guilt while copying files from the Internet, just proclaim the intellectual property rights and the norm of anti-piracy would be of little use for diminishing the unauthorized copying. Besides, the study found that people might not concern about the piracy issue when they have paid for using the P2P system. The popularity of the charging P2P system may suggest that people would like to pay something to reduce their guilty feeling about copying files. The success of iTunes may firmly support the above idea. Therefore, companies should try their best to apply and realize the benefits of the new technology to increase their consumers' welfare, instead of waiting and resisting the change and just declaring their rights and imposing the quilt of piracy upon their customers. Consumers may be more willing to respect the intellectual property rights of the companies if these companies make every endeavor to increase their consumers' benefits.

Abstract: A review of the previous research on small businesses in tourism and hospitality shows a growing interest in Internet marketing. However, the research that exists is contradictory. On the one hand, some researchers suggest that because the entry barriers are low, it is cost effective for small businesses to set up an Internet presence, which helps level the playing field between small and large firms [18]; [21]. However, other researchers indicate that e-commerce is not being adopted as readily by small tourism and hospitality businesses as one might have expected [17]; [6]; [31]. Clearly, more research is required in this area regarding Internet usage in small tourism and hospitality businesses. This study will therefore examine small businesses (less than 50 employees) – specifically Bed and Breakfasts (B&Bs) - to develop theories identifying factors that facilitate and inhibit the adoption and implementation of Internet technology in the accommodation sector.

Keywords: Internet, marketing, small businesses, online surveys.

I. Small Businesses and the Internet

The majority of research addressing issues of Internet technology has focused on the motivating factors behind developing an online presence rather than the barriers to adoption. Many studies have shown that low development and maintenance costs play a critical role in the decision to go online [18]; [10].

Research has also shown that many tourism and hospitality businesses, especially in the accommodation sector, can overcome the disadvantages of small size through their use of the Internet to grow by reaching consumers beyond their borders [18]; [17]; [13]. [22] explain that while a firm may not have an explicit international expansion strategy, the Web site automatically positions the firm in the international marketplace. Similarly, [12] suggest that the Internet can be a very powerful tool to assist small firms in overcoming the main barriers to internationalization and allow gradual change. [20] argues that the use of the Internet as a marketing platform offers small specialist firms in tourism considerable prospects to both reach and to cover traditional and emerging tourism markets. Others have suggested that the Internet can be a

powerful tool for delivering information [17], attracting affluent customers and relationship marketing purposes [10] and [11]; [3], improving service encounters [4], and for increasing customer service [1].

Despite the growing body of research in the area of small business Internet use, adoption of Internet technology amongst small firms is still slow. [25] and [1] have commented that many small firms have difficulties realizing the benefits of Internet technology. Similarly, [2] found that small firms devote little consideration to practical questions of Web site management. Research on the barriers to adoption of Internet technology amongst tourism and hospitality businesses is very limited, but the main concerns seem to be security [16]; [17], lack of technical expertise [6]; [31], the difficulty in analyzing and promoting the site [1], the fear of losing client rapport ([18]; [21], and simply a lack of an online market for the firm's products [31]. For small firms in the tourism sector [28] ranked the four most important barriers as start-up costs, lack of staff expertise, operating costs and the difficulty of providing adequate training.

II. Methodology

Initially, in-depth interviews with a convenience sample of 15 B&B owners were conducted in Alberta, Canada during the winter of 2003/2004. The main reason for conducting these interviews was to ensure that the online survey was comprehensive and captured all the relevant data. Grounded on material generated from the literature review, the interviews questioned about owners why they used the Internet (i.e., to market rooms, increase exposure, project a professional image, etc.); what factors influenced or constrained their use of the Internet; how much they used e-mail as a marketing or communication tool or as a vehicle for taking reservations; what were the key advantages and disadvantages of using the Internet; what were success strategies for converting surfers to buyers; and how they advertised their Web sites.

What was clear from the interviews is that the Internet has emerged as an important marketing tool for B&Bs with demonstrable impact on the bottom line, and has proved to be a cost-effective marketing option, especially when partnerships are formed. Most owners reported spending a large proportion of available marketing dollars on the Internet, and receiving the majority of their reservations from Web based marketing. Most of the operators are

selecting to put much of their available Internet promotions budget towards maintaining a paid presence on area online destination guides or even to combine in geographical regions to develop new online destination Web sites.

Based on the analysis of these interviews, and on the relevant literature reviewed, an online survey was developed and hosted on a university Web site. Comparative studies have shown online surveys result in the potential to reach higher numbers of people and achieve higher response rates while being cheaper to administer, especially for larger sample sizes [7]; [32], even if initial costs are higher than other survey methods. The relative speed and flexibility of online surveys are seen to be two major advantages. Additionally, there is the potential of reaching a large and growing audience of people on the Internet.

Despite the limitations associated with sample selection, the universe of online users (both business-to-business users and consumers) has grown to the point where it is considered a sub-group of such importance that it is worthy of study in itself – without the questionable practice of attempting to project these findings back to the more general, off-line population. Certainly, for targeting small business owners in a survey of how they use the Internet, an online survey would seem highly appropriate.

The survey instrument was piloted with 12 B&B owners in Alberta, and based on their feedback, the survey was further refined. Subjects were then recruited with a personal e-mail that directed them to the Web site to complete the survey. An e-mail address list of 1048 B&Bs was compiled from all the available guidebooks, online guides, and brochures. This approach was adopted given large e-mailing lists work better with some degree of personalization [26].

The questionnaire was divided into four sections. The first part asked respondents about their Web sites; years of operation, percentage of reservations made on the Web, reasons for having a Web site; dollars spent on the Web site; and tools they use on the Web sites. Secondly, perceived advantages and disadvantages of using the Internet were examined. The third part asked respondents what efforts they made to convert surfers into buyers, such as developing relationships with customers, employing professionals to design the Web site and answering queries. The last section inquired about some of the characteristics of the respondents and their businesses. All questions were closed-ended to aid completion. The survey was “live” for one month early in 2004. A follow-up e-mail was sent after two weeks as online survey response rates may only reach 25 % without a follow-up e-mail [15]. In total 353 useable responses were collected, giving a response rate of 33.7 %. 270 responses were received within three days, similar to previous online studies [15], and supporting the contention that one of the major advantages of online surveys is the speed of response [32]; [7]. The data were analyzed using SPSS for Windows. Chi-square analysis was used to reveal any significant relationships between variables.

III. Results

Of the 353 respondents, nearly half (49%) were University graduates, 30% had trade diplomas, and the remainder (21%) were high school graduates. A large proportion (39%) were in the 55-64 age bracket, 33% were aged between 45 and 54, and 12% were over 65. The remainder (16%) were under 45. Results indicated that the Internet was the key communication tool for B&Bs. Table 1 shows that a large proportion (88%) of owners said that customers found them via the Internet “often” or “always.” This supports the data referred to earlier indicating the widespread use of the Internet amongst travelers. Word of mouth and accommodation guidebooks were the second most popular communication tools. According to [27], word of mouth is far and away the dominant force in the marketplace, yet it is also the most neglected. A quarter of respondents were in the first two years of running their sites, 35% were in the third or fourth years of operation, and the remaining 40% had been operating their sites for five years or more.

TABLE 1

Communication Methods That Attract Bed and Breakfast Customers

How Customers Found B & B's	Often or Always	Never or Sometimes
	%	%
Internet	88	12
Word of mouth	62	38
Accommodation guidebooks	47	53
Tourist office/Chamber of Commerce	32	68
Brochures	31	69
Other guidebooks	17	83
In Canada, provincial or regional promotions	16	84
Signs	12	88
Magazines and newspapers	6	94
Direct mail	2	98

Respondents were asked why they had a Web site. Table 2 lists the reasons in order of importance. There is clearly a trend towards using the Web as a marketing tool and as an avenue for delivering information, although 56% do use the Web to make online reservations. A large percentage (83%) maintained a Web site in order to increase business exposure, and 81.5% used the Web to expand their customer base outside of Canada. These statistics are similar to those found in a past survey of B&Bs in Canada [18]. Web sites tended to be updated when necessary, and exactly 50% of respondents said they measured the efficiency of their sites.

TABLE 2

Reasons for a B&B Having a Web Site

Reason for Having Web Site	% of B&B Owners Who Agreed:
To use as a marketing tool	92.3
To increase business exposure	83.0
To expand customer base outside Canada	81.5
To target more customers with less expense	81.0
To expand customer base within Canada	79.8
To answer questions about accommodation	78.4
To project a professional image	75.6
To impart knowledge quickly	71.3
To use e-mail as a marketing or communication tool	71.3
To improve customer service	63.9
To make reservations directly	56.3
To provide quotes to customers	54.5
To level the playing field between small & big business	39.2
To offer paperless documentation	38.6
To obtain feedback from customers	27.6

Respondents were asked what tools they make use of on their Web sites. Very few used video or audio advertising, and only 16% offered information in other languages. The same low number used a secure server for making online credit card reservations. However, nearly half of respondents (46%) had links to other businesses to help customers make travel plans.

B&B owners were asked what they thought the advantages and disadvantages of using the Internet were. Table 3 lists these, in order of importance. Respondents clearly perceived more advantages than disadvantages, with internationalization and low cost being the main incentives for maintaining a Web presence. The majority of respondents (79%) also saw the ease of updating marketing information as a key advantage of the Internet over more traditional marketing tools. Building customer relationships was only seen by half the sample as an advantage of Internet marketing.

Security was seen as the greatest disadvantage of using the Internet. Interestingly, despite these concerns, only 14.5% used a secure server for online booking, and even less (5.7%) included a privacy policy. Another disadvantage perceived by 41.5% of respondents, was the inability to screen customers. Losing customer or client rapport has been highlighted before as a concern for small business owners [21] and in the interviews that preceded this survey, some of the owners had indicated that they still prefer to speak to potential customers on the telephone before taking a booking. [18] also found that B&B owners were concerned about the lack of rapport with clients and considered this drawback as an impediment to generating sales. Previous research on small firms without Web sites has found that

personal contact with customers through telephone conversations is very important for securing international sales [2].

TABLE 3

Advantages and Disadvantages of Using the Internet (B&B)

Advantages	%	Disadvantages	%
Can reach a worldwide marketplace	89.8	Not secure	44.0
Low cost	81.0	Cannot screen customers	41.5
Ease of updating information	79.0	Poor technical knowledge of owners	34.1
Interactivity	65.3	Customer privacy concerns	31.8
Building customer relationships	51.4	Too long to develop Web presence	25.0
Measurement of efficiency	45.7	Customers more likely to cancel	17.9
Transmission of sound and video	44.6	Cost	7.7
Customer belief in security	6.3		

Respondents were asked what they did to convert surfers into buyers. Table 4 ranks the methods used and also indicates any statistically significant relationships between methods and Internet reservations. The most popular methods were to answer queries within 24 hours (86%), provide as much information as possible (85%), keep the Web site up to date (71%) and make it easy for customers to reserve a room (63%). There was a significant relationship between the number of reservations made via the Internet, and answering queries within 24 hours ($\chi^2= 12.64$, $df=5$, $p<.05$), supporting the results of the in-depth interviews. Making it easy for customers to reserve ($\chi^2= 16.31$, $df=5$, $p<.01$), was also a factor relating significantly to bookings taken.

Nearly 60% of owners felt that employing professionals to design the Web site assisted in converting surfers into buyers, although there was no relationship between doing this and Internet reservations. However, those that improved their Web sites based on customers' observations were significantly more likely to take Internet reservations ($\chi^2= 13.56$, $df=5$, $p<.05$). There was a significant relationship between Internet reservations and the use of links to local businesses on Web sites ($\chi^2= 15.86$, $df=5$, $p<.005$). This supports both the qualitative research, and [25] claim that the success of e-commerce for small business depends upon the adoption of technology by other participants. There was also a significant relationship between those that

developed relationships with customers and the number of Internet inquiries that turned into reservations ($\chi^2= 17.27$, $df=5$, $p<.005$).

TABLE 4

Methods used to convert surfers into buyers

Methods	% of B&B Owners Who Agreed	Significant relationship to Internet reservations
Answer queries in 24 hours	85.5	$p<.05$
Provide as much information as possible	84.4	ns
Keep Web site up to date	70.7	ns
Make it easy to reserve a room	62.2	$p<.01$
Employ professionals to design the Web site	57.1	ns
Develop relationships with customers	53.1	$p<.005$
Have links to local businesses on travel plans	46.0	$p<.005$
Improve the Web site based on customers' observations	46.0	$p<.05$
Offer a 1-800 number for fulfillment	43.8	ns
Avoid the use of gimmiky technology	43.2	ns
Provide contact information on every page	38.9	ns
Develop simple and persuasive messages	34.1	ns
Provide references or personal comments	32.7	ns
Clearly identify the target audience	16.8	ns
Use a secure server for online booking	14.5	ns
Offer a lower/discount rate online	6.3	ns
Include a privacy policy	5.7	ns

ns=not significant

Chi-square analysis revealed other important relationships between variables. There was a significant relationship between those respondents that measured the efficiency of their sites, and the percentage of Internet inquiries that turn into reservations ($\chi^2= 15.73$, $df=5$, $p<.01$), suggesting that measuring efficiency of Web sites can result in increased Internet bookings. There was also a significant relationship between growth rates (in terms of overall bookings) and the years of operation of businesses ($\chi^2= 15.878$, $df=3$, $p<.001$), and the years of operating Web sites ($\chi^2= 22.034$, $df=6$, $p<.001$). This would tend to support the contention that small businesses are using the Internet in order to grow their businesses without expanding physically or incurring relocation expenses [19].

There was a significant relationship between the number of years of Web site operation and the number of Internet

inquiries that turn into reservations ($\chi^2= 24.47$, $df=10$, $p<.01$), indicating that more experienced operators were more adept at converting surfers into buyers. Finally, there was a significant relationship between the number of years of Web site operation and international bookings ($\chi^2= 18.76$, $df=9$, $p<.05$). This supports the contention that internationalization is positively affected by use of the Internet [8]; [22]; [12]. However, there was no statistical support for Davis and Harveston's suggestion that education level and the age of owners influence Internet success.

IV. Discussion

The results of this study suggest that B&B owners are using the Internet as a low-cost method of increasing their customer base especially from overseas markets. Success is closely related to online experience, the measurement of Web site efficiency, prompt responses to inquiries, making it easy for customers to reserve, the development of relationships with customers, customer adoption of technology, and the existence of online partners. These results support previous research referred to earlier in the article [10]; [28]; [9]; [8]; [25]. The findings also support previous research that has found a positive association between small businesses Internet use and growth [19]; [8], and internationalization [21]; [22]; [12].

However, B&B owners do not use the Web to its full advantage, supporting contentions that the use of online marketing efforts has been relegated to a relatively small number of marketing tools and tactics [5]; [2]. For example, few respondents in this study used the Internet to solicit feedback from guests, and only half used it to build customer relationships. However, the Internet can be a powerful tool for relationship marketing purposes [3]. Most marketers now accept that it is less expensive to attract repeat customers than to create new ones and this is the basic concept behind relationship marketing. In addition, many consumers too are looking to build relationships on the Web.

Respondents in this study are also missing out on the potential to make more Internet reservations. Only 15% of owners used a secure server for secure online booking, and only 7% had a privacy policy, even though they identified security as being the major disadvantage of using the Internet. Previous studies have shown that security concerns are a major reason consumers do not buy online [29]; [1], even though these concerns may be exaggerated. It would seem that the investment in secure servers would result in increased online bookings for B&B owners.

Finally, only half of the respondents measure the efficiency of their sites, despite the positive relationship with Internet bookings. Simple measures exist that can assess the effectiveness of a site, such as hits (the number of times a site is visited), unique visitors (the number of different viewers during a particular time period), and page views (the number of times viewers view a page). Inexpensive software applications are available that small businesses can use to

carry out these measurements.

In addition to examining critical issues surrounding the use of the Internet for small businesses, this study has also highlighted the potential of online surveys as a way of increasing response rates in a cost-effective manner. Without a follow-up email, the response rate achieved would have been 25% within three days of initial contact. A review of 180 mail surveys of business respondents in the 1990s calculated the average response rate to be 21% [23]. Clearly, a carefully designed, targeted online survey of small business owners can surpass this average. However, this survey population had a high degree of interest in the topic of the survey, and there may have been a novelty factor that encouraged responses.

However, non-response remains a problem. People change their e-mail addresses more often than they change their phone numbers [7], and it is a challenge to find e-mail lists that are fresh [26]. In this survey, 55 e-mails were returned from a total of 1048 (approximately 5%). Fortunately, researchers were able to find new e-mail addresses for 30 of these, although this was a time-consuming process. One advantage of using online surveys is the instant feedback of undeliverable mail. In the future, it is likely that researchers will have access to up-to-date commercial e-mail lists similar to today's mailing lists, both reducing the effort of obtaining and increasing the accuracy of e-mail address lists. If respondents from these lists can be targeted to be representative of a desired population, the logistics of e-mail surveying will be greatly enhanced.

V. Conclusion

This study suffers from a few weaknesses, mainly in sample selection. The sample was limited to just one industry (hospitality), and to one particular sector of that industry (the accommodation sector). Therefore, the results may be of only limited generalizability. The sample may suffer from a strong element of self-selection, since it included only small firms that were online and thus did not include firms who had made the decision not to go online. Caution should be given to the interpretation of survey results obtained from a self-selected sample [14]. The sample was biased towards English speaking firms, and therefore the results may not be applicable to the whole of Canada. Internet use is higher in Western Canada and Ontario than it is in French speaking Quebec [30]. Finally, the study was biased towards Canadian-based firms. This may be problematic since researchers have found that the motivations and barriers to Internet adoption can differ across national boundaries [24].

Further research is also needed to determine why customers are reluctant to make reservations on the Web. [18] discovered that although many people are browsing the Web pages of B&Bs, these consumers are not using the Internet to make reservations. An Internet-based methodology to investigate the effectiveness of B&B Web sites, and the behavior of visitors online would be a natural extension of this research.

Abstract: The role of Internet has been rapidly becoming inevitable to corporate and society. Across the world, governments and corporate have been working towards the better utilization of the internet. Initially, the Internet was perceived as communication media and now, slowly, metamorphosing into a powerful business media. The Internet provides a direct reach to end users, thereby, the corporate wish to use this to gain cost competitive edge. Many dot.com companies entered and exited the cyber space during early twenty first century, yet, many dot.com companies survived and succeeded in their business. Many brick & mortar companies intended to use the Internet and found they it did not work well. The faced the peculiar lacuna of misunderstanding Internet buyer behavior and could not figure out the categories of products/services the Internet users intend to buy. At this juncture, the authors did an extensive primary research among Indian Internet users in order to identify the willingness of Internet users to buy different products/services over Internet. Besides, they also found the status of Internet users in buying different products/services online. The authors focused on finding out which stage the Indian Internet user stands in consumer buying process. The research revealed positive outcomes which would be useful to corporate world to adopt and deploy for better use. This paper mainly focused on consumer perspective of Internet purchase in order to understand Indian Internet users psyche.

Keywords: Internet Marketing, Internet Buying Behavior, Consumer Buying Process.

I. Introduction

The Internet has started been transforming from Information and communication media to Business media as many companies across the world perceived the potential of this magic media to reach potential consumers in leaps and bounds of the world. Many conglomerates used this as a media to sell their products/services and used their own

models or thumb rules. Unfortunately, the companies involved in this cyber business could not find proper direction to woo the potential consumers. Yet, they did not shy away from their effort to push their products/services hard towards the consumers. Very few companies like Amazon.com involved in selling different products have started making profit out of this business and many burned their fingers very hard way such as Webvan.com, online grocery retailer etc. due to lack of proper business and revenue models. Finally, the companies identified that not all products/services could be sold over Internet and certain products/services could be sold. Hence, many companies changed their strategies and started using their websites as an information media to create awareness among the target group, which would help them to make their offline purchase.

I. 1 Need, Relevance and Significance of the Study

The authors understood the needs of the companies that desperately trying hard to figure out the exact profile and buying behavior of online buyer. Many research works have been done in abroad, especially in USA, yet the significant outcomes about exact profile and buying behavior of online consumers to be figured out. As far as Indian soil is concerned, the marketing research companies found out the browsing habits such as hours of browsing, place of browsing, purposes of browsing and products/services purchased online etc and continued to do so in these areas. They have not gone deep in analyzing the buying behavior of Indian consumers over online purchases. The authors identified this wide gap and defined a problem to find out proper solutions about the impact of cyber-marketing in consumer buying behavior and their perception about using Internet either an information or business media. The paradigm shift in Indian soil left the population to adopt the changes related to different aspects such as technology, life style etc. In this process, many became the ardent users of Internet users mainly for exchanging communication through e-mail, online chatting (real-time conversation –Non voice mode), downloading interested information, music, pictures etc. for free of cost. Some of the companies tried to make extension of these habits by providing paid e-mail

services, which faced a debacle (e.g. *Indiatimes.com* in India and *Netaddress.com* in USA). The online users backed away when it comes to paying money for services they enjoyed free of cost. Some of the companies tried to extend this by offering products even groceries online (*Fabmart.com* in India, *Webvan.com* in USA). Many followed suit such as *Chennaibazaar.com*, *Bababazaar.com* who act as a platform between buyers and sellers and enable them to make transactions over Internet. Some of the online retailers offer different variant of products (*Fabmart.com* etc) and some of them stick to certain products (*First and second. Com*) such as books, adopted the model of *Amazon.com*. Many entered into service arena by offering different services such as online share trading, banking, travel and hotel booking, holiday packages etc (*Sharekhan.com*, *ICICIDirect.com*, *Makemytrip.com* etc). Yet these online products/service providers could not reach the mass segment due to several infrastructure hiccups such as payment mode and logistics. It is identified most of Internet buyers in India prefer to buy CDs, Music, Books, Travel booking, holiday package online (TNS Interactive Global e-commerce Report 2002 and Web metrics 2002) This clearly shows that Internet buyers prefer to buy products/services do not need much of physical purchase as the trust plays a major factor in influencing target group's buying behavior as most of them prefer to do physical purchase (Tangible purchase i.e. touch, see, smell and feel products). In this study, the authors mainly focused on identifying the stages of consumers while they intend to make their purchase online. Normally In physical purchase, every consumer would undergo a three-tier process while he intends to buy a product/service such as cognitive (Information search), Affective (Evaluation of the information/alternatives collected/identified) and Behavior (make a purchase). The length of the above process would differ according to the investment he would intend to make on a product/service i.e. consumer involvement in purchase differs according to the investment he/she would make.

This is the crux of the authors' defined problem as they defined three types of products/services such as High involvement, medium involvement and low involvement. Involvement would be defined by four major factors viz. Price, Purchase intervals, Perceived risk and Personal emotional involvement (Ramesh Kumar S & Karan Bajaj, 2002).

High Involvement: Normally, a consumer would undergo a lengthy behavior process while he intends to buy high investment product/service such as TV, Car, Music System, Jewelry, Loan for House, Car, International holiday package, Investment of Funds etc. Hence, higher the investment, more the involvement the consumer exercise to buy a product or service as he could not switch to substitute brand or service as the investment is high. The products with higher prices, higher perceived risk, higher purchase intervals and high emotional involvement products such as Automobiles, Refrigerators etc. (Ramesh Kumar S & Karan Bajaj, 2002).

Medium Involvement: Generally, a consumer would

not exercise diligent care while he intends to buy a shirt, Fashion articles, selecting a domestic holiday package, booking a hotel room as it involved medium investment. Normally, all these purchase come under impulse purchase and the consumer would not use the articles for a long time and he/she may switch to substitute brand or service as the investment is medium.

Low Involvement: Usually, a consumer would not spend much time in searching information (cognitive) or evaluating (affective) the information collected before make a purchase (behavior) of FMCG products or perishable products or buying cinema tickets or booking a table at restaurant etc. which incur low investment as he/she could switch to substitute brand if dissatisfied with the product/service consumed. He/she could do so as the investment for the product/service is comparatively low and would not affect his/her buying decision. The products with low price, perceived risk, purchase intervals and emotional involvement products viz. Detergents, Cereals etc. (Ramesh Kumar S & Karan Bajaj, 2002).

Hence, the authors used the above-mentioned categories as the core aspect of the research as they identified the striking similarities between offline (physical) and online (purchase over Internet) purchase as consumers exercise same diligence of going through a lengthy process before buying a product/service (Fader 2002). So, the authors intended to identify the stages of consumer behavior process in which a consumer stands while he/she intends to use Internet a media to make his/her buying decision on different categories of products or services mentioned above. This would act as an eye-opener to the needy companies in Indian soil in order to identify the perception of consumers about utilizing the Internet to make purchase and also help them to devise strategies and upkeep their focus on wooing consumers to buy online.

The authors used to observe the dynamics of cyber-space from Internet to e-commerce and developed an interest to focus on analyzing consumers' perception on Internet especially about the utilization of former as information or business media. Also, they intended to analyze Internet users' willingness to buy product/service online. In order to identify their willingness, they intended to know the stand of consumers' in different stages of buying behavior in buying different categories of products/services online. They also observed the attempt made by many marketing research companies in identifying consumers' perception over Internet, but to in trivial areas like browsing habits, purposes, hours, place of browsing etc. None of the companies attempted to venture in depth to find out the behavioral process behind their purchase over online. Since, the selected problem is in very evolving stage as they witnessed the gradually transformation of Internet users to buy products/services online, but not in very encouraging trend as it is identified only 4% of Internet buyers from India buy over online against the global average 15% (TNS Interactive Global e-commerce report 2002). The study would be expected to unearth many queries, which eagerly waited by

many companies who desperately need to create a new segment of potential buyers in the cyber space and also would help them to make a proper positioning of product/service instead of placing all products/services online.

II. Literature Review

The importance of studying consumer Internet behavior as e-commerce grows in size and gaining significance and consumer researchers ought to take more effort to studying consumer Internet behavior on how consumers make the Internet a part of their consumption (Peterson, et al., 1997; Cowles and Kiecker, 2000). identified that the Internet is used as a more proactive marketing tool, inviting consumers interactively to access the web site to gain product information to facilitate their buying decision making process either online or offline Hazel, 1996). E-commerce managers/companies to understand the factors influence consumers buy online, so that they can develop effective strategies to encourage consumers to their web sites to spend time and money (Aldridge et al., 1997; Wysocki, 2000). It is found out that likelihood of buying should increase with increased use of the Internet. It vividly expresses that more exposure consumers gain over Internet would instill a trust in the media to move on to buying online (Aldridge et al., 1997). It is explained that the Internet has been used to facilitate online sales such as it acts as a means of communication about the companies sell product/services online/offline (information and communication media as it extends consumers ability to procure maximum information at their door step) (Bruno,1997). The consumer online behavior has shown that attitudes toward the Internet and toward online buying are systematically related to online buying behavior. (Eastlick and Lotz., 1999; Goldsmith and Bridges, 2000; Karson, 2000; Kartz and Aspden, 1997). It is found from many US examples support that more consumers use the Internet for research (evaluation) in the early part of buying decision-making process, than buying direct on the web. It subsequently led to purchasing the product by store or order on the telephone or fax (Ernst and Young, 1999). The significance of Internet Consumer behavior is attracting increased attention from Marketing and Consumer Researchers (Donthu and Garcia, 1999; Phau and Poon, 2000). The domain of activities are identified which could be called "Consumer Internet Behavior" that included Information gathering, consumption of information through exposure to advertising, shopping, which includes browsing, comparing products and deliberate information search, and online buying of goods, services and information (Goldsmith and Bridges, 2000) It is found that most of the researches on Consumer Internet Behavior have normally been descriptive in nature, focusing on gathering statistical information on products/services online and the demographic profile or characteristics of online buyers in order to give a glimpse of online consumer profile (Modahl, 2000; Murphy, 2000). It is identified that those who use the

Internet more are likely to buy more online than those who use it less and providing logic of more usage of Internet might induce consumers to gain more exposure which might lead to more trust over Internet activities. This might be the earlier stage of exercising purchase behavior over Internet by collecting information as the consumer believed the reliability of the information available over Internet (Feather, 2000). It is found out that the consumers those who gained experience with online buying with a small purchase at the earlier stage will likely to develop confidence and skills that facilitate more ambitious purchase. It clearly shows that the more experience will instill trust in consumers to buy expensive products over Internet (Seckler, 2000). It is identified that consumers who frequently seek product information online are more likely to engage in web purchasing. This trend is confirmed through overall purchase and all nine individual product categories. It vividly portrays the acquiring information about products/services over Internet is the positive approach that consumers exercise towards the Internet which may likely to turn out to be future purchase (Hyokjin et al., 2002). The study portrays that 60.5 % of the users considered Internet to be a very important or extremely important source of information (UCLA, 2003)

Yet, the authors could not obtain much of preceding work in Indian context for the defined problem of the impact of cyber-marketing on consumer buying behavior as he resorted mainly to reportorial data than the behavioral data especially in context to Indian soil. Though, Many authors in abroad studied and analyzed the behavior of consumers over Internet, yet, not very much in line with the defined problem. Albeit, the authors collected data related to browsing and conversion behavior of consumers related to United States of America with respect to certain web sites dealing selected products, not of wide perspective, which the authors selected for the study. Nevertheless, the data provided a tremendous help to the authors to lay a path to unearth many outcomes, which may be potential solutions to target group (companies looking for exact profile of Internet-buyer and her buying behavior related to different products/services).

III. Main Issue of the Paper

To understand the position of Indian Internet users in different stages of consumer behavior in buying different categories (High, Medium, Low) of products and Services over Internet.

IV. Methodology

The authors selected Bangalore, the Silicon Valley of India, as the reach location as it houses the population who has high technological quotient, computer and Internet knowledge. The study mainly focused on collecting primary data from the selected samples (N=570) from Bangalore. The probability and non-probability sampling techniques viz. quota sampling (Internet Users), Cluster sampling

(Bangalore), Stratified Random sampling (selected respondents represent different demographics of the population), Judgment sampling were used to provide fairly accurate outcomes for the study. Structured questionnaire comprised of 6 divisions. 3 divisions dedicated for products and 3 for services. The authors mainly used 5 point Likert Scale to gauge the willingness of the Internet users to buy over Internet. The questions in each division had been divided in to three major areas viz. Information, Evaluation and Purchase. The crux of the research is to identify which stage the Indian Internet users in buying different products/services online. The authors used Principle Component Factor Analysis to validate the primary data. 18 factors had been selected for analysis. Necessary tests had been conducted and outcomes were satisfactory and significant related to sphericity and sample adequacy (Refer Annexure). After the application of Rotated Component Matrix, 18 factors had been merged to 5 major components.

V. Results

In the 1st Component, the results showed more favorable towards utilization of services over Internet. Indian Internet users show more willingness to evaluate medium and high involvement services over Internet. The 2nd Component unearthed the psyche of Indian Internet users who shown more willingness in buying high involvement and low involvement products online. This behavior is very encouraging as the Indian Internet users intend to buy products as the Internet might provide a different experience (in terms of cost and product/model/feature comparison) than offline purchase. The 3rd Component and 4th Component portrayed that the Indian Internet users shown more interest in collecting information about low involvement products and services online. This vividly shows the Indian Internet users intention of collecting information about low involvement products in order to make offline purchase. This offers the competitive edge in having right information to buy right product to attain better experience. The 5th Component proved the Internet users' intention to collect information on medium and high involvement products online. It is evident from the study that the Internet users were agreed to the fact they intend to use Internet for evaluating services, buying products and collecting information, primarily about products.

VI. Suggestions to the Corporate World

The study is novel and unique nature of understanding the urge of Indian Internet users to use Internet to buy different products and services. The authors defined the problem for identifying the stages of internet users in consumer buying process in which it was identified that the users intend to evaluate services online, followed by buying products. Hence, Service bags the higher rating among the internet users with reference to online utilization. It is already proved that the Indian Railways subsidiary IRCTC has started

offering e-tickets over Internet which received overwhelming response. Also, banking, travel and tourism industry are the heavy spenders on online initiatives which received welcome response from the society. The corporate ought to take cue from the study, mainly focusing on right information for evaluation which instills trust among the Internet users. This would act as reinforcement for future consideration of internet purchase. The categorization of products and services and the stages of internet users would definitely act as eye openers. The companies sell products could focus more on providing right information online would ensure the purchase offline. Even, they could provide comparative analysis of competitors' products which would create a trust. The study clearly revealed the stages of the Indian Internet users in showing interest in buying different products and services online. The companies can device strategies accordingly.

VII. Scope for Further Study

This study conducted in Bangalore, India and could be conducted across the world with necessary modifications suitable to local culture and economic conditions. Moreover, the awareness and acceptance of Internet among the local population score more marks. This study would reveal many interesting outcomes and would solve the problem of understanding the psyche of Internet users in order to sell right products/services.

To conclude, the authors made an attempt to gauge the buying behavior of Indian Internet users towards buying different products and services through empirical study. The study revealed the services scored more marks than products. The internet users reached the stage of evaluating information online, which clearly shows the consumers believe the information available online are reliable. The scenario would change in future, where in, most of the internet users buy online to acquire right product/service to have better satisfaction and experience. This is the primary responsibility of the corporate world to take initiation, instill trust and acquire consumers online for their survival and success.

Abstract: As a result of the emergence of E-Commerce, e-marketing mix has been widely adopted by most businesses and companies. Currently, the tools of e-marketing mix are provided by the company web site so that the customers can decide whether the company portfolio of products and/or services suits their needs. If we can understand the psychological factors of customer behavior, businesses can know which customers are suitable. This paper presents the relationship between e-marketing mix of particular businesses and psychological factors of customer behavior in order to provide an easier way for both businesses and customers to find their target needs.

Keywords: Consumer Psychological factors, E-Marketing Mix, Internet Marketing

I. Introduction

As a result of the increased utility and bandwidth of Internet communications, the usage of web browsers has increased dramatically. Many users make use of browsers to get different types of information in different media such as text, graphic, animation, audio and video. Hundreds of businesses have exploited this great opportunity to create their own web sites that allow customers to purchase products directly from their browsers. Most commercial companies believe that they can generate a large amount of profit from the web.

Although many web businesses terminated operations or ceased to exist from April 2000 to December 2001, those e-retailers developed and introduced new internet-based marketing techniques (e-marketing), which have been widely considered in the formation of current marketing strategy.

Kalyanam & McIntyre (2002) identified more than 30 e-marketing tools in their review of: popular business press, research reports from industry, textbooks and the academic literature for e-marketing tools.

Before the electronic age, E. Jerome McCarthy (1960) introduced the 4Ps (product, price, place and promotion) standardization of the marketing mix as a core unifying construct. Later on, van Waterschoot and Van den Bulte (1992) pointed out that the components of "communication" address "barriers to wanting", whereas the sales promotion

function addresses "barriers to acting". They observed that "triggers to customer action" seem necessary in certain situations to induce the exchange. Hence, they termed sales promotion a "situational" function. On the basis of these distinctions, the marketing mix can be reclassified into the "basic mix" and the "situational mix". In addition, since the sales promotion mix can apply across the full spectrum of the basic mix (the rest of the traditional marketing mix), it is considered by van Waterschoot and Van den Bulte to be overlapping. The concepts developed by van Waterschoot and Van den Bulte (1992) can be summarized in the form of the following axioms:

Axiom 1: Marketing functions are the appropriate properties for the classification of marketing tools.

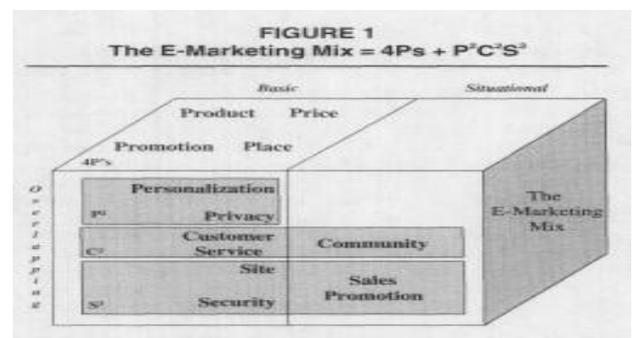

Axiom 2: Some functions are essential and others are situational in nature.

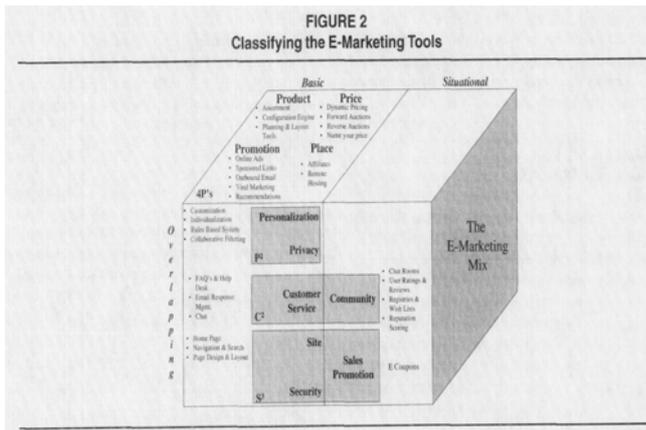

Axiom 3: Some functions have a moderating effect across other marketing functions and are called overlapping functions.

Axiom 4: Functions are accomplished by marketing tools.

Axiom 5: A tool can serve one or several functions.

Based on the above axioms, Kalyanam & McIntyre (2002) created a new E-marketing mix model as illustrated in Figure 1 and mapped the marketing tools and the terms in Table 1 to the new e-marketing mix model, as illustrated in Figure 2.

In the following tables (Tables 1A – 1D), four individual business web sites (randomly chosen) from each of the four types of businesses based on Sam K. M. & Chatwin C. R. (2005): Apparel, I.T. item, Jewellery and Car, are analyzed in terms of the e-marketing mix model from Kalyanam & McIntyre (2002).

According to the above comparisons, there are different e-marketing strategies used by different business web sites in a particular industry. Why are there different e-marketing strategies from different business web sites in a particular industry? It is due to the fact that their target customers are different. Figure 3 illustrates different requirements from customers and businesses:

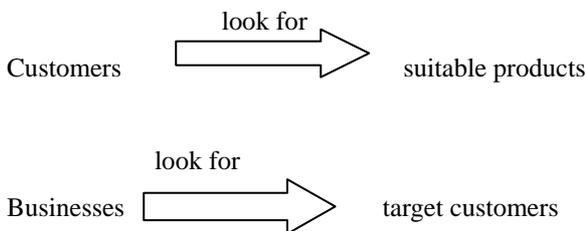

Figure 3: Different Requirements from Customers and Businesses

Services can be provided such that businesses can get only those target customers (relating to the e-marketing mix of a particular business) and at the same time customers can get their preferable products (relating to the psychological factors of customers). In this way, it is beneficial to both parties.

II. Psychological Factors of Customer Behavior

Based on the psychological factors from Sam K. M. & Chatwin C. R. (2005) of customer behavior, the following facts have been discovered:

1. Consumers have different psychological factors for different types of products
2. In addition to the psychological factors specific to product, it is necessary to consider the psychological factors specific to the web site (online business) as a result of the emergence of e-marketing.

According to (Retailers' Search Engines Boost Online Sales,

http://www.realseo.com/archives/cat_search_engines_news.html), there is a 40% increase in the total number of consumers who visited a retail website's search engine made an online purchase from 2003 to 2004. It shows that search engine has become more important. Online customers can enter search criteria, namely; budget, product features, brand name, portability and quality rating, to refine the product list displayed on screen (ref: http://www.spec-direct.com/Case_Studies.asp?page_id=17). Each of the above criteria is associated with a particular psychological factor of customer behaviour (Point 1 above) as shown in figure 4:

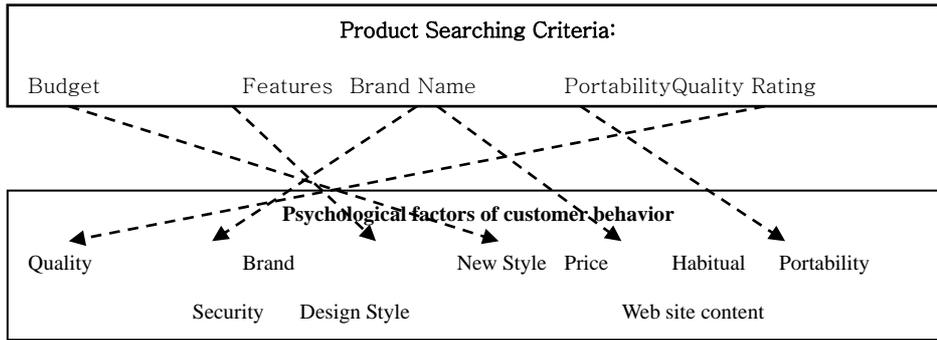

Figure 4: Relationship between Product searching criteria and customer psychological factors

III. E-Marketing Mix

E-marketing mix, when compared with the traditional marketing mix, should be designed in such a way that can reflect the current situation of E-commerce. The e-marketing

mix model designed by Kirithi Kalyanam & Shelby McIntyre (2002) can fully reflect the current situation by identifying basic and overlapping functions and mapping e-marketing tools to those functions. By integrating this e-marketing mix model with the diagram shown above, the following result is achieved, see figure 5:

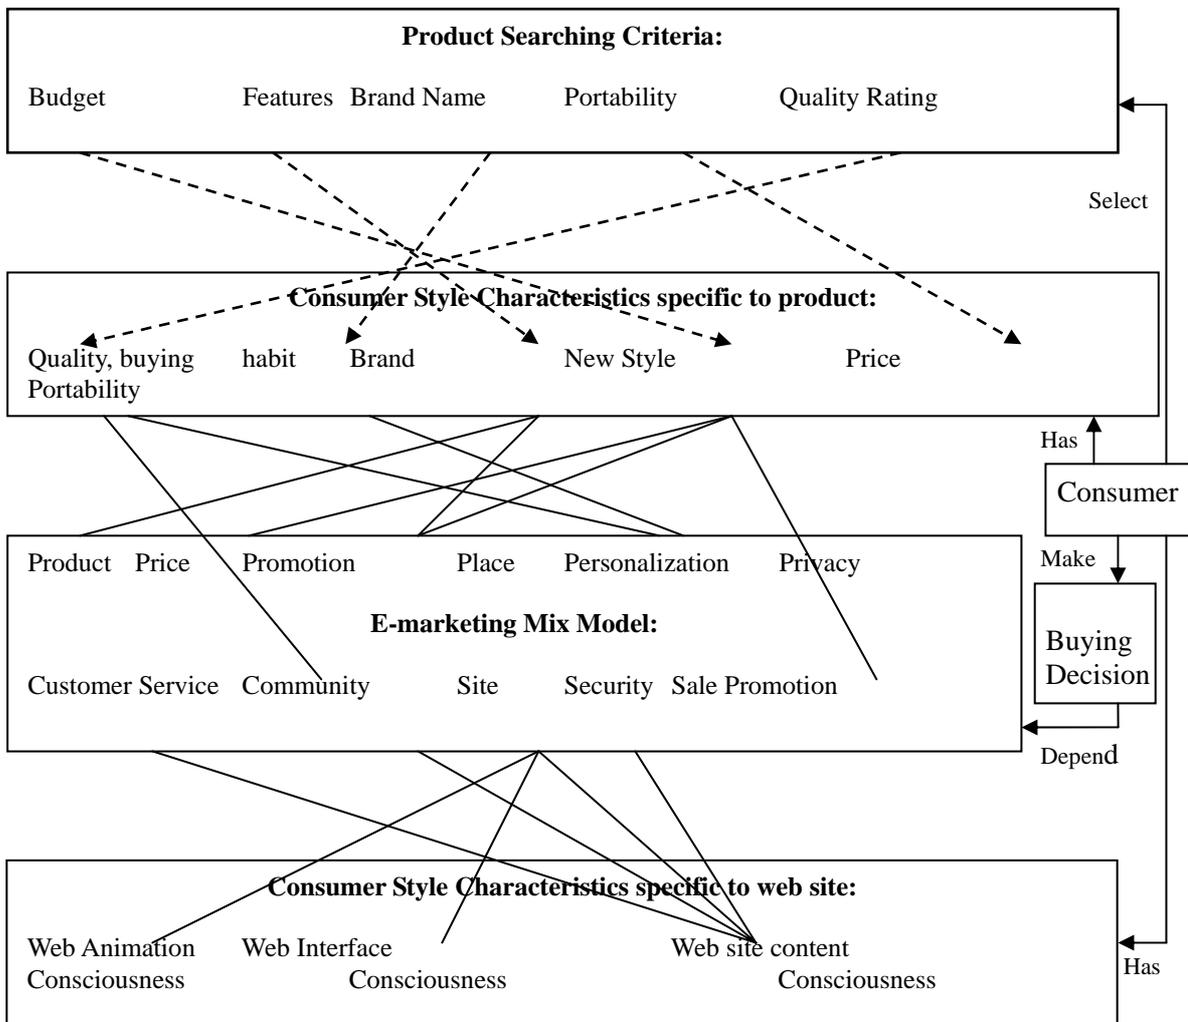

Figure 5: Relationship between E-marketing mix model and Internet Consumers' Decision-Making Styles

Relationship of E-marketing mix model & psychological factors specific to products

If customers demand new style products, they may prefer those web sites, which can offer customisation, allowing them to tailor-make their own products. In addition, they may also want those online businesses which frequently promote some new items on their web sites.

If the customers demand is for low price products, they may select those online businesses which can provide lower prices or e-coupon, or advertise sales promotions on their web sites.

If customers are getting used to particular brands or products, they may prefer those online businesses which can provide personalized services to them so that updated information about particular brands can be obtained easily.

If customers have a habit of buying the same high-quality products, they will be concerned about the user rating of these products and also the personalized services about the history of their purchasing records.

Relationship of E-marketing mix model & psychological factors specific to web site

If customers are annoyed by the effect of web animation and prefer a good design interface, only those web sites with less animation effects and a good user interface (e.g. list box) will be suitable for them.

If consumers make a high demand on the services (including searching, communication, security) and product information, those web sites which can provide: a strong searching mechanism, a good communication tool such as email facility, chat-room service, and a high security standard such as 128-bit encryption standard and detailed

product features - will be most suitable for them.

IV. Conclusion

By integrating the E-marketing mix model of a particular business with psychological factors of customer behavior, the target customers can easily be found. If only the target customers are allowed to enter the business web site and those visitors who are not their target customers are filtered out, it can reduce the workload on the business web site. Furthermore, when more target customers are directed to a particular business web site, the business can generate more profits. One of the future enhancements of this paper is to develop an intelligent agent to provide convenience to customers as well as attracting more potential customers to business web sites based on the corresponding e-marketing mix of particular business.

Abstract: The internet and its various applications have been found to be very effective in delivering marketing functions in general and advertising in particular. This paper presents an integrated approach about the way different internet marketing strategies can be used for advertising the degrees of an educational institution using a case study method. This is an important goal for educational institutions in Australia. The paper culminates with a recommendation and a discussion about the ways in which this goal can be accomplished. Challenges associated with the implementation of this integration, including spam, internet market research and target market identification are also discussed.

Keywords: Internet marketing, advertising

I. Introduction

New media technologies, such as the Internet and the World Wide Web (WWW) have been found to be the most important factor in the future of marketing in general and advertising in particular [1,21,38]. The WWW has the potential to facilitate the consumer relationship marketing and the communication between producers and consumers all the way from acquisition to retention. This has had fundamental implications for marketing and advertising, because audiences can now be 'atomized' rather than just fragmented [19,21].

Different products can be marketed and sold via the WWW [4,6] and university degrees are just one type of product that can be advertised online via the WWW or other internet functions. The goal of the educational institution is to increase student numbers, including local and international full-fee paying students. This is important for several reasons. One of these reasons is that student fees constitute an important source of revenue for the educational institution. In addition, they also contribute to the economic growth of the state as onshore students are expected to generate demand for other goods and services in the state economy and therefore contributing to its growth.

On the other hand, using the internet to advertise university degrees is likely to reduce the advertising costs considerably, while reaching a wider target audience [24,25].

Internet features like ubiquity, global reach, standardization, richness, interactivity, information density, and personalisation and customisation, if exploited properly have the potential to make online advertising of degrees effective and efficient [25].

James et al. (1999) indicate that in Australia students have limited knowledge to decide what courses to study, prior graduate satisfaction, career prospects, teaching and learning approaches, and teaching quality [22]. In addition, research also shows that students base their choice on the reputation of the degree rather than the overall reputation of the university which is offering it. Other important factors include degree recognition, and value for money [18]. This suggests that relevant information appears to be one of the important critical variables influencing student choices. Therefore, when advertising a degree, information concerning the factors above should be provided to prospective applicants in one way or another. Marketing of degrees to international students is particularly important given their impact to Australia's economy. For example, in 2000 Australian education providers generated of AUD3.7 billion from overseas students [14]. In addition, research shows that over half of university students, use the internet to facilitate choosing overseas education [18]. Therefore, internet marketing of tertiary degrees is important.

The aim of this paper is to address the question of how internet marketing can help an educational institution improve marketing and advertising its degrees. The paper is structured as follows. In section two, three different alternatives addressing the goal are identified and explained. A justified recommendation is presented in section three. Section four explains the ways in which the recommendation will help accomplish the goal. Challenges associated with the recommendation are identified and discussed in section five. Finally, section six summarises the paper.

II. A Review of Internet Marketing Strategies Used By Educational Institutions

The objective of this section is to present three different ways to address the goal presented in the previous section. The internet marketing literature suggests that there are a variety of possible options that can be used, such as direct email, search engine registration, banner, pop-up and rich media advertising, public relations, promotions, cross-media advertising, etc [13,25,29]. However, due to space

constraints only the first three options which seem to be more popular will be considered in detail.

Direct eMail. Increasingly, direct e-mail is being used as an effective, inexpensive and easy way to target potential customers [12,13,23]. As potential students are essentially the potential customers of educational institutions, personalised direct email can also be used to target these students in an ongoing manner with specific and relevant information concerning the degree they might wish to study. Direct e-mail campaigns can either be carried out in-house or outsourced to specialised email marketing organisations (e.g. www.siebel.com). If they are carried out in-house considerations should be made whether the educational institution has the capability, in terms of staff and network infrastructure, to respond to the anticipated volume of emails or follow-up queries. Failure to provide adequate prompt and personalised replies may have serious consequences and lead to dissatisfied students, who will consequently not only lose trust and commitment [18] but also pass on their negative experience and impressions to others via viral marketing [8,24,25,35]. At best the education institution should engage in a continuous email dialogue with prospective students until their degree-related queries have been satisfied. This dialogue will help build a degree brand [20]. Providing query email addresses and giving email queries high priority is important as it establishes trust in prospective students. This is likely to improve the response rate of potential students to email marketing campaigns [13].

However, researchers estimate that by 2005 there will be as many as 35 billion commercial emails sent every day [12]. This suggests that email marketing is likely to become hyper-competitive, and may also be used by competing education providers who also wish to market their own degrees. Therefore, it is important for email marketing campaigns to be designed in such a way that they remain visible and distinct to the potential students.

Search engine registration. Thelwall (2000) provides evidence that web users use search engines as part of their strategies to find information in the Internet. Specifically, usability studies show that “slightly more than half of all users are search-dominant...” (Nielsen, 2000, p. 224). This is consistent with a study by Gomes and Murphy (2003) who found that nearly half of the students involved in the study used search engines to locate the web sites of tertiary education providers. Nevertheless, evidence indicates that there is a significant number of web sites that are not registered with the major search engines [44]. Thelwall (2000) explains that this is attributed to the misunderstanding of the importance of search engines by web site designers and by the lack of knowledge of how to get web sites registered and remain registered. As a consequence, it can be concluded that the designers of the web pages of education providers featuring individual degrees should make these pages “search engine-friendly” (Thelwall, 2000, p. 151) and register its individual degree web pages with popular search engines (e.g. Google, Yahoo,

Altavista, etc.) [31,32]. Typically, this is done by indexing and HTML META tag inclusion of key words in the HTML pages featuring degree offerings.

Banner, Pop-up and Rich Media Advertising. Banner ads represent rectangular promotional areas of a web site which display a promotional or advertising message using eye-catching animated images [13,25]. When clicked on, a banner ad redirects a visitor to the web site which it is advertising. While banner ads are embedded on a host web site, pop-up ads appear on the screen as separate windows without a user having to call them directly. Rich-media ads use Flash, DHTML, Java, and streaming video and/or audio simulating television [25]. These three means of advertising can be used to advertise university degrees, however, there are a few facts that have to be considered.

The web site hosting the banners should be carefully chosen depending on whether it is popular with potential students. In addition, congruity considerations should be made how the attitudes of potential students towards a degree are affected when they view banners on web site hosts. Research shows that if a banner ad is hosted on a web site, the ad should be congruent with its host, alternatively the attitudes of the potential consumers (or students) towards both the web site and the products advertised by the banner ad may be harmed [30] which is consistent with the cognitive consistency theory [15].

In addition, banner advertising can be quite expensive and its cost (e.g. click-through rates, cost per action, etc.) depends on the popularity of the host as well as the time of the day when the banner ad is displayed and when most traffic is expected. Besides, in an effort to generate additional revenue, some hosting web sites overuse banners, therefore, individual banners are likely to become invisible and obscure and consequently lose some or all of their impact. Research results concerning the effectiveness of banner ads are mixed. Some studies show an increase in consumer loyalty ranging from 5 to 50% for different products [16]. Other studies show that the click-through rates for banner ads are around 0.5% and this is continually decreasing [43] and this is also substantiated by [26]. However, even if banner ads may never be clicked, they may have an impact on the attitude of the a visitor, but most importantly, they help with degree branding [21].

Pop-ups while grabbing the attention of visitors, they can be also irritating and therefore have negative effects due to their intrusive nature [13]. Rich media ads can be effective. DoubleClick, reports that approximately 28% of online advertising included some form of rich media in their web ads during the first quarter of 2003. With rich media presenting opportunities to be interactive, users in general, and potential university students in particular, can be forced to interact with the ad in some fashion [25]. As a matter of fact, rich media ads are often used to replace static banner ads as research indicates that the former has been found to be more effective than the latter in gaining consumer attention [9]. However, in order for rich media ads to be

effective, fast internet connections, such as broadband are required.

Having examined the three alternatives above, we believe that they should be viewed as complementary rather than as mutually exclusive. Therefore, educational institutions should adopt an integrated approach using at least two of the alternatives explained above. At best, all three should be used in conjunction with each other [19,38]. However, any steps towards implementing combinations of the above should be geared towards acceptable levels of Return on Investment (ROI) as all of the options above require varying degrees of investment outlays.

For example, the direct email alternative may be implemented in-house or it may be outsourced. In both cases the educational institution may incur primary costs to purchase the list of names to which emails will be sent [25]. The direct email alternative, if implemented in-house will require additional resources, including staff hours and probably network infrastructure upgrades. It may also require the establishment of email reply policies and the designation of dedicated counsellors to provide advice to potential students [6,25]. This is likely to be highly effective as it provides the greatest degree of personalisation and customisation to direct email, which research shows that potential students are likely to respond to positively [5,25]. On the other hand, outsourcing direct email will increase the cost incurred by the education institution in terms of fees payable to the contracted third party direct email service providers, but yet, unless these liaise strongly with the university counsellors, the extent of advice personalisation and customisation may be questionable. This is likely to undermine direct email benefits.

Search engine registration is probably the most inexpensive alternative and should therefore be carried out under any circumstances. Generally most popular search engines do not require payment for registration, although some may offer additional services and charge for them [13,25,40,45]. The only cost incurred with this alternative consists of costs associated with the additional development effort to make these pages search engine friendly. Web site usability studies show that more than half of all web users are search dominant, one fifth are link-dominant, where as the rest exhibits mixed behaviour [31] which supports the recommendation further. In addition, search engines have a huge user base both locally and internationally. Therefore there is no reason for search engine registration not to be carried out [44].

Banner ads are generally considered effective in increasing reach as they are likely to increase the target audience considerably. However, careful consideration should be made when choosing the websites to host these ads. For example, appropriate sites could be high school websites, or web sites of national and international tertiary admission centres, etc. As suggested earlier, a lack of congruity between the banner ads the websites hosting them can adversely affect both [21]. Cultural considerations of the audience likely to receive the ads should also be taken into

consideration [35]. Clearly suitable payment schemes should be considered and organised between the education institution and the websites hosting the banner ads. Pop-up ads are probably a poor choice and may undermine the effect of the message they are trying to advertise due to their intrusive nature. Further, using rich media ads may not be effective at this stage due to the requirement of appropriate internet infrastructure, such as broadband. Currently, Australia is still lagging almost 2 years behind other developed western nations with respect to residential broadband penetration and adoption, suggesting that the placement of rich media in websites targeting an Australian audience may be premature for the time being [37].

In summary, a detailed cost-benefit analysis should be carried out. In addition, a multi-phased approach should be undertaken, whereby the above options are implemented as increments, rather than all together in a big-bang fashion [11]. The benefit of this approach is that the education institution can monitor and therefore control costs and continuously compare them against the generated outcomes. Following this approach, will also allow undertaking responsive adjustments when results are not satisfactory.

III. The Benefits of an Integrated Approach

The benefits of an integrated approach can be actualised in three ways [25]. First, using the internet as a medium, the internet marketing via direct email, search engine registration and banner ads increases significantly the number of potential students that can be reached. Second, the internet has the potential to increase the richness of the content that can be provided without sacrificing interactivity while maintaining adequate levels of personalisation and customisation. Third, the internet has greatly increased the information intensity which can be provided to potential students.

With direct emails, educational institutions can establish e-mail policies which can include training employees and using standards for email response times and formats. Prompt and personalised email responses constitute good customer/student service [33]. Continuous email communication with prospective students will help institutions create a degree brand [20]. After being de-identified to protect privacy, email communications with potential students can be systematically stored in databases and data warehouses for further analysis [34]. Data mining, which consists of various analytical techniques to identify patterns in databases or data warehouses, can then be used to create profiles, behavioural patterns, and demographics for potential students [2]. These are useful because they help education institutions understand the requirements of prospective students and consequently be proactive in satisfying these requirements [39].

The educational institution can even go the extra mile and establish a Prospective Student Relationship Management System (PSRM), which can be modelled after customer relationship management (CRM) systems. A

PSRM would support the institutions efforts to be student-centric and therefore treat potential students as individuals rather than use one-size-fits-all strategies to treat them equally as parts of a market segment [7,42]. While evidence suggests that using CRM-like systems can be effective, their initial introduction requires the establishing of a positive and fluid institutional culture [35,42].

The obvious benefits of search engine registration is that registered degrees are likely to be listed in the 'top-ten' hit list when prospective students carry out searches using search engines. Being included in the 'top-ten hit list' is important because nowadays the market for tertiary degree is highly competitive. Therefore, being part of a 'top-ten' hit list is a convenient way to stand out from the crowd. Essentially, search engine registration is the equivalent of placing an entry in a phone or yellow pages directory: it increases the chances of offered degrees to be easily located [13].

Clearly, the first benefit that is provided by banner ads is additional exposure of degrees to potential students. As discussed in the previous section, the other benefit of banner ads (even if they are never clicked on) is that the help with degree branding [21]. Clearly, if banner ads are clicked on, they have aroused the visitor's interest. Consequently, the next step is to satisfy the prospective student's queries. If the page the visitor is taken to upon clicking the banner ad, does not provide the required information, the effectiveness of the banner ad is likely to be quickly undermined. Consequently, items like, Frequently Asked Questions (FAQs), links to real-time prospective student service chat systems, automated response systems, site maps, and email addresses should be clearly identifiable in prominent locations or even elegantly included as hot spots in the banner ad [25]. If these are properly designed in the banner ads or pages the banner ads redirect a visitor, cost savings are likely to be realised, as prospective students are likely to find the required information from webpage pages without needing to contact designated counsellors.

IV. Challenges in Implementing an Integrated Internet Marketing Approach

One of the important aspects that the educational design of an online unit needs to take into consideration includes the resources that are provided to the learners [20].

Although the challenges faced by educational institutions are those inherited by internet marketers in other industry, the industry specific characteristics present them with challenges other than those previously experienced or identified by other marketers. Three main challenges are considered, namely, spam, internet market research, and identification of the target market.

SPAM. One important issue that might hinder the effectiveness of direct email marketing is spam, which is unsolicited commercial email [10]. According to Laudon & Traver (2004) 45% of all internet mail in the US was spam.

Gervois (2004) suggests that two thirds of the email received in most households in Australia and New Zealand is spam. The implication of this is that email sent by an educational institution to potential students is likely to be unsolicited and therefore runs the risk of becoming invisible.

Although anti-spam legislation came recently into effect in Australia the amount of marketing email messages continues to grow [3,17]. Although the Australian Communications Authority is making serious attempt to control spammers, email users are increasingly becoming comfortable with opt-in communications [17].

In this context education institutions should seriously consider two important issues. Firstly, they have to ensure that they do not violate the Spam Act. In order to achieve this three basic rules should be satisfied: a) messages may not be sent without the recipient's prior implied or express consent; b) messages should include accurate sender information; and c) messages should allow receivers to opt-out or unsubscribe from future messaging [3,36,47]. Secondly, upon obtaining permission from potential students for degree-related advertising emails, the education institutions, should be creative in their design to sent distinct and visible messages.

Market research. The rapid diffusion of computers, digital and telecommunication infrastructures allows marketers and individual potential consumers to interact in an individualised manner [27]. This is applicable to educational institutions and their potential students. In order to increase the effectiveness of the direct email and banner advertising educational institutions should conduct market research, which would provide insights into what sort of information need to be included in an email, the best ways to design effective ad banners, as well as to present degree related information to potential students. This is important because it helps the education institution identify the requirements to satisfy its prospective students' needs [39].

While this information can certainly be gathered using traditional market research (e.g. surveys, interviews, etc.), internet-based market research (e.g. online surveys, online focus groups, etc.) constitutes another option and should be seriously considered [13,46]. For example, internet market research surveys exhibit several desirable features, including ease of use and low cost, while the response quality and the response rate rapidly tend to be at least equal if not superior to the traditional forms of survey. According to the results of the study conducted by Wilson and Laskey (2003) internet market research is effective in reaching teenagers who are likely to be more difficult to access via traditional means (e.g. phone and postal surveys) and who are potential respondents for educational institutions [46]. However, internet usage patterns are likely to be different among different users, it is therefore also possible for the collected data not to be representative of the population. Consequently, internet based research should be used as a supporting method to traditional market research rather than as a substituting alternative [46].

Target Market. Another important consideration is the identification of the target market which constitutes an important strategic decision for an education institution in particular [28]. This is important because it helps the institution position itself in the eyes of its target market which will eventually affect the perceptions of the potential students about the degrees that are offered [41]. In the case of educational institutions which need to advertise their degrees, the target market would clearly include year 11 and 12 high school students, tertiary transfers, mature-age and international students. If direct email is used, individuals and their email addresses need to be identified first before they can be contacted. This identification is associated with privacy concerns [25].

V. Conclusion

The goal of this paper was to propose ways in which internet marketing technologies can be used to advertise tertiary degrees by education institutions. The goal of the paper and its motivation were explained in section one. Three alternative ways to address this goal were discussed in section two. These alternatives include direct email, search engine registration, and banner, pop-up and rich media advertising. The recommendation that these three methods are complementary and should therefore be used in conjunction with each other is presented in section three. The benefits that the proposed recommendation is likely to deliver to the education institution are covered in section four. Finally section five discusses some challenges that likely to be encountered if the recommendation is implemented.

Abstract: A fashion web site provides consumers with the opportunity to search for information. It also enables them to shop unconstrained by time or location. This research evaluates the performance of the fashion web sites in New Zealand and examines how the web sites can improve. Forty New Zealand fashion web sites were examined using the web site evaluation model tailored for fashion sites. The results show that the majority of New Zealand fashion web sites are informational rather than transactional. Fashion web sites should focus on how to improve their web site quality and web site content in order to attract more potential consumers.

Keywords: Internet Marketing & Advertising, E-commerce.

I. Introduction

The number of Internet users is growing rapidly throughout the world. Growth in electronic commerce is explosive. Electronic commerce has impacts on how business is conducted and offers the possibility of extending or reinventing existing business models based on the openness and connectivity of the Internet [16]. Apparel products have become the third largest retail sales category on the Internet [5]. Many consumers are lured by the simplicity of online shopping experience from just browsing for fashion information to buying fashion products. New Zealand fashion organisations realise the importance of the Internet and that improvements in their web site are necessary to ensure they stay solvent. The Internet allows fashion organisations to establish themselves, promote their brand name and products. Fashion web sites need to attract those consumers most likely to buy in order to cover the costs of e-commerce and make a profit. Although some research on Internet fashion shopping behaviour has emerged, little attention has been devoted specifically to New Zealand fashion web sites. The purposes of this study are to evaluate the performance of New Zealand fashion web sites and to examine web site quality.

II. Literature Review

Not surprisingly, the number of Internet users around the

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 425 - 427.

world is growing tremendously. The worldwide number of Internet users are projected an increase to 1.46 billion in 2007 [4]. Current figures indicate that the New Zealand Internet population has reached 2.34 million and this figure is anticipated to continue to increase [4]. New Zealand has a small domestic market and a high degree of technology adoption when compared to other developed countries [17].

Academic research indicated that the consumer is more inclined to look beyond traditional retail venues for shopping alternatives [2]. The New Zealand Official Yearbook (cited in [10]) states that 79% of New Zealand businesses have Internet access, which is higher than averages found in comparable Organisation for Economic Co-operation and Development countries such as Australia and Canada. Nearly every company web site in New Zealand provides lists of products and services and most companies in New Zealand prefer to use the Internet as a means of providing information to customers and suppliers [15].

The New Zealand online fashion industry, although still in its infancy, is very much alive and will grow rapidly over the next few years [9]. This growth will result from the combination of an increasingly large number of online consumers and the growing number of fashion web sites. In evaluating the Internet as a fashion retail channel, a number of advantages added to the retailer have been identified by different scholars. These include direct communication with customers, access to a wider audience, cost savings and product selling available to consumers all the time [8] [6] [7] [13]. Additional advantages added to the online consumers include in-depth product information, two-way communication, demonstration of products in real time and up-to-date online information [14] [13].

A survey by Greenfield Online found that 58 percent of respondents shopped online to avoid crowded offline stores and 57 said Internet shopping saves time [1]. Availability of products/services, as in access to variety, the ability to scan more products and compare prices are significant reasons for shopping online [2].

III. Research Methodology

The main purpose of this research is to evaluate the performance of New Zealand fashion web sites and thereby to gain an understanding of how New Zealand fashion web sites can improve. As online content is expanding, there is an increasing need to control and manage the quality of the web

site content. Fashion web sites continue to grow in complexity, placing additional challenges for web designers. For fashion organisations that want to be online, meeting customer expectations is critical. Customers require timely, accurate information. Content analysis was used to assess and rank fashion web sites capabilities against the proposed model that serves as a benchmark. In this study, web site content analysis is carried out to measure the effectiveness of selected New Zealand fashion web sites. In order to gather appropriate dimensions and related attributes, we developed a tailored web site evaluation model to specifically analyse New Zealand fashion web sites adopting Ian Hersey's model (cited in [18]). Table 1 listed the categories and their related elements that are used to evaluate the fashion sites. They are in four categories namely Information, Transaction Service, Trust, and Non-Functional requirements. Table 1 has also listed the related elements that will be tested for appearance.

Information Category	Transaction Service Category	Trust Category	Non-Functional Requirements Category
Company Information	Negotiation	Legal Disclaimer	Aesthetic effect
Consumer Information	Payment	Privacy statement	Ease of use
Product Information	Order	Security	Innovation
	Delivery		Community
	After-sale service		
	Help		

Table 1: Categories & Elements of the Tailored Web Site Evaluation Model

IV. Results

Content analysis was conducted based on the tailored web site evaluation model. The sample fashion sites were evaluated by assigning a 0 or 1 score based on the presence or absence of the elements at the web site. A "1" score is assigned if the element is present or "0" score is assigned if the element is absent at the site. Forty New Zealand fashion web sites were selected for content analysis. Table 2 below presents the scores of the top twelve New Zealand fashion web sites.

The average score of all the 40 fashion sites is 14.8 out of 25 (59%), the median total score is 17 out of 25 (68%). With a possible total score of 25, a score of at least 12.5 (i.e. 50%) represents the elements required in order to achieve a 'pass'. 60% of the sample web sites scored more than 50%. These figures reflect a moderately high adoption of elements in the tailored web site evaluation model by the sampled New Zealand fashion web sites. 58% of the sample web sites are positioned as full e-commerce capability sites. Some of the high scoring sites are large organisations and some of the low scoring sites are large organisations too. That is, there is no relationship between a good web site and the size of the

organisations.

Rank	NZ Fashion Web Site	I	TS	T	NF	Total
1	Canterbury of New Zealand	7	10	3	3	23
1	Thread	7	9	3	4	23
2	Beggs Clothing	7	10	3	2	22
2	Ezibuy NZ Ltd.	7	10	3	2	22
2	Pumpkin Patch	7	10	3	2	22
2	NZ Pacific Jewellery, Skincare & Clothing	7	10	3	2	22
2	Christies Jewellery	7	9	2	4	22
3	Line 7	6	10	3	2	21
4	Shirleys Shoes	6	10	2	2	20
4	Sunsational Swimwear	6	10	2	2	20
4	Susanna Bernard	5	10	3	2	20
5	Fashion Factory	6	10	1	2	19

Table 2: Top 5 Scored New Zealand fashion web sites

V. Discussion

The majority of New Zealand fashion web sites are informational rather than transactional. This is consistent with the literature that most companies in New Zealand prefer to use the Internet as a means of providing information to customers, rather than for online sales [15].

After examining the forty sample New Zealand fashion web sites, we found that 58% of the web sites are positioned as full e-commerce capability sites. This closely matches previous similar research done by Paynter, Satikit and Chung (cited in [12]). Content analysis results show that the overall performance of the sample fashion web sites in the information category is relatively high with an average total score of 72% in this category. The results support the view that fashion organisations are utilising the Internet mainly as a platform for information distribution or product promotion rather than electronic retailing. Almost all of the sample fashion web sites provide information on the company's background, physical address and contact details. This is not a surprising result since consumers want to know with whom they are dealing and this is especially important for new virtual fashion organisations solely operating on the Internet. A very similar result was found in research by Paynter et al. (2001), where 74% of New Zealand e-tailing sites provided informational rather than transactional capability. Three of the thirty e-tailing sites examined were fashion ones, namely Pumpkin Patch, Farmers and Ezibuy. The average total score of the three fashion web sites in their study is 71.2% and the average total score of all thirty e-tailing web sites in their study is 70.2%. The content analysis results from our tailored web site evaluation model reveals that the average total score of all the forty sample fashion sites is 59% and the median total score is 68% which closely matches with previous similar research. Although pleasing results were found in the information category, New Zealand fashion web sites need to be more concerned in the trust and non-functional requirements category. Given the low average score (39%) in the trust category, fashion web sites did poorly in addressing privacy, security and legal (disclaimer) issues. The majority of fashion web sites asked

consumers for their personal information, this is consistent with previous research by Chung (cited in [3]) that 80% of New Zealand fashion web sites collected personal data and only small numbers of fashion sites provided a privacy statement. Consumers want to be connected to the Internet for a unique experience and they expect an interactive linkage to the Internet [11]. With an average score of 47% in the non-functional requirements category, New Zealand fashion web sites did not perform very well in this category. Although all of the fashion web sites performed very well in the aesthetic effect and ease of use elements, only a few fashion web sites implement advanced innovative features, online community and have entertainment value.

VI. Conclusion

The use of the Internet for the glamorous fashion industry has generated great excitement because it allows up-to-the minute information delivery, allowing the industry to broaden its market. Content analysis of the web sites of 40 New Zealand fashion organisations revealed their information, transactional service, trust and non-functional requirements. Content analysis looks at the components of the web sites and how they are used by the organisations to enhance their business. The result implies that there is a moderately high adoption of elements in the tailored web site evaluation model by the sample New Zealand fashion web sites. There is no relationship between a good fashion web site and the size of an organisation as we found in the results of content analysis. Fashion organisations are utilising the Internet mainly as a platform for information distribution or product promotion rather than electronic retailing.

Competitive Strategies for On-Line Advertisement-Place Auction

Zhang E

Shanghai University of Finance and Economics, Shanghai, China, 200433

Email: eezhangee@hotmail.com

Abstract: For the online problem of Internet Search Engines' Keyword Advertisement-place auction, two online models are present in this paper. The number of the auction phases is known or unknown beforehand respectively in the two models. For the first model we propose the Multi-Level of Accepted Price Strategy (abbr. MLAP) and prove it to be $O(\Phi^{1/4})$ -competitive, where Φ is the ratio of the highest bid to the lowest one in the auction. For the second model a strategy similar to the first one (abbr. MLAP1) is put forward and proved to be $(2\sqrt{\Phi} - 1)$ -competitive. Furthermore, the experimental results show that in both models the experimental ratios between what the optimal strategy and the online strategies gain are much better than the theoretical ones, indicating that the two strategies perform much better in practice than in theory. In practice, these strategies may help to realize the automatic auction of heterogeneous objects that have similar traits to advertisement-places.

Keywords: Advertisement-Place Auction; Online Strategy; Competitive Ratio.

I. Introduction

Since 1993, the advertisement-place auction has brought Chinese CCTV great revenue each year. On Nov. 18, 2004, it obtained a revenue of 5.482 billion yuan by auctioning some golden period advertisement-places of year 2005. Recently many Internet Content Providers (Abbr. ICP) adopt to price their advertisement-place by auction gradually [1]. In an auction, the highest bid wins the first advertisement-place, the second highest bid wins the second place, and so on. This is a kind of heterogeneous object auction in which each bidder demands one unit of object.

In benchmark auction model, the auctioneer auctions one object and each bidder demands one. The auctioneer designs an auction mechanism to maximize his revenue. In the online model, however, we use the competitive ratio to gauge the efficiency of an online strategy or mechanism. The competitive ratio is equals to the revenue

obtained by the optimal offline strategy to that by the online strategy [2].

There are lots of literature on online auction. Ziv Bar-Yossef et al. [3] presented an online model of digital object auction and studied the competitiveness of an online strategy in the condition of compatibility. They gave a $O(e^{\sqrt{\log \log h}})$ -competitive randomized strategy where h is the ratio between the highest and the lowest estimated values by bidders. Avrim Blum et al. [4] studied a digital multi-object online model. A randomized online learning strategy, called WM, was given and proved to be $O(e^{\sqrt{\log \log h}})$ -competitive. Both Ziv Bar-Yossef and Avrim Blum assumed that the estimated values of all the objects is in $[1, h]$ and each bidder can only select one of the l bids. That is, the bid is discrete. Thus, an interesting question is what the competitive ratio will be if a bid may be an arbitrary value in $[1, h]$. In this paper we will focus on the continuous case of bid price.

The rest of this paper is organized as follows. Section 2 discusses the first model where the auctioneer knows the number of auction phases at the beginning of the auction. An effective strategy is put out and proved to be $O(\Phi^{1/4})$ -competitive. The second model of unknowing the number of auction phases at the beginning is analyzed in section 3, and a competitive strategy is proposed. In section 4 some simulation results of the two strategies are presented. Finally, section 5 concludes this paper.

II. The Number of the Auction Phases Is Known Beforehand

II.1 Model Description

In this section we will discuss the case that the auctioneer know the number of bidders or the auction phases at the beginning. For expressional convenience, we call advertisement places heterogeneous objects. We first give the following four assumptions.

a) There are totally $m(\geq 2)$ heterogeneous objects. The price of each bid is in $[\underline{v}, \bar{v}]$ satisfying $\frac{\bar{v}}{\underline{v}} = \Phi$. The above information is the common knowledge.

b) The auctioneer obtains no value from a heterogeneous object if he keeps it. That is, the auctioneer gets a profit from the object only when it is sold successfully.

c) There are n bidders in the auction, only one of which arrives and bids at each phase. Denote by $\sigma = \{b_1, \dots, b_n\}$ the whole auction process where b_i is the bid of bidder i ($1 \leq i \leq n$). n is known by the auctioneer beforehand.

d) The auctioneer must decide whether to accept bid b_i on its arrival since b_i will leave the system if it has not been accepted before the arrival of the next bid.

By the assumption b), the auctioneer shall try to sell as many heterogeneous objects as possible, and for each object the price shall be as high as possible. The objective is to maximize the total revenue of accepted bids. More precisely, $\max \sum_{j=1}^m p_j$ where $p_j \in [\underline{v}, \bar{v}] \cup \{0\}$ is the accepted price for the j th heterogeneous object. $p_j = 0$ if the auctioneer keeps the j th object.

II.2 The Multi-Level of Accepted Price Strategy

According to the model given above, when a bid arrives, the auctioneer decides whether to accept the bid but not to assign an object to the bid immediately. The auctioneer also knows n and $[\underline{v}, \bar{v}]$ at the beginning of the auction. Thus, we give an effective strategy called Multi-Level of Accepted Price (Abbr. MLAP). The main idea of MLAP is to divide the bidding support $[\underline{v}, \bar{v}]$ into several sub-supports and accept a fixed number of bids in each sub-support.

MLAP is described as follows. Assume that there are w bids accepted at the beginning of the i th phase. If $n - i < m - w$, that is, the number of the rest phases is less than the number of acceptable bids, MLAP accepts all the bids arriving, including b_i . Otherwise, MLAP accepts x bids satisfying

$$\alpha \underline{v} \leq b_i < \sqrt{\phi \underline{v}}, \quad (1)$$

y bids satisfying

$$\sqrt{\phi \underline{v}} \leq b_i < \beta \underline{v}, \quad (2)$$

z bids satisfying

$$\beta \underline{v} \leq b_i < \phi \underline{v}, \quad (3)$$

and $(m - x - y - z)$ bids satisfying

$$b_i = \phi \underline{v} = \bar{v}, \quad (4)$$

respectively, where x, y, z $1 \leq \alpha < \sqrt{\Phi}$ and $\sqrt{\Phi} \leq \beta < \Phi$ are some positive constants determined later. The total number of accepted bids is at most m . In special, if b_i satisfies (4) and MLAP has accepted $(m - x - y - z)$ bids satisfying (4), then MLAP will accept b_i if only the total number of accepted bids is less than m . Similarly, if b_i satisfies (3) and MLAP has accepted $(m - x - y - z)$ bids satisfying (4) and z bids satisfying (3), then MLAP will accept b_i if only the total number of accepted bids is less than m . If b_i satisfies (2) and MLAP has accepted y

bids satisfying (2) but less than x bids satisfying (1), then MLAP will accept b_i and count the number of accepted bids by (1) plus 1.

II.3 Competitive Analysis

In this section we will analyze the competitiveness of MLAP. We first give the following theorem and the rest of this section is contributed to the proof of the theorem.

Theorem 1 *MLAP is $O(\Phi^{1/4})$ -competitive.*

Proof. We utilize the adversary strategy and worst case analysis to prove the theorem. Assume that an adversary always tries to design the worst bid input sequence to make MLAP behave worst, making the optimal strategy OPT obtain the most revenue and MLAP obtain the least. More precisely, the adversary will make MLAP accept the lowest bids as many as possible and OPT accept the highest bids as many as possible. For the whole auction process $\sigma = \{b_1, \dots, b_n\}$, denote by $M(\sigma)$ and $O(\sigma)$ the total revenues obtained by MLAP and OPT respectively. According to the construction of MLAP, there are four possible bid input worst cases.

Case 1. The highest bid in σ is less than $\alpha \underline{v}$. The adversary try to make MLAP accept the lowest bids as many as possible and to make OPT accept bids with value a little less than $\alpha \underline{v}$. In the first $n - m$ phases, all the bids equal $\alpha \underline{v} - \epsilon$ ($\epsilon \rightarrow 0^+$), and the rest m bids equal \underline{v} . OPT will accept m bids with value $\alpha \underline{v} - \epsilon$ but MLAP will accept the last m bids with value \underline{v} for all the bids do not satisfy the inequalities in the construction of MLAP. Thus, in this case the ratio of what OPT obtains to what MLAP obtains equals $\frac{O(\sigma)}{M(\sigma)} = \frac{m(\alpha \underline{v} - \epsilon)}{m \underline{v}} < \alpha$.

Case 2. The highest bid in σ is less than $\sqrt{\Phi} \underline{v}$. The adversary releases the first x bids with value $\alpha \underline{v}$, the following m bids with value $\sqrt{\Phi} \underline{v} - \epsilon$ and the last $n - x - m$ bids with value \underline{v} . MLAP will accept the first x bids and the last $m - x$ bids due to the construction of MLAP. However, OPT will accept the m bids with value $\sqrt{\Phi} \underline{v} - \epsilon$. Thus, in this case the ratio between what OPT and MLAP obtain equals $\frac{O(\sigma)}{M(\sigma)} = \frac{m(\sqrt{\Phi} \underline{v} - \epsilon)}{x \alpha \underline{v} + (m - x) \underline{v}} < \frac{m \sqrt{\Phi}}{x \alpha + m - x}$. Let $\frac{m \sqrt{\Phi}}{x \alpha + m - x} = \alpha$. We have that

$$x = \frac{(\sqrt{\Phi} - \alpha)m}{(\alpha - 1)\alpha}. \quad (5)$$

Thus, if the above equation holds the ratio between what OPT and MLAP obtain is at most α in this case.

Case 3. The highest bid in σ is less than $\beta \underline{v}$. The adversary releases the first x bids with value $\alpha \underline{v}$, the following y bids with value $\sqrt{\Phi} \underline{v}$ and then m bids with value $\beta \underline{v} - \epsilon$, and the last $n - x - y - m$ bids with value \underline{v} . MLAP will accept the first $x + y$ bids and the last

$m-x-y$ bids due to the construction of MLAP. However, OPT will accept the m bids with value $\beta\underline{v} - \epsilon$. Thus, in this case the ratio between what OPT and MLAP obtain equals $\frac{O(\sigma)}{M(\sigma)} = \frac{m(\beta\underline{v}-\epsilon)}{x\alpha\underline{v}+y\sqrt{\Phi}\underline{v}+(m-x-y)\underline{v}} < \frac{m\beta}{x\alpha+y\sqrt{\Phi}+m-x-y}$. Let $\alpha = \frac{m\beta}{x\alpha+y\sqrt{\Phi}+m-x-y}$. Together with equation (5), we have that

$$y = \frac{(\beta - \sqrt{\Phi})m}{(\sqrt{\Phi} - 1)\alpha}. \quad (6)$$

Thus, if equations (5,6) hold the ratio between what OPT and MLAP obtain is at most α in this case.

Case 4. The highest bid in σ is less than \bar{v} . The adversary releases the first x bids with value $\alpha\underline{v}$, the following y bids with value $\sqrt{\Phi}\underline{v}$ and z bids with value $\beta\underline{v}$, and then m bids with value $\bar{v} - \epsilon$, and the last $n-x-y-z-m$ bids with value \underline{v} . MLAP will accept the first $x+y+z$ bids and the last $m-x-y-z$ bids due to the construction of MLAP. However, OPT will accept the m bids with value $\bar{v} - \epsilon$. Thus, in this case the ratio between what OPT and MLAP obtain equals $\frac{O(\sigma)}{M(\sigma)} = \frac{m(\bar{v}-\epsilon)}{x\alpha\underline{v}+y\sqrt{\Phi}\underline{v}+z\beta\underline{v}+(m-x-y-z)\underline{v}} < \frac{m\Phi}{x\alpha+y\sqrt{\Phi}+\beta z+m-x-y}$. Let $\frac{m\Phi}{x\alpha+y\sqrt{\Phi}+\beta z+m-x-y} = \alpha$. Together with equations (5) and (6), we have that

$$z = \frac{(\Phi - \beta)m}{(\beta - 1)\alpha}. \quad (7)$$

Thus, if equations (5,6,7) hold the ratio between what OPT and MLAP obtain is at most α in this case.

Based on the above argument, if x, y and z satisfy the equations (5,6,7) respectively and inequality $x+y+z \leq m$, MLAP is α -competitive. Combining $x+y+z \leq m$ with equations (5,6,7), we have that

$$\frac{(\sqrt{\Phi} - \alpha)m}{(\alpha - 1)\alpha} + \frac{(\beta - \sqrt{\Phi})m}{(\sqrt{\Phi} - 1)\alpha} + \frac{(\Phi - \beta)m}{(\beta - 1)\alpha} \leq m. \quad (8)$$

The rest problem is to judge the existence of such an α that inequality (8) holds and $1 \leq \alpha \leq \sqrt{\Phi}$. Let $B = \frac{(\beta - \sqrt{\Phi})}{(\sqrt{\Phi} - 1)} + \frac{(\Phi - \beta)}{(\beta - 1)}$, inequality (8) turns out to be $\alpha^2 - \alpha B + B - \sqrt{\Phi} \geq 0$. Solving the inequality we have that $\alpha \leq \frac{B - \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$ or $\alpha \geq \frac{B + \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$. The solution $\alpha \leq \frac{B - \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$ is deleted since it does not satisfy $\alpha \geq 1$. Thus, $\alpha \geq \frac{B + \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$. Since the competitive ratio is an increasing function of α , when $\alpha = \frac{B + \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$, MLAP reaches the optimal competitive ratio. Let $F(\beta) = \frac{B + \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2}$. Taking the differential of β and equating it with zero, we get that $B' = 0$ or $-1 = \frac{B-2}{\sqrt{B^2 - 4(B - \sqrt{\Phi})}}$. The latter solution is deleted for $\Phi \geq 1$. By $B' = 0$, together with the definition of B , we

have that $\beta = 1 + (\sqrt{\Phi} - 1)\sqrt{\sqrt{\Phi} + 1}$ and then $B = 2\sqrt{\sqrt{\Phi} + 1} - 2$. Thus, $\alpha = \frac{B + \sqrt{B^2 - 4(B - \sqrt{\Phi})}}{2} = (\sqrt{2} + 1)(\sqrt{\sqrt{\Phi} + 1} - 1)$ and MLAP is $O(\Phi^{1/4})$ -competitive. The relevant values of x, y and z can be obtained by equations (5), (6) and (7). We complete the proof.

III. The Number of the Auction Phases Is Unknown Beforehand

III.1 Model Description

In this section we will discuss the case that the auctioneer does not know the number of the auction phases at the beginning. The assumptions of this model are basically the same as those of the previous model. The only difference lies in assumption c) where the auctioneer does not know n beforehand in this model. The objective is to maximize the total revenue of accepted bids.

III.2 The Multi-Level of Accepted Price-1 Strategy

Since the auctioneer does not know when the auction activity will end, we give an effective strategy called Multi-Level of Accepted Price-1 (Abbr. MLAP1). The main idea of MLAP1 is that no matter at which phase the auction ends, MLAP1 ensures that what it has obtained is at least a fixed factor of what OPT has obtained.

MLAP1 is described as follows. MLAP1 accepts $\frac{m}{\alpha}$ bids in $[\underline{v}, \sqrt{\Phi}\underline{v}]$, $\frac{(1-1/\sqrt{\Phi})m}{\alpha}$ bids in $[\sqrt{\Phi}\underline{v}, \bar{v}]$ and $\frac{[a-(2-1/\sqrt{\Phi})]m}{\alpha}$ bids with value \bar{v} respectively. The total number of accepted bids is at most m . In special, if MLAP1 has accepted $\frac{(1-1/\sqrt{\Phi})m}{\alpha}$ bids in $[\sqrt{\Phi}\underline{v}, \bar{v}]$ but less than $\frac{m}{\alpha}$ bids in $[\underline{v}, \sqrt{\Phi}\underline{v}]$, then a new bid with value in $[\sqrt{\Phi}\underline{v}, \bar{v}]$ will be accepted and count the number of the total accepted bids plus 1. Similarly, if MLAP1 has accepted $\frac{[a-(2-1/\sqrt{\Phi})]m}{\alpha}$ bids with value \bar{v} but less than $\frac{(1-1/\sqrt{\Phi})m}{\alpha}$ bids in $[\sqrt{\Phi}\underline{v}, \bar{v}]$ or $\frac{m}{\alpha}$ bids in $[\underline{v}, \sqrt{\Phi}\underline{v}]$, then a new bid with value in $[\sqrt{\Phi}\underline{v}, \bar{v}]$ or $[\underline{v}, \sqrt{\Phi}\underline{v}]$ will be accepted and count the number of the total accepted bids plus 1.

III.3 Competitive Analysis

In this section we will analyze the competitiveness of MLAP1. We give the following theorem and the rest of this section is contributed to the proof of the theorem.

Theorem 2 *MLAP1 is $(2\sqrt{\Phi} - 1)$ -competitive.*

Proof. The proof idea is similar to that of MLAP. For the whole auction process $\sigma = \{b_1, \dots, b_n\}$, denote by $M1(\sigma)$ and $O(\sigma)$ the total revenues obtained by MLAP1

and OPT respectively. There are two possible worst cases for MLAP1.

Case 1. The highest bid is less than $\sqrt{\Phi}v$. The adversary will release the first $\frac{m}{\alpha}$ bids with value v and the following m bids with value $(\sqrt{\Phi} - \epsilon)v$ and no more bid arrives. In this case, MLAP1 will only accept the first $\frac{m}{\alpha}$ bids and reject the following m bids due to its construction. OPT will accept the m bids with value $(\sqrt{\Phi} - \epsilon)v$. Thus, the ratio between what OPT and MLAP1 obtain equals $\frac{O(\sigma)}{M1(\sigma)} = \frac{(\sqrt{\Phi} - \epsilon)vm}{(m/\alpha)v} < \alpha\sqrt{\Phi}$.

Case 2. The highest bid is less than $\Phi v = \bar{v}$. The adversary will release the first $\frac{m}{\alpha}$ bids with value v and the following $\frac{(1-1/\sqrt{\Phi})m}{\alpha}$ bids with value $\sqrt{\Phi}v$, and m bids with value $(\Phi - \epsilon)v$ and no more bid arrives. In this case, MLAP1 will only accept the first $\frac{(2-1/\sqrt{\Phi})m}{\alpha}$ bids and reject the following m bids due to its construction. OPT will accept the m bids with value $(\Phi - \epsilon)v$. Thus, the ratio between what OPT and MLAP1 obtain equals $\frac{O(\sigma)}{M1(\sigma)} = \frac{(\Phi - \epsilon)vm}{(m/\alpha)v + \frac{(1-1/\sqrt{\Phi})m}{\alpha}\sqrt{\Phi}v} < \frac{\alpha\Phi}{1+(1-1/\sqrt{\Phi})\sqrt{\Phi}} = \alpha\sqrt{\Phi}$.

Based on the analysis of the above two cases, MLAP1 is $\alpha\sqrt{\Phi}$ -competitive. Moreover, the total accepted bids shall be no more than m , that is, $\frac{m}{\alpha} + \frac{(1-1/\sqrt{\Phi})m}{\alpha} \leq m$. Solving the inequality we have that $\alpha \geq 2 - 1/\sqrt{\Phi}$. Since the competitive ratio is an increasing function of α . Let $\alpha = 2 - 1/\sqrt{\Phi}$, then MLAP1 is $(2\sqrt{\Phi} - 1)$ -competitive. Hence, the proof is completed.

IV. Experiment

In the previous two sections we proposed two effective strategies for two models respectively and proved their competitiveness theoretically. In this section we will give some simulations and compare the experimental results to the theoretical ones.

The following is the simulation for both models. The original data are from www.baidu.com website. There are 83 bids for the keyword "Flower" on Feb. 12, 2005. The highest bid is 6.75 yuan and the lowest one is 0.3 yuan. Thus, for the model of knowing the auction phases beforehand, the bid phases $n = 83$ and the ratio between the highest bid and the lowest one $\Phi = 22.5$. The theoretical value of the competitive ratio of MLAP can be obtained by Theorem 1, equaling $(\sqrt{2} + 1)(\sqrt{\sqrt{\Phi} + 1} - 1) = 3.37$. On the other hand, in the experiment, the bid arrival sequence is equal to the data list in the website. some of the experiment results by MLAP are shown in form 1. $m = 20, 30, 40$ are the numbers of heterogeneous objects. For each m , the x, y, z values are figured out by equations (5), (6) and (7). We can see that the highest value of the competitive ratio equals 1.96 in the form, which is much less than the theoretical value. The reason is that the theo-

retical result is proved by worst case analysis. However, in practice, the worst case rarely happens.

Form 1 Some simulation results of the first model.

σ	n=20 σ			m=30 σ			m=40 σ		
Assigned-values σ	x, y, z=4, 8, 8 σ			x, y, z=6, 12, 12 σ			x, y, z=7, 17, 26 σ		
Online Revenue σ	90.11 σ	79.28 σ	64.65 σ	125.53 σ	118.33 σ	98.89 σ	168.37 σ	156.56 σ	109.37 σ
Optimal Revenue σ	124.74 σ	155.3 σ	91.66 σ	160.03 σ	123.24 σ	109.96 σ	182.24 σ	174.40 σ	120.04 σ
Competitive ratio σ	1.38 σ	1.96 σ	1.42 σ	1.27 σ	1.04 σ	1.11 σ	1.08 σ	1.11 σ	1.1 σ

Form 2 Some simulation results of the second model.

σ	m = 20 σ				m = 40 σ			
n σ	Online Revenue σ	Offline Revenue σ	E-ratio σ	T-ratio σ	Online Revenue σ	Offline Revenue σ	E-ratio σ	T-ratio σ
50 σ	43.01 σ	93.1 σ	2.16 σ	4.89 σ	81.84 σ	114.23 σ	1.40 σ	5.02 σ
17 σ	38.05 σ	53.55 σ	1.41 σ	4.81 σ	38.05 σ	53.55 σ	1.41 σ	5.53 σ
73 σ	43.01 σ	113.36 σ	2.64 σ	6.24 σ	81.84 σ	155 σ	1.89 σ	7.37 σ
32 σ	43.01 σ	73.25 σ	1.70 σ	4.62 σ	64.58 σ	78.08 σ	1.21 σ	4.98 σ
42 σ	43.01 σ	88 σ	2.05 σ	4.25 σ	81.54 σ	101.9 σ	1.25 σ	5.31 σ
31 σ	43.01 σ	71.48 σ	1.66 σ	4.02 σ	62.06 σ	75.56 σ	1.22 σ	4.35 σ
46 σ	43.01 σ	92.73 σ	2.16 σ	4.98 σ	81.84 σ	109.97 σ	1.34 σ	4.58 σ
51 σ	43.01 σ	55.01 σ	1.28 σ	5.54 σ	81.84 σ	100.87 σ	1.23 σ	6.02 σ
55 σ	43.01 σ	97.33 σ	2.28 σ	5.31 σ	81.84 σ	120.44 σ	1.47 σ	6.47 σ

For the model of unknowing the auction phases beforehand, the original data are the same as those of the previous model. The number of auction phases n are produced randomized in [1, 83]. For each n , we randomly select n numbers from the 83 bids, and the bid arrival sequence is randomized produced by the n bids. For each experiment, the relevant theoretical competitive ratio can be figured out by the n bids and Theorem 2, as shown in Form 2 below T-ratio. We set $m = 20, 40$ and obtain the experiment results by MLAP1. The optimal revenue, MLAP1 revenue and the competitive ratio below E-ratio in the experiment are shown in Form 2. Obviously, all the values below E-ratio are much less than those below T-ratio. The reason is the same as that of the previous model.

V. Conclusion

In this paper we analyze the online problem of network advertisement-place auction. We present two online models where the number of auction phases are known or unknown beforehand respectively. Two deterministic strategies are proposed and proved to be $O(\Phi^{1/4})$ and $(2\sqrt{\Phi} - 1)$ -competitive respectively where Φ is the ratio between the highest and the lowest bids in the auction. In practice, these strategies may help to realize the automatic auction of heterogeneous objects that have similar traits to advertisement-places. There are still

some problems that can be further analyzed. For example, whether there exist better deterministic strategies for the two models or what is the lower bound of deterministic strategies? Moreover, if a bidder can submit a vector of bids for different objects, then whether there exists an efficient strategy for this case?

Abstract: The popularity of the Internet has raised the number of people shopping online and offers opportunities for fashion businesses to promote or sell their products via the Internet. There are an increasing number of New Zealand fashion organisations launching a web site either for information distribution, promotional use or online retailing. It is believed that the online fashion industry has a tremendous potential in New Zealand. Four interviews were carried out within New Zealand fashion organisations with the focus being their tactics in creating Internet fashion sites and the determinants to make them successful ones. A successful fashion web site should have rich and high quality content, fast loading speed, easy for navigation and good graphics. It is important for New Zealand fashion organisations to frequently update their web site, offer new promotions, consider consumer preferences and improve from there.

Keywords: E-Commerce Management, Internet Marketing.

I. Introduction

New Zealand's small size, geographic isolation and technologically-aware population have all contributed to the widespread and rapid uptake of Information Technology [14]. New Zealand has a small domestic market and a high degree of technology adoption when compared to the rest of the developed countries [17]. Due to the unique ability of the Internet to attract customers in an efficient and timely manner, it offers consumers an additional channel for information and purchasing, as well as increased choice, convenience, competition among retailers, and cost savings. With technology advancing everyday, "the Internet will help create and promote many new innovations for the fashion industry" [18]. Fashion is a fast growing, creative, interesting and time-sensitive industry. Many fashion retailers have developed a web presence to compete in this fast-paced industry. The fashion industry is seasonal and trend-based and its products have a limited life span. Bell [4] also indicates that the fashion industry moves at a frenetic pace where new designs are frequently introduced, so rapid electronic distribution of information is highly desirable. Using the Internet, fashion companies can deliver up-to-date information to consumers in a cost-effective way,

communicate with customers and promote the brand name in an easier way. Apparel products have become the third largest retail sales category on the Internet [7]. Since fashion purchases represent a significant portion of online purchasing [7], the potential of the online fashion industry is enormous. Fashion web sites seek to develop effective strategies based on knowledge of their consumers [10]. This research may help online fashion marketers improve their strategies designed to entice customers to shop online.

II. Literature Review

There are many reasons why people like to shop online. According to Bhatnagar, Misra and Rao [5], convenience and saving time were cited as the top two reasons to shop online, where shopping from home can avoid hassles of parking, salespeople and checkout lines. A survey by Greenfield Online found that 58 percent of respondents shopped online to avoid crowded offline stores and 57 said Internet shopping saves time [1]. Availability of products/services, as in access to variety, the ability to scan more products and compare prices are significant reasons for shopping online [2].

While Internet technology enables the convenience of online shopping, it has shortcomings. According to Lee and Johnson [12], most Internet users purchased non-apparel items (for example, CDs, books, software) and only 12 percent of the users had purchased apparel and apparel-related items. Customers cannot physically examine, touch and test products or get hands on help when shopping online. Forsythe, Kim & Petee [9] also identified seven major barriers to online shopping. These include credit card security concerns, privacy concerns, lack of web site credibility, inability to judge quality, no real-time interaction opportunities, site navigation concerns and lack of loyalty.

Despite the rosy growth predictions, online fashion retailing still encounters numerous challenges. Buying clothing, footwear, jewellery and accessories online involves far more subjectivity than shopping online for products like books, software or electronics. A number of recent studies identified the causes for consumer hesitancy to buy fashion online. According to Rodriguez [15], the biggest hurdle is the customers' demand to simulate on the Internet the see, feel and touch experience when buying clothes. Customers want to know if the selected item fits them well and whether they would look good in those clothes. NPD Group found that 85% of online consumers were reluctant to shop for clothes online because they cannot try on the items. Beck [3]

states that even though the online apparel market has exciting growth, high product return rates persist and most consumers are still either hesitant to purchase apparel online or are dissatisfied with their online shopping experience.

The demographic profile for Internet shoppers are constantly changing, Ernst & Young conducted a study which revealed that the typical online purchaser was well educated, married, and had a high economic status [19]. Skelly [16] estimates that women spend about three times as much as men on the purchase of clothing online. Consumer's age influences online buying decisions. As people became mature, they learn more about the products in the marketplace through experience and form more confident opinions about what suits their likes and what does not [5]. We conducted in-depth interviews with representatives of New Zealand fashion organisations in order to explore the business strategies used by New Zealand fashion organisations in creating their web sites.

III. Research Methodology

In this study, the main purpose of the interviews was to capture an in-depth understanding of online fashion organisations' operations from the perspective of the online fashion organisation representatives. The interview "is a dynamic vehicle for exploring the rich and complex body of information possessed by an individual" [6]. The criteria for selected subjects were based on subjects must have had experience and have had knowledge of the New Zealand online fashion industry. Four representatives of fashion organisations agreed to participate in this study. The four subjects were chosen for their extensive knowledge and experience of the New Zealand online fashion industry.

Two of the interviews were conducted face-to-face. According to Cavana, Delahaye and Sekaran [6], the main advantage of face-to-face interviews is that the researcher can adapt the questions as necessary, clarify doubts and ensure that responses are properly understood by repeating or rephrasing the questions. Two of the interviews were conducted via e-mail format at the request of the interviewees. Mann & Stewart [13] said that e-mail interviews are a practical way to collect information from individuals who are geographically distant.

A preliminary information gathering stage was carried out before conducting the interviews. The four fashion organisations' web sites were observed and the organisations' background information was examined. The four structured interviews were conducted with a list of predetermined, standardised open-ended questions which are carefully ordered and worded in a detailed interview schedule. Some changes to questions were made in order to suit the circumstances of different organisations. The questions were pre-planned and cover topics on business operations, web site development strategies, current situation and future development of New Zealand online fashion industry.

IV. Results & Discussion

Electronic Commerce represents a new medium and a different means of delivering product. For the fashion retailers, the Internet does not change the nature of the product itself. Fashion e-retailers can learn from direct marketers because they have existing successful business strategies. Most New Zealand fashion organisations understand the benefits of using the Internet as a promotion/product or information distribution channel. The benefits of using the Internet specified by the organisations include brand awareness, international reach, a means to update information for consumers, more cost effectively than traditional promotion methods and gives them a shop window that opens 24 hours 7 days. One interviewee emphasised that the only way that New Zealand fashion organisations can compete both locally and internationally is by good web site design.

The important web site features as cited by organisations are: high quality images, fast loading speed, easy navigation and usability, provide e-newsletter, real live fashion show, fashion report, online communities and competitions for consumer to enter. New Zealand fashion organisations use banner advertisements, major search engines and directories and word of mouth to advertise and attract consumers to their sites.

All of the interviewees emphasised that their main target audiences are women as men are not interested as much as women in fashion. One of the interviewee asserted that women are major influences in buying men's fashion. Forsythe, Kim and Petee [9] also suggested that women are the primary purchasers of fashion products in traditional retail environments, so there is a need for fashion organisations to understand the online decision-making process among women to enhance online fashion purchases.

Fashion organisations need to have a long term, formal, strategic plan for their web site development. Most of the fashion organisations mentioned that they have achieved this. All of the interviewed organisations believed that the New Zealand online fashion industry will continue to grow and there are many opportunities to introduce New Zealand fashion to the world by using the Internet. The main problems as cited by organisations, were getting an income stream, the high cost to maintain the web site, consumer fears to buy fashion products online and security issues. One major challenge of Internet companies was they are struggling to reach profitability [8]. It is difficult for fashion organisations to get an income stream that will support the functionality and the quality of content and design. It is hard to get consumers to pay for online information, and the costs associated with maintenance of the web site are high. One interviewee stated that their web site currently does not post a profit, so they have added a print magazine. Another key barrier that discouraged people from buying fashion products online is the lack of feel and touch for the fashion products before they purchase. One of the top reasons that consumers mentioned for not purchasing fashion products

online was because of questions about fit. Some of the consumers prefer to try on the fashion products before making a purchase. For example, when buying clothes, consumers want to know if the selected product fits them well and whether they would look good in those clothes. Research also indicates that the majority of New Zealand fashion web sites are informational rather than transactional [11]. As New Zealand is a small country, it is all too easy for consumers to drive to a store and try on garments. Therefore it is difficult for fashion stores to sell online. The likelihood of a consumer purchasing a fashion product goes down as their perception of risk goes up.

The future of New Zealand fashion industry looks bright. It is predicted that all of the fashion organisations need a web presence in the future either for information distribution, promotion, e-retailing or to develop a loyal online community. The rapid growth of the Internet will lower the technological costs associated with establishing or maintaining a web site. As the entry cost to go online gets cheaper, more fashion organisations will launch a web site. Competition of the New Zealand online fashion industry will be more intense.

V. Conclusion

The New Zealand online fashion market is likely to become much more competitive as it becomes easier for traditional fashion merchants to conduct e-commerce. In general, a successful fashion web site should have rich and high quality content, fast loading speed, ease of navigation and good graphics. It is important for fashion web sites to frequently update their web site, offer new promotions, consider consumer preferences and improve their offerings over time. Fashion web sites should provide a safe shopping environment to consumers and inform consumers of the advantages to use the Internet to shop for fashion products. The main challenges faced by fashion organisations were getting the income stream from the fashion web sites and making it profitable. Above all, the New Zealand online fashion industry will continue to grow.

Abstract: This article has studied influences of three factors namely flashing (FF), consistency (CF) and distance (DF) to spatial location array of commodity objects in online shopping system. The findings show that reaction time (RT) of subjects in still representation is shorter than that in live representation; faster in the setting of being inconsistency between commodities and their text description than that of being consistency; in the condition of both Flashing (FSH) level and Consistency (CON) level, Un-flashing (UNFSH) level and Inconsistency (INCON) level, subjects RT in the setting of commodity object being farther from its description is shorter than that in being near. The research finds no discrepancies that three factors have any impact on subjects' accuracy rate. Further analysis finds that physical distance of commodities plays a major role in affecting spatial location array of objects, while conceptual distance ranks on the second place. Location-based visual attention has the biggest impact on spatial location relation of virtual reality setting, and object-based visual attention plays a second largest impact. The impact would be highly impressive when either physical distant or conceptual distance is conformed to experiences in real life, Singleton detection mode will play a role at the situation when coincidence of the said phenomenon and real life experience is less, which means distinct flashing (FSH) will lead to better effect at this particular situation, otherwise it is worse.

Keywords: E-commerce Management, Internet Marketing & Advertising, Attention theory, virtual reality, location relations, shopping system.

I. Introduction

Some research finds that virtual reality representations of commodity information in online shopping systems will encourage buyers to reach an positive assessment on commodity information, and further inspires their desire of buying behavior[1]. This finding and further studies on affecting factors of VR representation to human information behavior or buying behavior in e-commerce websites grab a lot of attention from scholars and researchers, and ongoing

studies are implemented, for example: user structure pattern of virtual experience in VR environment; the relation between structure pattern and users' direct or/and indirect experience[2]. Another finding related to the means of media representations shows that VR representations have more advantages in improving performance efficiency specially when buyers are familiar to shopping systems or face higher frequencies of buying activities than Text representation, therefore, object information represented in VR plays a significant role on the success of online shopping systems[3].

In terms of representation on specific blocks of the interface and their relations, conventional researches focus more on micro-cognition elements such as interface layout, the characteristics of font and color and their relations with viewing behavior [4], which also are the issues of web interface our attention should be paid to, not limited in this, a further intensive attention should be paid to the different features and models of these elements in web environment [5], while some results might not be well applied to object representation in VR, and existing researches on this issue are much more scarce so far.

VR representation, in a way, can be interpreted as a means of presenting spatial relation which is largely based on intuition. It can easily lead to misunderstanding due to its capacity of sending diverse information simultaneously, so more aid such as text description are employed to reduce misunderstanding and non-clarity while user interacting with spatial activities in VR, so user can differentiate specific objects from its background or other elements unrelated to establish information cognition and activities pattern in VR environment[6]. Some researchers, from another point of view, have studied shopping design in real life and its applicability at VR stores, the impact of VR shop individuality on user's behavior[7]. In VR shopping environment, the issues of information behavior and location relations among objects still need more attention. This paper mainly studies the impact of attention theory on objects and object relations in VR setting.

II. Visual Attention Theory

Attention, in terms of the cause, can be divided into two classes: passive attention and active attention, some researchers also name them as stimuli-driven attention or

target-driven attention [8], yet two classes of attention are not mutually exclusive, sometimes, the development or controlling of the attention is worked jointly by the two. Passive attention often involves two modes: singleton detection mode and feature search mode. Singleton detection mode refers to the distinct difference of the stimuli (stimuli refers to the means of commodity representation in online shopping system) from the background. Feature search mode refers to the consistency of stimuli features and task features. Therefore, visual attention can be led to specific locations because of all said features.

Attention selection to the stimuli consists mainly of two categories: location-based visual attention and object-based visual attention. Location-based attention believes that attention is influenced by spatial array-format of objects. The selection accuracy and speed of subjects to searching objects are better and faster when objects appear near than they appear far. Other research findings support that the selection of searching objects are influenced by not only spatial location, but also location relations among objects. That is what we called object-based attention. Both two categories of attention will be explicated further by demonstrating an example. To explain location-based visual attention, we present a figure (1) of rectangle. An object can appear at each corner of the rectangle randomly. Subjects are asked to report another object's identity which is associated with the object as soon as it appears. The speed and accuracy of subject selection is faster and better when two objects are spatially set closer than they are far[9]. To explain object-based visual attention, we present a figure (2) of two same sized rectangles, the appearance of an object (named A here) appears with eighty percentage at fixation, and Bs either on left or on right side of A appear with ten percentage at any possible places, but the distance to A from either B remain the same. Subjects are asked to report as soon as either B appears, and subjects RT when B and A are in the same rectangle is shorter than that when B and A are in two separate rectangles[10,11]. It also reveals that simple detection task is more applicable to structure locations of objects, while objects identity task will require lots of attention paid to objects representations[12].

Figure 1

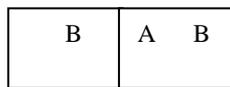

Figure 2

The research on visual searching finds that the speed of attention relocated to other objects and duration the attention kept on the objects have strong correlation with the relations among objects. The bigger discrepancies among objects exist, the longer the attention would be paid[13].

In VR representation of online shopping systems, users need experience different shopping sites and differentiate specific shopping objects while touring information space.

User attention will be constantly in the mode of stimuli or targets or the rotation of the two resulted from the changes of sites and man's cognition. Users will go through two subsequent stages: detection task and objects identity task. Detection task involves more direct experiences and attention to the location and space of the setting, while objects identity task involves more attention to specific object, its shape, its characteristic etc. To some extent, specific objects in VR shops should be distinguished from the background or other objects related since they have direct impact on buying decision and information activities. The demonstration of VR space can be the specific location relations of objects, the specific features of objects, or the combination of the two. The representation by either way will become clear in user mind when they catch more user attention successfully. In most case, the information related to objects should be placed in one sphere instead of two separate ones.

III. Hypothesis

Based on visual attention theory explicated previously, this article mainly focuses on spatial location relations among objects in VR setting, studies on effects of three factors to spatial location relations among objects have been made in VR online shopping system and three hypothesis are going to be validated. Namely, whether the result of task performed will be better? if 1. two objects sharing same characteristics are placed at a consistent location array. 2 two objects linking each other logically are near or placed in the same spatial range. 3 targeting object is distinct from its objects' background. In this article, objects and their description can be interpreted as two objects sharing same characteristics. Distance being either far or near can be interpreted as two objects being close or far. Objects are flashing will be interpreted as they are distinct from their background or vice versa.

IV. Method

Subjects : 80 sophomores from Beijing Forestry University (52 males, 28 females) are with little experiences of using computer, their average age is 20.13.

IV.1 Experimental Materials:

Eight VR settings has been employed, and each setting consists of three parts of shelf shaped like “ \wedge ”, each shelf has four booths divided by lines and placed at four corners of each shelf. Each commodity at booth accompanies a description indicating the nature of goods. Eight settings are different because of the array of three factors.

Flashing (FSH) refers to the change of commodity objects becoming either larger or smaller. Un-flashing (UNFSH) refers to the size of commodity objects remaining the same. Consistency (CON) refers that location relations of commodity objects and its description remain the same at

booth, namely it means commodity object always appears at lower left corner of the booth, while its description appears at upper right corner of the booth. Inconsistency (INCON) refers that location relations of commodity object and its description appear randomly at different places at booth. The definition of farther (FNR) or nearer (NR) depends on whether commodity object and its description are blocked off by a line while physical distance remains the same. If it is a line between commodity object and its description, it means FNR; if not, it means NR. Subjects can only view one booth containing four commodities while their entering into shopping settings. Subjects must “go around” if they want to view more booths or commodities. “Go around” and final selection of commodity objects here must be facilitated by moving mouse.

IV. 2 Experimental Task

A target object appears randomly out of 48 objects in the shopping center. Subjects navigate through the specific setting by means of the mouse. Subjects then click the “SELECT” button upon arrival at the target object, indicating completion of one task. The setting will disappear after task completion, and next target object will appear, which indicates the start of second task to be executed. Apart from objects, all commodities and their description in the setting appeared randomly.

IV. 3 Experimental Design

Three-factor within-subjects design (2x2x2) generated eight treatments which correspond with eight virtual reality settings. Eighty subjects were randomly grouped into eight teams evenly and assigned a treatment.

Independent Variables: Three factors and two levels in each factor, namely flashing factor (FF)-(flash vs un-flash), consistency factor (CF)-(con-incon) and distance factor (DF)-(farther vs nearer)

Dependent Variables:

1. Reaction Time (RT): The time a subject spends completing a task. Time begins when an object appears, and ends when the subject locates the object and clicks “SELECT.”
2. Accuracy: The percentage of all correct object-searching tasks performed by each subject. It is resulted from the ratio between the number of correct tasks done by subjects and the number of whole tasks to be done.

Controlled Variables:

Time Delay (TD): refers to about nine seconds lapsed while each scene appears on the screen of the computer.

IV. 4 Experimental Procedures

In each treatment (eight settings) subjects were first asked to read task instructions, and then perform a practice task in an attempt to let subjects be familiar to and understand the whole task to be implemented (practice task content was

unrelated to experimental task content). Subjects practiced ten search tasks before proceeding to the experimental tasks. As soon as a random target object appeared, subjects clicked “START”, then subjects navigated through shopping setting until the correct object was located, completing the search activity by clicking “SELECT.” A new random target object then appeared, initiating the second task. The search process was repeated twenty times by each subject, with the computer monitoring the whole process and recording all activities.

V. Experimental Results

V. 1 Reaction time (RT) under different treatments

Table 1: Reaction time under different treatments

FF	CF	DF	Mean(ms)	Deviance	Subjects
	CON	FNR	13811	4728	8
		NR	13910	3135	9
		Total	13864	3834	17
FSH	INCON	FNR	11975	1385	10
		NR	10976	2356	11
		Total	11452	1975	21
	Total	FNR	12791	3332	18
		NR	12296	3050	20
		Total	12531	3153	38
	CON	FNR	16103	6936	11
		NR	10848	3535	11
		Total	13476	6008	22
UNFSH	INCON	FNR	8922	1618	10
		NR	9551	2373	11
		Total	9255	2024	21

	Total	FNR	12733	5036	39
		NR	11197.9860	3175.2211	42
		Total	11937.2331	4219.9678	81

Flashing factor=FF

Consistency factor=CF

Distance factor=DF

In general, RT used by subjects in FSH ($X=12530.7288$ ms) is less than that in UNFSH ($X=11412.7485$ ms) ; RT in CON ($X=13644.7608$ ms) is less than that in INCON ($X=10351.6716$ ms) ; RT in FNR ($X=12733.3453$ ms) is less than that in NR ($X=11197.9860$ ms) . These RT scores are then log-transformed to normalize the data ($RT \rightarrow \text{Log}(RT+1)$), then conduct ANOVA analysis (GLM General Factorial, SPSS for Windows 8.0).

The results appear graphically in Figure 3 and Figure 4. overall differences among eight treatments are highly significant ($F(7,73)=3.895, p<0.01$) . The main effect for FF ($F(1,79)=5.478, p<0.05$) and for CF ($F(1,79)=12.827,$

$p < 0.01$) both are significant. The three-way interaction among three factors is significant ($F(1,79)=4.162, p < 0.05$), however, there is no main effect for DF ($F(1,79)=1.726, p=0.193$). There is also no significant two-way interaction between FF and CF ($F(1,79)=1.085, p=0.301$), between FF and DF ($F(1,79)=0.643, p=0.425$) or between CF and DF ($F(1,79)=0.951, p=0.333$).

Figure 3 and Figure 4 shows that subjects RT in CON level is longer than that in INCON level at each level of both DF and CF. In other conditions except FNR level and CON level under flashing factor, subjects RT in FSH level is longer than that in UNFSH level. In CON level, subjects RT in NR and UNFSH condition is shorter than that in other conditions. In INCON level, the speed in FNR and UNFSH condition is faster than that in NR and UNFSH while the speed in NR and FSH condition is faster than that in FNR and FSH.

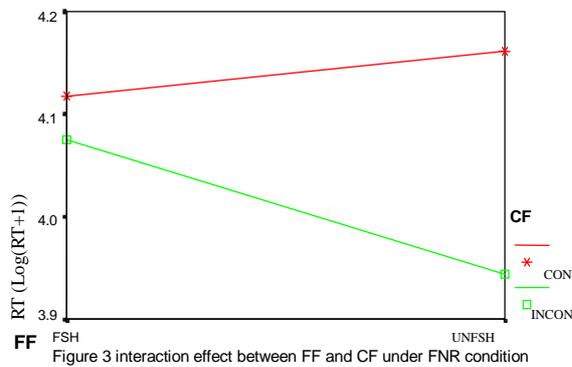

Figure 3 interaction effect between FF and CF under FNR condition

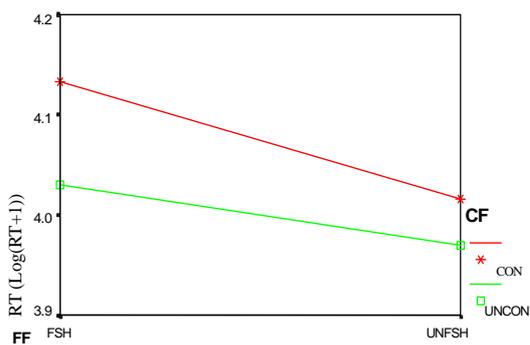

Figure 4 interaction effect between FF and CF under NR condition

V. 2 The accuracy under different treatments

Statistics analysis (GLM General Factorial in SPSS for Windows 8.0) shows that overall differences among treatments are not significant ($F(7,73)=1.466, p=0.931$). The main effect for FF ($F(1,79)=3.029, p=0.086$), for CF

($F(1,79)=1.194, p=0.278$) and for DF ($F(1,79)=2.644, p=0.108$) all are not significant. There is also no significant two-way interaction between FF and CF ($F(1,79)=0.042, p=0.837$), between FF and DF ($F(1,79)=2.699, p=0.105$) or between CF and DF ($F(1,79)=2.699, p=0.105$). The three-way interaction among three factors is also not significant ($F(1,79)=0.196, p=0.660$).

VI. Analysis and Discussion

In all, researching findings and hypnosis can't reach an agreement, and the impact of DF still remains unclear. The interaction of three-way factors will come to different results under different conditions.

The definition on CON level of consistency factor is that commodity object and its description are placed at diagonal corner in rectangle, actually, which makes the two being farthest physically. The definition of distance factor mainly refers to the conceptual distance between commodity objects and its description, and physical distance of two levels (FNR and NR) in distance factor is the same. It will be easier to understand that consistency factor involves physical location relation of the attention, while distance factor involves conceptual distance of the attention, and conceptual distance is a more objects-oriented process paid by attention, which is conformity with the said analysis. INCON level makes commodity object and its description nearest physically, which is coincidentally agreement with the setting at real life stores where tags are placed closely to commodities, therefore the similarity in location relations plays the greatest impact on subjects cognition, and help subjects identify objects at shortest time. CON level tells another opposite story at any conditions, that is results in Con level at any conditions are worse than that in INCON level.

Based on attention theory, the speed of human apperceiving live objects is faster than that of still objects if moving objects appear distinctly from the background. In CON and FNR condition, response speed of subjects encountering flashing objects is faster than that of unflashing objects, while in other conditions, opposite results are found, which is probably because subject mentality is required to identify objects description clearly first and give a judge whether they choose right targets, while flashing objects more easily grab subject's instinct attention. The process of this specific task would follow the pattern: subjects' attention moving to flashing objects first—then to objects description to identify the correction—then to search target object after judgment, the whole process slows down the cognition speed. If objects are not flashing, the attention of subjects will be paid directly to objects, which accelerates cognition speed. Therefore results of farther level in FSH and CON condition is better than that of nearer level because being farther further reduced the impact of distance. Apart from this, in other conditions, other factors affecting cognition is greater than flashing. In CON and FNR level, it can be interpreted as the worst cognition mode since both

physical and conceptual distance are fair faraway. Cognition results are better in other conditions because physical distance and conceptual distance are near. In other conditions, subjects RT in flashing level is shorter than that in un-flashing.

Based on the studies and experiments, the conclusion drawn is that physical-distance influence on location relations among objects is biggest, conceptual distance is on second place. In terms of attention theory, the influence on location relations by location-based attention is bigger than that by object-based attention. Performance results are better when the said phenomenon is coherent with experiences in real life. Singleton detection mode will play a role at the situation when coincidence of the said phenomenon and real life experience is less, which means distinct flashing will lead to better effect at this particular situation, otherwise it is worse. It helps us better understand and establish VR shopping settings, to use more location relations in physical terms to represent the relations of objects instead of conceptual terms; to place commodity objects which are similar to each other at more close locations as so to reveal more information about commodities, however location relations of three factors determining buying decision need be further studied.

Abstract: Digital watermarking is the best way to protect intellectual property from illicit copying. Digital watermarks hide the identity of an image or audio file in its noise signal. A pattern of bits inserted into a digital image, audio or video file that identifies the files copyright information. The purpose of this paper is to provide copyright protection for intellectual property that's in digital format. In this career we review digital watermarks an application of steganography.

Keywords: Internet, Security & Privacy, Intellectual Property, Copyright, Electronic commerce, Watermarking

I. Introduction

Before the advent of the Web, people made audiotape copies of music and videos to give to friends and family or used them for their own personal enjoyment activities were ignored by the producers, distributors, and artists who had the legal rights to the content MP3.com, Napster, and Intellectual Property Rights MP3.com enabled users to listen to music from any computer with an Internet connection without paying royalties Using peer-to-peer (P2P) technology, Napster supported the distribution of music and other digitized content among millions of users MP3.com, Napster, an Intellectual Property Rights MP3 and Napster claimed to be supporting what had been done for years and were not charging for their services Popularity of MP3.com and P2P services was too great for the content creators and owners to ignore MP3.com, Napster, and Intellectual Property Rights.)

To the creators and owners, the Web was becoming a vast copying machine MP3.com's and Napster's services could result in the destruction of many thousands of jobs and millions of dollars in revenue MP3.com, Napster, and Intellectual Property Rights .

December 2000, E-Music (emusic.com) filed a copyright infringement lawsuit against MP3.com

In 2001, Napster faced similar legal claims, lost the legal battle, and was forced to pay royalties for each piece of music it supported—Napster collapsed—in October 2003 it reopened as “for fee only” MP3.com, Napster, and Intellectual Property Rights . Existing copyright laws were written for physical, not digital content. The Copyright Infringement Act states, “the defendant must have willfully infringed the copyright and gained financially”.

The “no financial gain” loophole in the Act was later closed MP3.com, Napster, an Intellectual Property Rights (cont.)

The Results In 1997, the No Electronic Theft Act (NET) was passed, making it a crime for anyone to reproduce and distribute copyrighted works applied to reproduction or distribution accomplished by electronic means even if copyrighted products are distributed without charge, financial harm is experienced by the authors or creators of a copyrighted work MP3.com, Napster, and Intellectual Property Rights (cont.)MP3.com suspended operations in April 2000 and settled the lawsuit Napster suspended service and settled its lawsuits tried to resurrect itself as an online music subscription service with the backing of Bertelsmann AG filed. for bankruptcy in June 2002 purchased by Roxio with plans to revive Napster into a royalty-paying framework MP3.com, Napster, and Intellectual Property Rights .

What we can learn :All commerce involves a number of legal, ethical, and regulatory issues EC adds to the scope and scale of these issue What constitutes illegal behavior versus unethical, intrusive, or undesirable behavior?

Ethics is The branch of philosophy that deals with what is considered to be right and wrong ,What is unethical is not necessarily illegal.

Ethics are supported by common agreement in a society as to what is right and wrong, but they are not subject to legal sanctions Legal Issues Versus Ethical Issues .

Employees use e-mail and the Web for non-work-related purposes.

The time employees waste while surfing non-work-related Web sites during working hours is a concern Copyrighted trademarked material cannot be used without permission

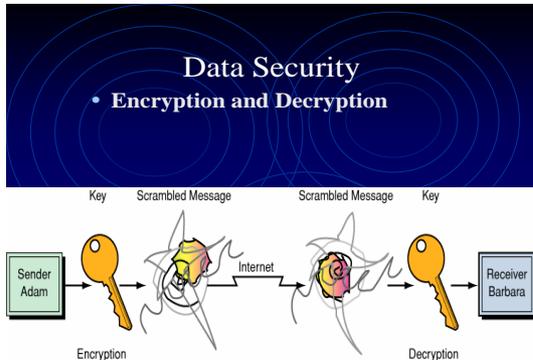

Post disclaimers of responsibility concerning content of online forums and chat sessions

Legal Issues Versus

There are ten topics used for Checking IP issues in e-commerce(by WIPO)

- 1- Understanding how IP relates to e-commerce
- 2- Taking Stock of your IP assets relevant to e-commerce
- 3- IP issues when you design and build your website
- 4-IP issues related to internet domain names.
- 5-How your e-commerce is affected by patents

- 6-IP issues in the distribution of content on the internet
- 7- Using care in disclosures on the internet
- 8- Important contracts on the internet
- 9- partnerships with government and educational system
- 10 – IP concerns about international transactions in e-commerce

Copyright is an exclusive grant from the government that allows the owner to reproduce a work, in whole or in part, and to distribute, perform, or display it to the public in any form or manner, including the Internet

Copyrights.

Copyright protection approaches Using software to produce digital content that cannot be copied Cryptography

Tracking copyright violations

Digital watermarks is Unique identifiers imbedded in digital content that make it possible to identify pirated works. Cryptography is the art of protecting information by transforming it ([encrypting](#) it) into an unreadable format, called [cipher text](#). Only those who possess a secret key can decipher (or [decrypt](#)) the message into [plain text](#). Encrypted messages can sometimes be broken by cryptanalysis, also called code breaking, although modern cryptography techniques are virtually unbreakable

Cryptography.

As the [Internet](#) and other forms of electronic communication become more prevalent, electronic [security](#) is becoming increasingly important. Cryptography is used to protect [e-mail](#) messages, credit card information, and corporate data. One of the most popular cryptography systems used on the Internet is [Pretty Good Privacy](#) because it's effective and free.

Cryptography systems can be broadly classified into [symmetric-key systems](#) that use a single key that both the sender and recipient have, and [public-key](#) systems that use two keys, a public key known to everyone and a private key that only the recipient of messages uses.

Range of Knowledge Management

II. Digital Watermarking

Digital watermarking is the best way to protect intellectual property from illicit copying.

Digital watermarks hide the identity of an image or audio file in its noise signal.

Controlling spam

Spamming is the practice of indiscriminately broadcasting messages over the Internet (e.g., .. junk mail)

Spam comprises 25 to 50% of all e-mail

Free Speech Versus Censorship and Other Legal Issues .

Electronic Mailbox Protection Act requires those sending spam to indicate the name of the sender prominently and include valid routing information

Recipients may waive the right to receive such information

Free Speech Versus Censorship and Other Legal Issues .

ISPs are required to offer spam-blocking software

Recipients have the right to request termination of future spam from the same sender and to bring civil action if necessary

Free Speech Versus Censorship and Other Legal Issues

Electronic contracts

Uniform Electronic Transactions Act of 1999 establishes uniform and consistent definitions for electronic records, digital signatures, and other electronic communications

–Shrink-wrap agreements or box-top licenses

–Click-wrap contracts

Free Speech Versus Censorship and Other Legal Issues (cont.)

Intelligent agents and contracts

Contracts can be formed even when no human involvement is present

A contract can be made by interaction between an

individual and an electronic agent, or even between two electronic agents

Free Speech Versus Censorship and Other Legal Issues (cont.)

Uniform Electronic Transactions Act (UETA) includes the following two provisions:

–Electronic records do satisfy the requirement for a contract

–Electronic signature is enforceable equal to a written signature on a paper contract

Free Speech Versus Censorship and Other Legal Issues .

Internet Gambling Prohibition Act of 1999 Online wagering illegal except for minimal amounts Provides criminal and civil remedies against individuals making online bets or wagers and those in the business of offering online betting or wagering venues Free Speech Versus Censorship and Other Legal Issues .

Taxing business on the Internet

Internet Tax Freedom Act passed the U.S. Senate on October 8, 1998 Barred any new state or local sales taxes on Internet transactions until October 2001 (extended by US Congress to 2006) Created a special commission to study Internet taxation issues and recommend new policies Free Speech Versus Censorship and Other Legal Issues .

The global nature of business today suggests that Cyberspace be considered :A distinct tax zone unto itself

Unique rules and considerations befitting the stature of the online environment Free Speech Versus Censorship and Other Legal Issues .

Tax-free policies may give online businesses an unfair advantage—Internet businesses should pay their air share of the tax bill for the nation’s social and physical infrastructure.

8- Important contracts on the internet

9-partnerships with government and educational system

10 – IP concerns about international transactions in e-commerce

- Cryptography
- Tracking copyright violations
- Digital watermarks: Unique identifiers imbedded in digital content that make it possible to identify pirated works

Content Ownership Protection
