Digital Watermarking is a form of steganography which embeds usually imperceptible or invisible markings or labels in digital data in the form of bits.

Digital Watermark

Interest in digital watermarks has grown out of an increasing interest in intellectual property and copyright protection.

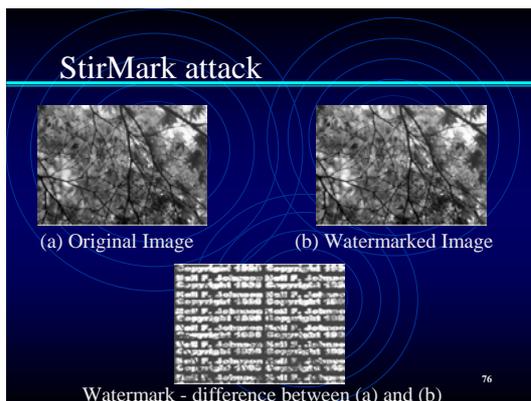

Digital Watermark .

Digital watermarks provide means of placing additional information within digital media so if copies are made, the rightful ownership may be determined.

III. Digital Watermark

Digital watermark ,a security software, are added to still images in a way that can be seen by a computer but is imperceptible to the human eye. A Digital watermark carries a message containing information about the creator or distributor of the image, or even about the image itself.

Digital Watermark (cont.)

Embeds imperceptible messages for tracking down the sites to check for abuses

- Encrypts data that only prospects users can read by using “Digital Key”
- Places icon or logo of copyrights’ owner in the corner of the screen or page

Embedded information

The embedded information is known as a watermark can provide, for example, information about the media, the author, copyright, or license information.

Digital Watermarking

- Embed visible / invisible watermark data into objects without changing the original document format and contents.

$$C = E(wm, P)$$

- Embedding watermark wm into object P , producing watermarked object C .

- Watermark can contain object ID, author’s name, terms of use, copyright date and so forth.

- Watermark can be either visible or invisible.

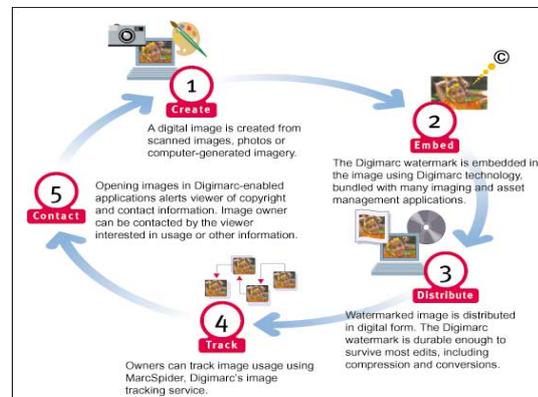

- Watermark recovery

$$D(C) = wm$$

- Applying watermark extraction to recover watermark, proving ownership.

- Good evidence in a copyright court.

- For a good watermark scheme it should be difficult to removed the watermark without knowing the embedding algorithm (and key).

Digital Watermarking - Examples

- Text – varying spaces after punctuation, spaces in between lines of text, spaces at the end of sentences, etc.

- Audio – low bit coding, random imperceptible noise, fragile & robust, etc.

- Images – least-significant bit, random noise, masking and filtering, etc.

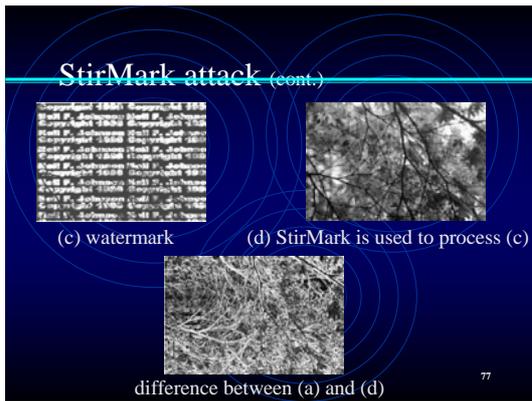

Digital Watermarking Example

Digital Watermarking – Purposes

Digital Watermarking – Qualities/Types

Digital Watermarking – Case Studies

- Text

- Image
- Audio
- Video

Digital Watermarking – Image

Digital Watermarking - Images

- Digimarc Image Bridge
- Inserts imperceptible digital watermarks onto images
- Digimarc MarcSpider
- Tracks all images with Digimarc’s watermark on the Internet

•Searches over 50 million images on the Internet a month
 MarcSpider report

Who is using ImageBridge and MarcSpider?

- Corbis
- Workbookstock.com
- The British Library

Success Story

- Cobris
- identifies up to 50 cases of unauthorized commercial use of its images per month

- Settled 28 cases in and out of court in 8 months
- Movie Market paid 1 million for the settlement

Digital Rights to Entertainment Media

- Internet makes it easy to transfer video content
- ~350k movies/day illegally downloaded via Internet.

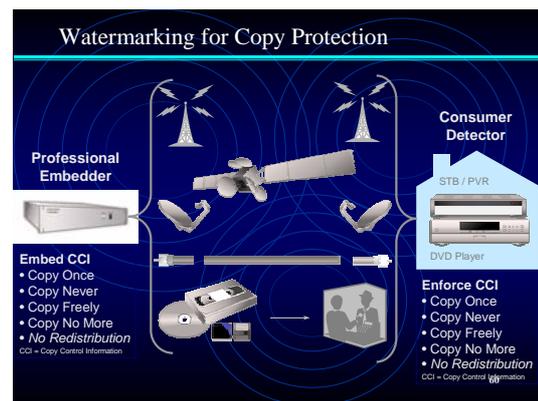

Broadband access enables transfer of full length movies in < 40 minutes

Next generation technology may reduce the time 45 seconds
 500k to 1mm simultaneous users find, reproduce and redistribute entertainment content via file sharing services

- Sales of audio and video packaged media dropping rapidly
- Record and CD sales down 10% last year

Top ten album sales dropped from 60mm in 2000 to 40mm in 2001

Digital Watermarking - Video

Watermark is insert into video by production studio, broadcast station, or cinemas

- Watermark contains copyright information and copying restriction information that indicates the video can be copy once, copy unlimited times, or never copy

- Video recording equipments manufactures have to agree with the code, and make the equipments accordingly

Digital Watermarking - Video

- Universal Pictures

- Insert digital watermarks in its movies including theatrical release, home video, video on demand, and broadcast movies

- Work with video recording makers in the next few years to ensure that new devices will complied the new standards

Video Watermarking Applications

Watermarking for Copy Protection

Copyright Protection Ecosystem

Philips Digital Network Water Cast

Who is using Water Cast?

- BBC

- Reuters

- EBU

Digital Watermarking - Audio

- Cannot effectively prevented illegal use of music on the Internet

- Identify the source of the music, and determine if the music is legal or not

- In 1999, a few companies including Liquid Audio, MP3, CDnow, formed a coalition to have digital watermark on distributed music on the Internet

Digital Watermark – National Security

- Insert watermark into ID card

- Carry secure information, which is used to authenticate and verify cardholder

- Harder for counterfeiter to replicate the ID card

Image Watermarking

Digital Watermark

Digital Watermark

Digital Watermark

Benefit from Implementing Digital Watermark Technology

- Communicate owner, image and/or transaction specific information, providing additional detail valuable for directing potential customers directly to appropriate licensing information.

Benefit from Implementing Digital Watermark Technology

- Facilitate image specific licensing and commerce opportunities by enabling each image to direct customers to image specific information on your Web site.

Digital Watermarking – Attacks

Attackers can seek to destroy watermark for the purposes of use without having to pay royalties to the originator of the content.

Types of Attacks

- Attackers have a visible target and can remove the watermark by cropping the image.

- Attacks on watermark may not necessarily remove the watermark, but disable its readability.

- Multiple watermarks can be placed in an image and one cannot determine which one is valid.

Types of Attacks (cont.)

- Robustness attacks – seek to degrade watermark beyond its utility value without altering the quality of the content so that the watermark cannot be detected

- Presentation – seek to manipulate content so that a detector cannot find the watermark in the file (i.e slicing an image into pieces and then reassembling it on a web site)

- Interpretation – create duplicate watermarks in order to create an ownership conflict

- Legal – challenging legal aspects of watermarking

- StirMark attack

- StirMark attack (cont.)

Question?

VWM: Protecting Movies from Piracy

- VWM Group formed March 2001

- Macrovision, Philips, Sony, NEC,

- Hitachi, Pioneer, Digimarc

- Copy prevention and play control

- Tens of Millions of dollars invested in watermarking technology

- Global standards initiatives

- US: DVD CCA bids submitted 11/01; decision before mid-year

- Europe: DVB-CP (coordinated through EBU)

- Japan: ARIB (broadcast standards organization in Japan)

- Market need becoming critical

- Production of DVD recordable devices ramping

- US debating mandatory copyright protection in all digital devices

Information Security Guidelines for Healthcare Institutions

Chao-Ming Chen

Institute of Healthcare Information Management
National Chung Cheng University, Taiwan
168, University Rd, Min-Hsiung Chia-Yi, Taiwan, R.O.C.
TEL: 886-5-2721500 FAX: 886-5-2721501
u8824341@yahoo.com.tw

Abstract: In recent years, the form of medical records already slowly changed from paper form to electronic form. The new information science and technology makes the transmission of information easier and convenient. On the other hand, the exposedness of individual privacy and information secret would be too difficult to keep and the use of new science and technology has increased the risk of information leakiness.

The information security problem appears slowly in the electronic medical record. People that are indiscreet and negligent could cause improper damage to the information management. For this reason, the security guidelines could help healthcare institutions to improve insider and outsider security problem. The security guidelines should refer to BS7799 and HIPAA that we would take many advantages. Finally, we must estimate the benefit from purchase, integration, management, operations, maintenance, time lost, clumsy interfaces and procedures etc. These may spend a lot memory and time, so we should evaluate the cost and risk of BS7799 and HIPAA in each item; it could help us to guide how to select low cost, low risk and high benefits standard item to create the security guidelines.

Keywords: Internet Security and Privacy.

Introduction

The Information System in 21 th already to become the hospital essential tool, specially may increase efficiency of information system and reduce the cost.. However, the computerization of health information, while offering new opportunities to improve and streamline the healthcare delivery system, also presents new challenges to security problems and individual privacy interests in personal healthcare data [4].And The medical record exchange and the share has hastened for the current situation, grows the security problem which comes, creates patient's privacy and individual data enormous threat .Patient's data has the high sensitivity, most did not hope has a mind the public figure to the data exchange when is carried on revises correct or steals, perhaps in exchange process because controls the tube not when creates the internal outside the data to release. .In health care, because of these security risks and the uncertainty of security requirements in electronic networks, providers often discourage the use of electronic networks for the transmission of most patient data and other sensitive

information [1], [7].

Recognizing the potential dangers to computerized patient information, Congress mandated the implementation of system security standards through the Health Insurance Portability and Accountability Act [(HIPAA) Public Law 104–191], requiring the adoption of security standards that take into account the technical capabilities of record systems used to maintain health information [4].So we ready need a guidelines that told Hospital's high level manager how to control risk、 risk management、 security plan....because all most managements have not any idea to security for Hospitals, if Manager have a security guideline , could help them to make security plan、 control Risk and Risk management. But the security standards like BS7799 or HIPAA have too many control objectives that hospitals could not implement all control objectives. Because of the most hospitals resources is limited.

Threats of Health Care Information

According to Daniel P. Lorence and Richard Churchill 's research that paper-base of Healthcare Institutions could provide more security more than computer-base of Healthcare Institutions.

This is because Healthcare Institutions even have a lot of security problem in paper base work. And what's security problem are in our Healthcare Institutions. The consensus among health care CIOs is that the most important threats to patient information confidentiality are the following Table 1[9]:

Table1

Threats
1.From inside the patient care institution <i>Accidental disclosures.</i> <i>Insider curiosity.</i> <i>Insider subornation.</i>
2.From within secondary user settings
3.Outsider intrusion into medical information systems

Table 1 show we the threats all most come from Insider of Healthcare Institutions So Healthcare Institutions must

have the better internal control mechanism.

BS7799 and HIPAA

The BS 7799 Code of Practice is intended for use as a reference document by managers and other persons responsible for the information security within an organization. It is intended as a standard for the management of information security rather than for the practice of information security itself. In other words, it does not set out to be a technical manual but rather describes the sorts of controls that should be in place and how they should be managed. It may be regarded as a basis upon which to build a security policy but is not meant to be a definitive list of the measures that should be in place in every organization.[8]. Common is suitable each industrial BS7799, because the Healthcare Institutions has its industrial characteristic, specially in organization surface, therefore should join following several projects to take the thanking improvement the goal.[10] :

1. Medical records protections stipulation, maintains the patient’s privacy not to violate.
2. The patient’s information security rights, stated and protection patients the right which goes see a doctor in the hospital.
3. Outside of hospitals the use patients data, outside the hospital organization or the unit request obtains patients data, should request to observe stipulation the hospital correlation.
4. Medical records storage, guarantees patients medical record storage the security.

The right of privacy speaking of sickness is extremely important, specially in the nowadays democracy social privacy is current the important subject which takes, studies according to Cai Chia Ting [2] pointed out 95% managers of Healthcare Institutions all thought the medical information security and the privacy are the present hospital management important topic. Especially in data exchange or share time we must need to consider the secure question. But based on the Healthcare Institutions characteristic should hold the privacy to patient information, the security, and the secret and so on the characteristic, this also is several important ideas which in HIPPA emphasized, especially on Healthcare Institutions.

What Kind of Assets Need to Protect.

The common information system security Threats has following several kind of like Table 2. all Healthcare Institutions must be select some important controls to protect because they resources is limit. Many organizations have developed information systems for the collection and storage of patient data, but do not adopt corresponding security committees or teams, nor security manager/officers or coordinators According to Daniel P. Lorence and Richard Churchill[3]

Table 2 [6]

Natural and political disasters	Fire or excessive heat, Floods, Earthquakes, High winds, War and terrorist attack.
Software errors and equipment malfunction	Hardware or software failures. Software errors or bugs Operating system crashes. Power outages and fluctuations. Undetected data transmission errors.
Unintentional acts	Accidents caused by: Human carelessness Failure to follow established procedures Poorly trained or supervised personnel Innocent errors or omissions. Lost, destroyed, or misplaced data. Logic errors.
Intentional acts (fraud & computer crime)	Sabotage Computer fraud Misrepresentation, false use, or unauthorized disclosure of data. Misappropriation of assets. Financial statement fraud.

How Analyzes the Information Security Weakness.

The BS 7799-2 specifies requirements for establishing, implementing and documenting information security management systems (ISMSs). It specifies requirements for security controls to be implemented according to the needs of individual organization.

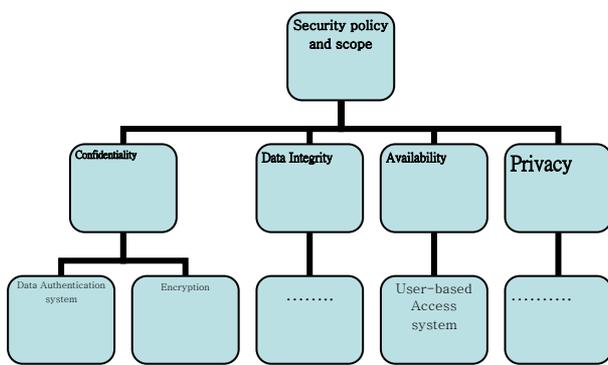

How to Establishing a Management Framework

The information safety control because HIPAA has considers the right of privacy protection the part, therefore uses HIPAA to discover the healing institute the item which must pay attention regarding the information security, finally coordinates the item which the electronic medical record clearing house must pay attention, and weakness which possibly can have on the present domestic electron medical record safe exchange overhead construction proposes the suggestion method. Must be able to complete the information to be safe first must finish the information security the management, first should appraise each control goal with can accept the risk which the risk and possibly can have, second is the selectivity control goal and reduces the risk to the scope which can accept, third avoids the risk and the shift risk arrives the third party, suggests the method, fourth carries on the safe plan which explained on front the development and the thorough execution and the revision, this for the information security and flow of and the executive program the internal control necessity, its specify and the method as follows explained: [5]

1. Define the information security policy and the scope of the information security management system:

First must look according to, security, the secret, uniformity major term and so on private dense launches lists our system scope and information security policy. Figure 1 shows an

example tree that the information security policy and the scope of the information security management system could be defined by the tree. We could List Confidentiality、 Data Integrity、 Availability and Privacy in the parent and we could list detail items in the subtree. That several information system needs to protect. appraised each control goal with can accept the risk which the risk and possibly can have: We want to decide on the protection policy which the medical record exchange security needs, and discovers the scope and the project which the electronic medical record exchange the system must protect, and appraised its risk with the resources which must consume, because resources limited, we are impossible to various information property all to make the consummation the protection, has the risk regarding each kind of possibility which the risk all must perform to calculate possibly occurs to have high.

2. Risk assessment and management:

selectivity controls goal and reduces the risk to the scope which can accept: This time must after various information property appraise grades makes the different rank in view of the different information property the protection, receives in view of the goal which must control carries on the security aspect the disposition and the tube controls, falls the risk the degree which can accept to us, exchanges by the electronic medical record said regarding the information bank protection, the material protection is count for much, may prepare under the enough resources situation as soon as to prepare in addition helps the main engine to carry on the backup the movement, can largely reduce the risk, and falls the risk which the information bank material drains to fall to the scope which may accept.

We should have clearly to know in the organization in this stage the material flow. The convention the organization of inside of the expert conference to obey HIPAA and the BS7799's control items confirm decides the important degree, and then List all of the control items in the checking table.(ex table 3). A score is determined for each alternative. The perfect alternative has a score of 1.0. The score for an alternative always lies between 0 and 1.0 and each score is determined independently of the scores of the other alternatives. Alternatives with identical scores are considered tied or equally close-to-perfect in the evaluation.

The weights to be used for the criteria, sub-criteria,and

the intensity levels at each level of the tree using pairwise comparisons are determined.Let $C(i,j)$ be a pairwise comparison that the decision-maker makes between two elements i and j ,which are children of a node in the AHP tree(the children are also nodes in the AHP tree). Each pairwise comparison can be interpreted as a ratio scale . For elements i and j on the same level of the tree, $C(i,j)$ can be interpreted as follows:[5]

$$C_{ij} = \frac{\text{The weight the decision-maker would like to assign to element } i}{\text{The weight the decision-maker would like to assign to element } j.} \tag{1}$$

$$\text{weight} = \frac{1}{\sum \text{row}(i)} \tag{2}.$$

Table3

	Outpatient System	Hospitalization System
Outpatient System	1	2
hospitalization System	1/2	1
weight	0.67	0.333

We could assign the information security of budget according to on table weight. Achieves most has the benefit the resource distribution and using the company information assignment, this uses above the information security, without the capital original assignment is insufficient.

3. avoids the risk and the shift risk to the third party:

We may the risk which may estimate avoid letting he occur, perhaps the risk by way of insurance giving to the insurance company which insures.

4. The Security plan development:

Finally we had to defer to a moment ago the risk height different project, started with organization resources how many to carry on the safe plan the plan and the development.

5. Implementation:

Carried on according to the information security plan content safely controls the tube, including organization's resources AND-OPERATION flow control, and the explicit definition power and responsibility, had the flaw regarding the process in which occurred to be supposed to record, then will be allowed to develop the security plan to take the improvement in the future the basis.

The conclusion

Security takes the degree on the present healing institute to the information not to be high, although knew has the information security but not to know how does, now this research specially chooses the electronic medical record material to exchange this subject, hoped can impel the electronic medical record exchange while the government

also to consider the information peaceful comprehensive thing, this research thought the information security and the electronic medical record material exchange is a body, is does not have the means to cut, therefore this research showed the information security control process, because the information security control is the information security basic condition, after achieves the information security control the request, the healing institute only then has the ability reference, This research establishment information security direction and composition. Healing institute's information is security also in the start stage, but also has quite many subjects not to have the means to make the detailed discussion in this research, why like does the healing institute affect the security the factor? The influence has in a big way? The risk has high? How deals with these security issues the countermeasure is what? ... And so on all is the quite interesting subject, might take the futurology subject the reference.

E-Literacy in Pacific Asia

Nena Lim¹, Colin Ferguson²

¹limn@unimelb.edu.au ²colinf@unimelb.edu.au

Department of Accounting and Business Information Systems
The University of Melbourne, Melbourne, VIC 3010, Australia

Abstract: Hesitant about Internet security has been a major obstacle to consumers' acceptance of electronic commerce. The objective of this paper is to assess how consumers in Pacific Asia perceive Internet security and how much they know about the topic. A total of 182 university students from Australia and Hong Kong SAR participated in this study. The results show that respondents in these two Pacific Asia regions had similar level of e-literacy. Both groups were unsure about Internet security and their self-assessed knowledge of Internet security was relatively low. A closer analysis of the data suggests that respondents have a tendency to over-estimate their understanding of the Internet security.

Keywords: Internet security and privacy, e-literacy.

I. Introduction

The rapid growth and influence of the Internet is increasingly pervasive in our everyday life. Businesses make use of the Internet to facilitate marketing, training, as well as improve their relationships with their suppliers and customers. Despite an increasing number of consumers who adopt electronic commerce, the overall adoption rate of electronic commerce has so far been below expectation [1]. As a result, much research tries to investigate what motivates consumers to purchase products or services online [2] [28]. For example, [35] examine choice and convenience issues. Interestingly, although security was considered to be a building block for electronic commerce growth [29] and hesitant about Internet security has been found to be a major obstacle to consumers' acceptance of electronic commerce [17] [27] [30] [31] [38] [40], most Internet security research focuses on developing more advanced and sophisticated Internet security measures [25] [36] [37] and assume consumers are knowledgeable about the topic [10].

Little research to date has examined how much consumers know about or understand Internet security. The importance of educating company staff electronic commerce (e-commerce) knowledge was emphasized in [34]. Researchers have proposed to investigate individuals' knowledge of security threats and countermeasures [7]. In another study, 275 undergraduate students from three different states in the United States were asked how they perceived Internet security and whether they knew any of the security control techniques used by business [17]. The

results show that 80% of respondents believed that Internet vendors use security control measures to protect customers. In addition, nearly 70% of respondents had heard of encryption, about 50% had heard of secure electronic transaction (SET), but only one-fourth had heard of secure socket layer (SSL). Nonetheless, hearing about certain security techniques equals neither understanding nor trusting of those security techniques.

Many consumers worldwide are attracted to use the Internet especially the WWW because of its friendly graphical user interface. Nevertheless, the majority does not know what security measures are used by businesses, how the measures work to enhance Internet security, and what limitations the measures have. Even experienced computer users or Internet users are likely to have only limited knowledge on Internet security. The problem is, without a reasonable level of knowledge of Internet security such as digital certificates, it means that security can be easily compromised because of the ignorance of users [36]. If a consumer is confronted with a warning regarding suspicious server digital certificate while accessing a Web-site, it is unlikely he/she understands what it means or knows what to do [16]. The objective of this study is to assess how consumers in Pacific Asia perceive Internet security and how much they know about the topic.

The rest of this paper proceeds as follows. Section 2 briefly describes the different components of Internet security. Section 3 describes the research methodology. Section 4 describes the technology adoption situations in Australia and Hong Kong SAR. Section 5 presents the research results. Finally, the paper is concluded in section 6.

II. Internet Security

As the Internet is boundless, how can one party be sure the identity of the other party in an Internet transaction and ensure information can be exchanged in a secure manner? One of the strategies businesses use to tackle this problem is the adoption of digital certificates (also known as electronic certificates) for Internet communications and transactions [3] [33]. Each digital certificate includes information such as the name of the certificate holder/organization, a unique serial number, the expiration date of the certificate, a copy of the certificate holder/organization's public key, and a digital signature of the certification authority. The objective of digital certificate is to verify the identity of an individual or organization in the cyber world. It is similar to real world how individuals use passports to identify themselves. The importance of digital certificates should not be

underestimated. An incident in 2001 which involved Verisign issued two certificates mistakenly as Microsoft staff has caused Microsoft Corporation to issue a major update of its software [8] [19].

The mechanism of digital certificates relies on a public key infrastructure (PKI) to achieve on-line authentication [8]. Based on a model of trust [12], a PKI is a system for issuing, distributing and using public keys used in public key cryptography [24] [37]. It comprises digital certificates, certificate authorities and key repositories, etc. [12] [24]. The underlying mechanism of a PKI relies on public key cryptography which was developed in 1970s [21] [24]. Public key cryptography involves two mathematically related keys - private and public keys. Private and public key pairs are issued by trusted third parties called certification authorities (CA) [39]. Under a PKI, individuals with no prior relationship can achieve confidentiality and authentication when they swap information over the Internet or conduct electronic commerce transactions [21]. As a result of a PKI system, individuals and organizations can digitally sign and encrypt email messages. Moreover, two parties, typically a business Web sever and a consumer, can set up a secure socket layer session to exchange information safely [26].

III. Research Methodology

To examine the research questions, we conducted a Likert-scale style survey. We chose samples from Australia and Hong Kong SAR because these two regions were ranked the highest in Pacific Asia in Economist Intelligence Unit (EIU)'s annual report on e-readiness in 2003. In that report, Australia ranked the 9th and Hong Kong SAR ranked the 10th (tied with Canada) [18]. Two Scandinavian countries, Sweden and Denmark, were ranked number one and two on EIU's 2003 e-readiness ranking. E-readiness measures a region's capability to benefit from the opportunities provide by the Internet. Factors considered in the EIU rankings include the following: connectivity and technology infrastructure, business environment, consumer and business adoption, legal and policy environment, social and cultural infrastructure, and supporting e-services.

In January 2004, questionnaires were distributed to one hundred and fifty undergraduate students who major in accounting in Hong Kong SAR. One hundred and forty questionnaires were returned but one was unusable because of missing data. A similar survey was conducted in Australia in September 2004. Questionnaires were distributed to sixty-two postgraduate students. Forty-two were returned. Participation in the study was voluntary and no incentive was provided.

IV. Computer and Internet Usage

By March 2004, Australia has a population of 20 million [6]. Sixty-six percent of households in Australia have computers at home and among these five million households, 80% also have Internet access [5]. While 83% of Australian businesses

use computers, only 23 percent of businesses have Web presence [4].

Similar situation of computer and Internet access in households was found in Hong Kong SAR. By 2004, Hong Kong SAR has a population of 6.8 million [13]. Sixty-eight percent of households in Hong Kong SAR have computers at home and nearly all these household (89%) have Internet access [14]. Nevertheless, the penetration rate of computer and Internet in the business sector is much lower in Hong Kong SAR than Australian businesses. Only 55% of Hong Kong SAR businesses use computers. The percentage of Web presence is even lower with only 14% [15].

The Hong Kong SAR government introduced a new multi-application smart identity card to its residents in August 2003. In addition to immigration purposes such as facilitating automated immigration clearance at border control points, a Hong Kong SAR smart identity card includes several non-immigration applications. Residents can now use the digital certificates embedded in their identity cards to update or check personal data kept by the government. With the embedded digital certificates, residents can encrypt email messages, conduct on-line share trading and on-line betting etc. [23]. Residents can use the digital certificate free for one year because the Hong Kong SAR government wants to encourage its people to adopt electronic commerce [32]. By the beginning of August 2004, over 420,000 smart identity card holders have opted for the free digital certificate [22]. This figure equals to around six percent of the population.

A high Internet connectivity rate or even ownership rate of digital certificate does not necessarily lead to individuals' acceptance of electronic commerce. The Finnish government issued a voluntary electronic identification card (EID) to its residents in 1999 [11]. It offered a low-priced digital certificate at 10 Euros to its residents. Nevertheless only ten percent of Finns were willing to pay for the digital certificate. It is unclear how many Finns use the certificates in the end [9]. Given the Finland example, this explorative study aims to investigate how the consumers in Pacific Asia perceive Internet security, how much they know about Internet security, and how ready they are in using digital certificates for electronic commerce transactions.

V. Results

V.1 Demographics

A total of 181 cases were used in the analysis. About two-third of respondents were female and the average age of respondents was 21.7. Furthermore, about two-third of respondents had five to eight years experience of using computer. The mean of Internet experience was 5.46 years. Nearly all respondents had computers at home (96.1%). A breakdown of the demographics of the two samples is shown in Table 1.

Among the 139 Hong Kong SAR respondents, 72% were female and 28% were male. They aged from 20 to 23. The average age was 20.8. Two-third of respondents had five to

eight years' experience of using computer. On average, respondents had 5.3 years experience of using the Internet. Ninety-nine percent had computers at home. Forty-five percent of Australia's 42 respondents were female and 55% were male. The Australian respondents had a wider age range from 21 to 37. About one-third of the respondents aged between 21 and 23. Their average age was 24.79. Similar to the Hong Kong SAR respondents, nearly two-third of the Australian respondents had five to eight years' experience of using computer. The ownership rate of home computer in Australia was slightly lower with only 86%. Yet they appeared to have more experience of using the Internet with an average of 6 years.

Table 1. Demographics of Hong Kong SAR and Australian respondents

*** significant at 0.001 level; ** significant at 0.01 level; * significant at 0.05 level

Statistical tests were conducted to compare the demographic features of the two samples. As data do not fulfill the assumptions of t-test, Mann-Whitney U test was used. The results of U-test show that Australian respondents were relatively older and had more computer and Internet experience than Hong Kong SAR respondents.

V. 2 Perceptions and knowledge

In addition to providing demographic details, respondents were asked to indicate the following in the surveys in a seven-point Likert scale: 1 indicates none, very insecure or very unlikely; 7 indicates very well, very secure or very likely.

- perception of Internet security
- self-assessed level of knowledge of Internet security
- self-assessed level of knowledge of public key infrastructure (PKI)
- self-assessed level of knowledge of certification authorities (CA)
- self-assessed level of knowledge of digital certificates
- intention to use digital certificate to encrypt emails
- intention to use digital certificate to access Internet banking services
- intention to pay fees to acquire/keep digital certificate

In view of the demographic differences noted above, responses of two samples on Internet security perception and knowledge were reported separately and Mann-Whitney U-test was used to investigate the difference across the two regions. Table 2 shows the comparison results. Overall, there was no significant difference between the two samples in terms of their perceptions and knowledge of the Internet security, and their intentions to use digital certificates. Respondents in both regions have a similar perception of the Internet security and perceived the Internet to be neither very secure nor very insecure (mean=3.83 and 3.55). The average self-assessed knowledge of Internet security in general of the Hong Kong SAR respondents was 3.68 and only one respondent indicated he/she had no knowledge of Internet security. The average self-assessed knowledge of Internet security in general of the Australian respondents was 3.57. The differences between the two regions on Internet perception and knowledge were statistically insignificant.

Table 2. Perceptions and knowledge on Internet security

Items	Hong Kong SAR (mean)	Australia (mean)	Mann-Whitney U-Test	
			Z-value	Sig. (2-tailed)
Perception of Internet security	3.83	3.55	-1.334	0.182
Knowledge of Internet security	3.68	3.57	-0.329	0.742
Knowledge of public key infrastructure (PKI)	2.35	2.86	-1.477	0.140
Knowledge of certification authorities (CA)	2.78	2.86	-0.270	0.978
Knowledge of digital certificates	3.29	2.90	-1.712	0.087
Intention to encrypt emails	3.15	2.71	-1.321	0.186
Intention to use digital certificates to access Internet banking services	3.57	3.83	-0.495	0.621
Intention to pay fees to acquire/keep digital certificates	2.46	2.54	-0.013	0.990

As the two samples showed no significant differences regarding their perceptions and knowledge, further analysis was conducted by aggregating all the respondents (Table 3). Interestingly, respondents' self-assessed knowledge of PKI (mean=2.46) in both regions was much lower than their self-assessed knowledge of Internet security (mean=3.66). Fifty-four Hong Kong SAR respondents indicated that they knew nothing about PKI. Such a discrepancy in knowledge existed also for respondents' self-assessed knowledge of certification authorities and digital certificates. The respondents' average knowledge of certification authorities and digital certificates

were 2.80 and 3.21 respectively. With reference to Table 2, Hong Kong SAR respondents' average knowledge of digital certificates was slightly higher than the Australian counterparts (Hong Kong SAR= 3.29; Australia = 2.90). It is unsurprising that the Hong Kong SAR respondents had a higher average knowledge of digital certificate than the Australian counterpart because more people owned digital certificate in the samples. Nevertheless, such a difference is statistically insignificant.

Most respondents in both regions were not keen to use digital certificates. Although studies have described emails as a killer application for the Internet [20] and most respondents used electronic mails regularly, more than half of the respondents indicated that it was highly unlikely for them to use digital certificates to encrypt email (mean=3.04). Their intention to use digital certificates for Internet banking were slightly higher (mean=3.67). With a mean of 2.48, respondents were unlikely to pay fees to acquire digital certificates.

Table 3. Perceptions and knowledge on Internet security of all respondents

Items	Mean
Perception of Internet security	3.77
Knowledge of Internet security	3.66
Knowledge of public key infrastructure (PKI)	2.46
Knowledge of certification authorities (CA)	2.80
Knowledge of digital certificates	3.21
Intention to encrypt emails	3.04
Intention to use digital certificates to access Internet banking services	3.67
Intention to pay fees to acquire/keep digital certificates	2.48

The Friedman test was then used to further examine the different types of self-assessed Internet security knowledge (Table 4). The results show that the levels of self-assessed Internet security knowledge were inconsistent (Chi-square=129.67). Further analysis shows that both Hong Kong SAR and Australian respondents' self-assessed levels of knowledge of Internet security in general were significantly higher than the others.

Table 4. Within-group comparison of Internet security knowledge

Items	Mean Rank
Knowledge of Internet security	3.14
Knowledge of public key infrastructure (PKI)	1.91
Knowledge of certification authorities (CA)	2.28
Knowledge of digital certificates	2.67
Friedman Test	
Chi-Square	129.67
Significance	0.000***
*** significant at 0.001 levels	

Likewise, the Friedman test was used to examine respondents' intentions to use and acquire digital certificates (Table 5). The results show that respondents' intentions were inconsistent. Respondents were more likely to use digital certificates for Internet banking instead of email application. More importantly, their intentions of using digital certificates were higher than their intention to acquire the certificates.

Table 5. Within-group comparison of intentions

Items	Mean Rank
Intention to encrypt emails	2.02
Intention to use digital certificates to access Internet banking services	2.30
Intention to pay fees to acquire/keep digital certificates	1.68
Friedman Test	
Chi-Square	29.135
Significance	0.000***
*** significant at 0.001 levels	

As this is an explorative study, we also examined the correlation among respondents' different perception and knowledge measurement items. Results of Spearman's Rho indicate that respondents' perception of Internet security was not related to their levels of knowledge and was only slightly correlated with their intention of using digital certificates for Internet banking. Nonetheless, their intentions to use digital certificate was significantly correlated to their levels of knowledge in Internet security.

VI. Discussions and Conclusions

In summary, the results of the study show that respondents were unsure how secure Internet is. Moreover, their self-assessed knowledge on Internet security was relatively low. In a Likert scale of 7, their lowest means of self-assessed knowledge was only 2.46. Similarly their intentions to use digital certificates were low with means between 3.04 and 3.67. Comparisons of two groups show that other than demographic differences, there was no significant difference between the two samples in any measurement item. That is, respondents in both regions have similar level of e-literacy and readiness to use digital certificates.

Further data analyses indicate that the self-assessed knowledge of several key concepts relating to Internet security (PKI, CA and digital certificates) of respondents in both Australia and Hong Kong SAR was significantly lower than their self-assessed knowledge of Internet security as a whole. Such inconsistency raises an interesting question: did consumers in Australia and Hong Kong SAR really know about Internet security or did they over-estimate their understanding? While one may argue that such overconfidence phenomenon is unsurprising, so far no empirical data was provided by any existing research to prove it.

Similar inconsistency was found over their intentions to use and acquire digital certificates. While the means of intention to use digital certificates were between 3.04 and 3.67, their intention to pay fees to acquire or keep digital certificate was significantly lower (mean=2.48). Results indicate that respondents might have intentions to use digital certificates, but they were not interested in paying fees to acquire the certificates. Although the residents in Hong Kong SAR will be given free certificates, they were as unlikely as their Australian counterparts to use the certificates. Results also suggest that between the two types of digital certificate application, respondents were more

likely to use digital certificates for Internet banking and did not concern much about confidentiality of their emails.

The results of the study are useful to Internet vendors as they reflect the level of e-literacy and consumers' intentions to use digital certificates in Internet transactions in Pacific Asia. Consumers need not be experts in Internet security but a basic understanding is necessary [16]. As respondents in both regions were university students, one may argue that generalization of conclusions should not be extended beyond this particular group of consumers. Nonetheless, being the "elites" of societies, if university students do not understand the concept of Internet security, how likely is it for the other consumers to understand it? As results indicate that respondents had low intention to pay for digital certificates, we recommend that if governments want to encourage e-commerce, they should provide free digital certificates to their residents. Moreover, results show that consumer's knowledge of Internet security is significantly related to their intentions to conduct Internet transactions. We recommend that in addition to promoting more digital certificate applications, governments should provide more education on Internet security to residents. People other than security professionals or students who major in computer science or information systems should have opportunities to learn about this topic. By understanding what digital certificates are, how they work and their pros and cons, consumers may be more willing to engage themselves in electronic commerce. With regard to further research in this area, researchers may consider developing a conceptual model and examine the interrelations among consumers' perception, knowledge and intention.

Abstract: Information technology has been widely applied in the fields of globally medical care, which makes the service apparently progress in its quality and efficiency. However, medical information that was stored in electronic form really causes the risk of leaking.

A good security risk management offers a positive guarantee for hospitals, which highly relying on information technology, while running their organization.

While carrying out risk analysis, the value of information assets, existing weakness, and potential threat from outside of this information system must be realized. It is quite important to determine the value of information assets for the security risk management.

With information age coming, there is the greater part of asset value not shown from the traditional balance sheets in accounting books. This kind of asset, which can't be shown on the balance sheet, is intellectual capital. In the study of information asset and intellectual capital, Ross et al. (1996) divided information assets into three kinds of capitals - human asset, technology asset and relationship asset. These play the same tune with the three key elements of intellectual capitals- human capital, structural capital and relational capital. Within numerous assessment methods of intellectual capital, balanced scorecard assesses intellectual capital value from the view of management and efficiency.

Hence, this research proposes utilizing the balanced scorecard to find out the assessment index of information assets for domestic medical institutes while carrying on risk management. Hopefully, the results of this research can be regarded as the references of risk management of information security for domestic medical institutes.

Keywords: Internet Security and Privacy.

I. Introduction

Hospitals are indispensable in the social, and undertake the first line rescue of health and safety. Therefore, there are many hospital requests that come from the law and the society from all walks of life. The biggest difference between hospitals and other professions service is that medical service matters person's health and the life and death. A slight mistake or a fault may bring about a regret

that is irrevocable or unable to make up. Therefore, hospitals and other general organizations have the enormous difference in the processing service and decision-making.

Information technology has been widely applied in the fields of globally medical care, which makes the service apparently progress in its quality and efficiency. However, medical information that was stored in electronic form really causes the risk of leaking. That's why people care most about rights of privacy after the electronic medical record was brought into practice. Also, legislation and the promotion of electronic medical record are influenced by this factor but not problems from technology (Dye, 1986; Hall & Rich, 2000) .

The United States formulated HIPAA (Health Insurance Portability and Accountability Act) in 1996. It was from the legal stratification plane to establish the right of privacy protection standard that can be observed by hospitals. In Taiwan, The Department of Health (DOH) has established a working group of "the medical information security and the privacy protection guiding principles" in order to strengthen patients' medical information security and the privacy protection. The working group has drafted "the medical information security and the privacy protection guiding principle".

After looking at the domestic and foreign laws and regulations, it can be understood that information security is very important for hospitals. The overseas government and the medical system none who does not devote to patients' electronic data security and the privacy protection hoped to formulate each kind of laws and regulations to make the medical system observe the protection standard. Because of the laws and regulations restrictions, hospitals must start to plan ISMS for each information security request. Risk management plays a critical role in protecting an organization's information assets. An effective risk management process is an important component of a successful IT security program. Therefore, the risk management process should not be treated primarily as a technical function carried out by the IT experts who operate and manage the IT system, but as an essential management function of the organization. (Stoneburner, G., A. Goguen, et al., 2002) .

Risk management includes two major parts - risk analysis and risk control (Boehm, 1991). While carrying out risk analysis, the value of information assets, existing weakness, and potential threat from outside of this

information system must be realized. It is quite important to determine the value of information assets for the security risk management, because the more indefinite the value of information assets in the organization is, the harder to realize which asset is so worthy and important that needs special protection or even being reduced or shifted its risk; or, with limited resources, the risk is acceptable because the value of the asset is low. Besides, managers of the organizations often rely on the value of the assets to determine the investment of information security. Now, there is not a standard measurement index to assess the value of information assets in the relevant information security management standards.

Hence, this research proposes utilizing the balanced scorecard to find out the indicators of information assets assessment for domestic medical institutes while carrying on risk management. The importance of each kind of information assets must be confirmed through the assessment indicators. The results of this research can be regarded as the references of risk management of information security for domestic medical institutes.

II. Information Security

The so-called information security is to apply the management and the technology to hardware, software and data. It avoided other people to read, add, delete and modify storing or transmitting data. The rigorous level of information security management and the precise level of technology were decided by the risk which information was exposed under the procedure or the technique.

Other definitions of information security were collected in table 1:

Table 1. The Definition of Information Security

Name	Year	Content
Eloff and von Solms	2000	Data or information system still conforms to the security demand after passing through a series of test.
Finne	1997	Information security means a number of measures taken to minimize the risks connected to information.
Schultz, Proctor, Lien and Salvendy	2001	Information security in its most basic sense is protecting computer-related assets such as computers, networks, data, programs, and the hardware components.
Parker	1997	Information security is concerned with information protection that includes individual conversation, printing files and automated records.

(Source : My reorganization)

Icove (1,995) thought that the generalized computer security contained several constructions:

- **Physical Security** : the protection of computer facility. Physical security avoids stealing and destruction of these facilities. Physical security also guarantees the computer facility against the natural disaster and all damage that is made by other environmental factor.
- **Personnel Security** : personnel security covers

widespread scope, promoting computer security is one goal of strengthening personnel security. The goal of personnel security is to prevent personnel's security threat. It is an important part of personnel security to investigate personnel's background and monitor the operations.

- **Communication and Data Security** : the goal of communication and data security is to protect data transmission security ,including mail, telecommunication, facsimile and Internet. Internet is in fashion; communication and data security already became one of projects that the enterprise should specially pay great attention to.

- **Operations Security** : the goal of operations security is to prevent the compute crime, and raise attention to the computer crime.

The following figure shows the concept of computer security that was proposed by Carroll.

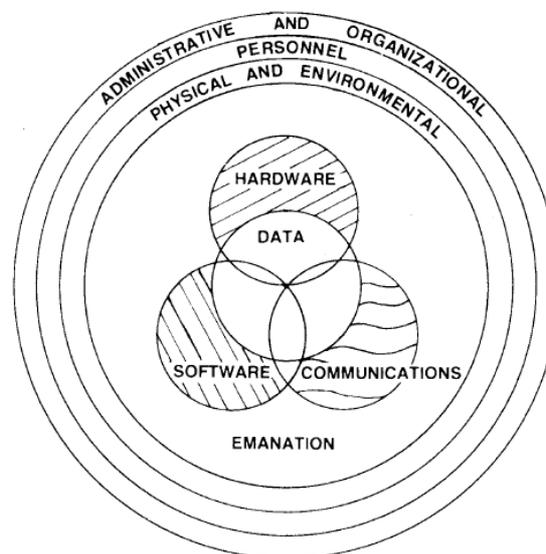

Figure 1. The Concept of Computer Security (Carroll,1987)

The technical tradition security concerning IT and information is typically defined by three aspects; confidentiality, integrity and availability (Gollman, 1999; Harris, 2002; Jonsson, 1995) .

Gollman (1999) define CIA as follows:

- **Confidentiality**: Prevention of unauthorized disclosure or use of computer systems and data
- **Integrity**: Prevention of unauthorized modification of computer systems and data
- **Availability**: Ensuring authorized access of computer systems and data when required

The definition of information security management which was proposed by Russell and Gangemi (1992) is that, "The information security management is to protect all things related with computer security, including computer, software, data, terminals, printers, tapes, disks, even the computer rooms." Consequently the managing of

information security should differ between organizations (Mintzberg 1983, Baskerville 1993).

Various authors (e.g., Siponen and Baskerville, 2001; Straub and Welke, 1998; Baskerville, 1993, Hitchings, 1995) suggest that the major problem with current approaches to managing IS security relates to the technical orientation of the solutions. They argue that the social and organizational aspects should be more considered in managing information security.

A good security risk management offers a positive guarantee for hospitals, which highly relying on information technology, while running their organization.

There is a discussion of the hospital information security problems in the following section. The first hospital information security problem is about internal personnel. Before computerizing, patient records in paper form had to prevent the natural disaster and stealing. Although now electronic patient record has been developed. It is still a big threat for internal personnel stealing. (Ross, 1996)

Software bugs and hardware failures occasionally corrupt messages. While mail, fax and telephone systems also fail, their failure modes are more evident than those of computer messaging systems. With poorly designed software, the figure could be substantially higher. (Ross, 1996)

Viruses have already destroyed clinical information, and a virus could conceivably be written to make malicious alterations to records. (Ross, 1996)

A malicious attacker might also manipulate messages. Sending email, which appears to come from someone else, is easy, and with some more effort it is possible to intercept mail between two users and modify it. (Ross, 1996)

By the literature, information security actually works in many ways, it involves technology, management even involves to policy, and legislation and so on, if everything get prepare in advance, many persecutions might be eliminated in the future.

III. Security Risk Management

Each industry has its unique commercial risk. In medical care industries, the commercial risk is patient safety, PHI and the right of privacy. Therefore, hospitals need the risk management. Besides IT risk assessment, hospitals also need the enterprise risk assessment to guarantee each person's responsibility. (Louis J. Carpenito, 2004)

Once the enterprise decides to establish the ISMS, the steps of risk management are inevitable. Generally speaking, the steps of risk management may be divided into the following four steps.

- I. Identification and Recognition
- II. Measurement and Evaluation
- III. Selection Risk Management Techniques
- IV. Implementing and Evaluation

Proper risk assessment planning is critical to the success

of the entire risk management program. Assessing risk requires cross-group interaction and for different stakeholders to be held responsible for tasks throughout the process. A best practice to reduce role confusion throughout the process is to communicate the checks and balances built into the risk management roles and responsibilities. While you are conducting the assessment, communicate the roles that stakeholders play and assure them the Security Risk Management Team respects these boundaries. The following table summarizes the roles and primary responsibilities for stakeholders in this phase of the risk management process.

Table 2. Roles and Responsibilities in the Risk Management Program

Role	Responsibility
Business Owner	Determines value of business assets
Information Security Group	Determines probability of impact on business assets
Information Technology--Engineering	Designs technical solutions and estimates engineering costs
Information Technology--Operations	Designs operational components of solution and estimates operating costs

(Source : The Security Risk Management Guide)

Business Owners have explicit roles in the risk assessment process. They are responsible for identifying their organizational assets and estimating the costs of potential impacts to those assets. Most information security professionals and non – technical stakeholders do not realize this connection automatically. Business managers often rely on the value of an asset to guide them in determining how much money and time they should spend securing it. At present, the methods of estimating the value of information assets are subjective. No objective tools or methods for determining the value of an asset exist.

IV. Information Assets and Value Estimate

The enterprise assets may be tangible or intangible. Both needs to be defined explicitly, business owner can explicitly estimate the value. The value of information assets is based on the impact degree to the organization. From the viewpoint of information security, the asset classification and the control are so important in the risk assessment.

The IT service combined tangible assets with intangible assets. Organization can first handle the most essential assets after the information asset classification has been done. Generally speaking, the information assets can be divided into five categories. The proportions of these five categories are not the same in different business projects, workflows, organization characteristics and culture. (Alberts, et al., 2003)

Security requirements outline the qualities of information assets that are important to an organization.

When the security requirements of an asset are violated, certain outcomes are possible (outcomes are directly related to security requirements in the table below).

Table 3. Relationship of Security Requirements to Outcomes

Security Requirement	Outcome
Confidentiality	● Disclosure of asset
Integrity	● Modification of asset
Availability	● Destruction of asset ● Loss of asset ● Interruption of asset

(Source : Health Information Risk Assessment and Management)

Asset values are based on the impact to the organization if the asset is lost. For some tangible assets, standard accounting procedures or replacement costs can be used. Acquired value for intangible assets can be estimated based on the loss to the enterprise. (Hutt, et al., 1995) The traditional measure of an asset is in terms of dollars. Reducing all assets to dollars makes for an easy comparison, and people are often comfortable thinking in terms of dollar values for assets. It can be very difficult, however, to reduce some intangible assets to dollar values. The cost of estimating statistically can be high in some cases, and statistical estimates may depend on subjective assumptions. Historical data, if available, can be useful in estimating the value of assets. In many cases relative rankings of asset values are sufficient. (Fites, et al., 1989) One way to estimate the value of assets is to consider what would happen if their security requirements were violated. Let's consider an example in which a medical center wants to protect its patient records. Staffs are concerned about the possibility of disclosing the patient records because this would violate the security requirement that sensitive information must remain confidential. If the information is disclosed to an unauthorized party, the fact that the information is no longer confidential has an impact on the organization. If the impact affects private medical diagnostic results or treatment plans, the value of the asset would be extremely high. On the other hand, disclosure of staffing assignments for nursing shifts, for example, might not have a serious impact on operations, so the asset value would be low. (Alberts, et al., 2003)

With information age coming, there is the greater part of asset value not shown from the traditional balance sheets in accounting books. This kind of asset, which can't be shown on the balance sheet, is intangible asset. It is also called intellectual capital. According to literature, intangible asset has taken the majority of the whole value in the software and IC industries.

The suggested measuring approaches for intangibles fall into at least four categories of measurement approaches. The categories are an extension of the classifications suggested by Luthy (1998) and Williams (2000).

- ❖ **Direct Intellectual Capital methods (DIC).**
- ❖ **Market Capitalization Methods (MCM).**
- ❖ **Return on Assets methods (ROA).**
- ❖ **Scorecard Methods (SC).**

The methods offer different advantages. The methods offering \$-valuations, such as ROA and MCM methods are useful in merger & acquisition situations and for stock market valuations. They can also be used for comparisons between companies within the same industry and they are good for illustrating the financial value of Intangible assets, a feature, which tends to get the attention of the CEOs. Finally, because they build on long established accounting rules they are easily communicated in the accounting profession. Their disadvantages are that by translating everything into money terms they can be superficial. The ROA methods are very sensitive to interest rate and discounting rate assumptions and the methods that measure only on the organization level are of limited use for management purposes below board level. Several of them are of no use for non-profit organizations, internal departments and public sector organizations; this is particularly true of the MCM methods. The advantages of the DIS and SC methods are that they can create a more comprehensive picture of an organisation's health than financial metrics and that they can be easily applied at any level of an organisation. They measure closer to an event and reporting can therefore be faster and more accurate than pure financial measures. Since they do not need to measure in financial terms they are very useful for non-profit organisations, internal departments and public sector organisations and for environmental and social purposes. Their disadvantages are that the indicators are contextual and have to be customised for each organisation and each purpose, which makes comparisons very difficult. The methods are also new and not easily accepted by societies and managers who are used to see everything from a pure financial perspective. The comprehensive approaches can generate oceans of data, which are hard to analyse and to communicate.

In Scorecard methods, one method is balanced scorecard. It belongs to the non-dollar method. Kaplan & Norton proposed this method in 1992. They proposed the concept of balance scorecard because enterprise's performance measurement and the strategy management should not only consider the financial aspect in new environment. It is an ideal way to contain company's intangible asset. This may make up the insufficiency of financial accounting. This idea is the same as asset value estimate in security risk management.

Within numerous assessment methods of intellectual capital, balanced scorecard assesses intellectual capital value from the view of management and efficiency. Many enterprises declared that they had already applied the balanced scorecard. Its performance measurement has covered the finance and the non-finance index. Such system is more balanced than the financial system.

The balanced scorecard includes four constructions to measure organization performance. The concept of balanced scorecard is suitable for the value estimate of intangible assets.

The balanced scorecard is used in the healthcare

institutes initially, but some articles had described the use of balanced scorecard in the healthcare environment and its potential benefit.

The healthcare institutes that have used the balanced scorecard consider the difference between BSC and other systems:

- The majority of measuring approaches were only suitable in partial management, clinical and diagnostic functions.
- Other measuring approaches were unlike BSC to provide leading indicators.

BSC can be used to express the strategy complexity and the interaction relations through the linkage of causal relations. The information of cost, quality and workflow can be easily and clearly exchanged.

V. Conclusions and Future Work

The enterprise assets may be tangible or intangible. Both needs to be defined explicitly, business owner can explicitly estimate the value. The value of information assets is based on the impact degree to the organization. From the viewpoint of information security, the asset classification and the control are so important in the risk assessment. The traditional measure of an asset is in terms of dollars. But balanced scorecard is different to the traditional method. It belongs to the non-dollar method. The concept of balance scorecard is that enterprise's performance measurement and the strategy management should not only consider the financial aspect in new environment. It is an ideal way to contain company's intangible asset. This may make up the insufficiency of financial accounting. This idea is the same as asset value estimate in security risk management.

The balanced scorecard is used in the healthcare institutes initially, but some articles had described the use of balanced scorecard in the healthcare environment and its potential benefit. Hence, this research proposes utilizing the balanced scorecard to find out the indicators of information assets assessment for domestic medical institutes while carrying on risk management. The importance of each kind of information assets must be confirmed through the assessment indicators. And the results of this research can be regarded as the references of risk management of information security for domestic medical institutes. Hospitals can use security risk management to take appropriate control, to reduce, to prevent, and to change its commercial risk. Then the hospital operation could be continuing.

It is a convenient and effective solution to use the electronic medical information for improving the quality of medical service. Hospitals can avoid the repetition and the waste of medical resources. They can achieve the purpose of saving the medical cost through the connectivity and the exchange of the electronic medical information.

Although there are many merits for using the electronic medical information, however, it still has the information

security problems such as data integrity, confidentiality, non-repudiation and identification. How to obtain the balance in reasonably using the electronic medical information and in protecting patients' privacy is a important issue that should be paid attention to when planning the electronic healthcare information service.

Abstract: In this paper we demonstrate a new impression of intrusion detection system. We use multilevel structure of intrusion detection systems to protect our network. Most of traditional report systems are complicated and hard to manage. In our system, our interface of report system is easy to read and manage. The most important is we use open source software to integrate our system. This can make the cost of intrusion detection system down and make our system flexible. It is convenient to user and network manager. In our system, we can integrate different intrusion detection system and report system into one system. It will become a trend nowadays.

Keywords: intrusion detection system (IDS), firewall, report system

I. Introduction

In recent years, the development of internet become more and more important, and made life convenience. Internet is usually used for research or the way to find information what you need in early years, so researchers are the main users of internet before. Internet is a versatile tool for people nowadays. We can send and receive E-mail, browse website, or find other information related our life in internet. Especially E-commerce, Internet has turn into important tool for modern people.

The conveniences of internet include information exchange and business transactions in internet. The rapid development of E-commerce gives the credit to internet because of its transmitting information is fast. Popular of internet also brings lots of security problems. We should pay much attention to security of E-commerce especially for enterprises. These security problems become important issues today. Most of enterprises use firewall to protect their data and network. But it is not enough. Problem of hacker attack becomes more and more changeable, and various types of virus and troy are increasing. The most important thing is the problem of artificial careless mistake. The security problems of enterprises network come form inside network of enterprises. Network security is hard to defend. Protecting network cannot bear using in the single firewall. For guarantee the security of information and electric business trade, it is indispensable to have an intact and convenience network protect structure.

The prevailing of e-commerce makes enterprises to pay

more and more attention in network security. Some enterprises think that is enough for network security to set up only firewall. But this is incorrect. Firewall only can be a basic network protection. The main function of firewall is to control who want to get into network. However, enterprises still have security problems with only set up firewall. In E-commerce, network packages represent all kinds of trade information. If enterprises cannot ensure the security of network safe, it will cause great money to lose by a small security problem. A simple network attack may cause millions dollars losing for enterprises. Furthermore, it will cause customer information or commercial materials outside of enterprises. Then the goodwill of this enterprise will be seriously injury. Hence, for E-commerce issue. Network security should be care seriously. Besides important of firewall in this issue, intrusion detection system is another important issue in our research.

Intrusion detection system as call IDS is a critical tool of network security. It has much capability, include of sniffing and checking network packages and generate alert log files when it detects network attack. Network structure that only has firewall is not tight enough. For this reason, the integration structure of firewall and instruction detect system turn into safer network security system.

What is the main difference between firewall and intrusion detection system? The mainly purpose of firewall is to identify different IP address and to open up server services for network outside. But the mainly purpose of intrusion detection system is to sniff packages and to detect suspicious packages. If we image that internet is an important road. Firewall looks like a traffic-police on this road. It determines whether you drive against traffic regulation or not, and it can also to fine you when you against traffic regulation. Intrusion detection system looks like a camera of testing speed on the road. It can take down cars which against traffic regulation and then convey car information for traffic-police. The disadvantage is that cannot find the car which against traffic regulation. And this is the largest different between firewall and intrusion detection system. In our research, we present a structure to integrate them.

Commonly intrusion detection system has some disadvantages. They are miscellaneous alert messages and commercialized intrusion detection system is too expensive and hard to maintain. Some of free intrusion detection systems have shortcoming with insufficient. And most important is that when you get alert messages or log files from firewall or intrusion detection system, these reports are uniform. The shortcomings of these reports are hard to read

and have no idea to alter according to user's demand. Even intrusion detection system or firewall is strong, and the reports from these places have no idea to let users or MIS understanding immediately. It conveys more trouble to maintain system and to protect network for MIS or users.

In order to solve illegal network connection and network attack. In our research, we introduce a multilevel network security structure. We call it Multilevel Network Security Structure (MNSS). In this structure, we clean up insufficient security of only firewall in network structure. And offer multilevel of network protection. The structure of our research is including firewall, intrusion detection system, and report system. Our system presents a high stability, high expanding with high capacity and efficiency, and easy to management. The best advantage is to make the whole system cost down. These advantages will be introduced in following paragraphs.

In MNSS, we also present a personal report system (PRS). This report system differs from other common report systems, it can add and delete report column according to user's requirement. Our report system will generate new report form according to user's requirement. It can also generate report according to different position of company. For example, leader of enterprises usually wonder to know whether the company meets a great network attack or not. He does not want to know every alert message in peacetime. Our report system can generate reports which boss interesting at the time. Our report system conveys convenience to most of MIS.

We will introduce MNSS and Personalize report system in detail in following chapters. Chapter 2 will introduce preview of intrusion detection system and its advantages and disadvantages. And intrusion detection system used by our research briefly. Chapter 3 will introduce system structure in detail. Chapter 4 is experiment. And last chapter is conclusion.

II. Preview

II.1 The Category of Intrusion Detection System

There are two categories of intrusion detection system. One is Host-based Intrusion Detection System (HIDS), and the other is Network-based Intrusion Detection System (NIDS). NIDS is typically used recently. Most of researches like to study NIDS which has flexibility used. In our research, we also use NIDS to develop our work. The intrusion detection system is divided into two parts, abnormal detection and misuse detection [1] [2]. We introduce in following briefly.

II.2 Abnormal Detection

Technique of this part is to analyze user behaviors and to use this information to find out whether this is normal used behavior. This method uses user behavior information which collects in advance to determine behavior normal or not. The algorithms of statistic and mathematical induction are used in this part of detection technique mostly. Importance of this

technique is how to define a normal and correct user behavior. The data for defining user behavior also influence user behavior or not. The advantages of these detection techniques are learning automatically. This function can prevent network attack which did not used before. The disadvantage of this technique is depending on user behavior which is collected to define normal model correct or not. If attacker attacks network by using normal user behavior define before, this technique does not find out this behavior correct or not. We will show these detection techniques of abnormal detection as following.

II.3 Neural Network

Neural Network (NN) has capacity of using a large number of data to train these data and learning from training data. There are more and more different applications for researcher in this technique [3]. So this technique also is used for one of intrusion detection system to detect user behavior.

II.4 Support Vector Machine

Support Vector Machine (SVM) and NN are from technique of artificial intelligence. This technique can also predict user behavior by training data set. Some researchers use this technique on intrusion detection system [4] [5], too.

II.5 Data Mining

Algorithms of data mining also apply to collect data and analysis data by some researchers before [6]. This technique can make new feature recognize rule to protect network. Hence, this intrusion detection technique has much security of network.

II.6 Statistical Algorithm

This kind of detection is similar to data mining method. This technique analyzes data collected to calculate a normal user behavior model by using statistical algorithm. The advantage of this technique is that you should understand statistic seriously in advance. And you must use complex mathematic to calculate final result.

II.7 Misuse Detection

The detection technique of misuse detection uses rule-base detection to define network attack. Defined rules will store in database. Intrusion detection system uses rule in database to analyze network package. Pattern matching is one of commonly used technique in this detection. Pattern matching applies on most of intrusion detection system. It has high detection rate on this technique. This technique can use network attack known by pattern matching rules in database. If system detects attack from network, it sends alert message to user or other protect system. User can understand what kind of attack happens through alert message. And user or system manager can defend this attack by information from alert message.

The key point of this technique is that we should collect large number of network attack already know to build

database. So system manager can use rules in database to match with network packet and find out is it network attack. However this technique cannot defend network attack by learning from expensive.

Some researcher used System Call to apply on intrusion detection system before [7]. Most of intrusion detection system mainly uses misuse detection to develop their system. Because of detection technique with pattern matching makes detection faster and convenience. And it has higher detection rate. Some of researchers work for combining abnormal detection and misuse detection into one system.

In our research, we use a commonly used freeware – Snort to be our intrusion detection system in our system. Our research uses iptable to be firewall in our system. We also use ACID to modify our report system, and it is called personal report system. We choice Analysis Console for Intrusion Database (ACID) to modify our system because of it can deal with the report from Snort and iptable. That is why we use these softwares to integrate our system.

Snort is a generally used intrusion detection system today. It has more resource internet. In the part of updating version is very fast because of it is open source software. So that Snort is a powerful and high security intrusion detection system. We will introduce Snort briefly as following.

II. 8 Snort

Snort is a real-time intrusion detection system developed by Martin Roesch. Snort is a lightweight Network-base intrusion detection system. It means when intrusion detection system detects package from network. It does not effect network overloading. Snort has lots of advantages. Snort is cross platform software. And it can work on Linux and Windows. There are three modes of snort. They are Sniffer Mode, Packet Logger Mode, and Network Intrusion Detection System Mode.

1. Sniffer Mode: This mode is used to sniff network

package.

2. Packet Logger Mode: Recording network package information.
3. Network Intrusion Detection System Mode (NIDS Mode): Analyzing network package, and detecting package from network by rule database.

Snort uses NIDS Mode to start intrusion detection, and the structure of intrusion detection shows on Fig. 1. There are four parts of structure of snort. They are Packet Decoder, Preprocessor, Detection Engine, and Output Stage. We introduce these parts first.

1. Packet Decoder: This part collect package from network. It copy broadcast package from network. And it will decode packages which collect from network. Decoded package will be sent to Detection Engine.
2. Preprocessor: This part mainly preprocess package from network. And it can increase detection rate and process speed. Snort provides eight preprocessors at present. Each preprocessor has different function. These preprocessors can choice by user requirement.
3. Detection Engine: Snort used brute force algorithm to do pattern matching in the early. But this algorithm costs much time and resources. Therefore, Snort provides a new algorithm to do pattern matching - Boyer-Moore pattern matching now. This algorithm saves much time than brute force algorithm. For speeding up time of pattern matching. Snort uses three-dimensional linked list data structure in detect engine. These functions make Snort more convenient and efficiency.
4. Output Stage: Output stage decides whether sends alert message or not according to detect engine. So that can generate log files or send alert messages to report system.

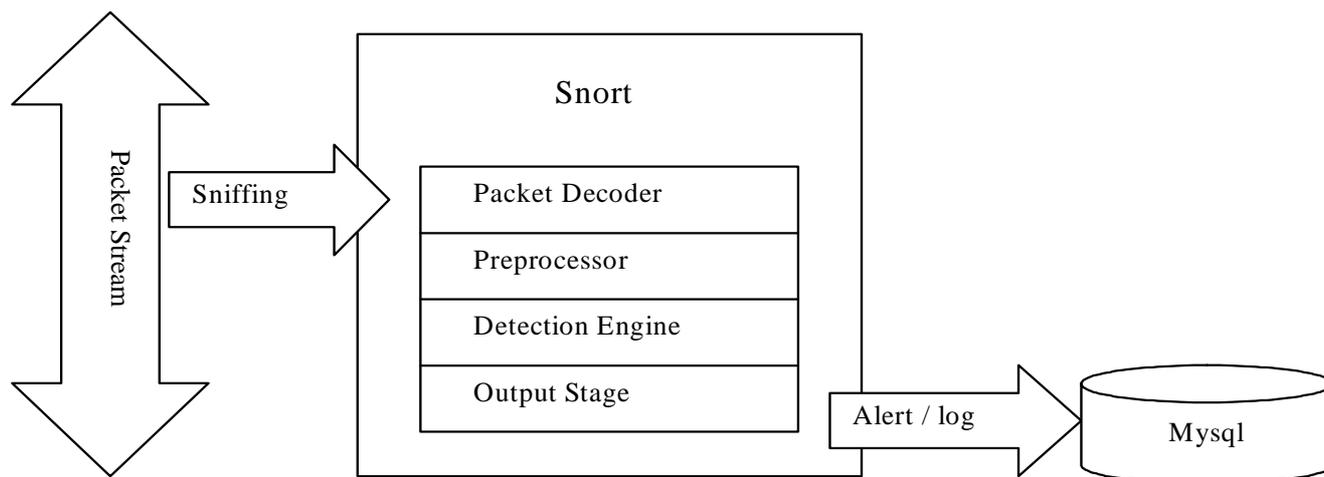

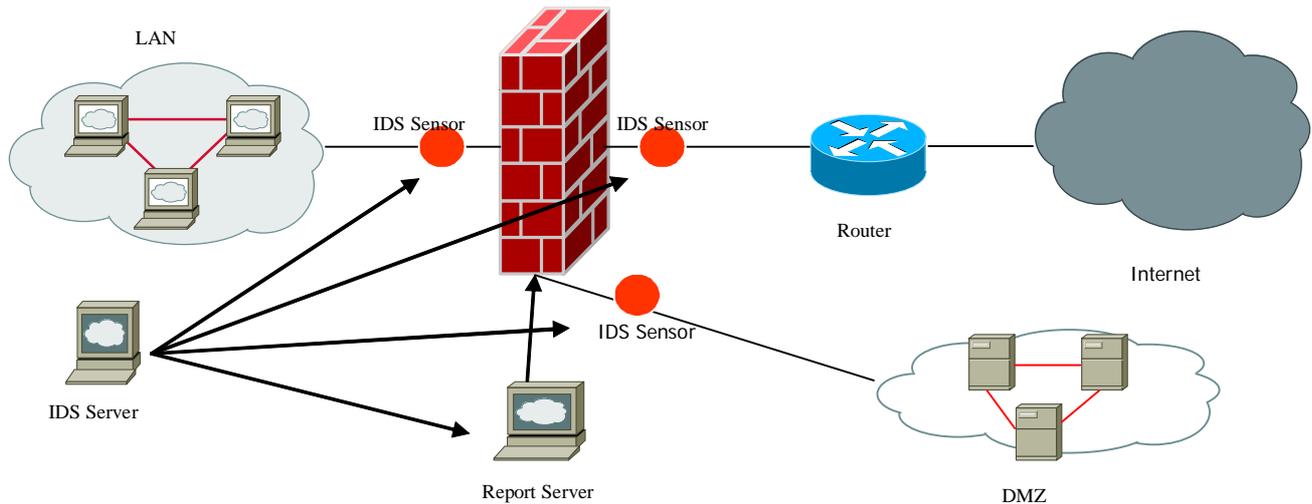

Fig. 1 Structure of Snort

2: System Structure

III. System Structure

Almost Network security systems only use firewall to do network protection before. This structure seems safe enough to general users. But it is danger for enterprises and some e-commerce of company. Hence intrusion detection system is developed for this reason. Most of companies use firewall and intrusion detection system to protect their information on network. It is a trend to use more than two different function systems to protect important information. There still has a problem in user confused of how to build a safer network environment. In our research, we provide a structure to solve this question. We use multilevel network structure for network security system. We find out most of problem from security issue happened before. We present an overall structure for network security. Such as most security problems are from wide-area network (WAN). So we set a sensor in WAN in order to collect information of WAN. In our research, we will set security measure on places where may occur security problem. In the following, we will introduce this structure detail on this chapter.

III. 1 Multilevel Network Security Structure (MNSS)

In order to solve problems mentioned pro paragraph, our research presents a structure call Multilevel Network Structure (MNSS). We integrate firewall, intrusion detection system, and report system into our structure. System structure will be shown in Fig 2.

Intrusion detection system sets three sensors on our structure. They are set in DMZ, in front of firewall (LAN) and behind firewall (WAN). The function of sensor in front of firewall (LAN) mainly checks whether someone attacks network or not. The function of sensor behind firewall (WAN) is to monitor attacks in wide-area network. Final, sensor in DMZ is to ensure servers are safe enough.

Therefore, we set every place where may be attacked by hacker or someone to ensure our structure is safe enough. This structure ensures that it cannot lose any probably attack by someone. And we also know where attack is happened through our structure.

The main advantage of intrusion detection system is this technique does not cause overloading of network. Because of intrusion detection system only sniffs network. Intrusion detection system was an assist tool for firewall to protect network before. Hence, when network attack comes from WAN or DMZ, the system does not know where attack is. So system does not send alert message to user or system manager in real-time. That is why we set three sensors in our structure.

The special of our structure is that we have an independent report system. We call it personal report system (PRS). PRS will introduce in later.

In our research, we use Snort, iptable, PRS to build our structure. Hence, the sensor in front of firewall is first line of defense in our network. Second is firewall. If attack appears in WAN, sensor behind firewall can find out it. Finally, PRS can tell user or system manager where attack occurs, so system manager can handle the situation. That is why we call it multilevel network structure.

In our research, all of systems in our structure are open source software, such as Snort, iptable, PRS. Properties of open source software are free, flexible, and maintain easily. Therefore, MNSS does not necessarily to use the same software which are using in our research, it can be changed into other software according to user's custom and requirement. In other words, the sensors also can replace with three different intrusion detection systems. It can make network security more faultless.

III. 2 Reduce System Cost

Intrusion detection system makes people condemn mostly

because of its expensive software price. Stable and multi-function security system should be bought from company who provides network security service. To enterprises, they should cost much money on building a security system when e-commerce develops in initial stage. This is whole enterprises worried.

Our research makes network security safer and cost down. And our research uses open source software to build system. Open source software is easily to learn because of its network resources. Document and software information is easy to get. In opposition to commercial software is hard to use and learn. And information of commercial software is hard to get. Using commercial software is a burden for system manager. MNSS allows user to choice different intrusion detection system and firewall according to their need, and it can make system cost down.

We also have a special capacity that when someone attack network in MNSS. This capacity can handle network attack real-time by user setting. It reduces time of dealing with network attack by system manager. MNSS can monitor 24 hours to save labor power and cost consume.

III. 3 Independent Report System

In our research, we separate report system to independent server. In commonly security system, intrusion detection system and report system are usually in one server. It cause intrusion detection system and report system cannot work when server down. At this moment, there is only firewall work in security structure and increasing danger in network.

In our structure, report system still work when server down. And report system can centralized manage log files and alert messages from intrusion detection system and firewall in order to avoid server overloading. The other advantage is report system still work when intrusion detection system and firewall change.

III. 4 Personal Report System (PRS)

Our report system calls personal report system (PRS). The system modify from ACID and system structure show in Fig. 3. PRS will introduce as following detail.

PRS uses SMNP protocol to receive log files and alert messages from intrusion detection system and firewall to centralize management. It preprocesses log files and alert messages and saves it to database. Our PRS provides a friendly user interface. This user interface lets user to set report column they need and save it. Database will receive information of which column user selected and send these columns to PRS. PRS uses these data from database to generate report, so we call it personal report.

PRS can generate different reports according to user's requirement. It makes user more convenience. PRS also can generate report base on different positions in company. Leader in company or department only wants to know serious attack about network security. Traditional report system generates only one or few format report for user reading. Leader in company does not want to see these reports. It is too long and complex. PRS does not have these

questions. It can make a great help and save lot of time to system manager.

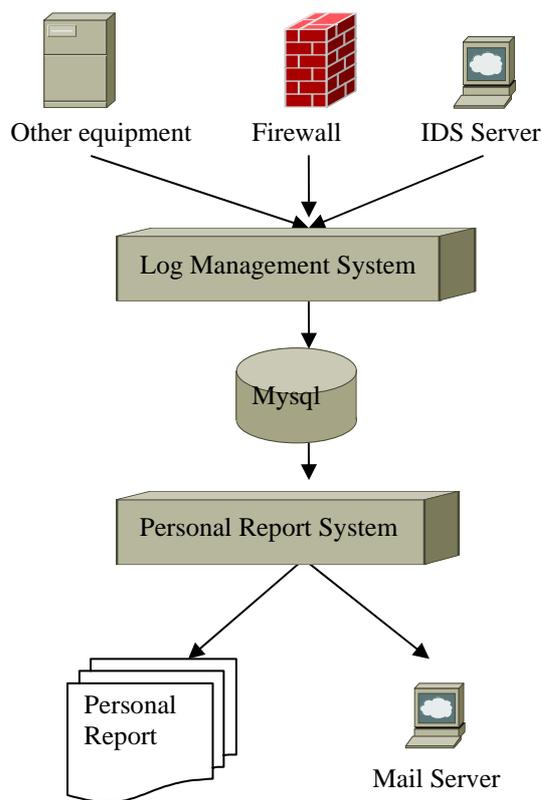

Fig.3 Personal report system structure

IV. Experiment and Analysis

Capacity of defend serious attack

Intrusion detection system must monitor network 24 hours continuously when MNSS is working. In the process of monitoring network, MNSS may detect an obvious network attack. Intrusion detection system only monitor network when network attack occurs before. Network security only uses firewall to defend, and it brings more burdens on firewall. And it must control by system manager. These situations make firewall and system manager more and more trouble.

Our structure has a capacity of defend obvious attack. It can detect and defend obvious attack from network immediately. The flowchart shows in Fig.4.

We use intrusion detection system to monitor network first. And then we define an obvious attack mode base on requirement. Intrusion detection system does extra process to obvious attack mode. In obvious attack mode, system set a time parameter T1 first. When this mode detects an obvious attack setting before, intrusion detection system monitors this attack continuously. Time between network attack occurs until PRS sends message to firewall sets to be T1 and than we set another parameter T (T is a threshold setting by user experience). If value of T1 bigger than T, PRS will send command lines to firewall, these command

lines can set by user in advance. Command lines in here will different base on firewall user used. Firewall can use these command lines from PRS to do some defend immediately.

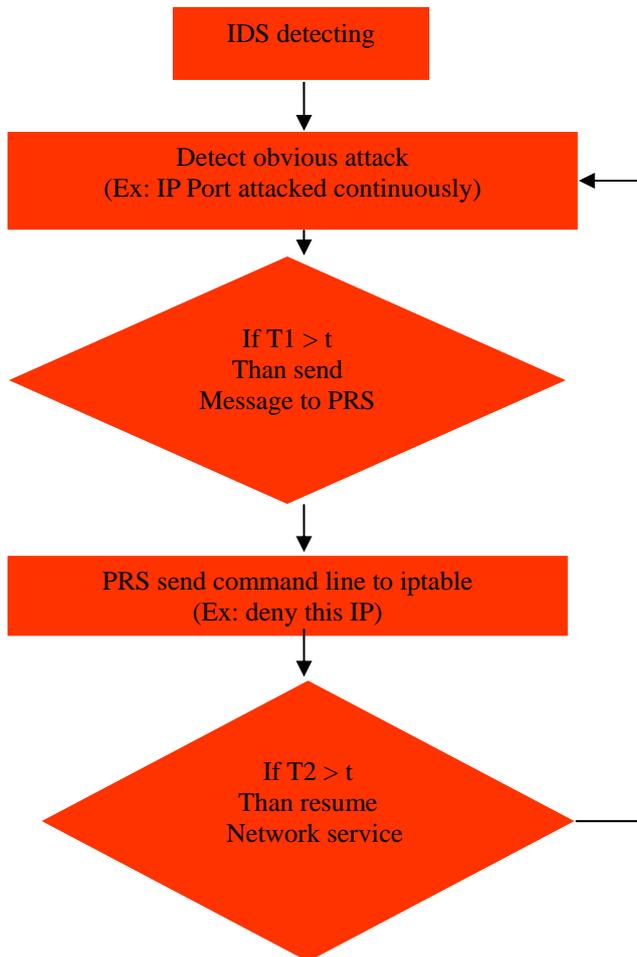

Fig.4 Flowchart of defend serious attack

For example, IP from 192.168.1.1 uses DOS to attack network. We set $T = 10$ minutes first. If DOS attacks network more than 10 minutes continuously, and a default command line for PRS is iptables `-A INPUT -s AttackIP -j DROP`. Therefore, when attack time bigger than 10 minutes, PRS will set command line to firewall (iptables is firewall used in our experiment). Firewall can deny this attack by command line sent by PRS. We will set one time parameter T_2 to resume network service. T_2 is a time across attack start to the end. When T_2 is bigger than 10 minutes, PRS will send iptables `-A INPUT -s 192.168.1.1 -j ACCEPT` to firewall. Firewall can resume service to IP from 192.168.1.1 at this moment.

IV. 1 Compare to Network Security System

In our research, why we use open source software to develop our system? There is a comparison of open source software and commercial software shows in table1. Information of this table is from report write by Dr. Ying-Dar Lin [8]. Open source software in this table is iptable. We can find open

source software is as well as commercial software in detection ability. But it has a great difference in price. It does not mean commercial software is expensive and weak. Because of commercial software has more other function of its system. In this table, we want to show open source software is cost down and still have a good detection in network security.

IV. 2 Display Report

In personal report system, we can analyze alert message sent from firewall and intrusion detection system. And the result shows in Fig.5. This figure shows frequency of alert message generating. And analysis information is collected by firewall and intrusion detection system. Such as source port, distant port, etc.

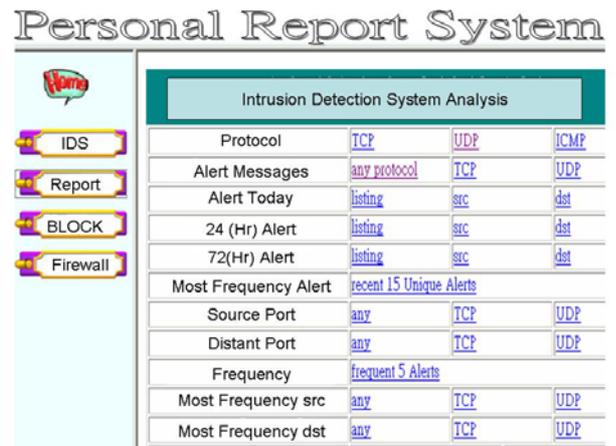

Fig.5: Analysis report

V. Conclusion

In this research, we present a multilevel network structure. This structure integrates intrusion detection system, firewall and personal report system to build more safety network.

All of our structure promotes to use open source software to build a system because of it can make cost down and make user or system manager more convenience and easy to maintain. Personal report system can generate different formats report by user setting. So user can generate report easy to understand and suit by himself. And it is special to generate different reports according to different positions in company.

PRS can use time parameter to send commend for firewall when network has an obvious attack. So that firewall can handle this attack immediately. In traditional situation, system manager gets alert messages and handles this attack wasting time. Our structure integrates network security concepts and reduces burden of system manager.

In our research, it cannot support all of intrusion detection system and firewall yet. We will keep on our research in maintain and development system. Structure

presents a basis structure, and it has more development in this structure. It can be build more function on this platform.

Abstract: Protection of privacy is one of important problems in data mining. The unwillingness to share their data frequently results in failure of collaborative data mining. This paper studies how to build a decision tree classifier under the following scenario: a database is horizontally partitioned into multiple pieces, with each piece owned by a particular party. All the parties want to build a decision tree classifier based on such a database, but due to the privacy constraints, neither of them wants to disclose their private pieces. We build a privacy-preserving system, including a set of secure protocols, that allows the parties to construct such a classifier. We guarantee that the private data are securely protected.

Keywords: Privacy, decision tree, classification.

I. Introduction

Business success often relies on collaboration. The collaboration is even more critical in the modern business world, not only because of mutual benefit it brings but also because the coalition of multiple partners will be more competitive than each individual. Assuming they trust each other to a degree that they can share their private data, the collaboration becomes straightforward. However, in many scenarios, sharing data are impossible because of privacy concerns. Thus, collaboration without sharing private data becomes extremely important.

In this paper, we study a prevalent collaboration scenario, the collaboration involving a data mining task: multiple parties, each having a private data set, want to conduct data mining on the joint data set that is the union of all individual data sets; however, because of the privacy constraints, no party wants to disclose its private data set to each other. The objective of this paper is to develop efficient methods that enable this type of computation while minimizing the amount of the private information that each party has to disclose.

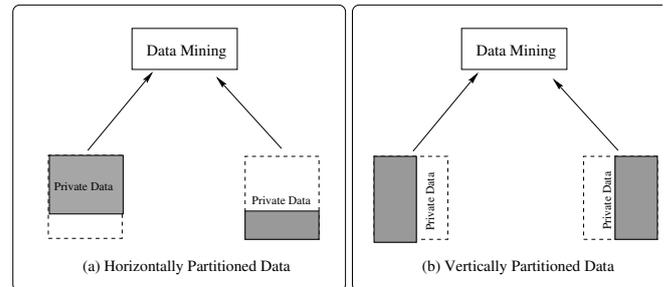

Figure 1:

Data mining includes various algorithms such as classification, association rule mining, and clustering. In this paper, we focus on classification. There are two types of classification between two collaborative parties: Figure 1(a) shows the data classification on the horizontally partitioned data, and Figure 1(b) shows the data classification on the vertically partitioned data. We study the classification on the horizontally partitioned data. In particular, we study how to build a decision tree classifier on private data. We have developed a privacy-preserving system that allows them to build a decision tree classifier based on their joint data.

II. Privacy-Preserving Decision-Tree Classification

Classification is an important problem in the field of data mining. In classification, we are given a set of example records, called the training data set, with each record consisting of several attributes. One of the categorical attributes, called the class label, indicates the class to which each record belongs. The objective of classification is to use the training data set to build a model of the class label such that it can be used to classify new data whose class labels are unknown.

Many types of models have been built for classification, such as neural networks, statistical models, genetic models, and decision tree models. The decision tree models are found to be the most useful in the domain of data

mining since they obtain reasonable accuracy and they are relatively inexpensive to compute. We define our problem as follows:

Problem 1 *We consider the scenario where n parties, each having a private data set (denoted by S_1, S_2, \dots, S_n respectively), want to collaboratively conduct decision tree classification on the union of their data sets. The data sets are assumed to be horizontally partitioned. Because they are concerned about the data privacy, neither party is willing to disclose its raw data set to others.*

Next, we give the notations that we will follow.

II.1 Notations

- e : public key.
- d : private key.
- P_i : the i th party.
- n : the total number of parties. Assuming $n > 2$.
- m : the total number of class.
- α is the number of bits for each transmitted element in the privacy-preserving protocols.
- N : the total number of records.

II.2 Decision Tree Classification Algorithm

Classification is one of the forms for data analysis that can be used to extract models describing important data classes or to predict future data. It has been studied extensively by the community in machine learning, expert system, and statistics as a possible solution to knowledge discovery problems. The decision tree is one of the classification methods. A decision tree is a class discriminator that recursively partitions the training set until each partition entirely or dominantly consists of examples from one class. A well known algorithm for building decision tree classifiers is ID3 [13]. We describe the algorithm below where S represents the training samples and AL represents the attribute list:

ID3(S, AL)

1. Create a node V .
2. **If** S consists of samples with all the same class C **then** return V as a leaf node labelled with class C .
3. **If** AL is empty, **then** return V as a leaf-node with the majority class in S .
4. Select test attribute (TA) among the AL with the highest information gain.
5. Label node V with TA .

6. **For** each known value a_i of TA

- (a) Grow a branch from node V for the condition $TA = a_i$.
- (b) Let s_i be the set of samples in S for which $TA = a_i$.
- (c) **If** s_i is empty **then** attach a leaf labelled with the majority class in S .
- (d) **Else** attach the node returned by **ID3**($s_i, AL - TA$).

According to ID3 algorithm, each non-leaf node of the tree contains a splitting point, and the main task for building a decision tree is to identify an attribute for the splitting point based on the information gain. Information gain can be computed using *entropy*. In the following, we assume there are m classes in the whole training data set. $Entropy(S)$ is defined as follows:

$$Entropy(S) = - \sum_{j=1}^m Q_j \log Q_j, \quad (1)$$

where Q_j is the relative frequency of class j in S . Based on the entropy, we can compute the information gain for any candidate attribute A if it is used to partition S :

$$Gain(S, A) = Entropy(S) - \sum_{v \in A} \left(\frac{|S_v|}{|S|} Entropy(S_v) \right), \quad (2)$$

where v represents any possible values of attribute A ; S_v is the subset of S for which attribute A has value v ; $|S_v|$ is the number of elements in S_v ; $|S|$ is the number of elements in S . To find the best split for a tree node, we compute information gain for each attribute. We then use the attribute with the largest information gain to split the node.

II.3 Cryptography Tools

In this paper, we use the concept of homomorphic encryption which was originally proposed in [18]. Since then, many such systems have been proposed [3, 15, 16, 17]. We observe that some homomorphic encryption schemes, such as [4], are not robust against chosen cleartext attacks. However, we base our secure protocols on [17], which is semantically secure [9].

In our secure protocols, we use additive homomorphism offered by [17]. In particular, we utilize the following characterizer of the homomorphic encryption functions: $e(a_1) \times e(a_2) = e(a_1 + a_2)$ where e is an encryption function; a_1 and a_2 are the data to be encrypted. Because of the property of associativity, $e(a_1 + a_2 + \dots + a_n)$ can be computed as $e(a_1) \times e(a_2) \times \dots \times e(a_n)$ where $e(a_i) \neq 0$. That is

$$d(e(a_1 + a_2 + \dots + a_n)) = d(e(a_1) \times e(a_2) \times \dots \times e(a_n)) \quad (3)$$

$$d(e(\alpha_1)^{\alpha_2}) = d(e(\alpha_1 \alpha_2)) \quad (4)$$

II.4 Privacy-Preserving Decision Tree Classification System

The privacy-preserving classification system contains several secure protocols that multiple parties need follow. There are five major steps:

- To compute $Entropy(S_v)$.
- To compute $\frac{|S_v|}{|S|}$.
- To compute $\frac{|S_v|}{|S|} Entropy(S_v)$.
- To compute information gain for each candidate attribute.
- To compute the attribute with the largest information gain.

The goal of our privacy-preserving classification system is to disclose no private data in every step. We firstly select a key generator who produces the encryption and decryption key pairs. The computation of the whole system is under encryption. For the purpose of illustration, let's assume that P_n is the key generator who generates a homomorphic encryption key pair (e, d) . Next, we will show how to conduct each step.

II.4.1 Computation of $e(Entropy(S_v))$

Protocol 1 To compute $e(Q_j)$

1. Each party computes their own share of $|S_v|$. Assuming P_1 gets c_1 , P_2 gets c_2 , \dots , P_n gets c_n .
2. P_n sends $e(c_n)$ to P_1 .
3. P_1 computes $e(c_n) \times e(c_1) = e(c_1 + c_n)$ and sends it to P_2 .
4. Repeat until P_{n-1} obtains $e(c_1 + c_2 + \dots + c_n)$.
5. P_{n-1} computes $e(\sum_{i=1}^n c_i)^{\frac{1}{n}} = e(Q_j)$.

Protocol 2 To compute $e(Q_j \log(Q_j))$

1. P_{n-1} generates a set of random numbers r_1, r_2, \dots , and r_t .
2. P_{n-1} sends the sequence of $e(Q_j), e(r_1), e(r_2), \dots, e(r_t)$ to P_n in a random order.
3. P_n decrypts each element in the sequence, and sends $\log(Q_j), \log(r_1), \log(r_2), \dots, \log(r_t)$ to P_1 in the same order as P_{n-1} did.
4. P_1 adds a random number R to each of the elements, then sends them to P_{n-1} .
5. P_{n-1} obtains $\log(Q_j) + R$ and computes $e(Q_j)^{(\log(Q_j)+R)} = e(Q_j \log(Q_j) + RQ_j)$.

6. P_{n-1} sends $e(Q_j)$ to P_1 .

7. P_1 computes $e(Q_j)^{-R} = e(-RQ_j)$ and sends it to P_{n-1} .

8. P_{n-1} computes $e(Q_j \log(Q_j) + RQ_j) \times e(-RQ_j) = e(Q_j \log(Q_j))$.

Protocol 3 To compute $e(Entropy(S_v))$

1. Repeat protocol 1-2 to compute $e(Q_j \log(Q_j))$ for all j 's.
2. P_{n-1} computes $e(Entropy(S_v)) = \prod_j e(Q_j \log(Q_j)) = e(\sum_j Q_j \log(Q_j))$.

Theorem 1 (Correctness). Protocol 1-3 correctly compute $Entropy$.

Proof In protocol 1, P_{n-1} obtains $e(Q_j)$. In protocol 2, P_{n-1} gets $e(Q_j \log(Q_j))$. These two protocols are repeatedly used until P_{n-1} obtains $e(Q_j \log(Q_j))$ for all j 's. In protocol 3, P_{n-1} computes the entropy by all the terms previously obtained. Notice that although we use $Entropy(S_v)$ to illustrate, $Entropy(S)$ can be computed following the above protocols with different input attributes. \blacksquare

Theorem 2 (Privacy-Preserving). Assuming the parties follow the protocol, the private data are securely protected.

Proof In protocol 1, all the data transmission are hidden under encryption. The parties who are not the key generator can't see other parties' private data. On the other hand, the key generator doesn't obtain the encryption of other parties's private data. Therefore, protocol 1 discloses no private data. In protocol 2, although P_{n-1} sends $e(Q_j)$ to P_n , Q_j is hidden by a set of random numbers known only by P_{n-1} . Thus private data are not revealed. In protocol 3, the computations are still under encryption, no private data are disclosed either. \blacksquare

Theorem 3 (Efficiency). The computation of $Entropy$ is efficient from both computation and communication point of view.

Proof To prove the efficiency, we need conduct complexity analysis of the protocol. The bit-wise communication cost of protocol 1 is $\alpha(n-1)$, of protocol 2 is $\alpha(3t+5)$. The total communication cost has the upper bound of $\alpha m(n+3t+4)$. The computation cost of protocol 1 is nN , of protocol 2 is $5t+3$. The total computation cost is upper bounded by $mnN + 5mt + 4m$. Therefore, the protocols are sufficient fast. \blacksquare

II.4.2 The Computation of $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$

Protocol 4 To Compute $\frac{|S_v|}{|S|}$

1. P_{n-1} sends $e(|S_v|)$ to P_1 .
2. P_{n-1} generates a set of random numbers: r_1, r_2, \dots, r_t .
3. P_{n-1} sends $e(|S|), e(r_1), \dots,$ and $e(r_t)$ to P_n in a random order. Note that $e(|S|)$ can be computed following the first four steps of protocol 1.
4. P_n decrypts each element, then sends the sequence of $\frac{1}{|S|}, \frac{1}{r_1}, \dots,$ and $\frac{1}{r_t}$ to P_1 in the same order as P_{n-1} did.
5. P_1 computes $e(|S_v|)^\varpi$ where ϖ denotes for each decrypted element, then sends the sequence to P_{n-1} in the same order as P_n did.
6. P_{n-1} obtains $e(\frac{|S_v|}{|S|})$ since he knows the original permutations.

Up to now, P_{n-1} has obtained $e(\frac{|S_v|}{|S|})$ and $e(\text{Entropy}(S_v))$. Next, we discuss how to compute $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$.

Protocol 5 To Compute $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$

1. P_{n-1} sends $e(\frac{|S_v|}{|S|})$ to P_1 .
2. P_1 computes $e(\frac{|S_v|}{|S|}) \times e(R') = e(\frac{|S_v|}{|S|} + R')$ where R' is a random number only known by P_1 , then sends $e(\frac{|S_v|}{|S|} + R')$ to P_n .
3. P_n decrypts it and sends $\frac{|S_v|}{|S|} + R'$ to P_{n-1} .
4. P_{n-1} computes $e(\text{Entropy}(S_v))^{(\frac{|S_v|}{|S|} + R')}$ = $e(\frac{|S_v|}{|S|} \text{Entropy}(S_v) + R' \text{Entropy}(S_v))$.
5. P_{n-1} sends $e(\text{Entropy}(S_v))$ to P_1 .
6. P_1 computes $e(\text{Entropy}(S_v))^{-R'}$ = $e(-R' \text{Entropy}(S_v))$, and sends it to P_{n-1} .
7. P_{n-1} computes $e(\frac{|S_v|}{|S|} \text{Entropy}(S_v)) + R' \text{Entropy}(S_v) \times e(-R' \text{Entropy}(S_v))$ = $e(\frac{|S_v|}{|S|} \text{Entropy}(S_v))$.

Theorem 4 (Correctness). Protocol 4-5 correctly computes $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$.

Proof In protocol 4, P_{n-1} obtains $e(\frac{|S_v|}{|S|})$. In protocol 5, P_{n-1} gets $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$. The computation uses the both properties of homomorphic encryption. ■

Theorem 5 (Privacy-Preserving). Assuming the parties follow the protocol, the private data are securely protected.

Proof In protocol 4, P_n sends $e(|S|)$ to P_n but it is hidden by a set of random numbers known only by P_{n-1} . Although P_1 receives a decrypted sequence, $\frac{1}{|S|}$ is also hidden by a set of random numbers. Thus, P_1 and P_n are prevented from knowing $|S|$. On the other hand, P_{n-1} is also hidden from knowing $|S|$ since all the terms he holds are under encryption. In protocol 5, although P_1 sends $e(\frac{|S_v|}{|S|} + R')$ to P_n , $\frac{|S_v|}{|S|}$ is hidden by a random number known only by P_1 . Therefore, private data are not revealed. ■

Theorem 6 (Efficiency). The computation of protocol 4 and protocol 5 is efficient from both computation and communication point of view.

Proof To prove the efficiency, we need conduct complexity analysis of the protocol. The total communication cost is $\alpha(3t + 4)$. The total computation cost is upper bounded by $6t$. Therefore, the protocols are very efficient. ■

II.4.3 The Computation of the Attribute With the Largest Information Gain

Following the above protocols, we can compute $e(\text{Entropy}(S)), \frac{|S_v|}{|S|} \text{Entropy}(S_v)$. What left is to compute information gain for each attribute and select the attribute with the largest information gain.

Protocol 6 To Compute Information Gain for An Attribute

1. P_{n-1} computes $\prod_{v \in A} e(\frac{|S_v|}{|S|} \text{Entropy}(S_v))$ = $\sum_{v \in A} \frac{|S_v|}{|S|} \text{Entropy}(S_v)$.
2. He computes $e(\sum_{v \in A} \frac{|S_v|}{|S|} \text{Entropy}(S_v))^{-1}$ = $e(-\sum_{v \in A} \frac{|S_v|}{|S|} \text{Entropy}(S_v))$.
3. He computes $e(\text{Gain}(S, A)) = e(\text{Entropy}(S)) \times e(-\sum_{v \in A} \frac{|S_v|}{|S|} \text{Entropy}(S_v))$.

Once we compute the information gain for each candidate attribute, we then compute the attribute with the largest information gain. Without loss of generality, assuming there are k information gains: $e(g_1), e(g_2), \dots,$ and $e(g_k)$, with each corresponding to a particular attribute.

Protocol 7 To Compute the Largest Information Gain

	g_1	g_2	g_3	\dots	g_k
g_1	+1	+1	-1	\dots	-1
g_2	-1	+1	-1	\dots	-1
g_3	+1	+1	+1	\dots	+1
\dots	\dots	\dots	\dots	\dots	\dots
g_k	+1	+1	-1	\dots	+1

Table 1:

	S_1	S_2	S_3	S_4	Weight
S_1	+1	-1	-1	-1	-2
S_2	+1	+1	-1	+1	+2
S_3	+1	+1	+1	+1	+4
S_4	+1	-1	-1	+1	0

Table 2:

1. P_{n-1} computes $e(g_i) \times e(g_j)^{-1} = e(g_i - g_j)$ for all $i, j \in [1, k], i > j$, and sends the sequence denoted by φ to P_n in a random order.
2. P_n decrypts each element in the sequence φ . He assigns the element +1 if the result of decryption is not less than 0, and -1, otherwise. Finally, he obtains a +1/-1 sequence denoted by φ' .
3. P_n sends +1/-1 sequence φ' to P_{n-1} who computes the largest element.

Theorem 7 (Correctness). Protocol 6-7 correctly computes the attribute with the largest information gain.

Proof In protocol 6, P_{n-1} obtains $e(\text{Gain}(S, A))$. In protocol 7, P_{n-1} gets the attribute with the largest information. We discuss the details as follows:

P_{n-1} is able to remove permutation effects from φ' (the resultant sequence is denoted by φ'') since she has the permutation function that she used to permute φ , so that the elements in φ and φ'' have the same order. It means that if the q th position in sequence φ denotes $e(g_i - g_j)$, then the q th position in sequence φ'' denotes the evaluation results of $g_i - g_j$. We encode it as +1 if $g_i \geq g_j$, and as -1 otherwise. P_{n-1} has two sequences: one is the φ , the sequence of $e(g_i - g_j)$, for $i, j \in [1, k] (i > j)$, and the other is φ'' , the sequence of +1/-1. The two sequences have the same number of elements. P_{n-1} knows whether or not g_i is larger than g_j by checking the corresponding value in the φ'' sequence. For example, if the first element φ'' is -1, P_{n-1} concludes $g_i < g_j$. P_{n-1} examines the two sequences and constructs the index table (Table 1) to compute the largest element.

In Table 1, +1 in entry ij indicates that the information gain of the row (e.g., g_i of the i th row) is not less than the information gain of a column (e.g., g_j of the j th column); -1, otherwise. P_{n-1} sums the index values

of each row and uses this number as the weight of the information gain in that row. She then selects the one that corresponds to the largest weight.

To make it clearer, let's illustrate it by an example. Assume that: (1) there are 4 information gains with $g_1 < g_4 < g_2 < g_3$; (2) the sequence φ is $[e(g_1 - g_2), e(g_1 - g_3), e(g_1 - g_4), e(g_2 - g_3), e(g_2 - g_4), e(g_3 - g_4)]$. The sequence φ'' will be $[-1, -1, -1, -1, +1, +1]$. According to φ and φ'' , P_{n-1} builds the Table 2. From the table, P_{n-1} knows g_3 is the largest element since its weight, which is +4, is the largest. ■

Theorem 8 (Privacy-Preserving). Assuming the parties follow the protocol, the private data are securely protected.

Proof In protocol 6, there is no data transmission. In protocol 7, we need prove it from two aspects: (1) P_{n-1} doesn't get information gain (e.g., g_i) for each attribute. What P_{n-1} gets are $e(g_i - g_j)$ for all $i, j \in [1, k], i > j$ and +1/-1 sequence. By $e(g_i - g_j)$, P_{n-1} cannot know each information gain since it is encrypted. By +1/-1 sequence, P_{n-1} can only know whether or not g_i is greater than P_j . (2) P_n doesn't obtain information gain for each attribute either. Since the sequence of $e(g_i - g_j)$ is randomized before being send to P_n who can only know the sequence of $g_i - g_j$, he can't get each individual information gain. Thus private data are not revealed. ■

Theorem 9 (Efficiency). The computation of protocol 6 and protocol 7 is efficient from both computation and communication point of view.

Proof The total communication cost is upper bounded by αm^2 . The total computation cost is upper bounded by $m^2 + m + 1$. Therefore, the protocols are very fast. ■

III. Overall Discussion

Our privacy-preserving classification system contains several components. In Section , we show how to correctly compute $e(\text{Entropy}(S_v))$. In Section , we present protocols to compute $\frac{|S_v|}{|S|} \text{Entropy}(S_v)$. In Section , we show how to compute information gain for each candidate attribute; we then describe how to obtain the attribute with the largest information gain. We discussed the correctness of the computation in each section. Overall correctness is also guaranteed.

As for the privacy protection, all the communications between the parties are encrypted, therefore, the parties who has no decryption key cannot gain anything out of the communication. On the other hand, there are some communication between the key generator and

other parties. Although the communications are still encrypted, the key generator may gain some useful information. However, we guarantee that the key generator cannot gain the private data by adding random numbers in the original encrypted data so that even if the key generator get the intermediate results, there is little possibility that he can know the intermediate results. Therefore, the private data are securely protected with overwhelming probability.

IV. Conclusion

Prior to conclude this paper. We describe the most related works. In early work on privacy-preserving data mining, Lindell and Pinkas [14] propose a solution to privacy-preserving classification problem using oblivious transfer protocol, a powerful tool developed by secure multi-party computation (SMC) research [22, 10]. The techniques based on SMC for efficiently dealing with large data sets have been addressed in [21]. Randomization approaches were firstly proposed by Agrawal and Srikant in [2] to solve privacy-preserving data mining problem. Researchers proposed more random perturbation-based techniques to tackle the problems (e.g., [5, 19, 7]). In addition to perturbation, aggregation of data values [20] provides another alternative to mask the actual data values. In [1], authors studied the problem of computing the k th-ranked element. Dwork and Nissim [6] showed how to learn certain types of boolean functions from statistical databases in terms of a measure of probability difference with respect to probabilistic implication, where data are perturbed with noise for the release of statistics.

The problem we are studying is actually a special case of a more general problem, the Secure Multi-party Computation (SMC) problem. Briefly, a SMC problem deals with computing any function on any input, in a distributed network where each participant holds one of the inputs, while ensuring that no more information is revealed to a participant in the computation than can be inferred from that participant's input and output [12]. The SMC problem literature is extensive, having been introduced by Yao [22] and expanded by Goldreich, Micali, and Wigderson [11] and others [8]. It has been proved that for any function, there is a secure multi-party computation solution [10]. The approach used is as follows: the function F to be computed is first represented as a combinatorial circuit, and then the parties run a short protocol for every gate in the circuit. Every participant gets corresponding shares of the input wires and the output wires for every gate. This approach, though appealing in its generality and simplicity, means that the size of the protocol depends on the size of the circuit, which depends on the size of the input. This is highly ineffi-

cient for large inputs, as in data mining. It has been well accepted that for special cases of computations, special solutions should be developed for efficiency reasons.

In this paper, we provide a novel solution for decision tree classification over horizontally partitioned private data. Instead of using data transformation, we define a protocol using homomorphic encryption to exchange the data while keeping it private. Our classification system is quite efficient that can be envisioned by the communication and computation complexity. The total communication complexity is upper bounded by $\alpha(m^2 + nm + 3tm + 4m + 3t + 4)$. The computation complexity is upper bounded by $mnN + m^2 + 5mt + 5m + 6t + 1$.

Abstract: This paper addresses the problem of data sharing among multiple parties, without disclosing the data between the parties. We focus on sharing of data among parties involved in a data mining task. We study how to share private or confidential data in the following scenario: without disclosing their private data to each other, multiple parties, each having a private data set, want to collaboratively construct support vector machines using a linear, polynomial or sigmoid kernel function. To tackle this problem, we develop a secure protocol for multiple parties to conduct the desired computation. The solution is distributed, i.e., there is no central, trusted party having access to all the data. Instead, we define a protocol using homomorphic encryption techniques to exchange the data while keeping it private. We analyze the protocol in the context of mistakes and malicious attacks, and show its robustness against such attacks. All the parties are treated symmetrically: they all participate in the encryption and in the computation involved in learning support vector machines.

Keywords: Privacy, security, support vector machine, secure multi-party computation.

I. Introduction

In this paper, we address the following problem: multiple parties are cooperating on a data-rich task. Each of the parties owns data pertinent to the aspect of the task addressed by this party. More specifically, the data consists of instances, each party owns her instances but all parties have the same attributes. The overall performance, or even solvability, of this task depends on the ability of performing data mining using all the instances of all the parties. The parties, however, may be unwilling to release their instances to other parties, due to privacy or confidentiality of the data. How can we structure information sharing between the parties so that the data will be shared for the purpose of data mining, while at the same time specific instance values will be kept con-

fidential by the parties to whom they belong? This is the task addressed in this paper. In the privacy-oriented data mining this task is known as data mining with horizontally partitioned data (also known as homogeneous collaboration [15].) Examples of such tasks abound in business, homeland security, coalition building, medical research, etc.

The following scenarios illustrate situations in which this type of collaboration is interesting: (i) Multiple competing supermarkets, each having an extra large set of data records of its customers' buying behaviors, want to conduct data mining on their joint data set for mutual benefit. Since these companies are competitors in the market, they do not want to disclose their customers' information to each other, but they know the results obtained from this collaboration could bring them an advantage over other competitors. (ii) Success of homeland security aiming to counter terrorism depends on combination of strength across different mission areas, effective international collaboration and information sharing to support coalition in which different organizations and nations must share some, but not all, information. Information privacy thus becomes extremely important: all the parties of the collaboration promise to provide their private data to the collaboration, but neither of them wants each other or any other party to learn much about their private data.

Without privacy concerns, all parties can send their data to a trusted central place to conduct the mining. However, in situations with privacy concerns, the parties may not trust anyone. We call this type of problem the *Privacy-preserving Collaborative Data Mining problem*. As stated above, in this paper we are interested in homogeneous collaboration where each party has the same sets of attributes [15] but has different sets of instances.

Data mining includes a number of different tasks, such as association rule mining, classification, and clustering, etc. This paper studies how to learn support vector machines. In the last few years, there has been a surge of interest in Support Vector Machines (SVM) [29, 28]. SVM is a powerful methodology for solving problems in nonlinear classification, function estimation and density estimation which has also led to many other recent developments in kernel based learning methods in gen-

eral [7, 25, 24]. SVMs have been introduced within the context of statistical learning theory and structural risk minimization. As part of the SVM algorithm, one solves convex optimization problems, typically quadratic programs. It has been empirically shown that SVMs have good generalization performance on many applications such as text categorization [13], face detection [20], and handwritten character recognition [16]. Based on the existing SVM learning technologies, we study the problem of learning Support Vector Machines on private data. More precisely, the problem is defined as follows: multiple parties want to build support vector machines on a data set that consists of private data of all the parties, but none of the parties is willing to disclose her raw data to each other or any other parties. We develop a secure protocol, based on homomorphic cryptography and random perturbation techniques, to tackle the problem. An important feature of our approach is its distributed character, i.e. there is no single, centralized authority that all parties need to trust. Instead, the computation is distributed among parties, and its structure and the use of homomorphic encryption ensures privacy of the data.

The paper is organized as follows: The related work is discussed in Section 2. We describe the SVMs training procedure in Section 3. We then present our proposed secure protocols in Section 4. We give our conclusion in Section 5.

II. Related Work

II.1 Secure Multi-Party Computation

A Secure Multi-party Computation (SMC) problem deals with computing any function on any input, in a distributed network where each participant holds one of the inputs, while ensuring that no more information is revealed to a participant in the computation than can be inferred from that participant's input and output. The SMC problem literature was introduced by Yao [31]. It has been proved that for any polynomial function, there is a secure multi-party computation solution [12]. The approach used is as follows: the function F to be computed is firstly represented as a combinatorial circuit, and then the parties run a short protocol for every gate in the circuit. Every participant gets corresponding shares of the input wires and the output wires for every gate. This approach, though appealing in its generality and simplicity, is highly impractical for large datasets.

II.2 Privacy-Preserving Data Mining

In early work on privacy-preserving data mining, Lindell and Pinkas [17] propose a solution to privacy-preserving classification problem using oblivious transfer protocol,

a powerful tool developed by secure multi-party computation (SMC) research. The techniques based on SMC for efficiently dealing with large data sets have been addressed in [14], where a solution to the association rule mining problem for the case of two parties was proposed.

Randomization approaches were firstly proposed by Agrawal and Srikant in [3] to solve privacy-preserving data mining problem. In addition to perturbation, aggregation of data values [26] provides another alternative to mask the actual data values. In [1], authors studied the problem of computing the k th-ranked element. Dwork and Nissim [9] showed how to learn certain types of boolean functions from statistical databases in terms of a measure of probability difference with respect to probabilistic implication, where data are perturbed with noise for the release of statistics. In this paper, we focus on privacy-preserving among the inter-party computation.

Homomorphic encryption [21], which transforms multiplication of encrypted plaintexts into the encryption of the sum of the plaintexts, has recently been used in secure multi-party computation. For instance, Freedmen, Nissim and Pinkas [10] applied it for set intersection. For computing set intersection, unlike [10], [2] and [27] proposed an approach based on commutative encryption. The work most related to ours is [30], where Wright and Yang applied homomorphic encryption [21] to the Bayesian networks induction for the case of *two* parties. The work that are closely related ours is [32], where Zhan et.al. present secure protocols for learning support vector machine over vertically partitioned data. In this paper, we develop a secure protocol, based on homomorphic encryption and random perturbation techniques, for multiple parties to build SVMs over horizontally partitioned data without compromising their data privacy.

III. Learning SVMs On Private Data

Support vector machines were invented by Vapnik [29] in 1982. The idea consists of mapping the space of input examples into a high-dimensional feature space, so that the optimal separating hyperplane built on this space allow a good generalization capacity. The input examples become linearly or almost linearly separable in the high dimensional space through selecting an adequate mapping [28]. Research on SVMs is extensive since it was invented. However, to our best knowledge, there is no effort on learning SVMs on private data. In this paper, our goal is to provide a privacy-preserving algorithm for multi-parties to collaboratively learn SVMs without compromising their data privacy.

III.1 Problem

We consider the scenario where multiple parties P_1, P_2, \dots , and P_n , each having a private data set (denoted by D_1, D_2, \dots and D_n respectively), want to collaboratively learn SVMs on the concatenation of their data sets. Because they are concerned about their data privacy, neither party is willing to disclose its actual data set to others. Specially, we consider the homogeneous collaboration where each data set contains the same number of attributes but different set of instances. Let m be the total number of attributes in each data set. Let N be the total number of instances, N_1 is the number of instances for P_1 , N_2 is the number of instances for P_2, \dots , and N_n is the number of instances for P_n . We further assume that the class labels are shared but the instance identifiers and actual attribute values are kept confidential.

III.2 Overview of Support Vector Machine

SVM is primarily a two-class classifier for which the optimization criterion is the width of the margin between the different classes. In the linear form, the formula for output of a SVM is

$$u = \vec{w} \cdot \vec{x} + b, \tag{1}$$

where \vec{w} is the normal vector to the hyperplane and \vec{x} is the input vector. To maximize margin, we need minimize the following [5]:

$$\min_{\vec{w}, b} \frac{1}{2} \|\vec{w}\|^2, \tag{2}$$

subject to $y_i(\vec{w} \cdot \vec{x}_i + b) \geq 1, \forall i$, where \vec{x}_i is the i th training example, and y_i is the correct output of the SVM for the i th training example. The value y_i is +1 (resp. -1) for the positive (resp. negative) examples in a class.

Through introducing Lagrangian multipliers, the above optimization can be converted into a dual quadratic optimization problem.

$$\min_{\vec{\alpha}} \Psi(\vec{\alpha}) = \min_{\alpha_i, \alpha_j} \frac{1}{2} \sum_{i,j=1}^N \alpha_i \alpha_j y_i y_j K(\vec{x}_i, \vec{x}_j) - \sum_{i=1}^N \alpha_i, \tag{3}$$

where α_i are the Lagrange multipliers, $\vec{\alpha} = \alpha_1, \alpha_2, \dots, \alpha_N$, subject to inequality constraints: $\alpha_i \geq 0, \forall i$, and linear equality constraint: $\sum_{i=1}^N y_i \alpha_i = 0$.

By solving the dual optimization problem, one obtains the coefficients $\alpha_i, i = 1, \dots, N$, from which the normal vector \vec{w} and the threshold b can be derived [22].

To deal with non-linearly separable data in feature space, Cortes and Vapnik [6] introduced slack-variables

to relax the hard-margin constraints. The modification is:

$$\min \frac{1}{2} \|\vec{w}\|^2 + C \sum_{i=1}^N \xi_i \tag{4}$$

subject to $y_i(\vec{w} \cdot \vec{x}_i + b) \geq 1 - \xi_i, \forall i$, where ξ_i is slack variable that allows margin failure and constant $C > 0$ determines the trade-off between the empirical error and the complexity term. This leads to dual quadratic problem involving Eq.[3] subject to the constraints $C \geq \alpha_i \geq 0, \forall i$ and $\sum_{i=1}^N y_i \alpha_i = 0$.

To solve the dual quadratic problem, we apply sequential minimal optimization [22] which is a very efficient algorithm for training SVMs.

III.3 Sequential Minimal Optimization

Sequential Minimal Optimization (SMO) [22] is a simple algorithm that can efficiently solve the SVM quadratic optimization (QO) problem. Instead of directly tackle the QO problem, it decomposes the overall QO problem into QO sub-problems based on Osunna's convergence theorem [20]. At each step, SMO chooses two Lagrange multipliers to jointly optimize, find the optimal values for these multipliers, and updates the SVM to reflect the new optimal values.

In order to solve for the two Lagrange multipliers, SMO firstly computes the constraints on these multipliers and then solves for the constrained minimum. Normally, the objective function is positive definite, SMO computes the minimum along the direction of the linear constraints $\sum_{i=1}^2 y_i \alpha_i = 0$ within the boundary $C \geq \alpha_i \geq 0, i = 1, 2$.

$$\alpha_2^{new} = \alpha_2 + y_2(E_1 - E_2) \eta, \tag{5}$$

where $E_i = y_i \alpha_i K(\vec{x}_i, \vec{x}) - y_i$ is the error on the i th training example, \vec{x}_i is the stored training vector and \vec{x} is the input vector, and η is the second derivative of Eq.[3] along the direction of the above linear constraints:

$$\eta = K(\vec{x}_1, \vec{x}_1) + K(\vec{x}_2, \vec{x}_2) - 2K(\vec{x}_1, \vec{x}_2). \tag{6}$$

Next step, the constrained minimum is found by clipping the unconstrained minimum to the ends of the line segment: $\alpha_2^{new,clipped}$ is equal to H if $\alpha_2^{new} \geq H$, is equal to α_2^{new} if $L < \alpha_2^{new} < H$, and is equal to $\alpha_2^{new,clipped} = L$ if $\alpha_2^{new} \leq L$. If the target y_1 is not equal to the target y_2 , $L = \max(0, \alpha_2 - \alpha_1)$, $H = \min(C, C + \alpha_2 - \alpha_1)$. If the target y_1 is equal to the target y_2 , $L = \max(0, \alpha_2 + \alpha_1 - C)$, $H = \min(C, \alpha_2 + \alpha_1)$.

The value of α_1 is computed from the new, clipped, α_2 :

$$\alpha_1^{new} = \alpha_1 + s(\alpha_2 - \alpha_2^{new,clipped}), \tag{7}$$

where $s = y_1 y_2$.

In the procedure of sequential minimal optimization, the only step accessing the actual attribute values is the computation of the kernel function K . Kernel functions have various forms. Three types of kernel functions are considered: they are the linear kernel function $K = (\vec{a} \cdot \vec{b})$, the polynomial kernel function $K = ((\vec{a} \cdot \vec{b}) + \theta)^d$, where $d \in \mathcal{N}$, $\theta \in \mathcal{R}$ are constants, and the sigmoid kernel function $K = \tanh((\kappa(\vec{a} \cdot \vec{b})) + \theta)$, where $\kappa, \theta \in \mathcal{R}$ are constants, for instances \vec{a} and \vec{b} .

To compute these types of kernel functions, one needs to compute the inner product between two instances. If the two instances belong to the same party, this party can compute the inner product by herself; if one instance (e.g., \vec{x}_1) belongs to one party (e.g., P_1), and the other instance (e.g., \vec{x}_2) belongs to another party (e.g., P_2), then P_1 can compute $(\vec{x}_1 \cdot \vec{x}_1)$ and P_2 can compute $(\vec{x}_2 \cdot \vec{x}_2)$. However, to compute $(\vec{x}_1 \cdot \vec{x}_2)$, different parties have to collaborate. How to conduct this inner product computation across parties without compromising each party's data privacy presents a great challenge. In next section, secure protocols are developed to tackle this challenge.

IV. Protocols

IV.1 Introducing Homomorphic Encryption

The concept of homomorphic encryption was originally proposed in [23]. Since then, many such systems have been proposed [4, 18, 19, 21]. We observe that some homomorphic encryption schemes, such as [8], are not robust against chosen plaintext attacks. However, we base our secure protocols on [21], which is semantically secure [11].

In our secure protocols, we use additive homomorphism offered by [21]. In particular, we utilize the following characterizer of the homomorphic encryption functions: $e(a_1) \times e(a_2) = e(a_1 + a_2)$ where e is an encryption function; a_1 and a_2 are the data to be encrypted. Because of the property of associativity, $e(a_1 + a_2 + \dots + a_n)$ can be computed as $e(a_1) \times e(a_2) \times \dots \times e(a_n)$ where $e(a_i) \neq 0$. That is

$$d(e(a_1 + a_2 + \dots + a_n)) = d(e(a_1) \times e(a_2) \times \dots \times e(a_n)) \quad (8)$$

$$d(e(a_1)^{a_2}) = d(e(a_1 a_2)) \quad (9)$$

IV.2 A Secure Protocol

Let's assume that P_1 has an instance vector \vec{x}_1 and P_2 has an instance vector \vec{x}_2 . Both vectors have m elements. We use x_{1i} to denote the i th element in vector \vec{x}_1 , and x_{2i} to denote the i th element in vector \vec{x}_2 . In order to

compute the $K(\vec{x}_1, \vec{x}_2)$, the key issue is how P_1 and P_2 compute the inner product between \vec{x}_1 and \vec{x}_2 without disclosing them to each other. In our secure protocol, P_1 adds a random number to each of her actual data values, encrypts the masked values, and sends the encrypted masked terms to P_2 . By adding the random numbers, P_2 is prevented from guessing P_1 's actual values based on encryption patterns. Firstly, one of parties is randomly chosen as a key generator. For simplicity, let's assume P_1 is selected as the key generator. P_1 generates a cryptographic key pair (d, e) of a semantically-secure homomorphic encryption scheme and publishes its public key e . P_1 applies the encryption key to each element of x_1 (e.g., $e(x_{1i} + r_i)$). P_2 computes $e(\vec{x}_1 \cdot \vec{x}_2)$. He then sends $e(\vec{x}_1 \cdot \vec{x}_2)$ to P_1 who decrypts it and gets $(\vec{x}_1 \cdot \vec{x}_2)$.

We describe this more formally as

Protocol 1 *INPUT: P_1 's input is a vector $\vec{x}_1 = \{x_{11}, x_{12}, \dots, x_{1m}\}$, and P_2 's input is a vector $\vec{x}_2 = \{x_{21}, x_{22}, \dots, x_{2m}\}$. The elements in the input vectors are taken from the real number domain.*

1. P_1 performs the following operations:

- (a) She computes $e(x_{1i} + r_i)$ s ($i \in [1, m]$) and sends them to P_2 . r_i , known only by P_1 , is a random number in real domain.
- (b) She computes $e(-r_i)$ s ($i \in [1, m]$) and sends them to P_2 .

2. P_2 performs the following operations:

- (a) He computes $t_1 = e(x_{11} + r_1)^{x_{21}} = e(x_{11} \cdot x_{21} + r_1 x_{21})$, $t_2 = e(x_{12} + r_2)^{x_{22}} = e(x_{12} \cdot x_{22} + r_2 x_{22})$, \dots , $t_m = e(x_{1m} + r_m)^{x_{2m}} = e(x_{1m} \cdot x_{2m} + r_m x_{2m})$.
- (b) He computes $t_1 \times t_2 \times \dots \times t_m = e(x_{11} \cdot x_{21} + x_{12} \cdot x_{22} + \dots + x_{1m} \cdot x_{2m} + r_1 x_{21} + r_2 x_{22} + \dots + r_m x_{2m}) = e(\vec{x}_1 \cdot \vec{x}_2 + \sum_{i=1}^m r_i x_{2i})$.
- (c) He computes $e(-r_i)^{x_{2i}} = e(-r_i x_{2i})$ for $i \in [1, m]$.
- (d) He computes $e(\vec{x}_1 \cdot \vec{x}_2 + \sum_{i=1}^m r_i x_{2i}) \times e(-r_1 x_{21}) \times e(-r_2 x_{22}) \times \dots \times e(-r_m x_{2m}) = e(\vec{x}_1 \cdot \vec{x}_2)$.

We need to show that the above protocol is correct, and that it preserves the privacy of P_1 and P_2 as postulated in Sec. 3.1.

Lemma 1 (*Correctness*). *Protocol 1 correctly computes the inner product $(\vec{x}_1 \cdot \vec{x}_2)$ against semi-honest parties.*

Proof When P_2 receives each encrypted element $e(x_{1i} + r_i)$ and $e(-r_i)$, he computes $\sum_{i=1}^m e(x_{1i} + r_i)^{x_{2i}}$ which, according to Eq.(9), is equal to $e(\sum_{i=1}^m x_{1i} \cdot x_{2i} + \sum_{i=1}^m r_i x_{2i})$ for all $i \in [1, m]$. He then computes $e(\vec{x}_1 \cdot \vec{x}_2 +$

$\sum_{i=1}^m r_i x_{2i}) \times e(-r_1 x_{21}) \times e(-r_2 x_{22}) \times \dots \times e(-r_m x_{2m}) = e(\vec{x}_1 \cdot \vec{x}_2)$ according to Eq.(8). After that, he sends it to P_1 who computes $d(e(\vec{x}_1 \cdot \vec{x}_2)) = (\vec{x}_1 \cdot \vec{x}_2)$. Therefore, $(\vec{x}_1 \cdot \vec{x}_2)$ is correctly computed. ■

Lemma 2 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof There are 2 points we need analyze. (1) Whether P_1 can obtain P_2 's private data. There is no information that P_2 sends to P_1 , thus, P_2 's private data cannot be disclosed to P_1 . (2) Whether P_2 can obtain P_1 's private data. What P_2 receives from P_1 is encrypted and masked element of P_1 's data. Since P_2 has no decryption key and doesn't know the random number used by P_1 , it is impossible that P_2 can obtain P_1 's private data. ■

Lemma 3 (Efficiency). *Protocol 1 is efficient from both computation and communication point of view.*

Proof To prove the efficiency, we need conduct complexity analysis of the protocol. The bit-wise communication cost of this protocol is $(2m + 1)\alpha$ where α is the number of bits for each transmitted element. The following contributes to the computational cost: (1) $2m$ encryptions; (2) $2m$ exponentiations; (2) $2m-1$ multiplications. Therefore, the protocol is sufficient fast. ■

V. Conclusion

In this paper, we consider the problem of collaboratively learning Support Vector Machines on private data. We develop a secure collaborative protocol based on semantically secure homomorphic encryption scheme. In our protocol, the parties do not need to send all their data to a central, trusted party. Instead, we use the homomorphic encryption and random perturbation techniques to conduct the computations across the parties without compromising their data privacy. As future work, we will develop secure protocols for the cases where more kernel functions are applied. We will also apply our technique to other data mining computations, such as secure collaborative clustering.

Abstract: Protection of privacy is a critical problem in data mining. Preserving data privacy in distributed data mining is even more challenging. In this paper, we consider the problem of privacy-preserving naive Bayesian classification over vertically partitioned data. The problem is one of important issues in privacy-preserving distributed data mining. Our approach is based on homomorphic encryption. The scheme is very efficient in the term of computation and communication cost.

Keywords: Privacy, security, naive Bayesian classification.

I. Introduction

Recent advances in computer networking and database technologies have resulted in creation of large quantities of data which are located in different sites. Data mining is a useful tool to extract valuable knowledge from this data. Well known data mining algorithms include association rule mining, classification, clustering, outlier detection, etc. However, extracting useful knowledge from distributed sites is often challenging due to real world constraints such as privacy, communication and computation overhead.

In this paper, we focus on privacy-preserving data mining in a distributed setting where the different sites have diverse sets of features. Specially, we consider the problem of privacy-preserving naive Bayesian classification that is one of the most successful algorithms in many classification domains. A Bayesian network is a high-level representation of a probability distribution over a set of variables that are used for constructing a model of the problem domain. It has been widely used in sales decision making, marketing systems, risk analysis, cost benefit factor inference in E-services, and other business applications. A Bayesian network have many applications. For instance it can be used to compute the predictive distribution on effects of possible actions since it

is a model of the problem domain probability distribution.

A naive Bayesian classifier is one of Bayesian classifiers under conditional independence assumption of different features. Over the last decade, the naive Bayesian classification has been widely utilized. Although the techniques that have been developed are effective, new techniques dealing with naive Bayesian classification over private data are required. In other words, we need methods to learn a naive Bayesian classifier over distributed private data. In this paper, we develop a novel scheme based on homomorphic encryption without compromising data privacy.

II. Related Work

In early work on privacy-preserving data mining, Lindell and Pinkas [13] propose a solution to privacy-preserving classification problem using oblivious transfer protocol, a powerful tool developed by secure multi-party computation (SMC) research [21, 10]. The techniques based on SMC for efficiently dealing with large data sets have been addressed in [20]. Randomization approaches were firstly proposed by Agrawal and Srikant in [2] to solve privacy-preserving data mining problem. Researchers proposed more random perturbation-based techniques to tackle the problems (e.g., [5, 18, 7]). In addition to perturbation, aggregation of data values [19] provides another alternative to mask the actual data values. In [1], authors studied the problem of computing the k th-ranked element. Dwork and Nissim [6] showed how to learn certain types of boolean functions from statistical databases in terms of a measure of probability difference with respect to probabilistic implication, where data are perturbed with noise for the release of statistics. The problem we are studying is actually a special case of a more general problem, the Secure Multi-party Computation (SMC) problem. Briefly, a SMC problem deals with computing any function on any input, in a distributed network where each participant holds one of the inputs, while ensuring that no more information is revealed to a participant in the computation than can be inferred from

that participant's input and output [12]. The SMC problem literature is extensive, having been introduced by Yao [21] and expanded by Goldreich, Micali, and Wigderson [11] and others [8]. It has been proved that for any function, there is a secure multi-party computation solution [10]. The approach used is as follows: the function F to be computed is first represented as a combinatorial circuit, and then the parties run a short protocol for every gate in the circuit. Every participant gets corresponding shares of the input wires and the output wires for every gate. This approach, though appealing in its generality and simplicity, means that the size of the protocol depends on the size of the circuit, which depends on the size of the input. This is highly inefficient for large inputs, as in data mining. It has been well accepted that for special cases of computations, special solutions should be developed for efficiency reasons.

III. Building Naive Bayesian Classifiers

III.1 Notations

- e : public key.
- d : private key.
- P_i : the i th party.
- n : the total number of parties. Assuming $n > 2$.
- m : the total number of class.
- α is the number of bits for each transmitted element in the privacy-preserving protocols.
- N : the total number of records.

III.2 Cryptography Tools

Our scheme is based on homomorphic encryption which was originally proposed in [17]. Since then, many such systems have been proposed [3, 14, 15, 16]. We observe that some homomorphic encryption schemes, such as [4], are not robust against chosen cleartext attacks. However, we base our secure protocols on [16], which is semantically secure [9].

In our secure protocols, we use additive homomorphism offered by [16]. In particular, we utilize the following characterizer of the homomorphic encryption functions: $e(a_1) \times e(a_2) = e(a_1 + a_2)$ where e is an encryption function; a_1 and a_2 are the data to be encrypted. Because of the property of associativity, $e(a_1 + a_2 + \dots + a_n)$ can be computed as $e(a_1) \times e(a_2) \times \dots \times e(a_n)$ where $e(a_i) \neq 0$. That is

$$d(e(a_1 + a_2 + \dots + a_n)) = d(e(a_1) \times e(a_2) \times \dots \times e(a_n)) \quad (1)$$

$$d(e(a_1)^{a_2}) = d(e(a_1 a_2)) \quad (2)$$

III.3 Introducing Naive Bayesian Classification

The naive Bayesian classification is one of the most successful algorithms in many classification domains. Despite of its simplicity, it is shown to be competitive with other complex approaches, especially in text categorization and content based filtering. The naive Bayesian classifier applies to learning tasks where each instance x is described by a conjunction of attribute values and where the target function $f(x)$ can take on any value from some finite set V . A set of training examples of the target function is provided, and a new instance is presented, described by the tuple of attribute values $\langle a_1, a_2, \dots, a_n \rangle$. The learner is asked to predict the target value for this new instance. Under a conditional independence assumption, i.e., $Pr(a_1, a_2, \dots, a_n | v_j) = \prod_{i=1}^n Pr(a_i | v_j)$, a naive Bayesian classifier can be derived as follows:

$$\begin{aligned} V_{NB} &= \operatorname{argmax}_{v_j \in V} Pr(v_j) \prod_{i=1}^n Pr(a_i | v_j) \\ &= \operatorname{argmax}_{v_j \in V} Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)} \end{aligned}$$

To build a NB classifier, we need to compute $Pr(v_j)$ and $Pr(a_i, v_j)$. $Pr(v_j)$ can be computed by the owner of v_j without breaching privacy. To compute $Pr(a_i, v_j)$, we need consider two aspects: (1) All the parties share the class label; (2) The class label is hosted by only one party. For the first case, $Pr(a_i, v_j)$ can be calculated by the owner of v_j without breaching privacy. For the second case, if the owner of v_j also owns the class label, he can compute $Pr(a_i, v_j)$. However, when a_i and v_j belong to different parties, the computation of $Pr(a_i, v_j)$ is challenging.

In this paper, we will design a privacy-preserving system to show how to compute a naive Bayesian classifier. The goal of our privacy-preserving classification system is to disclose no private data in every step. We firstly select a key generator who produces the encryption and decryption key pairs. The computation of the whole system is under encryption. For the purpose of illustration, let's assume that P_n is the key generator who generates a homomorphic encryption key pair (e, d) . The key generator should not host the class label. For the purpose of illustration, let's assume that P_1 holds the class label. Next, we will show how to conduct each step.

III.4 Privacy-Preserving Naive Bayesian Classification

III.4.1 To Compute $e(Pr(a_i, v_j))$

Protocol 1 .

1. P_l for $l \in [2, n]$ performs the following operations:
 - (a) She computes $e(a_{ik})$ s ($k \in [1, N]$) and sends them to P_1 .
2. P_1 performs the following operations:
 - (a) He computes $t_1 = e(a_{i1})^{v_{j1}} = e(a_{i1} \cdot v_{j1})$, $t_2 = e(a_{i2})^{v_{j2}} = e(a_{i2} \cdot v_{j2})$, \dots , $t_N = e(a_{iN})^{v_{jN}} = e(a_{iN} \cdot v_{jN})$.
 - (b) He computes $t_1 \times t_2 \times \dots \times t_N = e(a_{i1} \cdot v_{j1} + a_{i2} \cdot v_{j2} + \dots + a_{iN} \cdot v_{jN}) = e(\vec{a}_i \cdot \vec{v}_j)$.
 - (c) He computes $e(\vec{a}_i \cdot \vec{v}_j)^{\frac{1}{N}} = e(\frac{\vec{a}_i \cdot \vec{v}_j}{N}) = e(Pr(a_i, v_j))$.

Theorem 1 (Correctness). *Protocol 1 correctly computes $e(Pr(a_i, v_j))$.*

Proof When P_1 receives $e(a_{ik})$ ($k \in [1, N]$), he computes $t_k = e(a_{ik})^{v_{jk}}$. According to Eq. 2, it is equal to $e(a_{ik}v_{jk})$ for $k \in [1, N]$. He then computes $\prod_{k=1}^N t_k$ which is equal to $e(\vec{a}_i \cdot \vec{v}_j)$ according to Eq. 1. Finally, he computes $e(\vec{a}_i \cdot \vec{v}_j)^{\frac{1}{N}} = e(Pr(a_i, v_j))$. Therefore, the protocol 1 correctly computes $e(Pr(a_i, v_j))$. ■

Theorem 2 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof In protocol 1, all the data transmission are hidden under encryption. The parties who are not the key generator can't see other parties' private data. On the other hand, the key generator doesn't obtain the encryption of other parties' private data. Therefore, protocol 1 discloses no private data. ■

Theorem 3 (Efficiency). *Protocol 1 is efficient in terms of computation and communication complexity.*

Proof To prove the efficiency, we need conduct complexity analysis of the protocol. The bit-wise communication cost of this protocol is amN . The computation cost is upper bounded by $(m+2)N$. Therefore, the protocol is sufficient fast. ■

Via the above protocol, the class holder P_1 gets $e(Pr(a_i, v_j))(P_l)$ for $l \in [2, n]$ and $e(Pr(a_i, v_j))(P_l)$ denotes $e(Pr(a_i, v_j))$ for l th party. Next, we will show how to construct a NB classifier.

III.4.2 To Compute $e(Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$ for each $v_j \in V$

Protocol 2 .

1. P_1 generates a set of random numbers, r_2, r_3, \dots , and r_n .
2. P_1 computes $e(Pr(a_i, v_j)(P_2)) \times e(r_2) = e(Pr(a_i, v_j)(P_2) + r_2)$, $e(Pr(a_i, v_j)(P_3)) \times e(r_3) = e(Pr(a_i, v_j)(P_3) + r_3)$, \dots , $e(Pr(a_i, v_j)(P_n)) \times e(r_n) = e(Pr(a_i, v_j)(P_n) + r_n)$.
3. P_1 sends $e(Pr(a_i, v_j)(P_l) + r_l)$ to P_n where $l \in [2, n]$.
4. P_n decrypts them and obtains $Pr(a_i, v_j)(P_l) + r_l$ for $l \in [2, n]$.
5. P_n sends $Pr(a_i, v_j)(P_l) + r_l$ to P_l for $l \in [2, n-1]$.
6. P_1 computes $e(\prod_{v_j \in P_1} \frac{Pr(a_i, v_j)}{Pr(v_j)})$ for $a_i \in P_1$. Let's denote it by $e(G_1)$. P_1 sends $e(G_1)$ to P_2 .
7. P_2 computes $e(G_1)^{(Pr(a_i, v_j)(P_2) + r_2)} = e((Pr(a_i + v_j)(P_2) + r_2) \times G_1)$ and sends it to P_1 .
8. P_1 computes $e((Pr(a_i + v_j)(P_2) + r_2) \times G_1) \times e(-r_2 G_1) = e(\prod_{a_i \in P_1, P_2} \frac{Pr(a_i, v_j)}{Pr(v_j)})$ denoted by $e(G_2)$.
9. Continue until P_1 gets $e(\prod_{a_i \in P_1, P_2, \dots, P_n} \frac{Pr(a_i, v_j)}{Pr(v_j)}) = e(\prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$.
10. P_1 computes $e(\prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})^{Pr(v_j)} = e(Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$.

Theorem 4 (Correctness). *Protocol 2 correctly computes $e(Pr(a_i, v_j))$.*

Proof In step 3, P_n obtains $e(Pr(a_i, v_j)(P_l) + r_l)$ for $l \in [2, n]$. In step 6, P_1 computes $e(G_1) = e(\prod_{v_j \in P_1} \frac{Pr(a_i, v_j)}{Pr(v_j)})$ for $a_i \in P_1$ based on his own data. In step 9, P_1 obtains $e(G_2) = e((Pr(a_i + v_j)(P_2) + r_2) \times G_1) \times e(-r_2 G_1) = e(\prod_{a_i \in P_1, P_2} \frac{Pr(a_i, v_j)}{Pr(v_j)})$ according Eq. 1 and Eq. 2. Finally, P_1 obtains $e(\prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})^{Pr(v_j)} = e(Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$ according to Eq. 2. ■

Theorem 5 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof In protocol 2, all the data transmission, among the parties who have no decryption key, are hidden under encryption. Therefore, these parties cannot know the private data. In step 4, P_n obtains $Pr(a_i, v_j)(P_l) + r_l$ for

$l \in [2, n]$. Since it is hidden by a random number r_l known only by P_1 . P_n cannot get $Pr(a_i, v_j)(P_l)$. Therefore, protocol 2 discloses no private data. ■

Theorem 6 (Efficiency). *Protocol 2 is efficient in terms of computation and communication complexity.*

Proof The bit-wise communication cost of this protocol is upper bounded by $4n\alpha$. The computation cost is upper bounded by $8n$. Therefore, the protocol is sufficient fast. ■

Through the above protocol, $e(Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$ can be computed for each $v_j \in V$. Without loss of generality, let's assume P_1 gets $e(V_{NB_1}), e(V_{NB_2}), \dots, e(V_{NB_k})$. The goal is to find the largest one.

III.4.3 To Compute V_{NB}

Protocol 3 .

1. P_1 computes $e(V_{NB_i}) \times e(V_{NB_j})^{-1} = e(V_{NB_i} - V_{NB_j})$ for all $i, j \in [1, k], i > j$, and sends the sequence denoted by φ to P_n in a random order.
2. P_n decrypts each element in the sequence φ . He assigns the element +1 if the result of decryption is not less than 0, and -1, otherwise. Finally, he obtains a +1/-1 sequence denoted by φ' .
3. P_n sends +1/-1 sequence φ' to P_1 who computes the largest element.

Theorem 7 (Correctness). *Protocol 3 correctly computes V_{NB} .*

Proof P_1 is able to remove permutation effects from φ' (the resultant sequence is denoted by φ'') since she has the permutation function that she used to permute φ , so that the elements in φ and φ'' have the same order. It means that if the q th position in sequence φ denotes $e(V_{NB_i} - V_{NB_j})$, then the q th position in sequence φ'' denotes the evaluation results of $V_{NB_i} - V_{NB_j}$. We encode it as +1 if $V_{NB_i} \geq V_{NB_j}$, and as -1 otherwise. P_1 has two sequences: one is the φ , the sequence of $e(V_{NB_i} - V_{NB_j})$, for $i, j \in [1, k](i > j)$, and the other is φ'' , the sequence of +1/-1. The two sequences have the same number of elements. P_1 knows whether or not V_{NB_i} is larger than V_{NB_j} by checking the corresponding value in the φ'' sequence. For example, if the first element φ'' is -1, P_1 concludes $V_{NB_i} < V_{NB_j}$. P_1 examines the two sequences and constructs the index table (Table 1) to compute the largest element.

In Table 1, +1 in entry ij indicates that the information gain of the row (e.g., V_{NB_i} of the i th row) is not less than the information gain of a column (e.g., V_{NB_j} of

	V_{NB_1}	V_{NB_2}	V_{NB_3}	\dots	V_{NB_k}
V_{NB_1}	+1	+1	-1	\dots	-1
V_{NB_2}	-1	+1	-1	\dots	-1
V_{NB_3}	+1	+1	+1	\dots	+1
\dots	\dots	\dots	\dots	\dots	\dots
V_{NB_k}	+1	+1	-1	\dots	+1

Table 1:

	S_1	S_2	S_3	S_4	Weight
S_1	+1	-1	-1	-1	-2
S_2	+1	+1	-1	+1	+2
S_3	+1	+1	+1	+1	+4
S_4	+1	-1	-1	+1	0

Table 2:

the j th column); -1, otherwise. P_1 sums the index values of each row and uses this number as the weight of the information gain in that row. She then selects the one that corresponds to the largest weight.

To make it clearer, let's illustrate it by an example. Assume that: (1) there are 4 information gains with $V_{NB_1} < V_{NB_4} < V_{NB_2} < V_{NB_3}$; (2) the sequence φ is $[e(V_{NB_1} - V_{NB_2}), e(V_{NB_1} - V_{NB_3}), e(V_{NB_1} - V_{NB_4}), e(V_{NB_2} - V_{NB_3}), e(V_{NB_2} - V_{NB_4}), e(V_{NB_3} - V_{NB_4})]$. The sequence φ'' will be $[-1, -1, -1, -1, +1, +1]$. According to φ and φ'' , P_1 builds the Table 2. From the table, P_1 knows V_{NB_3} is the largest element since its weight, which is +4, is the largest. ■

Theorem 8 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof In protocol 3, we need prove it from two aspects: (1) P_1 doesn't get information gain (e.g., V_{NB_i}) for each attribute. What P_1 gets are $e(V_{NB_i} - V_{NB_j})$ for all $i, j \in [1, k], i > j$ and +1/-1 sequence. By $e(V_{NB_i} - V_{NB_j})$, P_1 cannot know each information gain since it is encrypted. By +1/-1 sequence, P_1 can only know whether or not V_{NB_i} is greater than P_j . (2) P_n doesn't obtain information gain for each attribute either. Since the sequence of $e(V_{NB_i} - V_{NB_j})$ is randomized before being send to P_n who can only know the sequence of $V_{NB_i} - V_{NB_j}$, he can't get each individual information gain. Thus private data are not revealed. ■

Theorem 9 (Efficiency). *The computation of protocol 3 is efficient from both computation and communication point of view.*

Proof The total communication cost is upper bounded by αm^2 . The total computation cost is upper bounded by $m^2 + m + 1$. Therefore, the protocols are very fast. ■

IV. Overall Discussion

Our privacy-preserving classification system contains several components. In Section , we show how to correctly compute $e(Pr(a_i, v_j))$. In Section , we present protocols to compute $e(Pr(v_j) \prod_{i=1}^n \frac{Pr(a_i, v_j)}{Pr(v_j)})$ for each $v_j \in V$. In Section , we show how to compute the final naive Bayesian classifier. We discussed the correctness of the computation in each section. Overall correctness is also guaranteed.

As for the privacy protection, all the communications between the parties are encrypted, therefore, the parties who has no decryption key cannot gain anything out of the communication. On the other hand, there are some communication between the key generator and other parties. Although the communications are still encrypted, the key generator may gain some useful information. However, we guarantee that the key generator cannot gain the private data by adding random numbers in the original encrypted data so that even if the key generator get the intermediate results, there is little possibility that he can know the intermediate results. Therefore, the private data are securely protected with overwhelming probability.

In conclusion, we provide a novel solution for naive Bayesian classification over vertically partitioned private data. Instead of using data transformation, we define a protocol using homomorphic encryption to exchange the data while keeping it private. Our classification system is quite efficient that can be envisioned by the communication and computation complexity. The total communication complexity is upper bounded by $\alpha(mN + m^2 + 4n)$. The computation complexity is upper bounded by $mN + 2N + 8n + m^2 + m + 1$.

Abstract: Privacy-preserving data mining in distributed environments is an important issue in the field of data mining. In this paper, we study how to conduct sequential patterns mining, which is one of the data mining computations, on private data in the following scenario: Multiple parties, each having a private data set, want to jointly conduct sequential pattern mining. Since no party wants to disclose its private data to other parties, a secure method needs to be provided to make such a computation feasible. We develop a practical solution to the above problem in this paper.

Keywords: Privacy, security, sequential pattern mining.

I. Introduction

Data mining and knowledge discovery in databases is an important research area that investigates the automatic extraction of previously unknown patterns from large amounts of data. They connect the three worlds of databases, artificial intelligence and statistics. The information age has enabled many organizations to gather large volumes of data. However, the usefulness of this data is negligible if meaningful information or knowledge cannot be extracted from it. Data mining and knowledge discovery, attempts to answer this need. In contrast to standard statistical methods, data mining techniques search for interesting information without demanding a priori hypotheses. As a field, it has introduced new concepts and are becoming more and more popular with time.

One of important computations is sequential pattern mining [1, 8, 2, 7, 3], which is concerned of inducing rules from a set of sequences of ordered items. The main computation in sequential pattern mining is to calculate the support measures of sequences by iteratively joining those sub-sequences whose supports exceed a given threshold. In each of above works, an algorithm is provided to conduct such a computation assume that the

original data are available. However, conducting such a mining without knowing the original data is challenging.

Generic solutions for any kind of secure collaborative computing exist in the literature [4, 5, 6]. These solutions are the results of the studies of the Secure Multi-party computation problem [9, 5, 6, 4], which is a more general form of secure collaborative computing. However, the proposed generic solutions are usually impractical. They are not scalable and cannot handle large-scale data sets because of the prohibitive extra cost in protecting data secrecy. Therefore, practical solutions need to be developed. This need underlies the rationale for our research.

The paper is organized as follows: Section 2 discusses the related work. We then formally defines the mining sequential patterns on private data problem in Section 3. In Section 4, we describe our secure protocols. Section 5 analyzes the security and communication cost of our solution. We give our conclusion in Section 6.

II. Mining Sequential Patterns on Private Data

II.1 Background

Data mining includes a number of different tasks. This paper studies the sequential pattern mining problem. Since its introduction in 1995 [1], the sequential pattern mining has received a great deal of attention. It is still one of the most popular pattern-discovery methods in the field of Knowledge Discovery. Sequential pattern mining provides a means for discovering meaningful sequential patterns among a large quantity of data. For example, let us consider the sales database of a bookstore. The discovered sequential pattern could be like “70% of people who bought Harry Porter also bought Lord of Ring at a later time”. The bookstore can use this information for shelf placement, promotions, etc.

In the sequential pattern mining, we are given a database D of customer transactions. Each transaction consists of the following fields: customer-ID, transaction-time, and the items purchased in the transaction. No

customer has more than one transaction with the same transaction-time. We do not consider quantities of items bought in a transaction: each item is a binary variable representing whether an item was bought or not. An itemset is a non-empty set of items. A sequence is an ordered list of itemsets. A customer support is a sequence s if s is contained in the customer-sequence for this customer. The support for a sequence is defined as the fraction of total customers who support this sequence. Given a database D of customer transactions, the problem of mining sequential patterns is to find the maximal sequences among all sequences that have a certain user-specified minimum support. Each such maximal sequence represents a sequential pattern.

Mining Sequential Patterns On Private Data

problem: Party 1 has a private data set D_1 , party 2 has a private data set D_2, \dots , and party n has a private data set D_n , data set $[D_1 \cup D_2 \cup \dots \cup D_n]$ is the union of D_1, D_2, \dots , and D_n (by vertically putting D_1, D_2, \dots , and D_n together.)* Let N be a set of transactions with N_k representing the k th transaction. These n parties want to conduct the sequential pattern mining on $[D_1 \cup D_2 \cup D_3 \dots \cup D_n]$ and to find the sequential patterns with support greater than the given threshold, but they do not want to share their private data sets with each other. We say that a sequential pattern of $x_i \leq y_j$, where x_i occurs before or at the same time as y_j , has support s in $[D_1 \cup D_2 \cup \dots \cup D_n]$ if $s\%$ of the transactions in $[D_1 \cup D_2 \dots \cup D_n]$ contain both x_i and y_j with x_i happening before or at the same time as y_j (namely, $s\% = Pr(x_i \leq y_j)$).

II.2 Sequential Pattern Mining Procedure

The procedure of mining sequential patterns contains the following steps:

Step I: Sorting

The database $[D_1 \cup D_2 \dots \cup D_n]$ is sorted, with customer ID as the major key and transaction time as the minor key. This step implicitly converts the original transaction database into a database of customer sequences. As a result, transactions of a customer may appear in more than one row which contains information of a customer ID, a particular transaction time and items bought at this transaction time. For example, suppose that datasets after being sorted by their customer-ID numbers are shown in Fig. 1. Then after being sorted by the transaction time, data tables of Fig. 1 will become those of Fig. 2.

*Vertically partitioned datasets are also called heterogeneous partitioned datasets where different datasets contain different types of items with customer IDs are identical for each transaction.

Step II: Mapping

Each item of a row is considered as an attribute. We map each item of a row (i.e., an attribute) to an integer in an increasing order and repeat for all rows. Re-occurrence of an item will be mapped to the same integer. As a result, each item becomes an attribute and all attributes are binary-valued. For instance, the sequence $\langle B, (A, C) \rangle$, indicating that the transaction B occurs prior to the transaction (A, C) with A and C occurring together, will be mapped to integers in the order $B \rightarrow 1, A \rightarrow 2, C \rightarrow 3, (A, C) \rightarrow 4$. During the mapping, the corresponding transaction time will be kept. For instance, based on the sorted dataset of Fig. 2, we may construct the mapping table as shown in Fig. 3. After the mapping, the mapped datasets are shown in Fig. 4.

Step III: Mining

Our mining procedure will be based on mapped dataset. The general sequential pattern mining procedure contains multiple passes over the data. In each pass, we start with a seed set of large sequences, where a large sequence refers to a sequence whose itemsets all satisfy the minimum support. We utilize the seed set for generating new potentially large sequences, called candidate sequences. We find the support for these candidate sequences during the pass over the data. At the end of each pass, we determine which of the candidate sequences are actually large. These large candidates become the seed for the next pass.

The following is the procedure for mining sequential patterns on $[D_1 \cup D_2 \dots \cup D_n]$.

1. $L_1 =$ large 1-sequence
2. for ($k = 2; L_{k-1} \neq \phi; k++$) do{
3. $C_k = \text{apriori-generate}(L_{k-1})$
4. for all candidates $c \in C_k$ do {
5. **Compute** $c.count$
(Section will show how to compute this count on private data)
6. $L_k = L_k \cup c \mid c.count \geq \text{minsup}$
7. end
8. end
9. Return $U_k L_k$

where L_k stands for a sequence with k itemsets and C_k stands for the collection of candidate k -sequences. The procedure **apriori-generate** is described as follows:

First: join L_{k-1} with L_{k-1} :

1. insert into C_k
2. select $p.litemset_1, \dots, p.litemset_{k-1}, q.litemset_{k-1}$, where $p.litemset_1 = q.litemset_1, \dots, p.litemset_{k-2} = q.litemset_{k-2}$
3. from $L_{k-1} p, L_{k-1} q$.

Figure 2: Raw Data Sorted By Customer ID and Transaction Time

Second: delete all sequences $c \in C_k$ such that some (k-1)-subsequence of c is not in L_{k-1} .

Step IV: Maximization

Having found the set of all large sequences S , we provide the following procedure to find the maximal sequences.

1. for ($k = m; k \geq 1; k--$) **do**
2. for each k-sequence s_k **do**
3. **Delete** all subsequences of s_k from S

Step V: Converting

The items in the final large sequences are converted back to the original item representations used before the mapping step. For example, if 1A belongs to some large

sequential pattern, then 1A will be converted to item 30, according to the mapping table, in the final large sequential patterns.

II.3 How to compute $c.count$

To compute $c.count$, in other words, to compute the support for some candidate pattern (e.g., $P(x_i \cap y_i \cap z_i | x_i \geq y_i \geq z_i)$), we need to conduct two steps: one is to deal with the condition part where z_i occurs before y_i and both of them occur before x_i ; the other is to compute the actual counts for this sequential pattern.

If all the candidates belong to one party, then $c.count$, which refers to the frequency counts for candidates, can be computed by this party since this party has all the information needed to compute it. However, if the can-

Alice	30 - 1A	10 - 2A	20 - 3A	(10, 20) - 4A	9 - 5A	15 - 6A	(9, 15) - 7A	5

N/A : The information is not available.

Figure 4: Data After Being Mapped

didates belong to different parties, it is a non-trivial task to conduct the joint frequency counts while protecting the security of data. We provide the following steps to conduct this cross-parties' computation.

II.3.1 Vector Construction

The parties construct vectors for their own attributes (mapped-ID). In each vector constructed from the mapped dataset, there are two components: one consists of the binary values (called the value vector); the other consists of the transaction time (called the transaction time vector). Suppose we want to compute the $c.count$ for $2A \geq 2B \geq 6C$ in Fig. 4. We construct three vectors: 2A, 2B and 6C depicted in Fig. 5.

II.3.2 Transaction time comparison

To compare the transaction time, each time vector should have a value. We let all the parties randomly generate a set of transaction time for entries in the vector where their values are 0's. They then transform their values in time vector into real numbers so that if transaction tr_1 happens earlier than the transaction tr_2 , then the real number to denote tr_1 should smaller than the number that denotes tr_2 . For instance, "06/30/2003" and "06/18/2003" can be transform to 363 and 361.8 respectively. The purpose of transformation is that we will securely compare them based their real number denotation. The comparison can be conducted pairwise. Next, we will present a secure protocol that allows n parties to compare their transaction time.

The goal of our privacy-preserving classification sys-

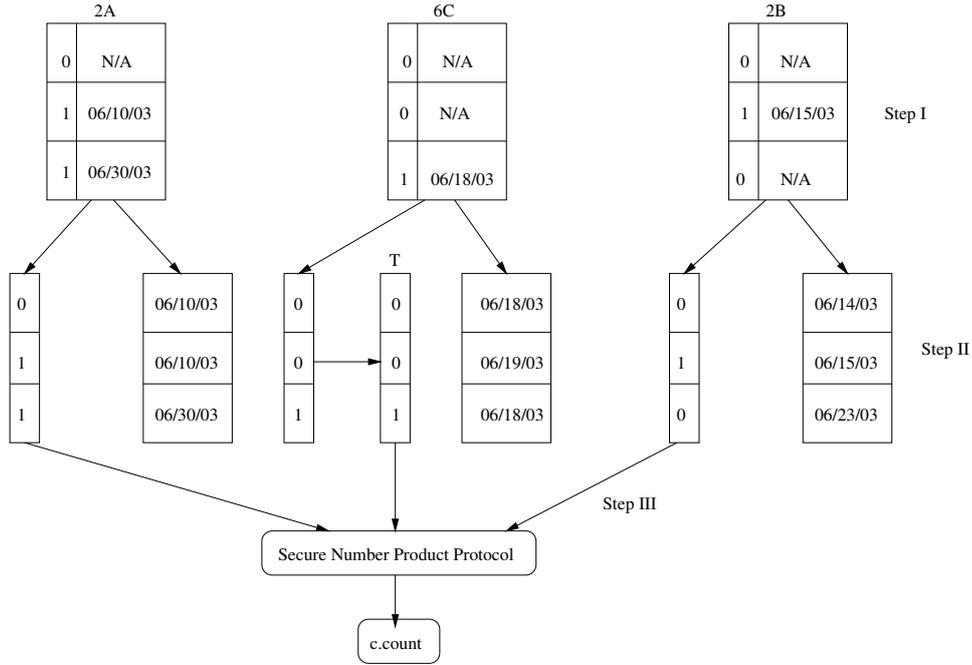

Figure 5: An Protocol To Compute c.count

tem is to disclose no private data in every step. We firstly select a key generator who produces the encryption and decryption key pairs. The computation of the whole system is under encryption. For the purpose of illustration, let's assume that P_n is the key generator who generates a homomorphic encryption key pair (e, d) . Next, we will show how to conduct each step.

II.3.3 The Comparison of Transaction Time

Without loss of generality, assuming there are k transaction time: $e(g_1), e(g_2), \dots$, and $e(g_k)$, with each corresponding to a transaction of a particular party.

Protocol 1 .

1. P_{n-1} computes $e(g_i) \times e(g_j)^{-1} = e(g_i - g_j)$ for all $i, j \in [1, k], i > j$, and sends the sequence denoted by φ to P_n in a random order.
2. P_n decrypts each element in the sequence φ . He assigns the element +1 if the result of decryption is not less than 0, and -1, otherwise. Finally, he obtains a +1/-1 sequence denoted by φ' .
3. P_n sends +1/-1 sequence φ' .
4. P_{n-1} compares the transaction time of each entry of vectors such as 2A, 2B, and 6C in our example. She makes a temporary vector T . If the transaction time does not satisfy the requirement of $2A \geq 2B \geq 6C$, she sets the corresponding entries of T to 0's;

otherwise, she copies the original values in 6C to T (Fig. 5).

Theorem 1 (Correctness). Protocol 1 correctly sort the transaction time.

Proof P_{n-1} is able to remove permutation effects from φ' (the resultant sequence is denoted by φ'') since she has the permutation function that she used to permute φ , so that the elements in φ and φ'' have the same order. It means that if the q th position in sequence φ denotes $e(g_i - g_j)$, then the q th position in sequence φ'' denotes the evaluation results of $g_i - g_j$. We encode it as +1 if $g_i \geq g_j$, and as -1 otherwise. P_{n-1} has two sequences: one is the φ , the sequence of $e(g_i - g_j)$, for $i, j \in [1, k](i > j)$, and the other is φ'' , the sequence of +1/-1. The two sequences have the same number of elements. P_{n-1} knows whether or not g_i is larger than g_j by checking the corresponding value in the φ'' sequence. For example, if the first element φ'' is -1, P_{n-1} concludes $g_i < g_j$. P_{n-1} examines the two sequences and constructs the index table (Table 1) to compute the largest element.

In Table 1, +1 in entry ij indicates that the value of the row (e.g., g_i of the i th row) is not less than the value of a column (e.g., g_j of the j th column); -1, otherwise. P_{n-1} sums the index values of each row and uses this number as the weight of the information gain in that row. She then sorts the sequence according the weight.

To make it clearer, let's illustrate it by an example. Assume that: (1) there are 4 elements with $g_1 < g_4 <$

	g_1	g_2	g_3	\dots	g_k
g_1	+1	+1	-1	\dots	-1
g_2	-1	+1	-1	\dots	-1
g_3	+1	+1	+1	\dots	+1
\dots	\dots	\dots	\dots	\dots	\dots
g_k	+1	+1	-1	\dots	+1

Table 1:

	S_1	S_2	S_3	S_4	Weight
S_1	+1	-1	-1	-1	-2
S_2	+1	+1	-1	+1	+2
S_3	+1	+1	+1	+1	+4
S_4	+1	-1	-1	+1	0

Table 2:

$g_2 < g_3$; (2) the sequence φ is $[e(g_1 - g_2), e(g_1 - g_3), e(g_1 - g_4), e(g_2 - g_3), e(g_2 - g_4), e(g_3 - g_4)]$. The sequence φ'' will be $[-1, -1, -1, -1, +1, +1]$. According to φ and φ'' , P_{n-1} builds the Table 2. From the table, P_{n-1} knows $g_3 > g_2 > g_4 > g_1$ since g_3 has the largest weight, g_2 has the second largest weight, g_4 is third largest weight, g_1 has the smallest weight. ■

Theorem 2 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof We need prove it from two aspects: (1) P_{n-1} doesn't get transaction time (e.g., g_i) for each vector. What P_{n-1} gets are $e(g_i - g_j)$ for all $i, j \in [1, k], i > j$ and $+1/-1$ sequence. By $e(g_i - g_j)$, P_{n-1} cannot know each transaction time since it is encrypted. By $+1/-1$ sequence, P_{n-1} can only know whether or not g_i is greater than P_j . (2) P_n doesn't obtain transaction time for each vector either. Since the sequence of $e(g_i - g_j)$ is randomized before being send to P_n who can only know the sequence of $g_i - g_j$, he can't get each individual transaction time. Thus private data are not revealed. ■

Theorem 3 (Efficiency). *The computation of protocol 1 is efficient from both computation and communication point of view.*

Proof The total communication cost is upper bounded by αm^2 . The total computation cost is upper bounded by $m^2 + m + 1$. Therefore, the protocols are very fast. ■

After the above step, they need to compute $c.count$ based their value vector. For example, to obtain $c.count$ for $2A \geq 2B \geq 6C$ in Fig. 5, they need to compute $\sum_{i=1}^N 2A[i] \cdot 2B[i] \cdot T[i] = \sum_{i=1}^N 2A[i] \cdot 2B[i] \cdot T[i] = \sum_{i=1}^3 2A[i] \cdot 2B[i] \cdot T[i] = 0$, where N is the total number of

values in each vector. In general, let's assume the value vectors for P_1, \dots, P_n are x_1, \dots, x_n respectively. Note that P_1 's vector is T . For the purpose of illustration, we denote T by x_{n-1} . Next, we will show how n parties compute this count. without revealing their private data to each other.

II.3.4 The Computation of $c.count$

Protocol 2 Privacy-Preserving Number Product Protocol

1. P_n sends $e(x_{n1})$ to P_1 .
2. P_1 computes $e(x_{n1})^{x_{11}} = e(x_{n1}x_{11})$, then sends it to P_2 .
3. P_2 computes $e(x_{n1}x_{11})^{x_{21}} = e(x_{n1}x_{11}x_{21})$.
4. Continue until P_{n-1} obtains $e(x_{11}x_{21} \dots x_{n1})$.
5. Repeat all the above steps for x_{1i}, x_{2i}, \dots , and x_{ni} until P_{n-1} gets $e(x_{1i}x_{2i} \dots x_{ni})$ for all $i \in [1, N]$.
6. P_{n-1} computes $e(x_{11}x_{21} \dots x_{n1}) \times e(x_{12}x_{22} \dots x_{n2}) \times \dots \times e(x_{1N}x_{2N} \dots x_{nN}) = e(x_{11}x_{21} \dots x_{n1} + x_{12}x_{22} \dots x_{n2} + \dots + x_{1N}x_{2N} \dots x_{nN}) = c.count$.

Theorem 4 (Correctness). *Protocol 2 correctly compute $c.count$.*

Proof In step 2, P_1 obtains $e(x_{n1})$. He then computes $e(x_{n1}x_{11})$. In step 3, P_2 computes $e(x_{n1}x_{11}x_{21})$. Finally, in step 5, P_{n-1} gets $e(x_{1i}x_{2i} \dots x_{ni})$. He then computes $e(x_{11}x_{21} \dots x_{n1}) \times e(x_{12}x_{22} \dots x_{n2}) \times \dots \times e(x_{1N}x_{2N} \dots x_{nN}) = e(x_{11}x_{21} \dots x_{n1} + x_{12}x_{22} \dots x_{n2} + \dots + x_{1N}x_{2N} \dots x_{nN})$ which is equal to $c.count$. ■

Theorem 5 (Privacy-Preserving). *Assuming the parties follow the protocol, the private data are securely protected.*

Proof In protocol 2, all the data transmission are hidden under encryption. The parties who are not the key generator can't see other parties' private data. On the other hand, the key generator doesn't obtain the encryption of other parties's private data. Therefore, protocol 2 discloses no private data. ■

Theorem 6 (Efficiency). *The computation of $c.count$ is efficient from both computation and communication point of view.*

Proof To prove the efficiency, we need conduct complexity analysis of the protocol. The bit-wise communication cost of protocol 2 is $\alpha(n-1)N$. The computation cost of protocol 2 is nN , of protocol 2 is $5t+3$. The total computation cost is upper bounded by $nN-1$. Therefore, the protocols are sufficient fast. ■

III. Overall Discussion

Our privacy-preserving classification system contains several components. In Section , we show how to correctly compare the transaction time. In Section , we present protocols to compute $c.count$. We discussed the correctness of the computation in each section.

As for the privacy protection, all the communications between the parties are encrypted, therefore, the parties who has no decryption key cannot gain anything out of the communication. On the other hand, there are some communication between the key generator and other parties. Although the communications are still encrypted, the key generator may gain some useful information. However, we guarantee that the key generator cannot gain the private data by adding random numbers in the original encrypted data so that even if the key generator get the intermediate results, there is little possibility that he can know the intermediate results. Therefore, the private data are securely protected with overwhelming probability.

In summary, we provide a novel solution for sequential pattern mining over vertically partitioned private data. Instead of using data transformation, we define a protocol using homomorphic encryption to exchange the data while keeping it private. Our mining system is quite efficient that can be envisioned by the communication and computation complexity. The total communication complexity is upper bounded by $\alpha(nN+m^2-N)$. The computation complexity is upper bounded by $m^2+m+5t+4$.

Abstract: Mobile commerce is becoming more and more popular which makes it possible to purchase goods and services anywhere and anytime. However, traditional payment schemes do not suffice for our demand as more novel commercial services were provided. Therefore, it's urgent to construct a safer and more convenient payment scheme for the forthcoming mobile era.

A mobile payment scheme is proposed in the paper. The scheme called MPDTN provides an ideal mobile payment with dynamic transaction numbers. Through it, consumers can pay fares by using mobile phones no matter in real store or virtual shop. Besides explaining our payment architecture and processes in detail, evaluation of the MPDTN's security from the aspect of defender and different roles of the attackers is provided in the paper. The investigation shows that, MPDTN can not only satisfy security criteria of confidence, integrity, authentication, and non-repudiation but also provide full transaction privacy to consumers.

Keywords: Security and Privacy, Mobile payment.

I. Introduction

Internet has become an indispensable part of our daily life. Various e-commerce including auction, e-shop, entertainment, etc. grows fast. More and more services can be provided via Internet. At the meanwhile, payment is becoming an important issue of the research about E-commerce.

On the other hand, mobile phones become more and more popular with the developing of mobile devices and telecommunication technologies. For example, each person has at least one mobile phone in Taiwan [1]. Besides, Wireless Application Protocol (WAP) and Wireless Markup Language (WML) makes the dream of surfing the internet through mobile devices come true [2]-[6]. Many commercial applications and services are developed and integrated into cell phones. The convenience of cell phone makes it possible to transact without restriction of time and place. The feature seems to explore the door of mobile commerce and attract consumer's eyes. The convenient and secure payment tool will play an important role during the evolution of m-commerce

Furthermore, the traditional plastic and electronic

currencies, such as credit card, smart card, or e-cash, have critical shortcomings that we have to overcome. Hackers or attackers can easily pretend to be the legal users and consume at will if they get the credit card numbers and the expiration date. The existing hole of security causes great losses to merchants, consumers, and banks. Most of important, the untrustworthy feeling restrains the development of novel payment tools and e-commerce.

In order to promote the m-commerce and improve existing payment schemes, the securer and more convenient payment tools are needed urgently. Due to the highly popular mobile phones and the well-developed telecommunication technology, payment via handsets is becoming a visual trend other than a dream. More and more investigations focus on the important issue. People expect that handset can do anything - no wallet and no cards.

A mobile payment scheme by using mobile phone is proposed in the paper. Mobile phones are the main payment media for transactions in the scheme. To reduce the risk of security and provide the user with higher privacy, the scheme called MPDTN provides the idea of "Mobile Payment with Dynamic Transaction Number". The second section introduces some of the existing mobile payment mechanisms. The third part goes into detail about MPDTN mechanism and its architecture. Evaluation of MPDTN's security from different points of view is investigated in section four. Finally, conclusions and possible future research are provided.

II. Related Works

Before introducing our model, we first review some existing mobile payment mechanisms and discuss their advantages and disadvantages.

Considering the transaction cost and the convenience, some mobile payment mechanisms using credit card numbers were proposed. Li used consumer's personal cell phone number as the transaction code instead of credit card number [7]. The author claimed that cell phones should take the place of credit cards when making transaction because of the convenience and the security of cell phone.

Step1: Li's payment process can be depicted as Fig.1. It includes the functions which the participators performed and the information transferred between participators. The process of Fig. 1 is illustrated as follows:

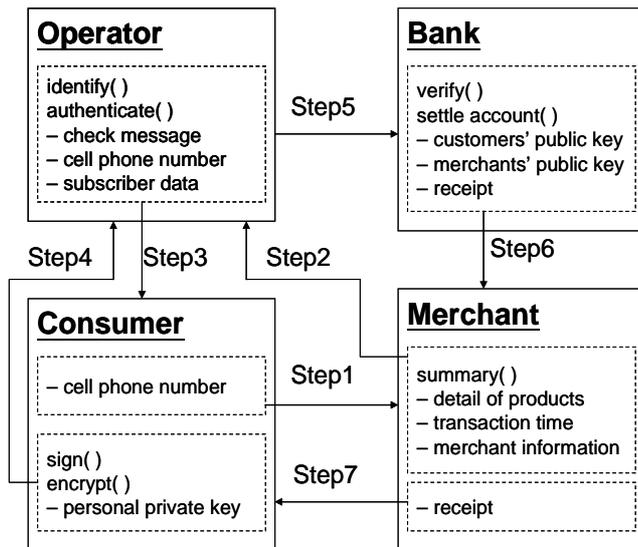

Fig. 1 Process of mobile credit payment

- Step2:** The consumer can buy products in the real store or the web store, and gives the seller his cell phone number. The merchant summarizes the transaction-related information, such as the product's ID, the transaction date and the customer's cell phone number. This activity is represented by the notation "summary()". Then, through wired network, he submits these data to the USSD (Unstructured Supplementary Service Data) sever of telecommunication service provider.
- Step3:** The operator then makes a USSD connection with the consumer through the phone number, and confirms the transaction information with the consumer after authentication.
- Step4:** After the consumer confirms the transaction information, he will use his personal private key which is stored in the SIM card of the mobile phone to sign the transaction data, and transfer the data back to the operator.
- Step5:** The operator delivers the signed transaction data to the cooperative bank.
- Step6:** The bank uses the consumer's public key to verify the consumer's identity and then checks his credit line. The bank also verifies the certificate of the merchant at the same time. After the verification, the bank deals with the transaction and transfers the receipt to the merchant.
- Step7:** The consumers get the result of the transaction from the merchant.

The advantage of the payment mechanism mentioned above is that we can reduce the consumers' risk even if the phone number is eavesdropped. Usually, it is very risky that consumers provide the credit card number and expiration date when paying with credit card. Besides, the usage of the digital signature in the SIM card can prevent the consumer identity from being forged.

Nowadays, transaction privacy that consumer desired is more and more emphasized. We cannot guarantee the privacy when making transactions by a consumer's phone number. Merchants may gather the consumer's consuming habits or promote their new products by sending messages if they know the phone numbers of the customers. This will bother the consumers to certain extent. Hence, how the payment mechanism provides the transaction privacy cannot be ignored.

Su designed and implemented a mobile payment system with high flexibility [8]. His proposal for mobile payment is similar to the mechanism mentioned before. When the customer transacts, he transferred a fixed "User Identification" to merchant instead of phone number. The merchant summarizes the transaction data and submits it to the operator. Then the operator confirms the transaction to the consumer through the phone number of the corresponding user identification.

Although consumers own their purchasing privacy to some degree by using the "User Identification", the operator still control the private transaction information. Moreover, because the "User Identification" is fixed, the merchants still can collect the consuming habits of certain customer. Therefore, we propose a mobile payment mechanism which not only satisfies the conditions of security, such as confidence, integrity, and non-repudiation, but also provide full transaction privacy by making use of dynamic transaction number. Rubin and Wright proposed a scheme in which a dynamic and limited-lifetime credit card number through symmetric encryption is used [9]. Since the credit card number can just be used a few times, it reduces the security risk. Considering the characteristics of our payment scenario, we adopt the asymmetric encryption protocol to produce a dynamic transaction number, and we believe that it can provide the consumer with the complete privacy during the whole transaction process.

III. Mpdtn Mechanism

The mobile payment mechanism we proposed uses the "dynamic transaction number" to ensure the confidence and privacy. The participators in the transaction process include the merchants, operators, and banks. We have two assumptions in the mechanism:

- The operator is trustworthy and will not disclose the sensitive information of the consumers.
- The communication network between participators is kept connective.

In the following, we will illustrate the payment mechanism in detail: the architecture of the payment mechanism is described in section one; the interactions between participants are illustrated in section two.

A. Architecture of payment system

The participators in our payment system include:

consumers, merchants, the operator, and banks.

Table 1. Abbreviations of the data used in the proposed mobile payment system

Abbreviation	Description
<i>PhoneNo</i>	The consumer's phone number
<i>BK_R</i>	The bank's private key
<i>BK_U</i>	The bank's public key
<i>OK_R</i>	The operator's private key
<i>OK_U</i>	The operator's public key
<i>Passwd_{Trans}</i>	The transaction password which is only known by the consumer and the operator.
<i>Passwd_{Acct}</i>	The account password which is only known by the consumer and the bank.
<i>RandNo</i>	A random number.
<i>TransNo</i>	The transaction number only created legally by the consumer.
<i>Price</i>	The total price of the goods.
<i>SerialNo</i>	A serial number generated by the merchant.
<i>Date-Time</i>	The date and time of the transaction.
<i>TransData</i>	The transaction data summarized by the merchant.
<i>Digest</i>	The message digest created by one way hash function. The inputs of the hash function are <i>TransData</i> and <i>Passwd_{Acct}</i> .
<i>TransRe</i>	The transaction receipt.
<i>Account_C</i>	The financial account of the consumer.
<i>Account_M</i>	The financial account of the merchant.
<i>Certificate_M</i>	The certificate of the merchant.
<i>ID_O</i>	The identity of the operator.
<i>Record</i>	The record of transferring accounts.
<i>PaymentRe</i>	The payment receipt.

● **Consumer:** The consumers can purchase the merchandise with cell phone at a store or website. The operator's public key is stored in the SIM card and used to generate the transaction numbers. The consumers can pay for the purchasing by using the transaction number.

● **Merchant:** The merchants provide goods to consumers. They might be real store or the web store. In the process of transaction, the merchants are responsible for summarizing and transferring the transaction data to the operator.

● **Operator:** The telecommunication operator plays an important role in the payment system. After receiving the transaction data from the merchants, the operator has

to confirm this transaction with the consumer using USSD (Unstructured supplementary service data) messages. The operator has asymmetric keys for data encryption, includes the public keys of all cooperative bank. In the proposed payment mechanism, the operator is assumed to be trustworthy. The operator has to check whether if the consumer is a legal subscriber of the payment service.

● **Bank:** The bank is responsible for settlement of accounts and the verification of consumers and merchants. After the settlement, the bank will transfer the receipts to consumer and merchant.

The detail of our payment mechanism is illustrated in next paragraphs, and the abbreviations of the relevant data used in the payment system are shown in Table 1.

B. Interactions between the participators

After the introduction of the participators, we now describe the interactions between the participants of the payment mechanism. There are three phases in our payment scheme: initiation phase, transaction phase, and settlement phase. We demonstrate each phase from the views of the participators.

1) **Initiation phase.** This phase includes the requirements and the preparations of each participant before the payment mechanism performs. Following, we will illustrate the initiation phase from aspects of each participant.

● **Consumer:** First, the consumer should have the mobile device, such as cell phone or PDA which the telecommunication module is embedded in. The mobile device must have the capability of data storage and cryptographic computing. In addition, the mobile device can also adopt the technology of short-distance wireless transmission to facilitate the procedure of mobile payment. The consumer needs to apply for the mobile payment service and transfer his financial account (*Acct_C*) to the operator. Then, the operator issues a personal transaction password (*Passwd_{Trans}*) and the public key of the operator (*OK_U*) to the consumer and stores these sensitive data in the SIM card of the cell phone.

In order to reduce the waiting time of payment, the consumer could generate the transaction number (*TransNo*) in advance before going shopping. The transaction number is generated by using the operator's public key to encrypt the consumer's phone number (*PhoneNo*), transaction password, and a random number (*RandNo*). The random number is generated by the cell phone and used to make the transaction number dynamic. After the generation of the transaction number, the customer can start to use the mobile payment service.

● **Merchant:** What ever real or virtual store the merchant is, it must have the capability of summarize the

transaction information. The merchant can communicate with the operator or the bank through the Internet. The real store needs a printer to print out the transaction receipt (*TransRe*). The web store can show the transaction receipt on the browser for the consumer to print it out. Besides, the real store can also facilitate the mobile payment by adopting the short-distance wireless transmission device.

For the security concern, the merchant need to apply for a digital certificate and download the certificate of the operator issued by the trusted certificate authority (CA). In the payment process, the merchant uses the public key of the operator to encrypt the transaction data.

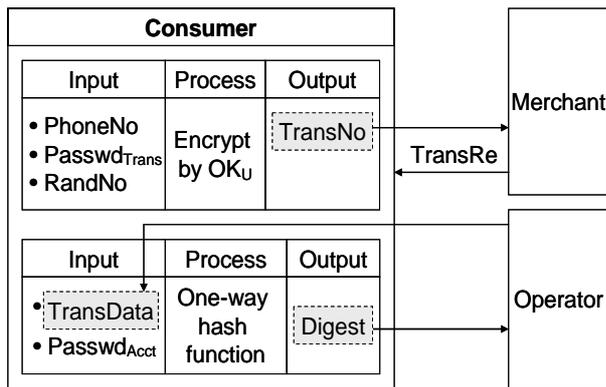

Fig. 2 Transaction phase of the consumer

● **Operator:** As for the operator, they have to maintain additional data in the database, such as the transaction passwords and the identities of the consumers' banks. After the customer applies for the mobile payment service, the operator will store the consumer's sensitive data in the secure database. The relation between the sensitive data and the corresponding consumer's phone number are protected by the operator. The operator also applies for its digital certificate and downloads all cooperative banks' certificates from CA.

● **Bank:** The bank also has to store additional data in the database, such as the account password (*PasswdAcc*) of the consumer which is different from the password of the cash card. Besides, the bank needs to maintain the transaction record for future inquiries. The same with the operator, the bank need to apply for its certificate, too.

2) Transaction phase. This phase describes the data transmission and processing of all participators during the payment process. We focus on the consumer, the merchant, and the operator.

● **Consumer:** To make the payment, the consumer transfers the transaction number and the identity of the operator (*ID_O*) to the merchant. The transaction number is a ciphertext encrypted by using the public key of the operator. As mentioned in the initiation phase, several transaction numbers could be generated before the

consumer goes shopping. After the merchant summarizes the transaction information, the consumer receives a transaction receipt as an evidence of this transaction from the merchant. The transaction receipt includes all transaction details, such as the product name, unit price of the product, and so on.

Then, the consumer has to wait for the USSD message from the operator to confirm the transaction. If the transaction information is correct, the consumer has to input the account password (*Passwd_{Acc}*) as a confirmation of his identification. The cell phone will hash the transaction data and the account password by a hash function while the account password is valid. After the hash function being performed, it will create a message digest (*Digest*). Finally, the consumer transmits the message digest back to the operator to finish the transaction confirmation as shown in Fig. 2.

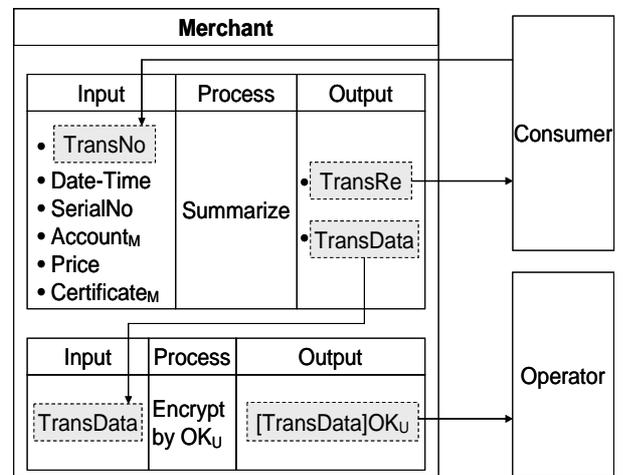

Fig.3 Transaction phase of the merchant

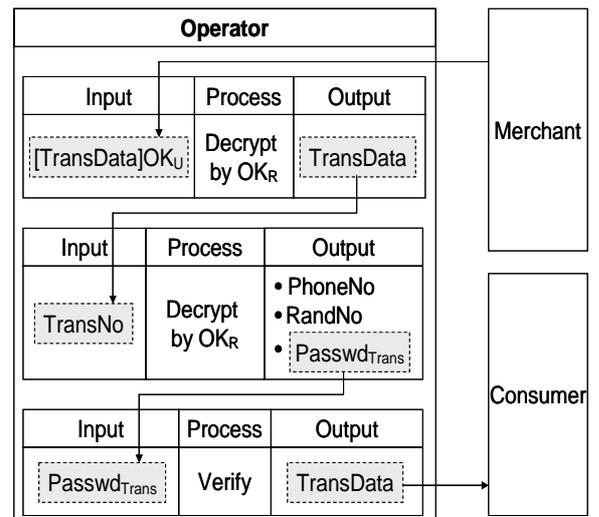

Fig. 4 Transaction phase of the operator

● **Merchant:** The merchant summarizes the required information into the transaction data (*TransData*), and encrypts the transaction data by using the operator's public key. Then, the merchant prints out the transaction receipt to the consumer as a verification of this transaction. All details about this transaction such as the item name and unit price are included in this receipt. The merchant transmits the transaction data to the operator according to the ID_O of the consumer for further confirmation. As shown in Fig. 3, the transaction data transferred includes the relative information except the details of the goods in order to ensure the transaction privacy of the consumer.

● **Operator:** The operator takes charge of the verification of the consumer and the transaction. After the operator receives the transaction data from the merchant, it decrypts the transaction data with its private key (OK_R) to get the transaction number. The operator further decrypts the transaction number and verifies the consumer's transaction password. If no error occurs in the verification, the operator will transfer the transaction data to the consumer through USSD connection for further check and waits for the consumer's response as depicted in fig. 4.

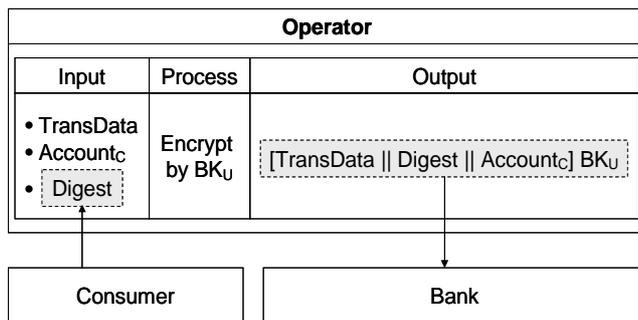

Fig. 5 Transaction phase of the operator (cont.)

Then, the operator will receive the message digest from the consumer if the transaction data is correct. The operator encrypts the transaction data, the message digest, and the consumer's bank account ($Account_C$) with the bank's public key (BK_U) and transfers these data to the cooperative bank for account settlement as shown in Fig 5.

3) Settlement phase. The settlement phase describes the verification and account settlement performed by the bank. When the bank receives the encrypted data from the operator, it uses its private key (BK_R) to decrypt the ciphertext. The bank can find the account password of the consumer by the corresponding financial account. Then the bank calculates the hash function over the concatenation of the transaction data and the account password of the consumer. If the comparison between the output of the hash function and the message digest from the operator is the same, the bank will further check the consumer's credit line and complete account settlement.

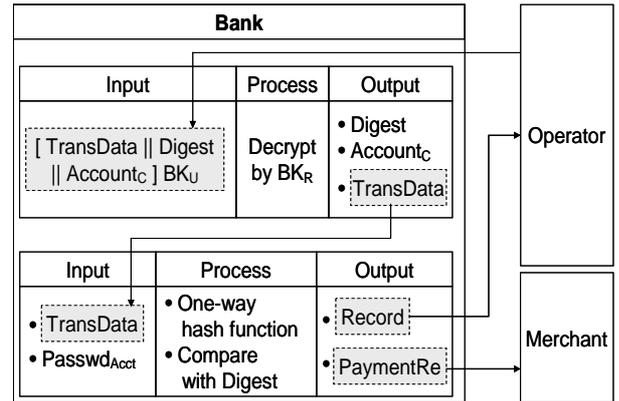

Fig. 6 Settlement phase of the bank

After settling account, the bank sums up the transaction and transfer the payment receipt to the merchant. The bank also needs to transmit the transaction record to the operator for avoiding the possible dispute. Then the merchant prints the payment receipt to the consumer, as shown in Fig. 6. Every transaction has to go through the transaction phase and settlement phase.

C. Overview of the payment process

In this section, we go into detail about the payment process of our scheme. Some notation should be explained at first. $X \rightarrow Y : Z$ denotes that a sender X sends a message or data Z to the receiver Y , $h(\)$ denotes a one way hash function, $M \parallel N$ denotes a concatenation of data M and N , and $[I] J$ denotes a message I encrypted by key J . In our payment scheme, the payment process includes seven steps. The transaction steps are as follows:

- Step 1) Consumer \rightarrow Merchant : $TransNo, ID_O$
- Step 2) Merchant \rightarrow Consumer : $TransRe$
Merchant \rightarrow Operator : $[TransData] OK_U$
- Step 3) Operator \rightarrow Consumer : $TransData$
- Step 4) Consumer \rightarrow Operator : $Digest$
- Step 5) Operator \rightarrow Bank :
 $[TransData \parallel Digest \parallel Account_C] BK_U$
- Step 6) Bank \rightarrow Merchant : $PaymentRe$
Bank \rightarrow Operator : $Record$
- Step 7) Merchant \rightarrow Consumer : $PaymentRe$

In step 1, when the consumer shops at a real store or a web store, he has to transfer the $TransNo$ to the merchant. The $TransNo$ is generated as follows:

$$TransNo = [PhoneNo \parallel Passwd_{Trans} \parallel RandNo] OK_U \quad (1)$$

The consumer can generate several transaction numbers and store them in the cell phone to facilitate the payment.

In step 2, after merchant received the $TransNo$, it

summarizes the transaction information into *TransData*.

$$TransData = TransNo \parallel Date-Time \parallel SerialNo \parallel Account_M \parallel Price \parallel Certificate_M \quad (2)$$

Then, the merchant prints out the transaction receipt to the consumer. The merchant also encrypts the *TransData* with OK_U and transmits it to the operator according to the ID_O received from consumer.

In step 3, the operator decrypts the data received from the merchant and gets the *TransNo*. The operator further decrypts the *TransNo* and gets the $Passwd_{Trans}$ of the consumer. The operator will check if the transaction password is correct. If the $Passwd_{Trans}$ is valid, the operator will transmit the *TransData* to the consumer through USSD connection.

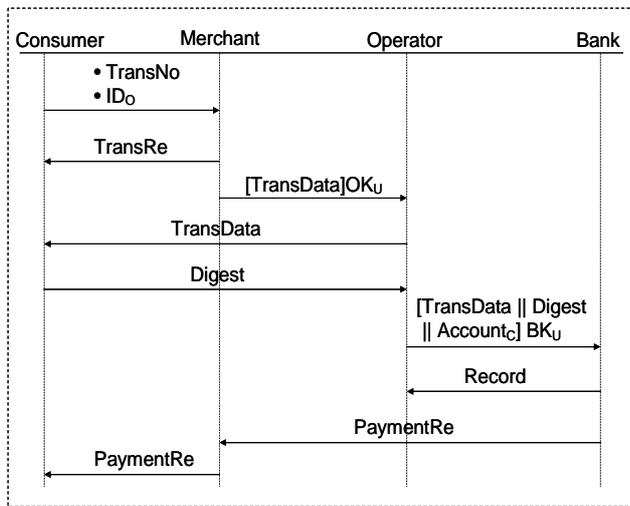

Fig. 7 Data flow of transaction procedure

In step 4, the consumer checks the *TransData* received from the operator. If this transaction is confirmed, the consumer is asked to enter the $Passwd_{Acct}$ for a hash function:

$$Digest = h(TransData \parallel Passwd_{Acct}) \quad (3)$$

The cell phone will create a message digest and send it back to the operator. But if the consumer rejects the payment or enters the wrong $Passwd_{Acct}$ three times, the operator will transfer a message to inform the merchant about the breach of the transaction.

In step 5, the operator summarizes the relative transaction information and encrypts them with the BK_U . The operator transmits the encrypted data to the bank through wired network.

In step 6, the bank decrypts the data received from the operator with its BK_R . The bank will find the corresponding $Passwd_{Acct}$ of the consumer according to the $Account_C$ and check if the $Passwd_{Acct}$ is valid. Then, the bank calculates the same hash function and compares it with the *Digest* as

follows:

$$\text{Check if } h(TransData \parallel Passwd_{Acct}) = Digest \quad (4)$$

If the result of the hash function is the same with *Digest*, the bank will settle accounts and transmit the payment receipt to the merchant. At the same time, the bank also transmits the transferring record to the operator and sends the short message to notify the consumer. In step 7, the merchant prints out the payment receipt to the consumer. The web store can show the payment receipt on the web browser, and the consumer can print it by himself.

Above, the payment mechanism has been demonstrated in detail. All data transferred between the participants are shown in Fig. 7. According to the security criteria, we evaluate our payment mechanism from different points of view in section four.

IV. Analysis of Security and Discussion

When we talk about security and related subject, some security requirements should be achieved, as mentioned in [10]-[13]. In this section, we evaluate our payment mechanism from two aspects: the aspect of the security criteria and the aspect of the attacker's role.

A. Evaluate from the aspect of security criteria

1) Confidentiality. We first consider the aspect of data storage; the sensitive data of transaction and the encryption keys are stored in the SIM card which is a tamper-resist device. And if the cell phone was lost or stolen by others, the verification of the PIN and the $Passwd_{Acct}$ prevent the cell phone from misusing by someone else. It is proven that even the SIM of legal user is cloned, the fraudulent usage can be detected quickly [14].

As for data transmission, the data between the merchant and the operator or between the operator and the bank can be transferred through the wired network such as ADSL, which use SSL transaction protocol to ensure the security of data. SSL is also a practical solution for ensuring end-to-end security of wireless Internet transactions even within today's technological constraints [15]. In our payment scheme, the data transferred in the wired network is protected by the public-key based algorithm which can prevent the confidential attack effectively [16]. For example, the RSA public-key encryption algorithm is used for the protection between the bank and the operator, and illustrated as follows:

The Operator has the public key of the bank: $BK_U = \{e, n\}$ and the bank has the corresponding private key: $BK_R = \{d, n\}$ (n is calculated from $p \cdot q$, p and q are both prime, e is a selected integer and the greatest common divisor of e and $(p-1)(q-1)$ is 1, d is calculated from $d = e^{-1} \text{ mod } ((p-1)(q-1))$). Let M be the plaintext and C be the ciphertext. The operator encrypts the secret transaction information with BK_U :

$$\text{Operator : } C = M^e \pmod{n}, M < n \quad (5)$$

Only one that has corresponding private key can decrypt the ciphertext and gets the secret information (i.e. in the example above, only legal bank that has the private key BK_R can decrypt the ciphertext).

$$\text{Bank : } M = C^d \pmod{n} = M^{ed} \pmod{n} \quad (6)$$

It is infeasible to determine d given e and n . Currently, a 1024-bit key size is considered strong enough for virtually all applications. Besides, the secure connection of USSD between the operator and the consumer is provided by the signal protection mechanisms of GSM/UMTS [17].

Table 2. Key sizes for equivalent security levels (bits).

Symmetric	ECC	RSA/DH/DSA
80	163	1024
128	283	3072
192	409	7680
256	571	15,360

2) Privacy. The transaction privacy of the consumer depends on the *TransNo* — it is very difficult for the merchant to get personal information of the consumer because it has no corresponding key to decrypt the *TransNo*. The *TransNo* is protected by the encryption of the asymmetric cryptography which is hard to be broken [18]. Some cryptographic algorithms which are suitable for the wireless communication were proposed, such as Elliptic Curve cryptography (ECC) [19]. A 571-bit ECC is currently equivalent in security to 15,360-bit RSA, as shown in Table 2. The smaller key size for equivalent security levels accounts for the performance advantages to be obtained from substituting ECC for RSA, especially in wireless environment. The Elliptic Curve cryptography is derived from the equation of elliptic curve:

$$y^2 = x^3 + ax + b \quad (7)$$

where a and b are elements of a finite field with p^n elements, p is a prime greater than 3. The detail about Elliptic Curve cryptography can be found in the reference [20].

Under the proposed mechanism, the merchant is unable to collect the purchasing habits of a consumer because of the secure protections of the asymmetric cryptography suitable for small hardware, such as ECC.

In the aspect of the operator and bank, only total amount of the price is in the transaction data. So, even though the operator and the bank knew well about the real identity of the consumers, they cannot know what merchandise the consumer has purchased (as shown in Fig. 4 and Fig. 6). In our payment mechanism, the consumers have the overall privacy.

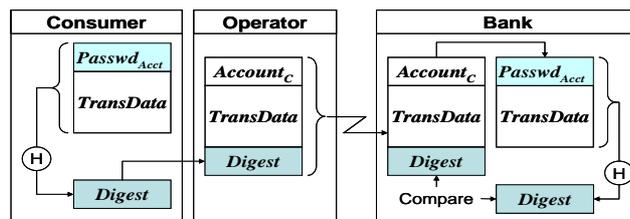

Fig. 8 Authentication using a one-way hash function

3) Authentication. The consumer is authenticated three times in our payment mechanism:

First, the cell phone verifies the PIN of the consumer.

- Second, the operator verifies the $Passwd_{Trans}$ after decrypting the *TransNo*.
- Third, the bank verifies the $Passwd_{Acct}$ of the consumer through message authentication using a one-way hash function depicted in Fig. 8.

With those three authentications, the risk of counterfeit is reduced to the minimum.

As for the merchant, the bank authenticates the merchant by verifying its certificate. The certificate of the merchant is issued from the trusted third party which could be the governmental institution, so it can restrain the malicious merchant. Sulin proposed a new design of trusted third party which is built on the current models of CAs but has enriched functionality [21]. They proposed a Trusted Third Party System Strategy (TTPSS). TTPSS is a sequential equilibrium strategy of the trusted third party system stage game. The TTP model can be very effective in promoting small business online transactions and consumer-to-consumer transactions. This authentication model could also be adopted in our payment scheme to expand the participants and to ensure the transaction effectiveness.

4) Non-repudiation. After the consumer confirms the transaction, he has to enter the $Passwd_{Acct}$ for the calculation of message digest. Then, the bank authenticates the consumer by verifying the message digest. Only the legal consumer and the bank can calculate the same *Digest* because the $Passwd_{Acct}$ is only known by them. The transaction is confirmed if the *Digest* was correctly verified, and the consumer cannot deny the transaction. The bank transmits the payment receipt to merchant after account settlement, so the merchant can avoid the risk of consumer's bad debit.

5) Integrity. After the merchant summarizes the *TransData*, it prints out the *TransRe* to the consumer. The bank transfers a *PaymentRe* to the merchant after the account settlement (as shown in Fig. 2). Then the merchant prints the *PaymentRe* to the consumer. These two receipts can be combined through the *SerialNo* of the transaction. The consumer can ensure the integrity of the transaction by comparing these two receipts.

6) Other Discussion. Besides the security criteria mentioned

above, our payment mechanism is also feasible. The main reason is that it will not take great cost to the participator to adopt the payment mechanism into his business model.

The consumer can generate the *TransNo* before going shopping. And the computational load can be reduced in the payment process because only hash function is performed by the cell phone.

B. Evaluation from the aspect of attacker's role

There are four participators in our payment scheme and any of them might be malicious except the operator. The operator is assumed to be trustworthy in our mechanism. We will discuss the possible attacks of the malicious participators and how to prevent them in our payment scheme in this section.

1) Malicious merchant—deny the transaction. In our payment scheme, the merchant needs to deliver the goods to the consumer after receiving the *PaymentRe*. The malicious merchant might refuse to deliver the goods and conceal the *PaymentRe* from the bank. But while the bank completes the account settlement, it will not only transfer the *PaymentRe* to the merchant but also send the consumer a short message which is used to notify the consumer of the completion of the payment. The bank also needs to transmit the transaction record to the operator for future inquiry. Therefore, after the consumer received the short message, the truth of the payment can be proved. The consumer can demonstrate the evidence of the payment from the transaction record preserved in the operator and bank.

2) Malicious merchant—steal the *TransNo* from the consumer. The malicious merchant might try to get the legal *TransNo* of the consumer by hook or by crook. If the merchant uses the *TransNo* which is stolen from the consumer to forge a transaction, the consumer will be aware of the misuse of the *TransNo*. In the step 3 of our payment process, when the operator confirms the transaction with the consumer through USSD connection, the consumer can refuse the transaction. Moreover, once the consumer found the misappropriation of the *TransNo*, he (she) can inform the operator to trace the malicious merchant through the digital certificate of the merchant.

3) Malicious consumer—fabricate the *TransNo*. The malicious consumer might try to forge the *TransNo* of another legal consumer to make a transaction. They might create a *TransNo* by getting wise to another consumer's *PhoneNo*. But the fake *TransNo* will soon be revealed because the malicious consumer cannot get the exact *Passwd_{Trans}* of the corresponding *PhoneNo*. Even if the malicious consumer is lucky enough to guess the right *Passwd_{Trans}*, he will not pass the transaction confirmation in the step 3 and the verification of *Passwd_{Acct}* in the step 4 of our payment scheme. The probability of guessing right the *Passwd_{Trans}* and the *Passwd_{Acct}* at the same time is very little.

4) Malicious bank—disclose the *Passwd_{Acct}*. Generally, the bank is trustworthy. However, the employee of the bank might benefit from disclosing the important consumer information. For example, the employee might eavesdrop to the *Passwd_{Acct}* of the consumer and sell it to the evildoer. But our payment mechanism is secure enough to be against the attack which the *Passwd_{Acct}* is misused. As for the consumer, the exact *Passwd_{Trans}* and *Passwd_{Acct}* are needed in every transaction. The transaction can not be complete without one of these two passwords. Besides, the transaction confirmation by the operator can prevent the transaction relative passwords from being misused by a malicious consumer. As for the merchant, it delivers the goods to the consumer only when the *PaymentRe* is received and no cancel message is received from the operator. The consumer authentication and the transaction confirmation executed by the operator can prevent the consumer and the merchant from losing on an illegal transaction.

5) Malicious merchant and bank—tamper the *TransData*. The malicious merchant might collude with the employee of the bank, and devise a way to tamper the *TransData* to make profit illegally. For example, the employee of the bank might tamper the *Price* of the transaction in our payment process. Because the bank knows the *Passwd_{Acct}* of the consumer, it can forge the original *Digest* and confirm the transaction. The malicious merchant might use the fake *PaymentRe* to take the place of the real one. But while the bank transfers the fake price into the account of the malicious merchant, the *Record* transmitted to the operator in the step 6 of the payment process will reveal the illegal activity. The *Record* is generated through the secure mechanism of the bank, and it is not easy to be tampered.

6) Malicious consumer and bank—forge the *PaymentRe*. The malicious consumer may cooperate with the employee of the bank. The malicious consumer might pretend to purchase goods in the merchant and refuse to pay for the transaction actually. Then, the employee of the bank may try to forge a *PaymentRe* according to the confirmation data transmitted from the operator to the consumer. But in our payment mechanism, if the legal consumer rejects the payment, the operator will notify the merchant that the payment is cancelled by the consumer. So, even if the merchant received the fake *PaymentRe*, it will have the sufficient reason to deny the transaction.

After the discussion and evaluation, our payment mechanism can ensure high security for all participators.

7) Malicious consumer and merchant—repudiate the transaction. The malicious consumer might collaborate with the malicious merchant to make the transaction inconsistent, and request for compensation from the bank. But the bank proceeds to transfer the account only after the identifications of the consumer and the merchant are

authenticated and the transaction is confirmed by the legal consumer. Therefore, the merchant and the consumer cannot deny the transaction and have no reason to ask the bank for compensation.

V. Conclusion

The development of the Internet, handset devices, and telecommunication technologies are changing the way of our life extremely, especially in commerce. Lots of novel business models emerge rapidly. However, the most important and insecure stage in the transaction is payment. Without an appropriate payment mechanism, any business model will be hardly put into practice. Therefore, we have an urgent need for designing a securer and more convenient payment mechanism.

The payment mechanism we proposed adopts the cell phone to be the payment tool. By making use of the transaction number, our payment mechanism provides many advantages:

- **Security:** Our payment scheme meets security criteria which includes confidentiality, authentication, integrity, and non-repudiation during the payment process. Besides, the risk can be minimized when the consumer loses the cell phone or the cell phone is forged because our method provides multiple authentications.
- **Full transaction privacy:** The merchant cannot get the real identification of the consumer because the transaction number is dynamically changed and protected by the asymmetric encryption. Besides, the operator and the bank cannot acquire the detail of the merchandise purchased by the consumer except the total amount of price. Therefore, no one except the consumer can gather the transaction habit.
- **Convenience:** The time of the payment can be shortened because the time-consuming operation of the encrypt algorithm can be done in the initiation phase. In other words, the transaction number can be generated and stored in the cell phone before the consumer goes shopping.
- **Low computational load of the mobile phone:** The operation of the consumer in the transaction phase can be only a one-way hash function. The speed of one-way hash function is approximately 100 times faster than that of the encryption/decryption of the secret-key system and the speed of the encryption/decryption of the secret-key system is about 100 times faster than that of the signature/verification of the public key system [13].
- **Feasibility:** In addition, the participators can adopt our payment scheme into their business model without additional cost of hardware. And it is implemented based on the existing network environment.

Besides the advantages mentioned above, we also evaluate the payment scheme from the aspect of security criteria and the attacker's role in detail. Our payment scheme has been proved that it can effectively prevent any

participator's malicious attack.

Our payment mechanism is very suitable for the payment from medium to large amounts of money because it has overall protection of security and full transaction privacy. And it can be more flexible if we integrate it with other payment systems, such as micro-payment system, e-cash and so on. Our mobile payment scheme has made great progress toward a more omnibus and secure payment scheme for the new era.

Extended Abstract

As many other areas of business, internet marketing has been under attack by social commentators and other consumer or general public organisations for alleged unethical practices. As sophistication of marketing tools and techniques improve and as the impact of the internet on society grows, ethical considerations must be addressed if public trust in the profession is to be secured and maintained.

While e-marketing is subject to the same general criticism as marketing from the general media, mainly about issues such as consumers' right, misleading information or freedom of choice, its specific characteristics make it a fertile ground for other, more specific ethical dilemmas than those previously experienced or identified by marketers. It is therefore useful, when examining the generic portfolio of marketing activities, to identify the specific nature of some e-marketing decisions, in order to identify where a specific ethical dilemma may arise. In other words, although the internet technology may not have generated any new or unique ethical issues, many of the controversies associated with this technology might warrant special considerations from an ethical perspective. Further, consumers' personal characteristics such as the individual's level of moral development and personality and cultural environment may impact also on consumer choices in a situation involving ethical issues.

Given the exploratory nature of the study, a convenience sample of avid Internet users was selected and asked to rate and rank ethical dilemmas. 41 ethical issues were encapsulated in the short descriptive scenarios provided as examples in the previous section and respondents were asked to rate these issues in terms of the ethicality of the situation and the importance of this issue when considering an internet site or an etailer/service provider. Although the inclusion of the examples (e.g. McDonald's) may have biased the sample by framing the respondents' perceptions of the issues, it was considered important as a means of focusing participants' responses. The majority of respondents (76%) were between the age of 19 and 22, with

even split between males and females. In terms of internet usage activities, the vast majority of respondents (64%) used the internet on a daily basis with another 30% using the internet 2 to 6 times a week. Thirty eight percent of respondents spent 1-2 hours each time they access the internet, followed by a 31% spending less an hour on the internet each time they access the internet. Many respondents (59%) had purchased goods on the internet while a staggering 82.6% used an online service. There was no significant difference between genders in terms of internet use.

The results showed that five out of the top ten issues are related to e-marketing practices targeting children, indicating that using the internet in targeting children is a serious consumer concern. Surprisingly, the fourth issue involves one of the consumer ethical issues – 81% of respondents consider purchasing prescription-only drugs online without a valid prescription unethical. The fifth issue relates to the content of advertising messages. A little over 80% (80.5%) of the respondents agreed or strongly agreed that using sex, nudity and racist languages in online advertising messages was unethical. Respondents also seemed to be concerned about online market research activities. Consistent with findings from previous research, about 80 per cent of internet consumers considered the intrusion privacy through data collection and spam is very unethical or unethical.

Further, two primary antecedents of ethical opinions can be identified from data collected: (1) user characteristics such as gender, nationality, and age; (2) user experience in terms of length and frequency of internet use, amount spent in online purchase and activities on the internet. For example, the Spearman's rank order correlation tests show that the positive association between frequency of internet use and opinions on using incentives on websites targeted at children, selling drugs online, grey importing and realtime pricing is significantly, but not very strong. This suggest that as internet use become more prevalent, consumers may become desensitised to some of the ethical issues that are prickly currently. It is important to note, however, that this is not intended to be an exhaustive list of antecedents to ethical opinions. Rather, these are variables that can be identified from existing research and are considered important for ethical opinions. More antecedents may emerge in the future as our knowledge of consumers' online interaction deepens.

In brief, this paper offers a critical examination and analysis of key ethical issues arising in the planning and execution of internet marketing practice. It provides a critical reflection on ethical implications of specific e-marketing strategies and practices and discusses the influence of user characteristics and experience on their opinions of ethical issues and consequences of those strategies and practices that marketing managers may consider in their decision making.

It is important to note the limitations of our study and, more particularly, the convenience nature of our sample. Further replicate research could be conducted using a sample with different demographic characteristics. Despite these limitations, our study showed that internet users are aware and concerned about ethical issues about e-marketing. Marketing professionals, therefore, should not ignore these concerns and they should examine their practices in the light of their consumers' ethical sensibility. Similar research with respect to knowledge, awareness and use of privacy protection strategies relevant to e-commerce is needed. For example, research should examine whether consumers are more aware of privacy protection strategies related to internet use. Further, will these ethical issues disappear as time goes on and consumer gain more internet experience? Longitudinal studies of consumers ethical opinions on internet marketing practices is warranted as e-business applications develop.

Determinants of Online Auction Participation: How Much Do Web Knowledge and Risk Perception Matter?

Sophia Wang¹, Jenny Tian²

1 National Dong Hwa University, Taiwan

2 University of Southern California, USA

Abstract: This study extends the research on online consumer behavior by examining the effect of Web knowledge and risk perception on individual attitude towards and intention to participate in online auction. The survey findings show that individuals with high Web knowledge tend to form positive attitudes towards online auction. By contrast, individuals who have heightened concerns about Internet privacy and security show less favorable attitudes towards online auction. Consistent with the attitude-intention model, attitude appears to mediate the effect of know and risk perception on intention. Research and practical implications of these results are discussed.

Keywords: Security, trust, privacy and reputation in e-business; Online auction; Online consumer behavior

I. Introduction

Online auction has become the newest trend of e-commerce. Some researchers argue that online auction epitomizes “the democratization of the Internet” because, potentially, anyone with an Internet connection can become a merchant [1]. The implications of Internet and database technologies for auction design have been widely discussed in the literature [2]. Many previous studies have also examined overt bidding behaviors of online auction participants, typically based on archival data collected from various auction sites [3]. Despite the increasing research attention, it remains unclear why some Internet users are more likely to participate in online auctions than others. Although much research has been done to classify observable bidding behaviors, we know little about the unobservable cognitive and psychological forces that drive these bidding actions.

Drawing upon the research on technology adoption and online consumer behavior, the present study is intended to identify the determinants of an individual’s attitude towards and intention to participate in online auction. Online bidding is conceptualized as a task involving high information processing demand and high outcome uncertainty. Therefore, we focus on two categories of determinants: knowledge and risk perception. A basic argument is that individuals with high Web knowledge and low perceived risk of the Internet tend to develop positive attitudes towards online auction. With a few exceptions [4], the effect of knowledge and risk perception on attitude and behavioral intention have

typically been examined separately in previous studies. This paper integrates the research on individual knowledge structure and risk perception (and its flip side – trust belief) into the belief-attitude-intention framework of human behavior [5].

II. Hypotheses

II.1 Web Knowledge

Web knowledge, or the level of understanding of the Internet as an information and communication mechanism, can be gained via direct experience of using the internet and/or from secondary sources (e.g., technical manuals). We measure Web knowledge along two dimensions: skill and experience. Web skills refer to an individual’s perception of how skilled he or she is at using the Internet. Measured as subjective knowledge, Web skills are similar to computer self-efficacy, defined as “an individual judgment of one’s capability to use a computer” [6]. Prior research has shown that computer self-efficacy reduces an individual’s computer anxiety and leads to a favorable attitude towards new technologies [7]. Similarly, in the context of online auction, individuals with high levels of Web skills may feel less anxious when viewing and searching the vast amounts of information about auction products, prices, shipping arrangements, payment methods, buyer and sellers, and so on.

The second dimension of Web knowledge is related to one’s direct experience of using the Internet, particularly for the purpose of shopping. The amount of purchase experience has often been used as a measure of consumer knowledge [8]. The attitude-intention model suggests that the more positive a person’s past experience about an object, the more positive beliefs he or she will hold about it. Familiarity based on previous experience helps reduce uncertainty and increase perceived behavioral control. Online auction is similar to online shopping in the sense that both involve economic transactions and financial payments. More important, both are particularly important predictor of attitude towards online auction. The more favorable online shopping experience that an individual has accumulated over time, the more likely he or she is to develop a positive attitude towards a related transactional mechanism – online auction. These arguments lead to the following hypotheses:

H1: Web skills are positively related to attitude towards online auction.

H2: Favorable Web experience is positively related to attitude towards online auction.

II. 2 Risk Perception

Online auction is not risk-free. In a virtual market of unseen participants and products, buyers and sellers are faced with the risk caused by information asymmetry. Since potential buyers have no physical access to the product in question, sellers can easily misrepresent the condition or the quality of their products. Auction participants also face the risk caused by opportunism. For example, buyers or sellers may decide not to abide by the contract. To make things worse, the cost of enforcing a contract is high relative to the value of the auction product / service in many cases, resulting in an absence of legal enforcement in the online auction community. In general, transactions conducted on the Internet are viewed as riskier than offline transactions. However, individuals hold different risk perceptions regarding the Internet and what matters for attitude formation is the risk as *perceived* by potential auction participants. We examine perceived risk in two ways. First, we argue that disposition to trust, defined as a general inclination to display faith in humanity and to adopt a trusting stance toward others [11], should be associated with a positive attitude towards online auction. Individuals with high levels of trust propensity tend to believe that people in general are trustworthy. This belief is neither situation-specific nor based upon knowledge of a specific trusted party. Therefore, disposition to trust may have greater influence over attitude and behavioral intention in situations where the transactional parties are unfamiliar with each other. Previous studies also establish that trust reduces risk perception [12].

We also examine situation-specific risk perception, that is, an individual's concern towards the Internet's reliability as a transactional medium. Two types of risk are predominant in the online environment -- perceived risk associated with privacy and security [13]. Various surveys have shown that Internet users are increasingly concerned about the unauthorized collection, improper storage, and inappropriate use of their personal data by online marketers. Closed related to this privacy concern is the concern about the security of transmitting financial information (e.g., credit card number). The anonymity on the Internet and the ambiguity of the online environment makes it difficult for consumers to distinguish trustworthy transaction parties from less trustworthy ones. Therefore, they may transfer their privacy and security concerns to the Internet -- the medium itself [14]. Individuals with high levels of perceived Web risk will then tend to avoid online auctions. These arguments lead to the following hypotheses:

H3: Disposition to trust is positively related to attitude towards online auction.

H4: Perceived Web risk is negatively related to attitude towards online auction.

II. 3 Attitude and Intention

The belief-attitude-intention framework views participation in online auction as a consciously intended behavior. This

framework suggests that an individual's performance of a specific behavior is determined by his or her intention to perform that behavior. Behavioral intention, in turn, is determined by attitude. The positive relationship between attitude and behavioral intention has been examined in various empirical contexts ranging from acceptance of Internet-based self services [13] to online shopping [15]. Consistent with the attitudinal model, this paper proposes that attitude should mediate the effects of Web knowledge and risk perception on intention to participate in online auction.

H5: Attitude mediates the relationships between Web knowledge and risk perception and intention to participate in online auction.

III. Methods and Results

Survey data were collected from a sample of 126 undergraduate students majoring in business administration and accounting. All theoretical constructs were measured using established scales. The exploratory factor analysis (EFA) shows that all items converge to form distinct factors and there is no cross-loading of items. The Cronbach's alpha coefficients for the measurement scales all exceed .70. These results provide further evidence for the validity and reliability of the measurement model.

Descriptive statistics are shown in Table 1. OLS regression analysis was conducted to test the hypotheses. The results are shown in Table 2. In Model 1, the dependent variable (DV) -- attitude was regressed on four independent variables (IVs). Consistent with H1 and H2, Web skills and favorable Web experience are both positively related to attitude towards online auction. Empirical support is also found for perceived Web risk (H4). However, the hypothesis that disposition to trust and attitude are positively related (H3) is not supported. We followed the four-step approach suggested by Baron and Kenny [16] to test the mediating effect of attitude on intention (H5). The regression results for Model 2 are similar to those for Model 1, indicating that three IVs (i.e., Web skills, favorable Web experience, and perceived Web risk) are significantly related to intention to participate in online auction. Model 3 shows that attitude has a significant and positive effect on intention. Finally, the full model (Model 4) shows that, except for attitude, all the other four IVs are no longer significantly related to behavioral intention. These results are consistent with a full mediation model, as suggested in H5.

IV. Discussion

In this study, we investigated the effect of Web knowledge and risk perception on attitude formation in the context of e-auction. We found that high Web knowledge positively affect an individual's attitude towards online auction that, in turn, translates into strong intention to participate in online

Table 1 Mean, Standard Deviation and Correlation

	Mean	s.d.	1	2	3	4	5	6	7

auction. On the other hand, individuals who had heightened concerns about Internet privacy and security showed less favorable attitudes towards online auction. The data support the mediation model in which attitude serves as a bridge psychological mechanism that links belief and behavioral intention. Interestingly, we did not find any relationship

between disposition to trust and attitude / intention. This may be due to the multidimensional usage dimensions of the Internet. A powerful mechanism for information search, communication, and transaction, the Internet would engage users and consumers with different personality traits. It might be difficult to observe the direct effects of personality traits on specific Web behaviors [14].

This study shows that both knowledge and risk perception matter for attitude formation in the context of online auction. Theoretically, these findings call for attention to an integrative framework about consumer behavior in e-commerce transactions. Practically, auction sites and online sellers will benefit through increased understanding of how concerns about Internet privacy and security may affect a customer's response to online transactions. This study also shows the importance of increasing customers' familiarity with a specific Web site. Auction sites, online stores, and individual sellers who list their products on an auction site should focus on Web features that are easy to recall and that can create a sense of familiarity (e.g., a carefully designed "about us" section and/or timely email reminders) because customers' positive specific experiences will lead to positive general beliefs and attitudes.

Future research should explore additional aspects of Web knowledge and risk perception. Moreover, research evidence has been mixed regarding the relationship between knowledge and risk perception. While some researchers suggest that knowledge helps reduce risk perception, others argue that more experienced and knowledgeable Internet users actually are more concerned about online risks. More research is needed to clarify this issue.

Abstract: This research aims to present a Web Services Security Framework for Ministry of Information and Communication Technology (MICT) in Thailand as referred to international standard BS7799 on information security management. With a pilot development of web services which based on e-government, the researcher used Ministry of Information and Communication Technology as a case study. In order to understand the developmental pilot, it's crucial to realize particularly in web services security and to determine proposed or existing system. Finally, it can be as standard guideline for Thai public organization for developing web services security framework.

Keywords: Web Services, Security, BS7799, ISMS.

I. Introduction

Today, Internet and information technology have played important role widely overall fields. It's obvious that related security system has been increasingly interested by public. Progressively, public affair service has been developed into e-government where major technology applied is Web Services. A medium for inter-exchanging data and services which security system is needed inevitably to protect valued data of user account. In this research, web service security framework has been devised by researchers utilizing Ministry of Information and Communication Technology in Thailand as a case study. The purpose of study is to examine and establish Web Services Security Framework for Ministry of Information and Communication Technology, and to assess security system of existing Web Services in Ministry of Information and Communication Technology under developed security framework.

The applied research as a government institution case study is based on BS7799 [8], an universally acceptable standard; data management standard for security, where its requirement covers overall performance procedures in both

data access and storage in organization. This aims to develop security framework applicable to reality performance and applied to other divisions in the same direction usefully.

Since the study is focused on management practices other than technical support. The deliverable results are technical and administrative web services security framework. The appropriation of security framework has been inspected by auditing expertises and referred to research literature in framework for web services security [4,5,6], web services security theory [1,2,3,13,14], web services standard [9,10,15] and information framework [12]. The study is designed to determine if existing and potential web services are somewhat to be have security maintained. In addition to continue development to acquire future integral information.

II. Review of Related Standard and Framework

II.1 BS7799 [8]

This British Standard has been prepared for business managers and their staff to provide a model for setting up and managing and effective Information Security Management System (ISMS). The adoption of and ISMS should be strategic decision for an organization. The design and implementation of an organization's ISMS is influenced by business needs and objectives, resulting security requirements, the processes employed and the size and structure of the organization. These and their supporting systems are expected to change over time. It is expected that simple situations require simple ISMS solutions.

This British Standard can be used by internal and external parties including certification bodies, to assess an organization's ability to meet its own requirements, as well as any customer or regulatory demands.

II.2 Associated Web Services Standards [1]

Various techniques were developed to solve the problems faced in web services regarding how to make it interoperable,

distributable, integratable, and so on. Some of these techniques were proposed by industry giants and became standards over time. We will look at a few of these standards.

XML

One of the emerging concerns of web-based programmers was how to transmit data across HTTP networks in an interoperable manner. XML emerged as an interoperable format. XML typically is stored as easily as readable text files. XML documents have a structure that can be parsed to quickly turn data into other formats, for example for database storage. Many vendors of storage products, such as database storage products, have enhanced their products to easily handle the XML formats. Standards have been developed for the structure of XML for messaging use. XML has enjoyed widespread adoption and adaptation, which quickly has made it the messaging standard.

RPC, XML-RPC, and SOAP

Remote object accessing technology began with the standard RPC calls, in which method could be invoked from one application to another remote one. The limitation of the RPC was that it work on connection-oriented, communication protocols, which cannot be used with the connectionless protocols used in the Internet.

Firewalls were another fundamental problem in the RPC systems. To use the RPC system on required protocol-specific filters with additional software, configuration, and additional management. The XML-RPC evolved in the process of solving these problems.

Another standard that emerged immediately after the XML-RPC was the SOAP. This defines the structure of message to be communicated across the Internet between a web service client and a host. SOAP emerged due to the problem of firewalls being primarily configured to access objects via HTTP. SOAP does not replace RPC, as it includes the SOAP-RPC and SOAP document styles, which is why it is the preferred HTTP-based message protocol.

WSDL

A web services is published for other to discover it and then use it. To be able to use it one needs to describe it, provide details for using it, and place it under the right category, similar to the Yellow Pages. The WSDL standards were developed to fulfill this requirement by creating a standard way of capturing the service description. In this, a service is described in terms of the operations (that is, input/output messages) and a set of interactions between a service provider and a service requestor. It describes the interface of how to interact with the service. The name of the service and a list of operations and their bindings make up the XML-based WSDL file.

From a security point of view, one should keep in mind that this is a plaintext file in ASCII, UTF-8, or some base64-encoded format.

UDDI

Web services needed a way to present a company's information in a manner that compared their features equally. Using search engines for this purpose was not the most efficient means of allowing business to interoperate with each other at a web services level, and as a result the UDDI directory of web services emerged.

The UDDI is a registry service project that provides a means for business hosting a web services to register with the worldwide registries. The project is focused on assisting business in finding each other by allowing the registration of a web services and the searching of registries to locate specific web services based on a number of criteria. The UDDI is not linked directly to any other standards initiatives or standards groups. However, it does take advantage of groups that provide standards and initiatives within the web services industry.

COBIT framework [12]

COBIT has been developed as a generally applicable and accepted standard for good Information Technology (IT) security and control practices that provides a reference framework for management, users, and IS audit, control and security practitioners.

COBIT, issued by the IT Governance Institute and now in its third edition, is increasingly internationally accepted as good practice for control over information, IT and related risks. Its guidance enables an enterprise to implement effective governance over the IT that is pervasive and intrinsic throughout the enterprise. In particular, COBIT's Management Guidelines component contains a framework responding to management's need for control and measurability of IT by providing tools to assess and measure the enterprise's IT capability for the 34 COBIT IT processes.

III. Research Design

This research has developed web services security framework. Ministry of Information and Communication Technology in Thailand was selected as sample, for its core matter for conducting e-government which major goals and responsibility of Ministry of Information Technology and Communication are maintained and achieved.

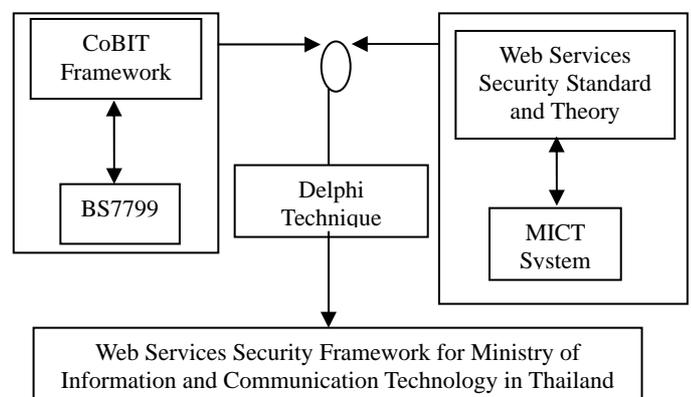

Figure 1: Conceptual design

As illustrated in Figure 1, on the left box is to determine jointing point between COBIT framework and BS7799. When they are applied to Ministry of Information and Communication Technology Web Services, the illustration as shown at the right box. Linkage of left and right box is to determine Web Services Security framework for Ministry of Information and Communication Technology in Thailand.

IV. Research Methodology

This research was applied research with referred to acceptably international standard for creating actually applied framework, or furthered development applied to other related fields in similar way.

Collected data is adopted from secondary data source; research literature, and a wide range of related technical articles and textbooks.

Another data collecting method used was Delphi Technique, which relevant expertise's opinions have been gathered to complement framework.

V. Preliminary Results

According to survey and collect data, we found that web services-related major responsibility of Ministry of Information and Communication Technology is to be navigator in e-government development through web services means, accountable for XML, SOAP, UDDI and WSDL web services creation in preparing process. Thus, the framework outcome is followed as;

1. Interchange or table of connection between requirement of BS7799 and security according to XML, SOAP, UDDI and WSDL.
2. Create ISMS document as specified in table of connection referred to BS7799
3. Add ISMS further information according to COBIT framework
4. Requirement based on BS7799 such as
 - 4.1 Security policy
 - 4.2 Organizational security
 - 4.3 Asset classification and control
 - 4.4 Personnel security
 - 4.5 Physical and environmental security
 - 4.6 Communications and Operations management
 - 4.7 Access control
 - 4.8 Systems development and maintenance
 - 4.9 Business continuity management
 - 4.10 Compliance

In addition, ISMS document used "Plan-Do-Check-Act" (PDCA) model, Plan (establish the ISMS) Do (implement and operate the ISMS) Check (monitor and review the ISMS) Act (maintain and improve the ISMS) and follows as;

- 1 Scope
- 2 Normative reference

- 3 Terms and definitions
- 4 Information security management system
- 5 Management responsibility
- 6 Management review of the ISMS
- 7 ISMS improvement

VI. Conclusion

The result indicated merely piloting development for actual application. Since BS779 requirement is considerably detailed, its connection to web service standard is impossible for all BS7799 detailed requirement. In addition, web service technology has been developed continuously and technically, along with increasingly additional new versions, specialized expertise is needed. Concerning to management and web service security, technical and managerial collaboration is necessary to allow effective regulation.

Framework created has been covered only web service on basic standard and operation by Information and Communication Technology, and not covered overall web service technology and system security modality.

BS7799 has been developed more strictly and progressed to new version of standard ISO27001, including to web service technology as significant element in future information technology. Additional standard prototypes should be given further attention to be researched and created so that they can be applied or established to web service standard particularly.

Abstract: This paper explores the consumer concerns about privacy in Internet e-banking and examines the impacts of several variables in relation to perceived privacy protection. The findings suggest that commercial banks must effectively minimize transaction errors, eliminate unauthorized use of personal data, control offensive access and maintain transactions records. Preventive management is vital to the enhancement of privacy of Internet banking and the consumer acceptance of Internet banking services.

Keywords: e-finance, Internet banking, consumers, privacy.

I. Introduction

Internet banking provides an effective electronic channel for delivering banking and financial services and enables individuals to access accounts anytime and anywhere. However, the spread of e-commerce activities increasingly causes privacy concern, which considerably affects the success of different e-businesses. As far as this is concerned, it is important for e-banking service providers to appreciate consumer expectation in privacy protection. This paper examines several variables in relation to the protection of privacy in the case of Internet banking. It also explores the impacts of these variables on consumer acceptance of the e-banking services.

II. Hypotheses

Numerous existing studies have examined the protection of privacy [3] [8] [9] [14] [15] [17]. For instance, Smith, Milberg and Sandra [17] measure individual's concerns about information privacy using several dimensions such as collection, unauthorized secondary use, errors and improper access. On the basis of previous work, this study applies several variables in relation to the perceived privacy and examines their influences in operational environments of Internet banking. These include personal data collection, data errors, unauthorized use of personal data, offensive access control, data loss, perceived privacy, attitude and behavioral intention to use Internet e-banking. Firstly, commercial banks have collected a large amount of personal data for different banking and financial services. Customers may be offended by the request of providing some sensitive

data in relation to individual privacy. Hence, Hypothesis 1 is proposed:

H1: The collection of customer data has a positive impact on perceived privacy.

Secondly, it is practically difficult to completely eliminate deliberate and accidental errors in business transactions. The assurance of data correctness and data integrity remains an important issue [9]. However, some firms have not taken enough steps to minimize errors in data processing [17]. The concern about transaction errors in banking environment may considerably affect individual perceptions of privacy. Therefore, Hypothesis 2 is proposed:

H2: The minimization of transactional errors has a positive impact on perceived privacy.

Thirdly, consumers might worry about that the information collected from individuals is used for unusual purposes without permission. Even within a company, for example, the information collected for research purposes may be used for marketing promotion [2]. In the banking industry, the data collected from loan applications may be used to sort customers into different categories for service promotion. In terms of unauthorized use of personal data, it may include secondary use of information and shares of customer contacts with other firms. As a result, it leads to a negative response from individuals [3] [17]. Therefore, Hypothesis 3 is proposed.

H3: The elimination of unauthorized use of personal data has a positive impact on perceived privacy.

Fourthly, there is a concern about offensive access, because someone is not properly authorized, may be able to view or work with a particular data [15]. The access to individuals account should affect the privacy level especially in e-banking environment. How to effectively control the unauthorized access is a critical administrative issue of an organization [17]. Hence, the following is proposed:

H4: The control of offensive access has a positive impact on perceived privacy.

Moreover, personal data and transaction records might be lost due to the removal of electronic data while it is transited. It might also be lost when someone accidentally erases the data in a database. If an individual assumed that there would be a loss of personal data through the use of an information system, little privacy of the application should be perceived [9]. The storage and data maintenance of

individual data remains an important task especially for bank operations management. Therefore, Hypothesis 5 is proposed.

H5: The elimination of data loss has a positive impact on perceived privacy.

Numerous studies suggest that attitude has a significant effect on behavior intention [1] [4] [5] [6] [7] [10] [11] [12] [13] [16] [18]. Attitude can mediate effective responses between beliefs and usage attention [4] [5]. Increasingly, consumers are seriously concerned about the protection of privacy associated with electronic commerce activities. Empirical work indicates that privacy is a significant factor influencing consumer willingness to use e-banking [15]. In general, those expecting a higher level of perceived security usually have a more favorable attitude towards the service [8]. Therefore, the Hypotheses 6.1 and 6.2 are proposed.

H6.1: Perceived privacy has a positive impact on consumer attitude towards Internet banking.

H6.2: Consumer attitude influences behavioral intention to use Internet banking.

III. Methods

The research methods include survey and statistical data analysis. The questionnaire includes a number of questions in relation to perceived privacy, consumer attitudes and behavior Intention to use Internet banking. In order to ensure content validity of the scales adopted, the items within the questionnaire were developed with reference to the existing literatures. The respondents were asked to indicate whether they have experience on the use of Internet banking. They were also asked to give their observations using a seven-point Likert-scale ranging from 1 to 7. Moreover, they were requested to provide demographic data such as gender, education, income and occupation. As a result, two hundred and ten useful responses were received at this stage. Finally, several procedures of the Statistical Package for Social Science were used to analyze the data collected.

IV. Results and Discussion

Multiple regression analysis has been conducted to test to the above-mentioned hypotheses. The results in Table 1 indicate that several exogenous variables have significant impacts on the endogenous variable ($F = 26.92$, $Sig. < 0.001$) and H2, H3, H4 and H5 are supported. The R^2 value of 0.383 suggests that 38.3% of the variance can be explained. In other words, the minimization of transactions errors, the elimination of unauthorized use of personal data, the control of offensive access, and the protection of customer data significantly affect the perceived privacy of Internet banking. In turn, the perceived privacy significantly affects consumer attitude towards Internet banking ($F = 29.06$, $\beta=0.35$, $Sig. < 0.001$) which also considerably influences their behavioral intention to use e-banking

services ($F = 100.41$, $\beta=0.57$, $Sig. < 0.001$). Therefore, H6.1 and H6.2 are supported.

It is generally understandable that an individual customer must provide necessary personal data when opening an account in a respectable financial institution. Therefore, the bank has little problem on the collection of customer personal data. However, it is desirable that the bank is able to identify any data problems and transaction errors and make prompt corrections in data processing. In addition, the elimination of unauthorized use of customer personal data is critical to the protection of customer privacy. It is not uncommon that some banks may intensively analyze the personal data of customers for the purpose of customer relationship management. Based on data-mining, banks may be able to appreciate the need of different customers. Although the banks usually have particular administrative procedures and regulations for data analysis, consumers are still concerned about the use of personal data. As far as this is concerned, the banks should ask the customers whether they are allowed to use the information for product and service promotions.

Table 1 Results of Regression Analysis

	β	t	$Sig.$
(Constant)		4.518	.000
Data collection	.035	.636	.525
Transaction errors	.166	2.566	.011
Unauthorized use	.231	3.363	.001
Offensive access	.138	2.000	.047
Data loss	.259	3.689	.000

Note: Adjusted $R^2 = 0.383$.

Furthermore, the banks must strictly control offensive access to Internet e-banking systems, in order to effectively protect the privacy of its customers. A consistent investment in the most advanced security technology is critical to enable the banks to immediately identify any unusual attempt to enter an e-banking account and to restrict different offensive attaches to the Internet banking systems. Finally, customers are concerned about the possible loss of transactions data, because it is beyond their control. The banks must be responsible for maintaining transactions records. An effective elimination of data loss should greatly enhance the customers' confidence in Internet banking services. In sum, the findings suggest that commercial banks must minimize transactional errors, eliminate unauthorized use of personal data, stop any offensive access, and maintain the personal data of customers. This will help enhance the perceived level of privacy protection. In order to encourage more people to use of Internet banking, they must adopt a series of security procedures to protect privacy in Internet e-banking services.

V. Conclusion

An understanding of customer concerns and expectations is essential for planning and promoting Internet e-banking services. It is also important for formulating competitive

strategy for business development. This study systematically identifies the privacy concerns from the customer perspective. Preventive management such as minimizing transactional errors, eliminating unauthorized use of personal data, controlling offensive access, and maintaining transactions data are vital to the protection of customer privacy, which also significantly affect individual attitude and behavioral intention to e-banking. The findings have practical implications for managing the existing Internet e-banking systems. Accordingly, commercial banks might develop and implement a series of administrative procedures to protect the privacy and security of e-banking services. Practically, there are various variables associated with the protection of individual privacy in different social and cultural environments. Therefore, the present study can be extended to explore other aspects which might affect consumer acceptance and adoption of Internet e-banking in different contexts.

Model of Information Security Engineering Based on SSE-CMM

Hong Yang, De-li Yang, Zhi Zheng
System Engineering Research Institute
Dalian University of Technology, China, 116023
EMAIL: yh.Maggie@163.com

Abstract: On the basis of the project thought of SSE-CMM, this paper presents a kind of information security engineering model based on SSE-CMM. And it expounds the concrete work at each stage in the course of security engineering in detail.

Keywords: Information System Security, Information Security Engineering, SSE-CMM

I. Introduction

I. 1 Information security engineering

With the rapid development of information technology and network technology, information system has been paid much more attention and widely used in the various aspects of our society. However, "information system security becomes a key question in the development of the global information society and gets more and more serious since there exists more problems: web attack, virus infected, wrong use by the interior staff. People take series of measures and technology to grantee the information system security. Such as physical separation, firewall, identity certification, visiting control, identity identification, audit etc. But system security problem is dynamic and covers many aspects: security technology, products, stuff, management and so on. Therefore, information system security is not only a technological process, but a social process as well. It must be dealt with as engineering and solved by the means of system engineering. Therefore the idea of information security engineering is put forward. Information security engineering^[1] is such a process that adopts concept, principle, technology and method of engineering to study, exploit, implement and maintain information and web system security in the enterprise rank. It combines engineering implementation flow, which is proved to be right by time, management technology and the best technology available now. To guarantee information system security according to the idea of information security engineering is to solve various problems in the whole security process.

I. 2 Problems existing in information security engineering

Since the idea of information system security was put forward in 1972, the evolution of the related theories and approaches has experienced several stages. It develops into

LAN, Internet environment from a stand-alone environment and changes its service object from the military field to commercial organization. It takes the approaches of system engineering as a comprehensive way to tackle all the problems rather than just unitarily depend on the technology^[2].

Traditional system security engineering is regarded as a special engineering activity. Its aim is to apply the information protection technology to the established system structure and design norms. It focuses on the final system and products. Furthermore, it usually does not take the investigation about the basic protection demand of the company. This kind of approach lacks of the process control of the information system security structure and makes the security engineering activity separate from the system engineering activity. This will bring about the problem about the security vulnerability and lead to the system unsteadiness. In order to solve these problems and make it well applied, the information system security must be combined with the system engineering and the information system engineering must be integrated. It should be a process going in step with the process of the integrated system engineering. If it does not run like this, it will result in the uncertainty of the measures of system security. Then the users cannot get the available risk rank of the system correctly.

I. 3 The significance of researching information security engineering

The significance of researching information security engineering is determined by the properties^[3] of the information security.

(1) Information security is of sociality

The content of information security assurance is more universal and comprehensive than ever before.

(2) Information security is of comprehensiveness

Information security problems should be considered in overall aspects and the extent of the system security depends on the weakest part of the system.

(3) Information security is a process and has lifecycle

A holistic security process include at least the confirmation of security target and principle, risk analysis, requirement analysis, security strategies research, security architecture research, the confirmation of security implementation field, testing and selecting of security technology and products, security engineering implementation, security engineering implementation

surveillance and management, security engineering test and running, education on security consciousness and technology training, security assessment and examination, emergency response etc. This is a lifecycle of holistic information security engineering. After security assessment and examination, a new lifecycle begins. This is a continuously to-and-fro and upward corkscrew security model.

(4) Information security is dynamic

Information technology is developing, while the level of the hacker is also improving. Security strategies, security architecture and security technology should be adjusted dynamically in order to make the security system function furthest. Then the whole security system will be in a dynamic process and keep on renewing and improving.

(5) Information security has multi-levels

Multi-level security technology and approaches should be used to remove security risk.

(6) Security is relative

Security is relative. Absolute security does not exist.

Therefore, information security engineering is complicated system engineering. It involves exploitation, integration, operation, maintenance and management of information system. It is closely linked with web integration, exploitation and application. With the dramatic increase in informatization degree of our country's national defense, government, enterprises and society, the challenge of information system security becomes more and more serious. SSE-CMM is not practical in operation; In addition, the research on information security engineering is not mature in our country. In this case, to modify and improve SSE-CMM and to conduct research on its engineering, practicability under our country's circumstances is of great realistic significance to guide the development of information security engineering in our country.

II. General Research At Home And Abroad

There are two kinds of research thoughts in the history of information security engineering approach development.

One thought is ISSE (Information System Security Engineering), based on the system engineering process approach. The idea of ISSE appears as early as 1993 in the <handbook of information system security engineering > constituted by the state security administration in the U.S.A. ISSE puts emphasis on the application system engineering of information security. Specifically speaking, information system security engineering is to apply the special security technology (communication security technology, computer security technology and internet security technology) to the each stage of the information system lifecycle in order to guarantee the demands for the information system to be satisfied by following the viable security strategies and at

the same time to resist the appreciable threats. It is a methodology that demarcates the engineering elements by time-dimension. There should be many requirements running through the whole process, especially the assurance requirement of information security, but ISSE lacks of the special discussion on this issue. Besides, the content of information security is very complicated. One holistic process of information security engineering usually involves many complicated security fields, however, the time process does not show clearly in some fields^[1].

The second thought is SSE-CMM (System Security Engineering Capability Maturity Model) based on the process capability maturity model. It roots in CMM, put forward by information security technicians from NSA. It was first published in Oct 1996 and renewed in Apr 1999. This model tries to make information security engineering become a mature measurable advanced subject by taking the process management.

Information security engineering has been studied for over 10 years abroad. The researchers in different countries have put forward various methods. Literature^[4] puts forward an example of SLPS (Software Lifecycle Process Standard) based on IEEE/EIA12207, which is a information system security engineering model. Literature^[5] discusses the viewpoint of information system security analysis and design based on BPM technology. It combines security risk analysis and organization operation process analysis. Literature^[6] analyzes a series of information system security processes about how to define and transfer risks, how to integrate security to target structure and how to deal with the original system limitation when many systems are integrated to a larger one. Literature^[7] shows the idea of increasing the systematic structure related to security levels. This idea aims at Web applications and is based on SSE-CMM with 3 levels. Literature^[8] advances another method, which regards security as a part of the exploitation of the whole system.

The research on information security engineering theory and approaches in our country has just begins. At present, the research is mainly based on the model SSE-CMM. Literature^[9] advances the thought and ways of exploitation and introduces the basic thought and architecture of this model. Literature^[10] put forwards the V lifecycle model on the basis of this model. Literature^[11] bring forwards the opinion that complicated information system security engineering management can be turned into a strict dependable system by SSE-CMM and demonstrates its structure, property and application. Literature^[12] advances information system security lifecycle model, which centers the risk analysis. It is also based on SSE-CMM and aims at the lifecycle of information system.

III. Research Approaches

Since information security is a matter of system engineering based on process, the model SSE-CMM can be regarded as the theoretical basis of the information security engineering management and can be used to guide the specific

management tasks in the process of the security engineering implementation. This model is based on the process and dynamically controlled.

III. 1 System Security Engineering Capability Maturity Model

The SSE-CMM has two dimensions, “domain” and “capability.” The domain dimension contains 11 process areas, which cover all major areas of security engineering. They are Administer Security Controls, Assess Impact, Assess Security Risk, Assess Threat, Assess Vulnerability, Build Assurance Argument, Coordinate Security, Monitor Security Posture, Provide Security Input, Specify Security Needs and Verify and Validate Security. The SSE-CMM divides security engineering into three basic areas: risk, engineering and assurance.

Among them, risk process refers to the risk analysis focusing on the system plans to implement security engineering. It analyzes all kinds of elements that probably threaten the system, the vulnerability of the system itself and the influence on the system if the threatening elements play a role. Engineering process is a complicated process. According to the result of the risk analysis, some related system demands and applicable laws and policies, the engineering staff and the clients together identify and define the system security demands. Then they found out the project after considering all the elements, such as cost, quality, technology risk and the difficult degree of use etc. This project is used to guide the exploitation and construction of the security system and test it continuously to guarantee the risk not to reach the unacceptable degree. Assurance process is to test and validate the process of security engineering and the result of the quality and consequently make sure whether the system security is credible. With the incessant implementation of these three processes, the process ability of the engineering staff grows unceasingly.

SSE-CMM itself is not a security technology model, but it offers the key process areas of information security engineering. It can guide each part of the whole engineering and consequently turn the complicated information system security construction into a strict engineering architecture.

III. 2 Information security engineering model based on SSE-CMM

Just like above description, SSE-CMM is a security framework model. It should combine the practical circumstances to discuss the approaches when implementing security engineering. So a model of information security engineering based on SSE-CMM is produced. It combines the security process put forward by academician Shen Chang-xiang.

Figure 1 demonstrates a holistic periodicity of information security engineering. This is a continuously to-and-fro and upward corkscrew security model. It starts from confirming security target/principle, then passes security risk analysis and other series of process, at last comes to security

assessment/examination. Then a new periodicity begins.

(1) Confirm security target and principle

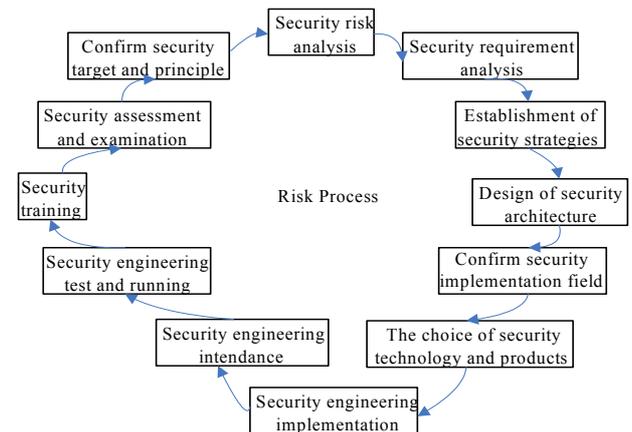

The intended security target and principles of the information system should be confirmed according to the system security requirement and the standards of the country and the same industry as well as the related policies and rules.

(2) Security risk analysis

Security risk analysis is an effective way of assessing information security. According to the confirmed security target and principle, it can focus on the unsafe elements to analyze the security risks that exist in the system, such as the system threats and vulnerability and the risks that they result in. It can assess the intending loss quantity happened to the whole system once the resource get short or is damaged.

There are many ways of doing risk analysis. They can be classified into three types: quantitative risk analysis approaches, qualitative risk analysis approaches and the hybrid risk analysis approaches of the both.

Fig. 1 Model of information security engineering based on SSE-CMM

(3) Security requirement analysis

Security requirement analysis is to investigate the information system on the base of the security risk analysis. The investigation should be all-round, systematic and detailed. Its aim is to ensure the system target, collect the datum and demands for them and make sure the users' requirement. Requirement analysis is a process of further understanding and describing the object system.

(4) Establishment of security strategies

System security strategies should be put forward on the base of the result obtained by analyzing the information system risk. The establishment of them should also be combined with security target and security requirement, besides following the related information security standards and rules. System security strategies are the guidance of the further design of the security system. They are the rules and responsibility that all the departments and staff in the

organization should abide by. They provide a guide framework to guarantee the information system security.

(5) Design of security architecture

Information system security structure is to put the secure elements into the information system structure, and make a description about the relationship among the elements concerned with the fulfillment of security, that is, to describe how the system is organized to meet the security need and make the information system security be an all-around, comprehensive and multi-level holistic security framework.

(6) Confirm security implementation field

The specific implementation field of security strategies should be confirmed.

(7) The choice of security technology and products

Security technology and products should be chosen based on the security architecture. The optional security technology are like these: identity certification technology, digital signature technology, visit accreditation management technology, web supervisory technology, technical segregation technology and interdiction technology etc. Security products are firewall, identity certification system, visit control system, VPN channels, and so on.

(8) Security engineering implementation

The core in the period of security engineering implementation is to establish security baseline used in the whole process management according to the property of the information system and security requirement. In the process of implementation, specific technology and management approaches should be adopted based on the different information systems.

(9) Security engineering intendant

Each part of the whole security engineering should be supervised and examined. Such as flow, rate of progress and quality.

(10) Security engineering test and running

Security engineering should be tested and run in order to find out hidden troubles and careless omission of security, and then the engineering quality can be improved.

(11) Security training

All the staff in the organization should receive the education on the consciousness of security and get the technology training.

(12) Security assessment and examination

Security of information system should be assessed according to the assessment standards and guideline. At the same time, the implementation of information system security strategies should be also examined. The faultiness of requirement analysis should be found out timely in order to improve security strategies.

IV. Conclusion

In the face of hidden trouble and crises of the information era, information system security is not just the simple accumulation of technology and security products. It must be dealt with by means of theories and approaches of information security engineering. However, information security engineering is still faced with a great challenge since the information security engineering standards at home and abroad have just been published. Therefore, the approaches and model of information security engineering as well as the specific guidelines focusing on the different kinds of information system need further research.

Abstract: Cybertechnology has had a significant impact on our social and moral systems. Ethics is a branch of philosophy that deals with what is considered to be right and wrong. One of the ways in which ethical standards in the public service in South Africa can be promoted is by developing Codes of Conduct that set a standard of behaviour to be followed within specific occupational categories. One occupational category is Information and Communication Technologies (ICT). The diversity of ICT applications (such as supply chain management) and the increased use of ICT (such as e-Business) have created a variety of ethical issues. Kantian Ethics is based on the idea that duty is fundamental and 'principle based'. The authors suggest that principle based theory should serve as backdrop to a Code of Cyberethics for a public service entity (a metropolitan municipality) in South Africa.

In this paper the concepts of cybertechnology and cyberethics are introduced. eThekweni Municipality, the most populous municipality in South Africa, is selected as the environment for the formulation of a Code of Cyberethics. The methodology for the formulation of a Code of Cyberethics for eThekweni Municipality is described.

Keywords: Cyber Law, Cyberethics, Intellectual Property Rights.

I. Introduction

Cybertechnology has had a significant impact on our social and moral systems. Ethics is a branch of philosophy that deals with what is considered to be right and wrong. Ethics is the study of what is good or right for human beings [9]. During the years, philosophers have proposed many ethical guidelines. It should, however, be noted that what is unethical may not necessarily be illegal. Thus, in many instances, an individual or organisation faced with an ethical issue is not considering whether to break the law. One of the ways in which high ethical standards in the public service

can be promoted is by developing Codes of Conduct that set a standard of behaviour to be followed within specific occupational categories [7]. One occupational category is Information and Communication Technologies (ICT). In this paper the formulation of a Code of Cyberethics for eThekweni Municipality in South Africa is described.

Cyberethics can be understood as a branch of applied ethics [26]. In today's complex environment, interpretations of 'right' and 'wrong' are not always clear. 'Right' actions are those that it is useful to praise, 'wrong' actions are those that it is useful to blame [17]. The 'right' ethical answer may or may not be the answer that is prescribed by law; in fact depending on the ethical assumptions made, the two may on occasion be in conflict [18]. The challenge is to make essential ethical decision-making explicit so as to make it better [21]. Although tailor-made Codes of Conduct will not be sufficient in themselves, they should be viewed as an integral part of integrating ethics management with the broader public management environment [7].

Many organisations develop their own codes of ethics. A code of ethics is a collection of principles intended as a guide for employees in an organisation. The diversity of ICT applications (such as supply chain management) and the increased use of ICT (such as e-Business) have created a variety of ethical issues. Ethical theories are theories about justifying our moral actions [16]. They propose the appropriate reasons on which our moral decisions should be based. The structure of this paper is as follows: Ethical theories with a focus on principle based theory are introduced. The concepts of cybertechnology and cyberethics are discussed. The methodology for the formulation of a Code of Cyberethics is described. Some concluding remarks are then given.

II. Ethical Theories

During the past centuries, a broad range of ethical theories has been developed to identify how we should determine what is actually good not only for one's self but also for others. Ethical theories attempt to answer the question, why

be ethical? Ethical theories provide a framework for analysing moral issues via a scheme that is internally coherent and consistent as well as comprehensive and systematic [26]. From the literature, one key ethical theory is Kantian Ethics.

One of the basic tenets of Kantian Ethics is based on the idea that duty is fundamental and is 'principle based'. Principle based theory is one that bases the value of an action on the nature of the action itself. One advantage of duty ethics is that it gives a powerful and clear framework for stating codes of ethics. Another advantage is that it is impartial: the same rules apply to all persons. For example, eThekweni Municipality's published Disciplinary Procedures, applies to all its employees. It is argued that principle based theory should therefore serve as backdrop to formulating a Code of Cyberethics.

II. 1 Principle Based Theory

Principle based theory emphasises that moral actions should be in accordance with a pre-established rule or rules. The expectation is that progress toward an objective standard of moral behaviour will be made if people based their actions on fixed rules. It is argued by the authors that an example of fixed rules, is a Code of Cyberethics.

A well-known proponent of a rule based theory is Immanuel Kant (1724 - 1804). He was convinced that all rational thinking people should be able and willing to subscribe to a basic rule that should govern all moral behaviour. This basic rule can be expressed as follows: act in such a way that your action could be a universal law. Kant was convinced that such a strategy will improve the quality of moral decisions and enhance the respect that people pay each other [16]. One advantage of this approach is that it provides for the obligations that we have towards other persons (for example, ICT software developers) in our respective social roles. One problem associated with this approach is that contrary to Kant's expectation, all rational thinking people do not conclude to the same rules for moral behaviour. For example, in the ICT domain there may be dissension whether one may distribute copies of downloaded music from the Internet using, for example, eThekweni Municipality's ICT infrastructure.

In South Africa, legislation compels municipal officials and councillors to make full disclosures in respect of gifts and business interests in respect of municipal tender processes. With effect 1 October 2005, eThekweni Municipality was required by law to bring into effect a supply chain management policy that will revolutionise the way it undertakes business (including e-Business) and to ensure greater transparency and fairness in the tender process. As a result hereof, eThekweni Municipality has 'decided to introduce a set of processes and ethical standards which ... will allow us to stop practices and ensure greater transparency' [21]. The concept of cybertechnology is now discussed.

III. Concept of Cybertechnology

Cybertechnology refers to a wide range of computing and communication devices, from stand-alone computers to 'connected' or networked, computing and ICT [26]. Networked devices can be connected directly to the Internet or to the other devices through one or more privately owned computer networks. Privately owned networks, in turn, include Local Area Networks (LANs) and Wide Area Networks (WANs). The Internet and privately owned computer networks, such as LANs and WANs, are perhaps the most common and well-known examples of cybertechnology. Cyberethics refers to the study of moral, legal and social issues involving this technology. The focus of this paper is on the moral issues embraced by cyberethics from a principle based theory perspective.

IV. Cyberethics

Some researchers use the term 'computer ethics' to describe the field that examines moral ethics pertaining to ICT, see for example, [8] and Johnson [10]. With concerns about ethical issues involved (the Internet in particular), other researchers use the term 'Internet ethics' [11] instead. It is felt by the authors that ethical issues are not limited to the Internet or to computing machines as they also include privately owned computer networks and ICT. Hence for the purposes of this paper, the relatively new term 'cyberethics' [19, 26] is used to capture some of the wide range of moral issues involving cybertechnology.

It is proposed that cyberethics is a more accurate term than either 'Internet ethics' or 'computer ethics' for two reasons:

- the term 'computer ethics' can connote ethical issues construed as pertaining to stand-alone or 'unconnected' computers. However, with the advent of networked systems, a computer system may nowadays be thought of more accurately as a new kind of *medium* as opposed to a *machine*; and
- the term 'computer ethics' may suggest a field of study that is concerned exclusively with ethical issues involving ICT professionals. The field of cyberethics is not linked to an analysis of moral issues that affect only these professionals [26].

Crimes committed in cyberspace require cyber laws. At the Convention of Cybercrime held on 23 November 2001 in Budapest, Hungary, thirty member states of the Council of Europe signed the first international treaty on criminal offences committed against or with the help of ICT such as the Internet.

IV. 1 Codes of Ethics

The value of codes is often overstated: on their own and unaccompanied by the appropriate habits, expectations and sanctions, codes of conduct are of little value [21].

Furthermore the appropriate basis for codes of conduct is often equally misunderstood: what legitimises codes is not stakeholder consent but ethical content. Nevertheless, codes of conduct (such as a proposed Code of Cyberethics for eThekweni Municipality) can be extremely useful. By communicating corporate purposes explicitly regarding controversial matters (such as copying someone else's software for personal use) and by clarifying which stakeholder expectations are legitimate, codes of conduct can eliminate ignorance as an excuse. Furthermore they can be an effective tool for sharpening business accountability and improving corporate governance. For example, while eThekweni Municipality respects the rights to privacy, it will make information available at its website at <http://www.durban.gov.za> to ensure that its supply change management policy is transparent [25].

An information governance framework should contain measurable and strategic goals which will be beneficial for the provider and citizens and promote ethical standards. For eThekweni Municipality's supply chain management policy, a 'code of ethical standards has been established for officials to promote mutual trust and respect and provide where business can be done with integrity' [25]. Professionals in the public service are custodians of the public trust and therefore have to be worthy of that trust [7]. For a discussion of a trust model for e-Business in South Africa, see for example, [4].

Codes must be properly structured and should not reflect the prevailing values or culture of the organisation (such as eThekweni Municipality). For example, when the existing culture is less than perfect, enshrining it in a code merely reinforces bad practice - what it prescribes must be better than the existing norm. A code of conduct is **not** a survey of employees' ethical attitudes [21]. It is meant to express, for example, eThekweni Municipality's fundamental aims and values and it is for the eThekweni Municipality to state what those aims and values are. It sets out what constitutes ethical conduct for the business (such as e-Business) and its validity depends solely on the correctness of the values and principles it expresses - not on employee agreement. Ideally, stakeholders will share the values embodied in the code. However, if they do not it is the stakeholders (eThekweni Municipality employees) and not the code which should be changed. One needs to take 'into consideration that citizens' expectations of government are to a large extent influenced by their interaction with municipalities, mainly because of the types of services that are rendered' [7]. Such are the challenges for the formulation of a Code of Cyberethics for eThekweni Municipality.

Codes of ethics involve the formalisation of some rules and expected actions [27]. Violation of a code of ethics may lead to the termination of employment. Similar procedures exist in eThekweni Municipality's Disciplinary Procedures. Codes of ethics are valuable for raising awareness of ethical issues and clarifying what is acceptable behaviour in a variety of circumstances. In the case of eThekweni Municipality, an ICT Code of Cyberethics does not exist and

the formulation of one is required to prevent Internet abuse and misuse by employees. Organisations are increasingly faced with serious legal and liability issues stemming from wrongful use of software by their employees [22].

The acceptance of a Code of Conduct is a very central part of being a professional [7]. Codes of ethics have limitations because of their nature to generalise acceptable behaviour - despite the variations in social and ethical values that may exist in different communities. This will need to be taken account of when formulating a Code of Cyberethics for eThekweni Municipality. For example, it will be arrogant to impose on eThekweni Municipality employees the ethical ICT standards developed in and appropriate for Hong Kong, or indeed doing the reverse. However, such impositions do appear to be commonplace and they tend to lead to outright rejection (rather than to higher ethical standards, which may be the intention). The stakeholder theory of business typically holds that business is accountable to all its stakeholders and that the role of management is to balance their competing interest [21]. According to eThekweni Municipality's Disciplinary Procedures, the 'maintenance of discipline is the responsibility of management'.

IV. 2 Employee Involvement

Employee involvement can be valuable [21]. A code will be most effective if it addresses matters which actually cause concern. Sternberg [21] suggests that it is sensible to consult stakeholders (especially employees) to determine what situations are genuinely problematical. This approach was undertaken by the authors. Informal discussions were held by the first author with colleagues at eThekweni Municipality. Some of the cybertechnology and related concerns raised by these colleagues are reflected in Table 1.

Table 1. Cybertechnology and related concerns raised by the first author's colleagues at eThekweni Municipality

No	Concern raised
1	May I copy someone else's software for my own personal use and distribute it?
2	May I download music/video from the Internet for personal use and distribute it?
3	May I access private and confidential information without consent and distribute it?
4	May I access other's desktops or laptops without consent?
5	May I take programs that I have done for eThekweni Municipality and keep it for personal use or use it at another employer?

Consultation can provide useful information about the stringency (or laxity) of employees' ethical standards and the degree of ethical diversity prevailing in eThekweni

Municipality's heterogenous workforce. Furthermore by making eThekweni Municipality employees part of the code-making process may improve compliance with the Code of Cyberethics: since employees feel that they have had a role in formulating it, they are more likely to understand the code and observe its strictures. However, human beings are generally capable of discovering the modes of life that are best suited to themselves as individuals [24]. Research into why so many Codes 'die' indicates that many things can go wrong in the process of institutionalising codes [7]. These mistakes can include the way the Code was developed, written, distributed and enacted.

Once the Code of Cyberethics has been formulated and adopted by the eThekweni Municipality Strategic Management Team (Stratman), the document should form part of the City Manager's Standing Orders. Publishing a formal code serves as an explicit signal of eThekweni Municipality's commitment to ethical business conduct. By proclamation and Stratman endorsing the values it proclaims, they must make it clear that it will be enforced and they also show that they consider themselves to be bound by it. To be worthy of respect, the adopted Code of Cyberethics must apply and be seen to apply to every employee in eThekweni Municipality. This underscores one of the advantages of duty ethics.

IV.3 Intellectual Property

Intellectual property is the intangible property created by individuals or organisations. To varying degrees in different countries, intellectual property is protected under laws relating to copyright, trademarks, patents and trade secrets. The copying of software is generally seen to be of greatest concern - at least to the software developers [27]. Software piracy, the unauthorised copying of computer software, is widespread in many organisations today [12]. In eThekweni Municipality's Disciplinary Procedures, an employee may be dismissed for dishonest behaviour or wrong disclosure of privileged information.

The topic of intellectual property rights (IPR) is seen to be important since it relates to the fundamental right to private property - especially property that represents the fruits of one's endeavours, see for example, [13]. IPR protects the way ideas are expressed but not the ideas themselves [27]. IPR may be seen as a mechanism for protecting the creative works of individual people and organisations. However, this is problematic in societies that place less value on individual freedom and more on social order. In many developing countries, Steidlmeier [20] suggests that 'individual claims on intellectual property are subordinated to more fundamental claims of social well-being'. In these countries (including South Africa), the welfare of society is considered to be more important than that of any individual.

Much of the IPR discussion relates to the debate about rights and duties. Software developers demand the right of stringent legal protection for the fruits of their labour and compensation for resources expended in software

development. Consequently consumers are then deemed to have a duty to pay for that software (whether it is in code, music, video or other digitised forms) and to respect the intellectual property by not stealing (copying or downloading it, for example, from the Internet).

V. Data and Information Privacy

The notion of privacy has become one of the most contentious issues of the global information age due to the capability of computers to perform actions previously impractical or impossible. Computers are able to advance exponentially and make unmanageable tasks practically possible [5].

Table 2. Summary of six data protection principles from the Office of the Privacy Commissioner's Office for Personal Data, Hong Kong (Source: Retrieved 10 October, 2005 from <http://www.pco.org.hk>)

No	Narrative	Associated Explanatory Text
1	Purpose and manner of collection	Data should be collected in a fair and lawful manner. Data users should explain to data subjects what data is being collected and how it will be used
2	Accuracy and duration of retention	Personal data that has been collected should be kept accurate, up-to-date and for no longer than is necessary
3	Use	Data must be only be used for the specific or directly related purpose for which it was collected. Any other use is conditional on consent of the data subject
4	Security	Suitable security measures should be applied to personal data
5	Information availability	Data users should be open to the kind of data they store and what they use it for
6	Access	Data subjects have the right to access their personal data, to verify its accuracy and to request correction

Agranoff [1] defines (data) privacy as the 'claim of individuals, groups or institutions to determine for themselves when, and to what extent, information about them is communicated to others'. Charlesworth and Sewry [5] note that privacy includes considerations of the conflicts between society's right to know and individual's right to privacy. Nevertheless the right to privacy is not absolute. It

varies considerably in different cultures, as it has to be balanced by society's right to know. A detailed set of data privacy principles comes from the Privacy Commissioner's Office for Personal Data (PCOPD), Hong Kong and promulgated in December 1996. A summary of the six PCOPD data protection principles is reflected in Table 2.

These principles are designed to enshrine the reasonable rights and duties of both the data subject (the person described by the data) and the data users (those who possess the data). Sternberg [21] states there is a fundamental importance of accountability to ethical business conduct and good corporate governance. This researcher suggests that the tools which can be used to promote accountability is a code of conduct.

VI. eThekwini Municipality Environment

Following South Africa's second local government elections held on 5 December 2000, in terms of Proclamation 343 of 2000 (KwaZulu/Natal) dated 19 September 2000, the new Durban Metropolitan Uicity Municipality (DMUM) came into existence in the province of KwaZulu/Natal, South Africa. DMUM has subsequently been renamed to eThekwini Municipality. eThekwini Municipality comprises the former Durban Metropolitan Council (which includes the North Central and South Central Councils), the North Local Council, the South Local Council, the inner West City Council, the Outer West Local Council and the Umkomaas Transitional Local Council. For a discussion of ICT considerations in the eThekwini Municipality Area, see for example, [2, 3].

eThekwini Municipality employs approximately 22,000 employees. There are some 6,000 networked desktops (personal computers, thin clients and laptops) and electronic communication is via Novell's GroupWise (Client version 6.5). A total of 5,806 GroupWise accounts are in existence. There are approximately 1,500 Internet accounts utilising either Internet Explorer or Netscape Navigator web browsers. Given the magnitude of this ICT connectivity in terms of LANs and WANs and the potential for abuse and misuse of cyberotechnology by employees, there is thus a need to formulate a Code of Cyberethics for eThekwini Municipality.

The methodology for the formulation of the Code of Cyberethics for eThekwini Municipality is as follows:

- disseminate the authors' validated survey instrument (see extract in Table 3) to eThekwini Municipality employees who have Internet accounts;
- qualitatively and quantitatively analyse the responses received to completed survey questionnaires. From the scored responses, themes, patterns and trends will be synthesized. Sturgeon [23] notes that ethics is an appropriately empirical discipline;
- draft a proposed Code of Cyberethics based on eThekwini Municipality's (1) vision and mission; (2) moral and social values which the organisation wants reflected in all its activities; and (3) values that

reflect characteristics of the organisation's approach to achieving its mission. Particular attention is to be paid to cyberotechnology situations which appear to be genuinely problematic;

- when the Code of Cyberethics is breached, eThekwini Municipality's Standard Disciplinary Procedures must be followed. The Code of Cyberethics should form part of an eThekwini Municipality employee's Conditions of Service;
- present the proposed Code of Cyberethics to eThekwini Municipality's Stratman for ratification and adoption;
- incorporate the document in the City Manager's Standing Orders; and
- utilise an appropriate and effective communication mechanism for the adopted Code of Cyberethics to eThekwini Municipality employees.

Table 3. Extract of Ethics Statement Survey for eThekwini Municipality employees

(Acknowledgement: This extract is an adapted version of the Ethics Statement Survey by Alan Peslak, Penn State University, Dunmore, PA, USA. Retrieved 10 October, 2005 from <http://wsistdevel.sn.psu.edu/ist/arp14/eths1/webform1.aspx>)

Please indicate your level of agreement/disagreement with the following information and communication technology related statements.

Strongly agree - Agree - Undecided - Disagree or Strongly disagree

I may copy someone else's software for my own personal use

- G Strongly agree
 G Agree
 G Undecided
 G Disagree
 G Strongly disagree

Please tick any of the following factors that affected your answer (you may tick more than one)

- G I believe that the potential harm done to others would be minimal
 G I believe that most view this activity as acceptable
 G I believe that any harm that would take place would be to people I do not know
 G I believe the number of people harmed would be minimal
 G I believe that negative effects of this action would occur a very long time from now
 G I believe that the potential harm done to others would be high
 G I believe that most view this activity as wrong
 G I believe that any harm that would take place would be to people I know
 G I believe the number of people harmed would be high
 G I believe that negative effects of this action would occur very soon

McCabe [14] found the existence of a corporate code of ethics was associated with significantly lower levels of self-reported unethical behaviour in the workplace. Ethics is not just about Codes – a code is only a small element of the process. Since eThekwini Municipality is about employees and structures (and not only documents), one needs to ensure that both employees and structures within which people

operate support ethical practices. It is argued by the authors that the approach described above will underscore Kant's rule based theory whereby the principle of an action that is being considered becomes the basis for everyone's action in eThekweni Municipality and all its employees will be willing to live in such a society as defined by the adopted Code of Cyberethics.

VII. Conclusion

Cleek and Leonard [6] state that 'emphasis should be placed on how the codes are communicated, enforced, and used, as a basis for strengthening the culture of the organization'. McClenahan [15] suggests that 'being consistent in policies and actions, rewarding ethical conduct, treating employees fairly, and providing better executive leadership' work best to reduce unethical conduct. A commitment to the moral treatment of employees is one of the preconditions for continued excellence [16]. Effective communication of the Code of Cyberethics to eThekweni Municipality employees can help eliminate situations wherein employees complain that they have not been made aware of corporate expectations regarding private Internet usage. Furthermore the development of a Code of Cyberethics will also ensure that its supply chain management and e-Business responds effectively and efficiently to citizens' needs and improve the communication process with citizens.

A proposed statement of core values and a corporate Code of Cyberethics that is effectively communicated and reinforced by strong eThekweni Municipality management support, enforcement processes that support employees when they are faced with difficult dilemmas should help eThekweni Municipality create and maintain an environment conducive to ethical decision-making. With such an environment, there is a strong likelihood that situational characteristics of a dilemma will cause an eThekweni Municipality employee to reach an unethical decision should be reduced.

Document Recommendation in Organizations with Personal Folders

Chiu-Wen Huang, Chin-Hui Lai, Duen-Ren Liu
Institute of Information Management
National Chiao Tung University
Hsinchu, Taiwan

Abstract: In organizations, knowledge workers usually have their own personal folders that store and organize needed codified knowledge (textual documents) in taxonomy. In such personal folder environments, providing knowledge workers needed knowledge from other workers' folders is important to facilitate knowledge sharing. This work adopts recommendation techniques to provide knowledge workers needed textual documents from other workers folders. Experiments are conducted to verify the performance of various methods using data collected from a research institute laboratory. The result shows that the CBF approach outperforms other methods.

Keywords: Knowledge Management, Document Recommendation, Collaborative Filtering, Content-based Filtering.

I. Introduction

Sharing sustainable and valuable knowledge among knowledge workers is a prominent activity of knowledge management. Organizational knowledge and expertise are usually codified into textual documents, including forms, letters, papers, manuals and reports, to facilitate knowledge capture, search and sharing [7].

Knowledge workers tend to keep their codified knowledge in their own personal folders. Textual documents stored in each worker's personal folder are usually organized into categories in taxonomy. In such personal folder environments, providing knowledge workers needed knowledge from other workers' folders is important to facilitate knowledge sharing. Conventional knowledge management systems (KMSs) have provided search function to help knowledge workers find needed knowledge. However, very few KMSs have considered the issue of proactively providing knowledge workers needed knowledge in personal folder environments.

Recommender systems [2] seem to be an effective solution for proactively providing knowledge workers needed knowledge. Conventional application domains of recommender systems are "Music", "Movie" or "Product" recommendations. Various recommendation methods have been proposed for recommender systems. Collaborative Filtering (CF) assumes that items (e.g. documents) from like-minded users are often relevant. Collaborative filtering utilizes preference ratings given by various users to

determine recommendations to a target user based on the opinions of other similar users. Content-based Filtering (CBF) utilizes profile matching to determine recommendation to target users. In application to recommend documents, Content-based filtering provides recommendations by matching user profiles (e.g., interests) with content features (e.g., feature vectors of documents). Each user profile is derived by analyzing the content features of documents accessed by the user.

LIBRA system [6] is an example of content-based filtering, which recommends books based on book information extracted from Web pages. Siteseer [8] used collaborative filtering to provide Web page recommendations based on the bookmarks of the user's virtual neighbors without considering the categorization of bookmarks. Knowledge Pump [4] used CF techniques to recommend documents based on personal profiles of interest. In these systems, each user stores his/her documents in a commonly agreed classification scheme rather than a personalized one.

RAAP [3] is an example of hybrid system developed to classify and recommend bookmarks retrieved from the Web. The InLinx system [1] also supports the classification and recommendation of bookmarks retrieved from the Web based on content analysis and virtual clusters. Middleton et al. [5] presented an ontological user profiling approach to recommend academic papers. Recommended papers are those match the user's profile and have also been read by similar users.

This work investigates recommendations of textual documents in personal folder environments. Each knowledge worker has his/her own folder that store documents into personalized categories, namely categories defined by himself/herself. We adopt recommendation techniques to provide knowledge workers needed textual documents from other workers folders. Conventional document recommender systems assume a common category schema without considering personalized categories. Our proposed approaches combine filtering and text categorization to recommend documents to target worker's personalized categories. The recommendation proactively notifies knowledge workers regarding peer-reviewed documents, and therefore knowledge diffusion is evolved from 「Pull」 to 「Push」. By means of knowledge diffusion, knowledge workers can learn from each other and eventually elevate work productivity and efficiency. Experiments are conducted to verify the performance of various methods using data collected from a research institute laboratory.

II. Methodology

This section presents the proposed document recommendation methodology that aims to fulfill the goal of push-mode knowledge diffusion. In the organization, documents, manuals, reports, know-how and the like from people in the same project team or from people with similar working experience are of great help. Fig. 1 shows knowledge sharing in personal folder environments. Knowledge workers used to manage his owned document repository by storing documents in different categories. Each knowledge worker shares their own documents to others.

The proposed methods recommend documents stored in other knowledge workers' folders to the target worker's right category. One of the ways to reuse the knowledge in the enterprise is to sharing the knowledge by interflow of knowledge documents. However, the received documents are another burden because knowledge workers have to spend time on managing them. Classification is the basic to manage documents for users to quickly access and store them. However, different people have different criteria to classify documents.

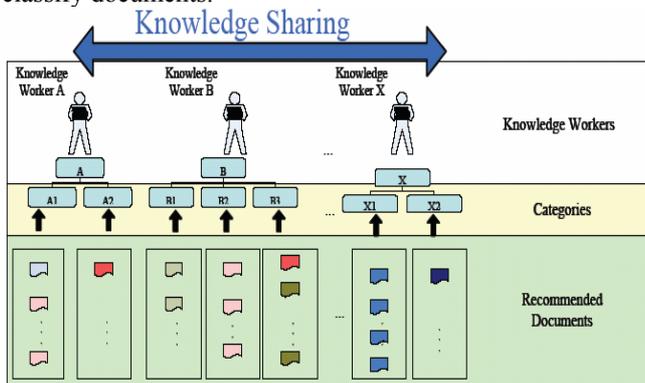

FIG. 1. Recommendation for knowledge sharing

Our approach tries to find the recommendation candidates by examining the document and category profiles to predict if a document is suitable to be recommended to the target category. We proposed two kinds of recommendation methods: content-based filtering and collaborative filtering in order to recommend documents in the personal folder environment. As a result, explicit knowledge embedded in knowledge workers' personal folders is circulated from peer to peer to facilitate knowledge sharing.

II.1 Methods Based on Content-Based Filtering

Based on the concept of content-based filtering recommendation, we divide this methodology into three phases. Phase 1 is profile generation; phase 2 is document filtering; and the last phase is recommendation list generation.

In phase 1, the method generates three kinds of profiles, including Document Profile (DP), Category Profile (CP) and User Profile (UP).

Document Profile (DP)

Let d_j be a document, and let $DP_j = \langle dt_{1,j}: dw_{1,j}, dt_{2,j}: dw_{2,j}, \dots, dt_{n,j}: dw_{n,j} \rangle$ be the feature vector (document profile) of d_j where $dw_{i,j}$ is the weight of a term i that occurs in d_j . Notably, the weight of a term represents its degree of importance to represent the document (codified knowledge). The well-known *tf-idf* approach is often adopted for term weighting [9][10]. Let the term frequency $df_{i,j}$ be the occurrence frequency of term i in d_j , and let the document frequency df_i represent the number of documents that contain term i . The importance of term i to a document d_j is proportional to the term frequency and inversely proportional to the document frequency, which is expressed as Eq. (1).

$$dw_{i,j} = \frac{1}{\sqrt{\sum_i \left(dt_{i,j} \times \left(\log \frac{N}{df_i} + 1 \right) \right)^2}} dt_{i,j} \times \left(\log \frac{N}{df_i} + 1 \right) \quad (1)$$

where N is the total the number of documents and the denominator in the right side of Eq. (1) is a normalization factor to normalize the weight of term.

Category Classifier (CC)

A classifier for a category is constructed through *tf-idf* approach which is employed to extract the discriminating terms and their weights among categories of a knowledge worker. Let $CC_r = \langle cct_{1,r}: ccw_{1,r}, cct_{2,r}: ccw_{2,r}, \dots, cct_{n,r}: ccw_{n,r} \rangle$ be the category classifier of c_r where $ccw_{i,r}$ is the weight of a term i that occurs in CC_r . Let the term frequency $ctf_{i,r}$ be the occurrence frequency of term i in c_r , and let the category frequency cf_i represent the number of categories in target user u that contain term i . The weight of term i in a category c_r is proportional to the term frequency and inversely proportional to the category frequency, which is expressed as Eq. (2).

$$cw_{i,r} = \frac{1}{\sqrt{\sum_i \left(ctf_{i,r} \times \left(\log \frac{L_u}{cf_i} + 1 \right) \right)^2}} ctf_{i,r} \times \left(\log \frac{L_u}{cf_i} + 1 \right) \quad (2)$$

where L_u is the total the number of categories in user u . Notably, the denominator in the right side of Eq. (2) is a normalization factor to normalize the weight of term.

User Profile (UP)

The profile of a user u_x is represented as a feature vector of weighted terms derived by analyzing documentation set owned by u_x . After the documents are pre-processed and represented in the form of term vectors, UP_x is derived by averaging the feature vectors (i.e. centroid approach) of documents in u_x . Let D_x denote the set of documents in u_x . Furthermore, the user profile (feature vector) UP_x of user u_x

is defined as the centroid vector obtained by averaging the feature vectors of documents in D_x . Let $uw_{i,x}$ denote the weight of a term i in UP_x . $uw_{i,x}$ is derived as Eq. (3).

$$uw_{i,x} = \frac{1}{|D_x|} \sum_{d_j \in D_x} dw_{ij} \quad (3)$$

Phase 2 applies recommendation scheme to filtering documents of low similarity. Content-based recommendation mainly computes the similarity between category classifier and document profile.

The cosine formula is a widely adopted scheme to measure the similarity degree between two items x and y . The cosine of the angle between their corresponding feature vectors Q and R is computed as given by Eq. (4). The degree of similarity is higher if the cosine similarity is close to 1.0.

$$\text{sim}(x, y) = \text{cosine}(Q, R) = \frac{Q \cdot R}{|Q||R|} \quad (4)$$

The method considers both the similarity of document profile to the category classifier and user profile. The predicted rating $\hat{p}_{a,j}$ of recommending document d_j to the category c_a of the target user u_x is expressed in Eq. (5):

$$\hat{p}_{a,j} = (1 - \alpha_{CBF}) \text{Sim}(CC_a, DP_j) + \alpha_{CBF} \text{Sim}(UP_x, DP_j) \quad (5)$$

where $\text{sim}(CC_a, DP_j)$ is the similarity of CC_a and DP_j and $\text{sim}(UP_x, DP_j)$ is the similarity of UP_x and DP_j (u_x is the owner of C_a). α_{CBF} ranges from 0 to 1 and will be decided by the analytical experiments.

The last phase is to generate a recommendation list of document-category pairs for allocating documents to destination categories. The document-category pairs are sorted according to their predicted ratings. The pairs with top-N highest rating are selected for recommendation. Notably, those documents that the target user already has are not included in the recommendation list.

II. 2 Methods Based on Collaborative Filtering

This method uses the opinions of other knowledge workers with similar profiles to make recommendations. Two approaches are developed including Collaborative Filtering (CF) and Collaborative Filtering based on Joint coefficient (CF-J).

II. 2. 1 Collaborative Filtering (CF)

There are also three phases in the proposed CF approach. Phase 1 generates the needed profiles. The category classifier is mainly used to determine which category a document should be allocated to, and thus is suitable for classification purpose. However category classifier is not suitable to derive similar neighbors, since the discriminating terms may distort the similarity of categories in different

users. Thus, category profile is defined to compute the similarity of categories, and is further used to find category neighbors. Similar to the generation of user profiles described in section 2.1, the centroid approach is used to derive the category profile.

The profile of a category c_a is derived by analyzing the set of documents in c_a . Each document d_j is pre-processed and represented as a feature vector DP_j . Let D_a denote the set of documents in c_a . Furthermore, the category profile CP_a of category c_a is defined as the centroid vector obtained by averaging the feature vectors of documents in c_a . Let $cw_{i,a}$ denote the weight of a term i in CP_a . $cw_{i,a}$ is derived as Eq. (6). Notably, category profile does not consider the effect of terms in discriminating the category of a user.

$$cw_{i,a} = \frac{1}{|D_a|} \sum_{d_j \in D_a} dw_{ij} \quad (6)$$

Phase 2 identifies the neighbors of the target category. The similarity between CP_s is derived to decide neighbors. For recommending a document d_j to the target category c_a , the neighboring categories (neighbors) of c_a is selected from categories that contain d_j . The cosine formula is used to determine the similarity of CP_s . We use the k-NN based method for choosing neighbors.

Phase 3 derives the predicted rating of document-category allocation. In addition to the profiles, the CDR (Category-Document-rating) / UDR (User-Document-rating) matrix is needed to record the rating of categories/users on documents.

There are two approaches to derive the ratings, binary approach and profiling approach. The binary approach derives the ratings based on the criteria whether the category/user contain the document. If a category c_a contains a document d_j , the rating value of c_a on d_j , $CDR_{a,j}$, is 1; otherwise, the value is 0. If the category c_a is owned by the user u_x , i.e., u_x has document d_j , the rating value of u_x on d_j , $UDR_{x,j}$, is 1; otherwise, the value is 0. The profiling approach uses the similarity of category/user profile and document profile to derive the rating. The rating value of c_a on d_j , $CDR_{a,j}$, equals $\text{sim}(CP_a, DP_j)$, i.e., the similarity of the category profile of c_a and the document profile of d_j . The rating value of u_x on d_j , $UDR_{u,j}$, is set to $\text{sim}(UP_x, DP_j)$, i.e., the similarity of the user profile of u_x and the document profile of d_j .

The CDR/UDR generated by the binary approach is called binary CDR/UDR, while the CDR/UDR generated by the profiling approach is called non-binary CDR/UDR. Eq. (7) computes the predicted rating of recommending document d_j to the category c_a of the target user u_x .

$$\hat{p}_{a,j} = \frac{\sum_{c_b \in c_a's \text{ neighbor}} (1 - \alpha_{CF}) \text{Sim}(CP_a, CP_b) \times CDR_{b,j} + \alpha_{CF} \text{Sim}(UP_x, UP_y) \times UDR_{y,j}}{\text{Number of } c_a's \text{ neighbors}} \quad (7)$$

where $\text{sim}(UP_x, UP_y)$ is the similarity between UP_x and

$UP_y, sim(CP_a, CP_b)$ is the similarity between CP_a and CP_b , c_b belongs to c_a 's neighbors, u_y is the owner of C_b . $CDR_{b,j}$ is defined in phase 3. α_{cf} is a parameter to adjust the relative importance of category similarity and user similarity.

Finally, the scheme generates a list of candidate document-category allocation. The procedure is the same as the CBF described in phase 3 of section 2.1.

II. 2 Collaborative Filtering Based on Joint coefficient (CF-J)

CF-J is similar to CF. The difference between CF and CF-J is the similarity computation. CF calculates the similarity by weighted term profiles. The joint coefficient approach (CF-J) calculates the similarity based on the joint coefficient, which represents the relationship between two categories/users decided by the number of the documents they have in common. The more they have, the more similar they are. Equation (8) is the formula to compute the joint coefficient ($Jcof$) in CF-J.

$$Jcof(c_a, c_b) = \frac{2 \times N_{a \cap b}}{N_a + N_b} \quad (8)$$

where N_a and N_b is the number of documents in c_a and c_b respectively, and $N_{a \cap b}$ represents the intersection of documents that both c_a and c_b have. The binary CDR is used to derive N_a , N_b and $N_{a \cap b}$. Similarly, joint coefficient between two users u_x and u_y can be defined as $Jcof(u_x, u_y)$.

CF-J uses joint coefficient instead of profile similarity to derive the predicted rating as expressed in Eq. (9).

$$P_{a,j} = \frac{\sum_{c_b \in c_a's \ neighbor} (1 - \alpha_{CF-J}) Jcof(c_a, c_b) \times CDR_{b,j} + \alpha_{CF-J} Jcof(u_x, u_y) \times UDR_{y,j}}{\text{Number of } c_a's \ neighbor} \quad (9)$$

III. Experiment and Evaluation

Experiments using a real application domain were carried out for recommending research papers in a research institute laboratory.

III. 1 Experimental Setup

Knowledge workers have their own folders storing documents (research papers) that assist them in writing theses or accomplishing research projects. There are 11 users, 35 categories and 1062 documents. The sparsity in the data sets is 99.96%. For each category, there are at least ten documents in order to provide enough information of the codified profiles. We also limit the level of categories to be

one. Those categories with level higher than one will be aggregated into their level-1 ancestors. The data set was divided into an 80% training set and a 20% testing set. The training set includes documents stored in workers' personal folders, and was used to generate recommendation list. Testing data was used to verify the recommendation quality of various methods.

Two metrics, precision and recall, are commonly used to measure the quality of recommendation. These two metrics are also extensively used measures in information retrieval [10]. Recall is the fraction of relevant documents that can be located.

$$\text{Recall} = \frac{\text{number of correctly recommended documents}}{\text{number of relevant documents}} \quad (10)$$

Precision is the fraction of recommended documents (predicted to be relevant) that are really relevant to workers.

$$\text{Precision} = \frac{\text{number of correctly recommended documents}}{\text{number of recommended documents}} \quad (11)$$

Documents relevant to a worker u are those documents owned by u in the test set. Each relevant document is associated with its corresponding category owned by u . Such relevant document with associated category is called a relevant document-category pair of u . Correctly-recommended documents are those in the recommended document-category pairs that match the relevant document-category pairs of u .

F1-metric can be used to balance the trade-off between precision and recall [10]. F1-metric assigns equal weight to precision and recall, and is given by,

$$F1 = \frac{2 \times \text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \quad (12)$$

III. 2 Experimental result

We compare different factor of CF. CF-Binary, CF-Profile and CF-J uses binary ratings, profiling ratings and joint coefficient, respectively, as described in section 2.2. The $\alpha_{CF} / \alpha_{CF-J}$ is used to tune the weight of predicted rating contributed from Category similarity and user similarity. The α values for CF-Binary, CF-Profile and CF-J, are 0.5, 0.0 and 0.2, respectively, which are decided according to the highest average value. Fig. 2 shows the comparison (F1-metric) of CFs under different Top-N. CF-Binary is relatively better than the CF-Profile method. This indicates that the rating part in the CF-Profile approach does not provide useful rating information by using the profiling approach. The failure of CF-Profile might result from the rating part of formula (the similarity of category and document) which could not truly represent user's rating on the documents. Therefore, the CF-Profile method could not effectively recommend the right document to the right category. Consequently, we adopt the CF-Binary method rather than the CF-Profile Method to represent the CF

method in further comparisons.

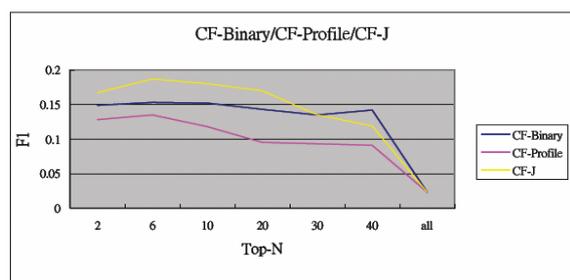

FIG. 2: Comparison of CF and CF-J under different Top-N

Fig. 2 also shows that CF-J achieves better result in smaller Top-N and CF-Binary works better in larger Top-N. The number of overlapped documents among different categories is usually small. Hence, CF-J performs worse when recommending more documents. α_{CF-J} and α_{CF} are set to 0.2 and 0.5, respectively. This indicates that the opinions from the similarity of user profiles provide constructive effect in improving recommendation quality.

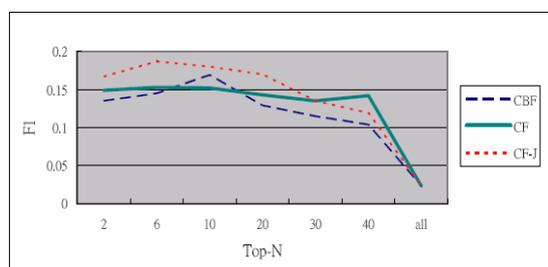

FIG. 3: Comparison of CBF and CF methods

Fig. 3 shows the comparison of CBF, CF (CF-Binary) and CF-J under different Top-N. The CBF uses Category Classifier (CC) to provide content-based filtering. α_{CBF} is set to 0 for CBF. The result shows that the CF and CF-J performs better than CBF. CF-J gain better performance when Top-N is smaller; however, when Top-N is getting larger, CF (CF-Binary) method provides better recommendation quality.

IV. Conclusions

This work investigates the issue of sharing codified knowledge stored in workers' personal folders. Various

recommendation approaches are proposed to recommend codified knowledge to the right category of workers' personal folders. The proposed approach provides workers needed relevant documents from other workers' folders to facilitate knowledge sharing. The explicit codified knowledge can circulate around the organizations by sharing codified knowledge from personal folders. The proposed work can reduce the efforts and manpower in document classification and improve knowledge sharing among organizations.

Application of Knowledge Management in Organizational Management

Seyed Kamal Vaezi, Ph.D.

vaezi_ka@yahoo.com

Abstract: In fact, any task that uses and applies knowledge can benefit from the structure of knowledge management, and that covers most managerial and professional activities. Therefore, like other management 'fads' before, many existing business practices (such as information management and intelligence gathering) are coming under the knowledge management umbrella. Similarly, information systems solutions, such as document management and data warehousing are being similarly relabeled.

Structurally, the use and sharing of knowledge must be aligned with all of the factors described in the paper. The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and measures of each must be common. Most importantly, knowledge growth and use must be specifically tied to the individual and team objective setting, incentive and reward mechanisms of the organization.

Keywords: Knowledge Management, Organization, Innovation Cycle

I. Introduction

Today knowledge is accepted as an important basis for competitive advantages and many organizations are beginning to establish knowledge management systems. Within the last few years many organization tried to design a suitable knowledge management system and many of them were successful.

Managing an organization's knowledge is the latest pursuit of those seeking competitive advantage. The interest in knowledge management has surged during the last few years, with a growing number of researches publications, conferences and investment in knowledge management initiatives. (skyrme,2000)

There are numerous definitions of knowledge management. Knowledge management or KM is an integrated ,systematic approach to recognize, manage and share all of the department's information resources, including databases, documents, strategies, policies and procedures .In this process management creates a new environment where knowledge and experience can easily be shared and also enables information and knowto emerge and

flow to the right people at the right time so they can act more efficiently and effectively.(smith,2001) Briefly KM is "the explicit and systematic management of vital knowledge and its associated processes of creating, gathering, organizing, diffusion, use and exploitation, in pursuit of organizational objectives."(Skyrme.2000)

There are many types and forms of knowledge e.g. facts, know-how, specific skills, procedural knowledge etc. A common interpretation is that of a knowledge hierarchy that goes from data (facts and figures) to information (data with context) to knowledge (information with meaning) to wisdom or intelligence (knowledge with insight). (see figure 1)

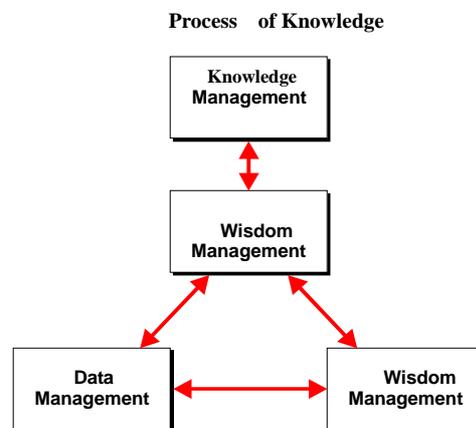

Figure 1

Today knowledge management is accepted as a decisive quality in most developed organizations. The know-how and expertise of the work-force is an important factor for the success of companies and strongly influences the effectiveness and efficiency of the business processes and their development. The concept of Knowledge Management (KM) receives high strategic consideration across multiple sectors. In the management area, KM is specifically relevant due to the knowledge of the the new product development process, which is especially interested in learning from the lessons of the past.(Thoben,2000)

The range of knowledge management activities is extensive, and touches many aspects of organization operations, for example (see figure 2) Creation of knowledge databanks – finding best tasks and expert directories, understanding market intelligence, Application of efficient and Effective information management systems for gathering, censoring, filtering, classifying and storing of information, Creation of knowledge into business processes e.g. through the use of

help screens in computer procedures or access to experts from icons.

Development of knowledge centers - focal points for knowledge skills and facilitating knowledge flow ,Reuse of knowledge at customer support centers e.g. via case-based reasoning, Usage of collaborative technologies, especially intranets or groupware, for rapid information access, Creation of Knowledge webs - networks of experts who collaborate across and beyond an organization's functional and geographic boundaries.(Skyrme,2000)

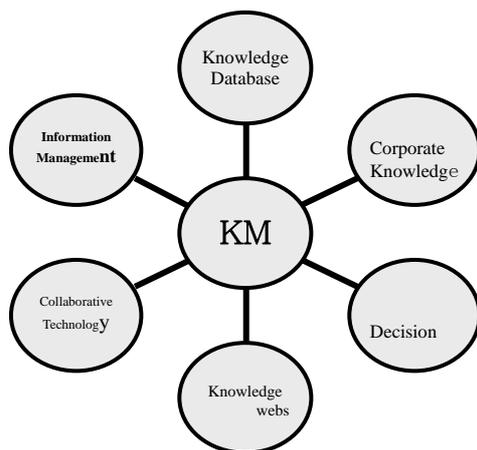

Figure 2 Range of Knowledge Management

Despite the rapid development of KM , most managers believe that much has still to be accomplished. A typical evolution of knowledge management within an organization goes through several phases.(skyrme,2000)

Informal: knowledge management is being practiced to some level in some parts of the organization (although it may not be recognized as such or called 'knowledge management') but formal knowledge management is recognized as a formal project or programme

Then is the time for expansion of the knowledge by using of knowledge management as a regulation grows in practice across different parts of the organization.

Also there is a degree of co-ordination of knowledge management activity; knowledge can be more easily shared across departmental boundaries by a good organizing.

Incorporated knowledge are formal standards and approaches that gives every employee access to most organizational knowledge through common interfaces And finally we can implant the KM. Knowledge management is part-and-parcel of any tasks; it blends impeccably into the background.(see figure 2)

KM Processes

The Knowledge of organization can develop in two primary ways: improve the processes of having knowledgeable people and develop the processes of sharing knowledge among them.(burlton,1998)

Individual knowledge is an skill improved with use, not

consumed when applied, nor lost when transferred, a vital challenge is to attract and retain knowledgeable and motivated personnel. These sentiments are often echoed in service based organizations yet when the state of the processes which are supposed to deliver these is examined we usually find fragmented conflicting practices at best. One way to start to deal with the challenge is to improve the processes which hire staff, align incentives with the business outcomes of value, recognize and payment, train, develop human potential, provide varied experience, and support staff to share experience. The same is generally true for acquiring knowledge from the outside through partnerships, hiring of consultants, research consortia etc. If these supposed enabling processes do not deliver appropriate enablers then knowledge will not translate to action. The objective is to enhance our ability to perform. Performing is a subsequent act.

On the other hand For creation corporate knowledge Organizational size is a major factor in KM programs. Size matters since the larger the organization, the more potential knowledge exists but at the same time the harder it is to identify its source and get access to it with a trust relationship among the potential collaborators. The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and methods of each must be common. Most importantly, knowledge growth and use must be specifically coupled to the individual and team objective setting, incentive and reward mechanisms of the task The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and measures of each must be common. Most importantly, knowledge growth and use must be specifically tied to the individual and team objective setting, incentive and reward mechanisms of the enterprise. The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and measures of each must be common. Most importantly, knowledge growth and use must be specifically tied to the individual and team objective setting, incentive and reward mechanisms of the enterprise. The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and measures of each must be common. Most importantly, knowledge growth and use must be specifically tied to the individual and team objective setting, incentive and reward mechanisms of the enterprise optimize the knowledge richness/ease of access dilemma.

In larger organizations, especially, process becomes critical and advanced process renewal aims to optimize knowledge flow for example time to market of new product ideas is a important factor in fast moving industries such as electronics, telecommunications and banking. This procedure must exploit knowledge effectively and efficiently and it must not drag or fail. Processes which embed knowledge in other processes or enablers are paramount. They must generate, collect, structure, store, and distribute and share or stagnation will set in. Collaborative workflow processes which require a well defined flow of activity from knowledge worker to knowledge worker must have well designed connective tissue. Collaborative workgroup processes which require shared research, design and development must have the mechanisms for ongoing sharing of interim and unproven results without professional fear or suspicion. Official and unofficial teams must have shared measures and incentives.

The processes and needs for good individual and corporate knowledge assume that a number of factors are in place which will ensure that the knowledge market operates successfully. Mainly, corporate knowledge requires individual knowledge, the mechanisms and opportunities for sharing, reasons for sharing and individual actions around knowledge to be driving towards the same solutions and outcomes as the business processes.

It is significant that all member of organizations understand what they know and don't know. They must also realize when they should collaborate and when they know enough to simply act. They must be aware of what knowledge exists and who has it or access to getting it. They must also understand why they are doing what they are and what makes an appropriate result.

All individuals must have the ability to identify and get connected to the sources of better knowledge when they need to collaborate or get help They will require access to those who know in either personal and/or electronic forms. They will require the time availability and organizational authorization from all parties in the collaboration as well as their management. They will also require access to suitable repositories of best practices and guides through effective equipments.

Those involved with knowledge sharing or transfer must first have the personal dedication to improve their own knowledge. This may be through personal learning and training, learning on the job or exploiting opportunities provided through business programs. Whether buyers, sellers or brokers, they must sense openness to sharing with others. They must also truly believe that a trust culture is in place which will encourage communication and sharing rather than punish those who expose themselves. There must also be incentives and rewards to use or share knowledge which are in synch with the incentives and time availability of others. There must be a win-win view of support for all. They must want to share.

II. Application of KM Techniques

However, today's practice in KM still lacks from significant drawbacks and the existing knowledge is captured and capitalised only to a small degree. The reasons for this are manifold, and one of the most critical factors is time. Though many employees are willing to document and utilise existing knowledge, they do not have the time to do this in the pressure of day-to-day business life. Consequently, there is a strong need for methods and tools with utmost user friendliness for rapid Knowledge Management (Thoben, 2000)

In practice, knowledge management is the deployment of a set of tools and techniques that are used to help organizations manage the two knowledge cycles :Innovation cycles and knowledge sharing cycles .In innovation cycle we talk about creating ,codifying ,embedding and diffusing of the knowledge in the organization and in knowledge sharing cycle we focus on identifying, gathering, organizing ,sharing ,learning, applying and evaluating of knowledge in the organization.

In innovation cycle (see figure 3)in the first step we try to create and exist the knowledge by using creativity techniques of structured problem solving ,Creative abrasion: where people form different perspectives discuss ideas, business simulations and models to provide new insights as to how things works, Skilful dialogue to reveal assumptions and to surface new ideas and finally Morphological analysis which is a specific approach in which the functions of a product are described and new combinations or alternative sought.

In the second step we must codify the knowledge in our organization by Designing methods and disciplines which have formal approaches for design; these represent knowledge that was once tacit or ad-hoc and has now been systematized, often into computer-based applications. Many such applications have some core algorithms that embody design rules based on past experience. Also we can use PDM (Product Data Management) for storing information about components that go into a complex product (widely used in the aerospace industry).

These Methodologies are particularly relevant to process design or the deign of work activities; a methodology in the form of procures, guidelines and workbooks represents codification of good practice

In the third step we embed the koweledge by Prototyping: initial 'proof of concept' of new knowledge, it can also be the prototyping of computer applications or even documents, Packaging the knowledge which is made explicit and organized into some form of package, such as a document or a software

To embed knowledge into routine activities.

The final stage in this process is an effective marketting for promulgathing new knowledge especially throw E-marketing .(see figure 3)

In knowledge sharing Cycle ,the first step is identifying the knowledge by information audit which is a process of

identifying core knowledge needs ,Knowledge mapping for visual presentation of the structure of knowledge .text mining for identifying core concepts and finally conceptual mapping for showing relationships between different entities.

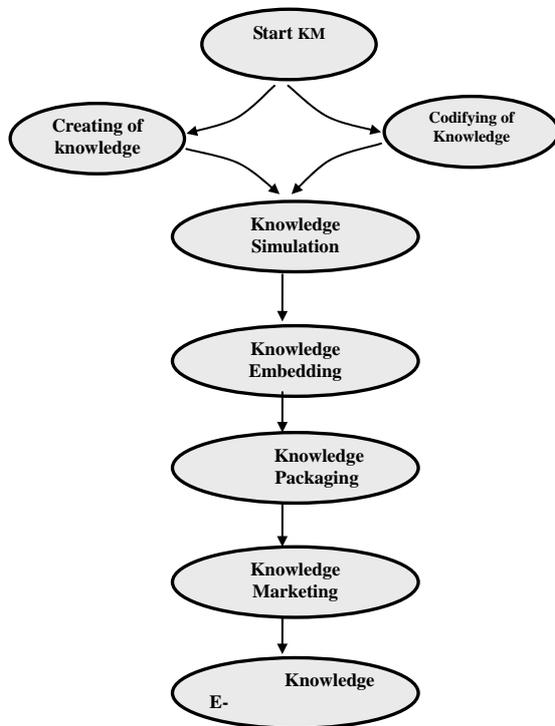

Figure 3 Innovation Cycle of KM

Now is the time for information gathering. We can gather the information by interviewing and also software that searches the internet

After organizing the information by data base systems we cab share the knowledge. For Knowledge sharing we need a knowledge management programme to connect knowledge providers with knowledge users and also to develop and share knowledge around a common vision or common problem. Also we need document management systems to formalize and share explicit knowledge around a key corpus of documents

By cross-functional teams we can also share the knowledge.Teams with people from different disciplines and organizational units; such teams are a good way of sharing knowledge – especially informal knowledge - across normal discipline or organizational boundaries.

Finally we can establish Knowledge centres like the corporate library; a knowledge centre will typically staffed by information scientists (librarians) who act as a conduit between the requester and suppliers of knowledge

In the applying stage we package knowledge by putting knowledge in a form that makes it more widely accessible and support our decision systems.In this process we can also use Case based reasoning (CBR)for

interpreting a situation based on analogues from the past or related situations. CBR is a particular type of artificial intelligence software.

And finally we must Evaluate the knowledge .for this purposes we need KM assessment which is an assessment of activities within a knowledge management programme, gauged against generally accepted good practice and also we need a formal approach for classifying intellectual capital into its components (typically human capital, customer capital, structural capital and intellectual property) and developing metrics to assess how it is changing over time.

At the end we need benchmarking to compare of a specific process with other organizations or units carrying out the same process.(see figure 4)

The above list is used to indicate the many ways in which knowledge management manifests itself within an organization. As the discipline of knowledge management becomes more established, each technique becomes better understood, documented and diffused. Many techniques have associated computer tools that make them easier to implement and diffuse through an organization.

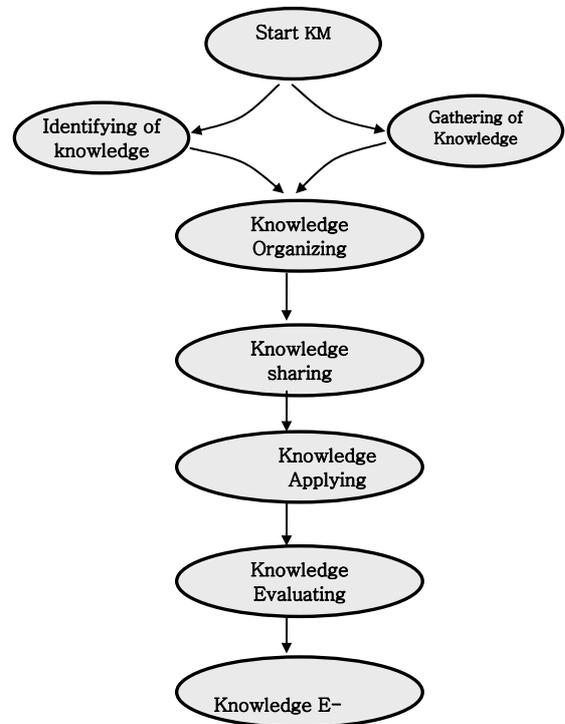

Figure 4 Knowledge Sharing Cycle

III. Conclusion

In fact, any task that uses and applies knowledge can benefit from the structure of knowledge management, and that covers most managerial and professional activities. Therefore, like other management ‘fads’ before, many existing business practices (such as information management and intelligence gathering) are coming under the knowledge

management umbrella. Similarly, information systems solutions, such as document management and data warehousing are being similarly relabeled.

Structurally, the use and sharing of knowledge must be aligned with all of the factors described in the paper. The development and application of knowledge must be relevant and in context to the business direction and the stakeholders needs. Optimum knowledge application, sharing, and flow is only delivered as part of the business processes of the organization. The objectives and measures of each must be common. Most importantly, knowledge growth and use must be specifically tied to the individual and team objective setting, incentive and reward mechanisms of the organization.

Abstract: Information technology has changed the way organizations function. This resulted in the reliance of help desks to deal with information technology related areas such as hardware, software, and telecommunication. Besides, the adoption of business process reengineering and downsizing have led to the shrinkage of the size of help desk. The shorter information technology product life cycle has worsened the situation by increasing the already sizeable help desk's user base. Consequently, the help desk has to cover more information technology products and resolute more technical enquiries with less staff. Thus, the outcome is clear that users have to wait comparably longer before help desk staff is available to offer assistance. This paper describes the contribution of knowledge management in retaining knowledge and solving "knowledge leaking" problem. The research presents the development of user self-help knowledge management system to re-distribute incoming enquiries so that simple and routine technical enquiries can be resolved without help desk intervention.

Keywords: Knowledge Management, Help Desk.

I. Introduction

Help Desk (HD), also named as computer call centre, contact centre, Information Technology (IT) assist centre or support centre, is an access point to provide IT-related advice, information or troubleshooting action to user. Its responsibilities include first line incident support, day to day communication between IT department and user, business system support and service quality report generating [3, 17]. The widespread application of information technology has resulted in majority of organizational activities to be automated and electronic-based. This trend has led to increase coverage of HD's roles and responsibilities in the organizations. The organizations rely on HD to provide technical assistance on all aspects of information technology related areas such as hardware, software, applications and telecommunication.

The complexity of the business systems has created

infinite number of technical and functional problems. This complexity also means that the users are not able to work at optimal productivity when they are faced with technical problem related to the system. In other words, organization may face potential loss in income, whether direct or indirect, immediate or future. The above situations have resulted in shift of HD's role from a traditional non-profit-making function to an important management asset that plays a vital role to ensure organization-wide Information System (IS) is working accurately and smoothly.

One of the existing challenges for HD is how to manage knowledge in an effective manner. The widely exploitation of IT has significantly increased HD's coverage on software, hardware, network connections and other IT related areas. It is not unusual for a single HD to cover hundreds of thousands of software, hardware, application programs and network connections. Sometimes it is difficult even to memorize all the names of the applications and systems used in the organization. What exacerbate the situation is the adoption of management methodology such as Business Process Reengineering (BPR) and downsizing. This leads to the shrinkage of the sizes of help desks because the overall budget has been reduced. This not only reduced a significant number of experienced HD staff, but also led to the loss of priceless knowledge which is considered to be crucial for the daily operation within the HD boundary. On the other hand, the shorter product life cycle in IT industry makes the predicament even worse. The IT product life cycle accelerates at an unbelievable rate that even a brand new product can be obsolete as soon as it hits the market. As a result, the already sizeable user base covered by the HD and the number of incoming enquiries are increased speedily in direct proportion to the shorter product life cycle. According to a research conducted by the Help Desk Institute, most respondents in the HD industry have said their call volume has been increasing every year in the past ten years [2].

When the HD is expected to cover more IT products and resolute more technical enquiries with less staff. The outcome is clear, the user has to wait comparably longer before the HD staff is available to pick up the call. Heckman and Guskey [12] report that "help unavailable when needed" is the major reason for service delivery failure in HD which in turn leads to user dissatisfaction. Thus, HD is desperate for a method that can deal with the above problems. This

paper discusses the role of Knowledge Management (KM) in HD to overcome the above challenges. This paper also includes the discussion of how generic KM process can be customized within the HD environment by developing a user self-help Knowledge Management System (KMS) as an online self-help tool to improve the support process in the HD.

The rest of paper is organized as follows. Section 2 provides background of KM. Section 3 discusses the evolution of KM in HD. The proposed future of KM within the HD industry is outlined in Section 4. Finally, conclusion is given in Section 5.

II. Background of Knowledge Management

HD experts use both tacit and explicit knowledge to solve user's problem. Tacit knowledge refers to skills, perceptions, assumptions and experiences that reside in the staff's brain whereas explicit knowledge refers to written document, such as technical manual and guide book. KM, a methodology to manipulate tacit and explicit knowledge, has the capability to address "knowledge leaking" problem caused by BPR and downsizing [6, 21, 24]. To examine whether this contribution of KM can be extended to HD, it is critical to review the background of KM.

Back to mid 1980s, tools and techniques such as Total Quality Management (TQM), downsizing and BPR were developed by western companies to aid in re-gaining market share occupied by the Japanese Company. However, both input and improvement are short-termed because these solution approaches are generic and easily available to all rival companies. Once an approach is proven successful, the rival company duplicates and adopts the same practice [23]. The practice of downsizing, BPR and outsourcing, which aims for process optimization as well as cost and time saving, have resulted in loss of many experienced employees along with their capability and knowledge which in turn has "drained" away organization's inspiration and creativity [6]. Thus, organizations have to re-pay high, severe and long-term price in return for transient benefit. The worst is after several years of downsizing and BPR, companies in western world are now competing with each other on equal cost, quality and delivery performance levels. This means that the company has difficulties in differentiating with other challengers. What intensify the already fierce battlefield is the availability of cheap labour in Asian and other developing countries. Thus, the concept of KM is emerged to sustain long term competitive advantage by preserving organizational knowledge [26]. Knowledge is now recognized as one of the most important management assets because knowledge enables organizations to utilize and develop resources, enhance their fundamental competitive ability and develop sustainable competitive advantage [23]. In other words, knowledge allows an organization to do better than rivals.

KM is designed to manage and capitalise on knowledge that accumulates in the workplace [18]. This is achieved by

organizing formal and direct process to create, store and retain knowledge for the benefit of the organization [10, 24]. The entire process of KM (as illustrated in Figure 1) is divided into five stages: create, store, make available, use and evaluate knowledge [4, 27]. There are four methods to create organizational knowledge by means of the interaction between explicit and tacit knowledge [21]. The first method is socialization. It is the process of developing tacit knowledge from tacit knowledge embedded in human or organization through experience sharing, observation and traditional apprenticeship. The second method is called externalization. This is the process of turning tacit knowledge into new explicit knowledge simply by transforming tacit knowledge in the form of document such as manual and report. The third method is combination. This is the process of merging and editing "explicit knowledge from multiple sources" into a new set of more comprehensive and systematic explicit knowledge. The last method is internalization. This is the process of embodying explicit knowledge as tacit knowledge by learning, absorbing and integrating explicit knowledge into individual's tacit knowledge base.

The second and third stages of KM, store and make available, are often linked with technologies. Explicit knowledge created is collected and stored in some form of database or knowledge base in which the users have the right to access by using "search and retrieve" tools, intranets, web access and applications, groupware and so on [1, 22, 24]. Whether knowledge can create value or not, it is directly connected to the fourth stage of KM because knowledge has little value without use [10]. Though the application of knowledge is varied in accordance with business nature, the focus is still on how to make use of knowledge to improve the current value chains. The fifth stage of KM is knowledge evaluation. This phrase eliminates incorrect or outdated knowledge [1]. In other words, organization must keep creating new knowledge and to replace any knowledge that has become invalid [10].

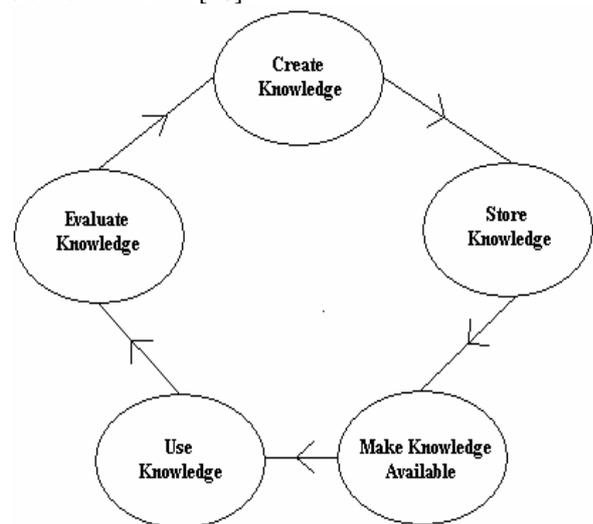

FIGURE 1: The Five Stages of Knowledge Management [4, 27]

III. Evolution of Knowledge Management in Help Desk

Basically, HD composed of HD support staff and technical equipment. Nevertheless, the actual axis of the overall support process in HD is knowledge. When user requires technical support, this means s/he lacks sufficient IT related knowledge to carry on her/his duty. The HD staff is responsible to help to solve the problem by using knowledge resides in some sort of repository, such as human's brain, database or technical manual. One can easily imagine the predicament if HD only contains staff and equipments. When the five stages of KM together with IT are applied to preserve technical knowledge in HD, the combination works perfectly well in preserving HD's knowledge (see in figure 2). The technical knowledge is converted by both externalization and combination. Externalization is used to convert skill, technique, experience and perception from experts into explicit knowledge and combination is used to combine and revise explicit knowledge from manual, guidebook and training documentation into a more systematic and organized knowledge. In this way, both types of knowledge are converted to a form that can be stored in the electronic repository. Structure Query Language (SQL) can be applied to allow the HD staff to retrieve the required knowledge from the repository. More advance techniques such as search engine, agent technology and artificial intelligence can also be applied to retrieve this knowledge. The retrieved knowledge is used to resolve user's problem. The shorter product life cycle in IT also means the knowledge resides in the repository is required to be evaluated regularly in order to maintain its validity. The outdated knowledge is either renewed and stored into the repository or removed permanently from the repository.

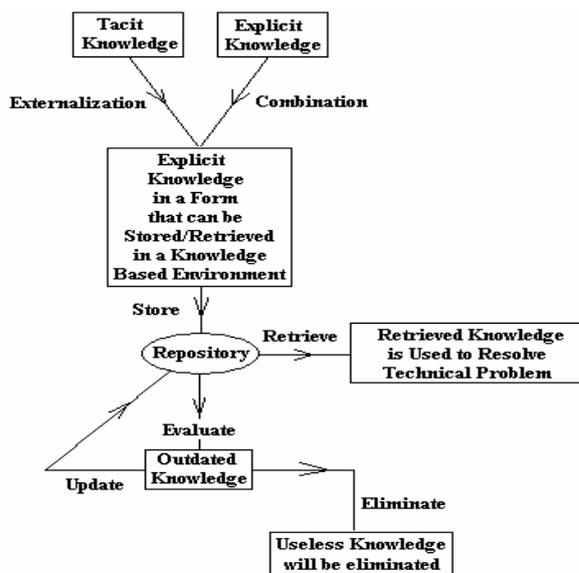

FIGURE 2: The Generic Process of Knowledge Management in Help Desk Environment

These five stages have provided a framework to preserve knowledge in the HD. Undoubtedly, in order to maximize its effect, a certain degree of customization may be required depending on the organizations. Although literature has shown that research has been conducted on the application of KM in HD, most of them are focused on technical aspect of how to store and retrieve knowledge and only a handful covers the entire KM process in HD [5, 7, 8]. To effectively customize the five stages of KM, it is essential to have a thorough understanding on how knowledge is managed along with the evolution of HD. Thus, a brief overview on the development of knowledge handling techniques in the HD is given in the following section.

III. 1 Past and Present

At the early stage, decentralized HD model was very popular. Organizations often have more than one HD in 1980s. Various HDs were established by departments, branches and IT work groups. For example, there were nine different HDs in Western Kentucky University in which user had to determine which HDs to call, depending on where the problem was, what the problem was and when the problem occurred [14]. The decentralized HD model shares the belief that diverse support issues could be referred to related HDs easily so that timely response could be acquired. At that time, each HD had its own collection of training manual, guidebook, technical manual and other paper-based documentations in which computer knowledge was stored and organized. Decentralized HD worked well together with this primeval knowledge handling technique in the very beginning because computer system was simple and straight forward. So it was quite easy for the HD staff to locate the right piece of knowledge from the low-quantity paper-based manuals. On the other hand, the effort required to update the paper-based documentation was light because computer life cycle was relatively longer.

As IT infrastructure grew more complicated and organization-wide information systems were interconnected with a large number of hardware and software, the classification of problem domains became not so distinct. Users became confused with multiple HDs and they were often being directed from one HD to another before obtaining a correct solution. Then, organizations started to adopt centralized HD model [17]. The idea is to merge various HDs into one and user only needs to memorize a single telephone number for all IT related enquiries. This makes HD the first and single point of contact. Nevertheless, the adoption of HD consolidation also challenged the traditional way to manage IT knowledge. Rather than to allow IT knowledge to be scattered in multiple collections of paper-based documentations, centralized HD was required to merge all of them into one. Obviously, the conventional paper-based manipulation method could not afford the sudden burst of knowledge from various HDs. One can easily imagine the clumsiness of the combined paper-based documents. Moreover, IT knowledge, resided in the combined paper-based version, would be extremely hard to

search and update. As long as HD staff realized that electronic repository could provide assistance, they started migrating IT knowledge into computer file system that has the capability to accommodate huge amount of IT expertise. However it has its disadvantage in which there is a lack of flexibility in handling knowledge. Very often a programmer is required to implement complicated programs even in simplest knowledge retrieval and storing tasks. Then the emergence of database technology overcomes the shortcomings in the file system. Database technology not only provides a more structured way to manage knowledge, but the simplicity and easy-to-learn ability of SQL also allow the HD staff to create, store, retrieve, use and review knowledge effectively and efficiently. Because of the about advantages, database technology has assisted the development and standardization of information and knowledge in HD industry.

Expert system is another useful tool to manage IT knowledge, especially on how knowledge is "made available" [26]. Expert system is considered as an appropriate tool in the HD industry due to the characteristics of scarceness, diverseness and expensiveness of expertise [11]. The ever expansion of IT makes the HD staff not able to fully understand and handle the enterprise-wide systems. As a result, it is impossible for the HD staff to offer immediate assistance if one of the experts with a particular knowledge is unavailable. Conversely, HD staff is able to provide recommendation and solution for a routine or even complex problem simply by entering its description and symptoms to the expert system. Then the embedded inference engine will try to find the best diagnostic method from the knowledge base where IT expertise or knowledge is resided. The application of expert system ensures not only the availability of expertise but also minimizes the problem solving duration and cost. However, Middleton [19] argues that expert system and other artificial intelligence related system are not as popular as predicted. Though expert system offers an intelligent method to retrieve knowledge, Czege [7] points out some shortcomings in the HD expert system. These include high cost and time consuming in knowledge acquisition as well as knowledge base maintenance, high complexity of problem domains, not user friendly and difficulties in system development

Nowadays, some global corporations with offices all over the world implement another model called distributed or virtual HD model. This model promotes HDs of multiple physical locations. Users can still keep in touch with them by using one contact number through the modern call routing technology [25]. In this way, HD is able to operate twenty-four hours a day, seven days a week regardless of the location. For example, Morgan Stanley, one of the largest investment banks in the world, consists of four HDs in different sites (USA, England, Japan and Hong Kong) which enable them to provide enterprise-wide twenty-four hours HD service. Though distributed HD may only have one electronic knowledge repository that located in one particular office, the innovative data communication

technology allows the HD staff to store, retrieve and update knowledge regardless of geographical and time limitation.

E-support is another innovative support model that is believed to lead to a new revolution in the HD industry in the nearest future; it can be achieved due to its ability to provide better, faster and cheaper service. Broome and Streittwieser [2] specify that all support actions that use internet or web as the primary communication channel should be included as e-support. One of the key stimuli in promoting e-support is the emergence of web-based tools. Users can make use of email or web form to contact the HD ignoring its actual service hours or users can access online resources, such as knowledge base and Frequently Asked Question lists (FAQ), to look for information that is useful to resolve their existing difficulties. Furthermore, the HD staff is capable of conducting web training or using remote control technology to help user to resolve their problems. The concept of e-support breaks through the customary KM border by expanding the third and fourth stages of KM (make knowledge available and use knowledge) to the user.

IV. Proposed Future of Knowledge Management in Help Desk

The five stages of KM have standardized the process of organizing knowledge in the HD. What is more, the combination of KM and database technology enables the HD to manipulate enormous amount of knowledge in a structured way. Both tacit and explicit knowledge are converted in a form that can be stored in knowledge base. The knowledge can later be retrieved and used by HD staff and user. No doubt that KM succeeds in dealing with the loss of knowledge caused by BPR as well as downsizing, but is that all the contribution that KM can make to the HD industry? Nonetheless, the potential of KM is far beyond that: effective customization in KM has the capability to aid HD in going through the existing challenges and enables HD to control the ever increasing user base. The best method to stop the expansion of user base is to slow down the IT product life cycle, but this approach is perceptibly out of HD's control. Moreover, slowing down the IT product life cycle may cripple an organization's profit and competitive advantage. The clue to control user base lies in the composition of the incoming enquiries. Knapp and Woch [15] state that 80% of enquiries request no specialized knowledge. Dawson and Lewis [9] point out that close to 50% of calls to ITS help desk at Deakin University are related to login name and password. Both researches indicate that the majority of incoming technical problems and enquiries are classified as simple and routine. Rather than calling HD, users are capable of solving simple and routine technical problems themselves if sufficient knowledge and guideline are provided. The concept of e-support sustains the idea of transferring part of the troubleshooting duty from the HD to users. When the users have problems, they can solve their problems by searching related solution from online knowledge base or FAQ.

However, online user knowledge base normally shares the same design as the one access by the HD staff. If the knowledge base is designed to support “keywords search” in which users have to locate the most appropriate solutions by entering a few keywords that best describe the problems, users often do not know how to use the right jargons to explain the problems. Although they may successfully use their own words to depict the problems, the “keyword search” may return ten or even more solutions which will deepen users’ frustration. The complexity of the user interface can drive away novice users or even users classified as medium-skilled. Similarly, FAQ is always overlooked by users because its mechanism lacks the ability to support users in dynamic and flexible manners.

IV.1 Proposed Re-distributed Knowledge Management Model

To ease the overloaded HD, we propose a new mechanism to re-distribute simple and routine enquiries in the KM process within the HD environment. We propose to develop the user self-help KMS as a replacement to the legacy online knowledge base and FAQ in order to improve the support process in the HD.

Let us define the phrase “simple and routine technical enquiries” first. Simple and routine technical enquiries in this paper are referred to technical problems that can be solved by user if adequate relevant information is provided without direct or indirect intervention from the HD staff. These enquiries can be categorized into four types: account and password enquiries, service guidelines, hardware and software enquiries and miscellaneous enquiries. The account enquiries include account setup, termination, maintenance, login problem and suspension, whereas password inquiries include password retrieval, reset, syntax information and password invalid. On the other hand, service guidelines refer to guidelines on hardware installation, software installation, software purchasing, hardware purchasing and service performance. The hardware and software enquiries include performance and functional concerns in relation to the hardware and software. The miscellaneous enquiries include queries on missing and corrupted files, unreachable website and server plus their performances.

The above categories may need to vary depending on the types of software and hardware, users, users’ skill sets and business processes. To identify routine and simple enquiries, we propose to use the reports generated by the HD Management System and the Automatic Call Distribution System (ACD). These reports provide data and information on problem type, resolution method, call duration (time required to solve the problem) and so on. By inspecting the reports in a regular manner, the HD manager can work out which enquiries are routine and simple. For example, the HD management report may have indicated that there were many enquiries about “email login failure” in which most of them were related to “password invalid” and the required resolution method was merely to “reset password”. Thus by matching the above information with call duration in the

ACD report, the HD manager could confirm the enquiries as simple and routine because the duration for each call was short. However, the advice of the HD staff can never be overlooked. Hence the classifications of the enquiries that have been deduced by the HD manager must be verified by the HD staff to ensure the accuracy. The proposed mechanism of identifying simple and routine enquiries is illustrated in figure 3.

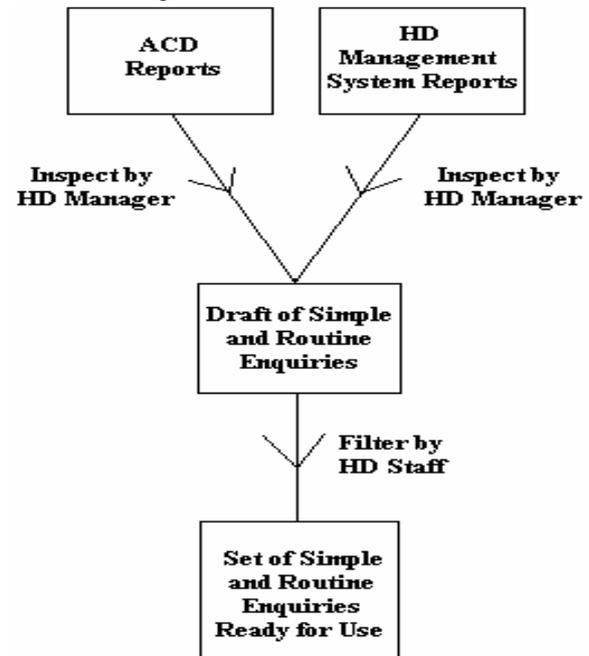

FIGURE 3: Proposed Mechanism to Identify Simple and Routine Technical Enquiries.

To effectively re-distribute simple and routine technical enquiries, the proposed mechanism will be added to the generic KM process and the resulting model is shown in figure 4. Rather than storing explicit knowledge into repository straight a way after externalization and combination, the proposed mechanism will be applied between these two steps, with the aim to distinguish the knowledge into two categories: 1) simple and routine and 2) complex. While simple and routine knowledge is stored in the proposed user self-help KMS, the complex one is resided in the general knowledge repository. Consequently, user can first access the proposed user self-help KMS and look for the most appropriate solution in accordance with the associated IT problems. Only if the solution is not available in the proposed self-help KMS, then the user will contact the HD for assistance. The repository where complex IT knowledge is resided, will be used by the HD staff to answer complicated technical enquiries. This model also allows the proposed system to be tailor-made in accordance with user’s skill sets. Because IT knowledge often contains a lot of technical terms and jargons, the HD staff can rephrase and simplify the resolutions that store in the self-help KMS to ensure users can understand the resolution methods.

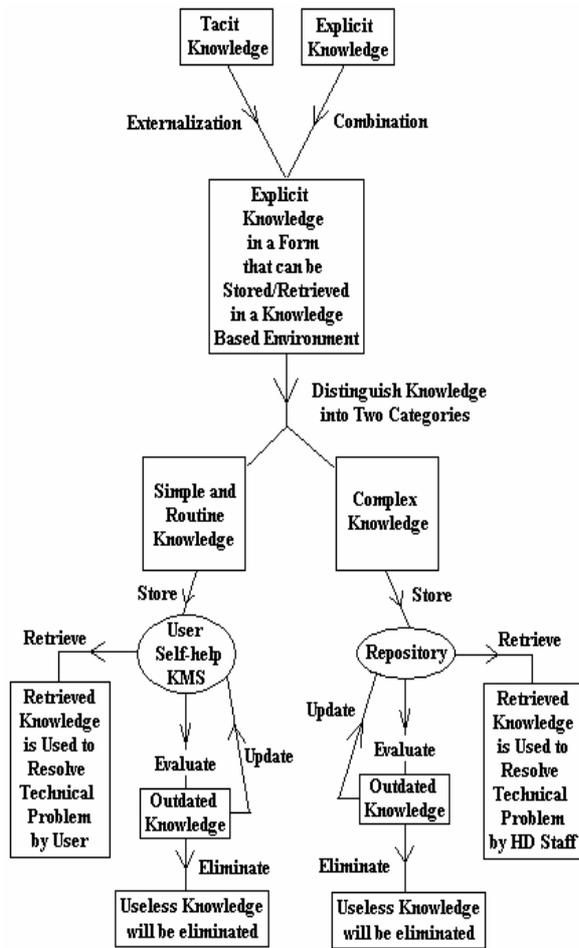

Figure 4: Proposed Re-Distributed Knowledge Management Model in HD

The basic architecture of the proposed user self-help KMS is shown in figure 5. There are five basic components within the architecture: user’s browser, two software agents (interface and search agent), resolution knowledge base that stores solutions for simple and routine enquiries and the interface database that stores information required to facilitate user communication. Software agent is a computer program that behaves like human and is capable of autonomous actions in pursuit of specific goal [16, 20]. Software agent technology can be used to free user from onerous search duty by dedicating itself to look for the most suitable solution in the extensive knowledge base based on user’s requirement. Moreover, it is also capable of facilitating user communication and description of problems.

Though traditional programming approach is able to develop a similar system, using software agent approach to develop the proposed user self-help KMS tends to: 1) be more natural in depicting and modeling the complexity reality, 2) reduce problems associated with coupling of components, and 3) reduce difficulties associated with managing relationship between software components [13]. In practice, systems developer can customize the system based on the actual needs of both users and the organizations

by inserting different attributes into software agents. Examples of agent characteristics include autonomy, reactivity, proactiveness, collaborativeness, mobility, adaptability, personality, temporal continuity, communication ability, flexibility, learning ability and intelligence [13, 16, 20]. The agent approach also minimizes the re-programming effort for system updating and maintenance because adding, converting, removing or replacing an agent is relatively easier than any other existing approach [13]. The unique characteristics in software agent technology enable the HD to customize its own user self-help KMS based on this architecture. This architecture can be modified to suit different HD’s criteria: 1) by adding extra software agent, 2) by removing software agent, 3) by inserting additional attributes into software agent and 4) by removing existing attributes from software agent. For example, if it is decided that additional feature in which the user can choose to conduct an online consultation with the HD staff (in case the user cannot find any suitable solution), then the system can add an additional communication agent which possesses the ability to facilitate online consultation. This type of customization is straightforward and does not require major changes to the system.

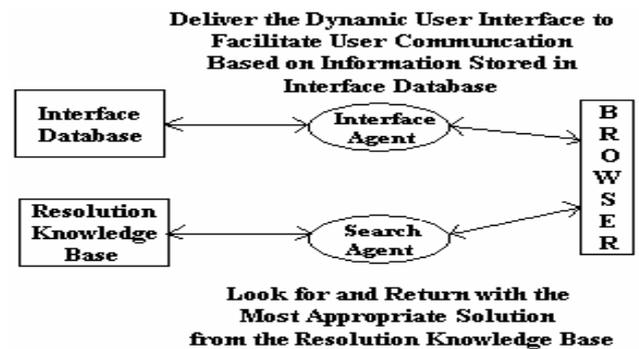

FIGURE 5: Proposed Architecture of User Self-Help KMS

The proposed user self-help KMS also makes use of modern web technology as a mean to deliver the system. The system is delivered by internet and appeared on the browser to facilitate the interaction with user and delivering user request for resolution. The following steps describe how the system will be deployed.

- To activate the system, the user simply clicks on the target URL. Subsequently, the interface agent that possesses communication capability will deliver a dynamic user interface to the browser, based on the information stored in the interface database. The dynamic and interactive communication capabilities of the interface agent provide an “easy to use” user interface in helping user to present and identify the problems. A simple implementation of dynamic user interface is shown in figure 6. Firstly the interface agent interacts with user by asking user to select a problem type on the user interface. Based on the input, the

interface agent will generate the next category of possible problem scenarios. This type of interaction will continue until the agent has gathered sufficient information to process the query.

- When the problem is described through the deployment of the interface agent, the search agent will be deployed to search for possible solutions. The search agent which possesses “the ability to act autonomy” is responsible for this task. Here, “the ability to act autonomy” refers to the capability of an agent to perform its task without direct control from the user or with only minimum supervision and direction. To achieve the preset goal of finding the most appropriate resolution, the search agent will be deployed as soon as the agent is able to “sense” sufficient information has been gathered. The search agent will then examine the contents in the knowledge base, make its own decision to select a solution according to user’s problem description and return the solution to the user.

FIGURE 6: Simple Implementation of Dynamic User Interface

V. Conclusions

The generic KM process enables HD to create, store, make available, use and evaluate both tacit and explicit knowledge.

These five stages not only allow HD to manipulate enormous amount of knowledge, they also solve the problem of knowledge loss associated with BPR and downsizing. By adding the proposed simple and routine technical enquiries identifying mechanism and user self-help KMS to the generic KM process, simple and routine technical enquiries are re-distributed in a way that users can look for their own solutions instead of calling HD. Since a sizeable amount of enquiries are now re-routed to the user self-help KMS, HD staff can be freed up to handle high level support issues, to participate in proactive support activities and to attend regular trainings. From the user perspective, rather than waiting in a long queue for a simple resolution, user can look for the most appropriate solution simply by using the system regardless of time and geographical restrictions. Alternatively, for those who have complicated enquiries, the waiting and troubleshooting durations will now be shorter because more staff are available and fewer users are in the queue. This means the user can now enjoy a better, quicker and more direct service. Economically speaking, the user self-help KMS is an extremely cost-effective support method because the average cost for a web self-help transaction is four hundred times less than a telephone transaction and eighty times less than an email transaction [2]. Finally, the potential to convert the radical habit in user’s dependence upon the HD as well as promote self-learning atmosphere cannot be overlooked as an old Chinese proverb says “Give a man a fish and you feed him for a day. Teach a man to fish and you feed him for a lifetime.”

Email: zhangm@sacredheart.edu

Abstract: In this study, the performance impacts of information systems (IS) support for two key knowledge management activities (knowledge creation and knowledge sharing) were assessed with both survey and archival data. The results showed that IS support for knowledge creation and IS support for knowledge sharing had direct positive effects on labor productivity. Coupled with unique, complementary organizational resources, both types of IS support exerted positive effects on profitability.

Keywords: knowledge management, information systems, firm performance, competitive advantage.

I. Introduction

With the widespread recognition of knowledge as a critical source of sustainable competitive advantage (Spender & Grant, 1996), developing and mobilizing value-creating knowledge for competitive advantage and superior economic performance becomes a central issue facing academics and practitioners alike. In the field of IS management, the past decade has witnessed a proliferation of research on IS roles in knowledge management (see Alavi & Leidner (2001) for a review of the related research). While much of the extant literature has identified various ways a firm can use IS to generate and leverage its knowledge resources for improving its competitive position and performance (Gold et al., 2001), it remains unclear whether such IS deployment would actually result in positive economic returns for the firm, due to little empirical evidence linking IS support for knowledge management directly to the bottom-line performance of firms.

Moreover, while IS have traditionally been viewed as one of the key enabling tools for knowledge management, researchers have increasingly entertained the notion that IS alone would not lead to knowledge-based competitive advantage and that other organizational resources need to work in conjunction with IS in order to generate the economic benefits from IS support for knowledge management (Ciborra & Patriota, 1998; Davenport et al., 2001). Unfortunately, discerning the moderating effects of complementary organizational resources on the performance impacts of IS support for knowledge management has received little attention in the extant literature. This study

was undertaken to assess the performance impacts of IS support for two key knowledge management activities: knowledge creation and knowledge sharing. The study also examined and tested the potential moderating effects of certain unique organizational resources that complement the IS support.

II. Theory and Hypotheses

II. 1 IS Support for Knowledge Creation and Firm Performance

While nowadays knowledge (e.g., insights and ideas) is often distinguished from data and information (e.g., facts and numbers) in the literature (Drestke, 1981), it is well recognized that data and information are indispensable to knowledge creation (Kogut & Zander, 1992). The communication and storage capabilities of IS can be used to enhance a firm's ability to collect critical information for creating useful knowledge. The electronic communication capabilities of IS allow the firm to overcome time, geographical and organizational barriers in gathering data and information (Stroud, 1998). The ongoing increases in storage capacities of IS along with automatic capturing, on-line access and user-friendly interface greatly expand the firm's capacity to retain more data with completeness and precision and facilitate information access and retrieval (Huber, 1991). Moreover, expert systems and case-based reasoning systems facilitate the capture and accumulation of valuable and firm-specific expertise and skills (Lado & Zhang, 1998) and extract valuable knowledge from existing databases (Chopoorian et al., 2001).

IS can also be used to enhance a firm's ability to obtain valuable information from external sources in a timely and efficient manner. With online access to various external databases, executive information systems (EIS) enable managers to search and retrieve a large amount of external information in a timely manner (Young & Watson, 1995). Web-based network systems (e.g., extranets) facilitate the collection of information about customers and market trends (Stroud 1998). There is growing empirical evidence that IS support for external information gathering has led to improvements in firm performance. Several field studies of inter-organizational systems have reported faster response to market changes and significant operational efficiencies accruing from IS-enhanced information exchange between firms (Scott, 2000). EIS research has also indicated that IS support for environmental scanning has led to improved

productivity, more successful new product introduction, and improved decision making (Ahituv et al., 1998).

Hypothesis 1: IS support for knowledge creation is positively related to firm performance.

II. 2 IS Support for Knowledge Sharing and Firm Performance

It is evident in the literature that IS can play an important role in the knowledge sharing process. Early studies of the electronic communication systems found that the systems greatly increased the speed and spread of information delivery and supported synchronous communication (Adam et al., 1993). More recent communication systems (e.g., Lotus Notes) and systems with sophisticated search technologies (e.g., semantic network and adaptive pattern recognition processing) foster company-wide exchange of best practices and facilitate the process of matching solutions to problems (Goodman & Darr, 1998). Moreover, video conferencing allows for the transmission of information and knowledge in rich media (Fulk & DeSanctis, 1995). Web-based intranets reduce costs and time in preparing and transferring information in ultra-rich content and promote information sharing across global boundaries (Boudreau et al., 1998). Intranets also facilitate contacts between individuals that seek information and knowledge and those who possess them by supporting electronic bulletin boards, discussion groups and corporate directories (Andreu & Ciborra, 1997). Aside from facilitating internal knowledge sharing, IS allow the firm to share critical information and knowledge with its business partners for economic gains (Scott, 2000).

There is growing evidence that firms may enjoy performance improvements from IS support for information and knowledge transfer. Goodman and Darr (1998) have found that computer-aided systems helped firms increase sales, market share, customer satisfaction and organizational productivity by facilitating the sharing of useful information and expertise in a timely and cost-effective manner. Case studies of IS support for cross-functional sharing and integration of information in both manufacturing and service firms have also documented such operational benefits as improved productivity, reduced lead times and increased flexibility (Goldhar & Lei, 1995). Moreover, research on the organizational benefits of intranets has reported lower communication costs and higher labor productivity associated with the use of intranets (O'Dell & Grayson, 1998). In a recent study, Andersen and Segars (2001) have found a positive impact of IS enhancement of internal communications on the financial performance among large companies.

Hypothesis 2: IS support for knowledge sharing is positively related to firm performance.

II. 3 Moderating Effects of Unique, Complementary Organizational Resources

It is evident from several streams of research that a firm's

organizational culture and structure are instrumental in influencing its ability to derive competitive benefits from IS-enhanced knowledge creation and sharing. Recent research on organizational barriers to knowledge management suggests that firms may not be able to turn data and information into useful knowledge and organizational results from their IS without a supportive organizational culture and structure (Davenport et al., 2001). Even if new knowledge is created from employing IS, sharing the new knowledge may be limited by cultural and structural constrictions (Ciborra & Patriota, 1998). The absence of organizational culture and structure that support the smooth implementation and use of IS has been documented as a major cause of many system failures in the IS implementation and adoption literature (Constant et al., 1996). The business process reengineering research also shows that firms whose structures and processes are not aligned with their new IS have experienced difficulty in reaping the benefits of the IS (Keen, 1993). Aside from affecting the economic impacts of IS-based knowledge creation and sharing, firm-specific organizational culture and structure make it difficult for competitors to imitate the IS they complement because organizational culture and structure tend to be intangible and costly to imitate (Barney, 1986).

A firm's unique competitive scopes (geographic, segment, vertical, and industry) can also affect its ability to effectively use IS for knowledge creation and sharing. For instance, firms with a broad geographical presence and product breadth are in a better position to generate and exchange more expertise among more locations and product lines than those with narrow geographical and product coverage (Feeny & Ives, 1990). Firms can also combine the scale advantage from their unique vertical integration and related diversification with IS to develop and transfer critical skills and expertise from multiple markets for competitive advantage (Clemons & Row, 1991).

Hypothesis 3: The interaction between IS support for knowledge creation and unique, complementary organizational resources is positively related to firm performance.

Hypothesis 4: The interaction between IS support for knowledge sharing and unique, complementary organizational resources is positively related to firm performance.

III. Methods

III. 1 Sample and Data Collection

The data tapping the independent and moderating variables were gathered via a mail survey. The data about the performance and control variables were obtained from the Research Insight database. The target respondents of the survey were senior IS executives in large firms in the U.S. Before mailing the survey instrument to the target respondents, the instrument was pre-tested and refined for content validity and item clarity with CIO from five large companies headquartered in a mid-western state. Of the 778 firms that received the questionnaires, a total of 153 usable

responses were returned (20% response rate).

III. 2 Measures

Based on the above literature review, six items were developed to measure IS support for knowledge creation and five items to measure IS support for knowledge sharing. For each item, the respondents were asked to indicate the extent to which their IS had provided a particular type of support during the previous three years on a five-point, Likert-type scale with anchors ranging from "Very great extent" (=5) to "No extent" (=1). A joint factor analysis of the eleven items revealed two factors explaining about 50% of the total variance and corresponding with IS support for knowledge creation ($\alpha = .80$) and IS support for knowledge sharing ($\alpha = .72$), respectively.

Unique, complementary organizational resources were defined as a set of firm-specific organizational resources that complemented IS support for knowledge creation and IS support for knowledge sharing. In keeping with Feeny and Ives (1990) and Clemons and Row (1991), this measure included unique organizational culture, unique organizational structure, and unique competitive scopes (geographical area, breadth of products, vertical integration, and range of related industries). The respondents were asked to indicate the extent to which the use and implementation of their IS required each of these six resources on a five-point, Likert-type scale with anchors ranging from "Very great extent" (=5) to "No extent" (=1). A factor analysis of the six items revealed a single factor explaining about 50% of the total variance, confirming the unidimensionality of the scale ($\alpha = .80$).

Both profitability and labor productivity were used to assess the performance impacts of IS support for knowledge creation and IS support of knowledge sharing. A popular profitability ratio, return on sales, was chosen to measure profitability. Labor productivity was measured as sales to employees. To smooth annual fluctuations and average out short-term effects, a three-year average was used for both dependent variables. Moreover, six control variables were used to control for industry conditions, firm size, technological resources and organizational slack.

III. 3 Analyses and Results

To test the hypothesized main effects and moderating effects, two sets of hierarchical regression analyses were performed, using ROS and sales to employees as the dependent variables. The results indicate that IS support for knowledge creation and IS support for knowledge sharing were both associated with sales to employees at the .05 significance level. Both variables also interacted with unique, complementary organizational resources in predicting ROS at the .05 significance level.

IV. Conclusion

Contrary to the growing skepticism towards the performance impacts of IS support for knowledge management (Husted &

Michailova, 2002), the findings from this research suggest that IS may represent more than a strategic necessity for knowledge management and that IS support for two critical knowledge management activities can actually lead to superior economic performance. Hence, firms should continue to invest in and deploy IS resources to facilitate the development and sharing of valuable and firm-specific knowledge.

While generally confirming the competitive value of IS support for knowledge management, the moderation results herein reveal that the profitability impacts of the IS support depend on the presence of certain firm-specific, complementary organizational resources. Absence such resources, both types of IS support only influenced labor productivity. Accordingly, it is not sufficient for firms to simply invest in IS to facilitate knowledge creation and knowledge sharing if they expect profitability gains from such IS investments. Firms also need to invest in the development and leveraging of other firm-specific resources that not only facilitate the implementation and exploitation of IS for knowledge creation and knowledge sharing, but also make such IS less susceptible to imitation.

PO Box 42, Tweed Heads, NSW 2485, Australia
E-mail: jxu@scu.edu.au

Abstract: This research aims to examine the factors influencing the knowledge management practices in Australian SMEs. Primary data was collected by studying companies in Tweed and Gold Coast areas. Besides the academic contribution to the field of knowledge management, this research will be able to provide applicable and practicable suggestions on the knowledge management practices to SMEs in Australia.

Keywords: Knowledge Management, SMEs, Qualitative Methods, Content Analysis

I. Introduction

As a result of the changing market places (from capital assets market to knowledge economy), competition, and the rapid development of technology, organizations are starting to pay more attention to maximize their knowledge-based assets. More and more organizations are starting to realize that knowledge is their most important asset and the knowledge-related assets will be the base of sustainable competitive advantage and the foundation of success in the 21st century [34]. Organizations are understanding and accepting the fact that the most important source of wealth and basic economic resource in the contemporary society, the “knowledge society” called by Drucker [12], is knowledge and information [31]. When a business faces competitors that perform well in areas such as planning, marketing, products, customer services, structure, organizational resources management, effective management of knowledge may be the only weapon to win the competition [8]. Researchers (such as Drucker [12], Sveiby [29]; Nonaka & Takeuchi [21]; Davenport & Prusak [7], among many others) bring out that knowledge and intellectual capital are an organizations’ primary sources of production and value and tangible assets such as land, plant, equipment are rarely their most valuable assets. Through successful knowledge management, organizations are able to act intelligently to sustain their long-term competitive advantage through developing, building, and deploying its knowledge assets [36].

A lot of research have been done on the knowledge management in large organizations. However the literature on the knowledge management in SMEs is very limited. For

example, only 31 articles could be found on “knowledge management and SMEs” in Proquest 5000 database when a search was made on June 1, 2005. There is a lack of empirical study in the area of knowledge management in SMEs, especially in the Australian context. The only literature on KM in Australian SMEs can be identified is Braun [6], which suggests a conceptual model mapping access to knowledge flows within SMEs. In the mean time, there exists an argument that large organizations in Australia may not be the most innovative sources of knowledge management. Sveiby [28, <http://www.sveiby.com/articles/KnowledgeOrganizationsAust.html>] says that “If we wish to see the future of corporate Australia, we don’t need a crystal ball or sophisticated forecasts by economists. All we need to do is to visit some of the small fastest growing and most successful knowledge companies. The management styles they are pioneering and the strategies they are pursuing will be the case stories taught in the standard curriculum of the management schools of Australia”. This research is aimed to address this gap. This research investigates the knowledge management practices in SMEs in Australia. This study addresses the following research questions:

- (i) to identify various factors and variables of KM benefits, and
- (ii) to explore and develop a model of KM Benefits

II. The Background

“Knowledge management is... an approach to adding or creating value by more actively leveraging the know-how, experience, and judgment reside within and, in many cases, outside of an organization.” [26, p. 80].

This definition highlights important elements of knowledge management. The “know-how” aspect of KM emphasizes the “explicit” knowledge, which can be easily captured and codified [5]. On the other hand the “experience” and “judgment” aspects of KM reflects the “tacit” or “implicit” knowledge, which is difficult to capture and formalize [5]. The definition also emphasizes that primary purpose of knowledge management is to add or create “value”.

Based on the literature [24] [25] [21] [3] [15], knowledge basically can be divided into two categories: tacit knowledge and explicit knowledge. Some common applications of tacit knowledge are problem solving, problem finding, and

prediction & anticipation [15]. Tacit knowledge basically consists of two dimensions: cognitive and technical elements [21]. The cognitive dimension of tacit knowledge refers to “mental models”, which assist human beings in interpreting and understanding the world around them; individuals’ perspectives, beliefs, and opinions are some examples of tacit knowledge [21]. The technical element of tacit knowledge includes things such as know-how, crafts, and skills [21]. Tacit knowledge is personal and context-specific; therefore it is more difficult to formalize and communicate [21]. Contrasting to tacit knowledge’s subjective nature, explicit knowledge is more objective and generally can be codified or documented in formal or systematic format [21]. Information in the databases, library, and Internet are some examples of explicit knowledge. Tacit knowledge has much higher value than explicit knowledge since people always know more than they can tell [29, p. 34] [20]. Furthermore, in order to apply explicit knowledge in practices, it must be converted to the tacit knowledge [20]. For example, students have to understand the knowledge, i.e., concepts, definitions, theories, formulas, they learn in the classroom and books before they can apply them to interpret, understand, and solve the problem in reality.

Many of the past studies on innovation diffusion have applied the model(s) by Ajzen & Fishbein [1] (Theory of Reasoned Action (TRA) and Davis [9] (Technology Acceptance Model (TAM)). Basically these researchers have suggested that some external factors influence the perceptions about an innovation, i.e. “External Factors” → “Perceptions”. This simple model is generic in nature and is likely to be applicable, with some adjustments, in various innovation diffusion processes. As mentioned before, the aim of this research is to study, via field study, various factors and variables affecting KM benefits and to investigate to what extent the above generic model is applicable in developing a comprehensive model of KM Benefits.

III. The Operation of Field Study

III.1 Qualitative Research Paradigm

The paradigm of the research is qualitative, in which field study has been used as the research method [23] [37]. The field study adopts a semi-structured interview approach to better understand the participants’ views on knowledge management. The literature review provides the framework for developing and refining the interview questions. It is very common to get qualitative data through interviews. Evidence exists that the interviewing has been used as an effective tool to collect data for thousands of years [33]. Like any other research method, field study involves choosing a sample of companies using either random or non-random method [37]. The details of the field study research process are presented in the subsequent sections below.

III.2 Sample

A convenience sampling procedure was undertaken to select

companies who were willing to be included in the field study. It is noted that convenience sampling is frequently undertaken in business research [37]. Main selection criterion was that the companies must be involved in various stages of knowledge management. Ten companies were selected from the list of companies where our Australian MBA students were employed in Tweed and Gold Coast areas. At least a key person in the company, who has the knowledge of knowledge management, was contacted for interview.

III.3 Data Collection

Semi-structured interview technique was used as the primary vehicle to collect data. The interview plan followed the guidelines of Whiteley et al. [33] and Patton [23]. The final interviews was scheduled as per the convenience of the interviewees, so that there will be minimum disruptions and interruptions in their working schedules. A pre-interview session was conducted first via telephone, which provided each interviewee an idea about the interview process and gave them some food for thought. Each interview lasted for about one hour. With the permission of the interviewees, each interview was recorded using a micro-audio recorder. Each interview was transcribed the following day in order to reflect on the body language and other non-verbal cues fresh from memory.

III.4 Data Analysis via Content Analysis Approach

One of the challenges in qualitative research is data analysis. A number of tools and techniques are available in the literature [18]. These tool(s) must be selected based on the objectives of the research. Since the research in this stage was more exploratory than confirmatory in nature, “content analysis” was chosen as a method in analyzing the interview transcripts [4]. Two-stage content analyses was carried out for data analysis. Stage one dealt with single interview transcripts, while stage two dealt with cross interview transcripts [18].

IV. Results and Discussions

IV.1 Demographic Information

Table-1 presents the demographic information on the companies, which are at different stages of knowledge management, involved in the field study. It is noted that there are two community services clubs, tourism and hospitality service, two real estate services, two health services, two education providers and one IT firm. The size of the company varied from 7 staff to around 200. Table-1 also presents the interviewees’ positions in their organizations.

All companies have adopted some form of knowledge management practices, which are supported by different technologies.

IV.2 Factors and Variables of KM Benefits in SMEs

Altogether six factors and fifty-two variables, which have impact on the knowledge management practices, were identified from different companies via extensive content analyses as described earlier. The six primary factors are:

External inspiring factor, Individual factor, Organizational factor, Management support factor, and KM technology factor and Expected Benefits of KMS.

It is interesting to note that out of 53 variables only five variables are mentioned by all ten companies and one variable is mentioned by nine companies. Some variables are only mentioned by one or two companies. The six variables, chosen by all ten companies, are: “*Competitive Pressure*”, “*Customer Demand and Expectation*”, “*Top Management Support/ Leadership*”, “*Organizational Structure*”, and “*Organizational culture*”. Participants of the field study felt that their companies’ initiative on knowledge management have been ignited by the tough competition and intensive competitive pressure in the market place and challenges from customers, who are demanding more value-for-money and expecting better services. Organizations exist within an “open” environment where external influences such as changes in the marketplace influences internal operation [32] [19]. Through fostering collaborative practices and knowledge sharing, knowledge management facilitates the learning about the external environment [14] and the implementation of a successful change management program responding to the external environment [19]. The organizations are implementing knowledge management to learn and respond to their customers better. Through effective knowledge management programs, businesses is also able to provide more enhanced or/ and new products and services. Literature, such as Alavi & Leidner [2]; suggest that knowledge about customer and customers are most important knowledge domains for businesses.

Management and leadership play critical roles in knowledge management [22]. Management provides vision and energy to stimulate and sustain effective knowledge management practices and systems. Leaders have direct impact on the organization’s culture and its knowledge management approaches. Without management’s commitment and emphasis on knowledge management, people won’t take it seriously [10].

Those at the top of an organization should have to find the knowledge needs of the business. Simply investing money in IT only can produce more examples of KM failures and waste of investment. Leaders have to take account issues such as culture, structure, process, training and development. More attention should be given to people since businesses make profits through selling and effectively using their knowledge (tacit knowledge) [28] [16]. One important challenge for leaders is how they can embed knowledge into people’s day-to-day work to help them do their jobs more effectively and efficiently [17]. Besides being role models for learning and knowledge sharing, leaders are responsible for creating a climate of trust where people can share knowledge with confidence [22]. All the

interview participants express the view that support from top management, i.e., understanding the importance of knowledge management, commitment, leadership, is crucial for the success of knowledge management s in organization. For example, the leadership process in General Electric (GE) is all about sharing knowledge and creating knowledge. The top management in GE has focused on the importance of sharing knowledge. The knowledge sharing practice starts at the top [16].

All the participants of the field study share the importance of organizational culture, which influences the effects of other factors (i.e., technology, management practices) of knowledge management practices [30], in contributing to the success of knowledge management. Organizational culture has been increasingly recognized as a major barrier to knowledge management [11] [13]. Organizations have to create an environment where people feel comfortable and are willing to share their knowledge. A knowledge-oriented culture challenges people to share knowledge throughout the organization [7] [13]. In the mean time, the benefits of knowledge management need to be demonstrated, and knowledge-sharing practices should be rewarded with tangible (i.e., financial rewards) and intangible (i.e., recognition) incentives [10].

There is a general agreement among participants that organizational structure facilitates the knowledge sharing and cross-boundary collaboration. Organizations with flexible and organic structure are more likely to achieve the perceived benefits of knowledge management than those organizations that are rigid and bureaucratic [13]. Organizations with a rigid structure must be prepared to re-engineer its organizational structure to facilitate effective knowledge management.

IV. 3 Relationships Among the Factors

Table-2 presents the links among the factors of KM benefits. Column 1 presents the pairs of factors and corresponding direction of links. Information on perceived causal links was sought during the interview process and was extracted from the interview scripts via content analysis. For example, “EI & EB” in row 1 of Table-2 represents that “External Inspiring factor” (EI) impacts “Expected Benefits factor” (PU), and this link has been identified in all the ten companies From this table a causal model of KMS diffusion can be traced for different companies.

IV. 4 A Combined KM Benefits Model

Figure-1 presents the combined model of KM Benefits which has been developed selecting the variables and links mentioned by at least 2 companies. Looking at Figure-1, it is observed that the basic KM Benefits model of “External Factors” → “Expected Benefits”, which was obtained from the literature, applies quite effectively for KM. However, it must be highlighted that the factors and variables are different and very specific to KM practices in SMEs.

IV. 5 Research Implications

Figure-1 presents the comprehensive model of KM benefits. This model is unique in the sense that it has been developed based on the data obtained from ten interviews in ten different companies. Although no formal propositions are developed in this paper, the model can still be taken as a research model for further investigation. For example, a causal modeling approach (structural equation modeling) can be undertaken to test the model. Figure-1 would serve as the basic research model for further exploratory research to develop and test appropriate research hypotheses.

IV. 6 Managerial Implications

Figure-1 also presents a practical model of KM benefits. All the factors/sub-factors and variables have been obtained from the real world. Companies planning to embark on KM can consider the variables of Figure-1 as “criteria” of successful implementation of KM. It must be noted that not all criteria of Figure-1 will be applicable for all companies. A careful analysis is first needed to select the appropriate criteria for the company.

V. Conclusions and Future Study

This paper presents a comprehensive study to determine the factors and variables of KM benefits. In doing so it takes a qualitative field study approach. Six companies took part in the study, which resulted in eight interviews with key person(s) in the companies. The participating companies were in various stages of KM practices. The interviews were transcribed by the researchers and the contents were analyzed thoroughly using a structured process. The analyses resulted in six factors and 52 unique variables. Company specific individual diffusion models were first developed which were then combined to develop a comprehensive KM benefits model.

Five variables identified to be significant for KM success were: “Competitive Pressure”, “Customer Demand and Expectation”, “Top Management Support/ Leadership”, “Organizational Structure”, “Organizational culture”, and “Top Management Support”. These variables were mentioned by all the ten companies. Organizations planning to embark on KM or currently practicing some parts of KM should look into these variables carefully for successful implementation of KM.

This study contributes to the KM literature in the following ways. It used a qualitative research method to develop the factors, variables and comprehensive model. The research was thus exploratory in nature. It must be mentioned that most of the existing research in KM are quantitative in nature, i.e., hypothesis testing confirmatory type. The comprehensive model can be used to undertake further research and thus add value to the literature on knowledge management. The paper elaborated on how the combined model can be used to undertake further research and how it can also be used for practical applications in companies which are embarking on KM.

The researchers’ future plan is to study the combined

model further using a structural equation modeling approach. This part of the research will use a quantitative approach, which will test a number of hypotheses and the model itself.

Abstract: This research intends to identify the differences and similarities of knowledge management in Large organizations and Small and Medium size enterprises (SMEs). Primary data were collected by interviewing five large businesses and ten SMEs. Besides the academic contribution to the field of knowledge management, this research will be able to provide applicable and practicable suggestions on the knowledge management practices to businesses in Australia.

Keywords: Knowledge Management, SMEs, Australia, Qualitative Methods, Content Analysis

I. Introduction

Knowledge management is not new. Human beings have been practicing knowledge management as early as 4,000 years ago when the earliest civilization evolved [44]. Knowledge management refers to a systematic and organizational specific framework to capture, acquire, organize, and communicate both tacit and explicit knowledge of employees so that other employees may utilize them to be more effective and productive in their work and maximize organization's knowledge [1] [11]. Knowledge management includes four knowledge processes: knowledge creation, knowledge storage, knowledge distribution, and knowledge application [1] [43].

Literature has defined knowledge management (KM) in a number of ways [5] [7] [8] [14] [22] [34]. For example, Carayannis [6, p. 219] suggests that knowledge management "can be viewed as a sociotechnical system of tacit and explicit business policies and practices. These are enabled by the strategic integration of information technology tools, business processes, and intellectual, human, and social capital". Wiig [43, p. 458] defines knowledge management as "the field of deliberately and systematically analysing, synthesizing, assessing, and implementing knowledge related changes to attain a set of objectives". Sveiby [38, <http://www.sveiby.com/articles/IntellectualCapital.html>] describes knowledge management as "the art of creating

value and form an organization's intangible assets". Sarvary [33, p. 95] defines knowledge management as "a business process". It is the process through which firms create and use their institutional or collective knowledge. Saffady (1998, p. 3) views knowledge management as "the systematic, effective management and utilization of an organization's knowledge resources". Malhotra [21], <http://www.brint.com/interview/maeil.htm>) defines knowledge management as "Knowledge Management caters to the critical issues of organizational adaption, survival and competence in face of increasingly discontinuous environmental change. Essentially, it embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings". American Productivity & Quality Center [3, p. 7] views knowledge management as "the strategies and processes of identifying, capturing, and leveraging knowledge to help the firm compete".

In this study, the definition by Ruggles [31] is adopted, which is as follows:

"KM is.... an approach to adding or creating value by more actively leveraging the know-how, experience, and judgment reside within and, in many cases, outside of an organization." [31, p. 80].

This definition highlights important elements of knowledge management. The "know-how" aspect of KM emphasizes the "explicit" knowledge, which can be easily captured and codified [5]. On the other hand the "experience" and "judgment" aspects of KM reflects the "tacit" or "implicit" knowledge, which is difficult to capture and formalize [5]. The definition also emphasizes that primary purpose of knowledge management is to add or create "value".

Based on the literature [2] [18] [26] [29] [30] [35], knowledge basically can be divided into two categories: tacit knowledge and explicit knowledge. Some common applications of tacit knowledge are problem solving, problem finding, and prediction & anticipation [18]. Tacit knowledge basically consists of two dimensions: cognitive and technical elements [26]. The cognitive dimension of tacit knowledge refers to "mental models", which assist human beings in interpreting and understanding the world around them; individuals' perspectives, beliefs, and opinions are

some examples of tacit knowledge [26]. The technical element of tacit knowledge includes things such as know-how, crafts, and skills [26]. Tacit knowledge is personal and context-specific; therefore it is more difficult to formalize and communicate [26]. Contrasting to tacit knowledge's subjective nature, explicit knowledge is more objective and generally can be codified or documented in formal or systematic format [26]. Information in the databases, library, and Internet are some examples of explicit knowledge. Tacit knowledge has much higher value than explicit knowledge since people always know more than they can tell [37, p. 34] [25]. Furthermore, in order to apply explicit knowledge in practices, it must be converted to the tacit knowledge [25]. For example, students have to understand the knowledge, i.e., concepts, definitions, theories, formulas, they learn in the classroom and books before they can apply them to interpret, understand, and solve the problem in reality.

A lot of research has been done on the knowledge management in large organizations. However the literature on the knowledge management in comparison between large businesses (more than 200 staff) and SMEs (less than 200 staff) is very limited. This research is aimed to address this gap. This research investigates the knowledge management practices in SMEs in Australia. This study addresses the following research questions:

- (i) to identify significant factors of knowledge management in large and small & medium businesses
- (ii) to identify the differences and similarities of these significant factors

II. The Operation of Field Study

II. 1 Qualitative Research Paradigm

The paradigm of the research is qualitative, in which field study has been used as the research method [28] [45]. The field study adopts a semi-structured interview approach to better understand the participants' views on knowledge management. The literature review provides the framework for developing and refining the interview questions. It is very common to get qualitative data through interviews. Evidence exists that the interviewing has been used as an effective tool to collect data for thousands of years [42]. Like any other research method, field study involves choosing a sample of companies using either random or non-random method [45]. The details of the field study research process are presented in the subsequent sections below.

II. 2 Sample

A convenience sampling procedure was undertaken to select companies who were willing to be included in the field study. It is noted that convenience sampling is frequently undertaken in business research [45]. Main selection criterion was that the companies must be involved in various stages of knowledge management. Five large businesses and ten small and medium size companies took part in the study. At least a key person in the company, who has the

knowledge of knowledge management, was contacted for interview.

II. 3 Data Collection

Semi-structured interview technique was used as the primary vehicle to collect data. The interview plan followed the guidelines of Whiteley et al. [42] and Patton [28]. The final interviews was scheduled as per the convenience of the interviewees, so that there will be minimum disruptions and interruptions in their working schedules. A pre-interview session was conducted first via telephone, which provided each interviewee an idea about the interview process and gave them some food for thought. Each interview lasted for about one hour. With the permission of the interviewees, each interview was recorded using a micro-audio recorder. Each interview was transcribed the following day in order to reflect on the body language and other non-verbal cues fresh from memory.

II. 4 Data Analysis via Content Analysis Approach

One of the challenges in qualitative research is data analysis. A number of tools and techniques are available in the literature [23]. These tool(s) must be selected based on the objectives of the research. Since the research in this stage was more exploratory than confirmatory in nature, "content analysis" was chosen as a method in analyzing the interview transcripts [4]. Two-stage content analyses was carried out for data analysis. Stage one dealt with single interview transcripts, while stage two dealt with cross interview transcripts [23].

III. Results and Discussions

III. 1 Demographic Information

Table-1& 2 presents the demographic information on the companies involved in the field study. It is noted that among 10 SME participants (see Table-2) there are two community services clubs, tourism and hospitality service, two real estate services, two health services, two education providers and one IT firm. The size of the company varied from 7 staff to around 200. In the meant time, among five large business participants there are two government organizations and four private companies (one mineral resource, one consulting, one engineering and one software development). Size of the company varies from 200 staff to over 4000 staff. One private company and one public organization have knowledge manager or chief knowledge officer on board. All companies are involved in various stages of knowledge management Table-1& 2 also presents the interviewees' positions in their organizations.

III. 2 Significant Factors of Knowledge Management

Table-3 presents significant factors of knowledge management for both large and S&M businesses. The six significant factors of KM for SMEs, chosen by all ten companies, are: "*Competitive Pressure*", "*Customer Demand and Expectation*", "*Top Management*

Support/ Leadership”, *“Organizational Structure”*, and *“Organizational culture”*. The four significant factors for large businesses, chosen by all five companies, are: *“Organizational Culture”*, *“Organizational Structure”*, *“Top management support”*, and *“Benefits to individuals”*.

Table-3 Significant Factors of Knowledge Management

	SMEs	Large Businesses
External Factors	Competitive Pressure Customer Demand and Expectation	
Internal Factors	Top Management Support/ Leadership Organizational Structure Organizational culture	Organizational Culture Organizational Structure Top management support Benefits to individuals

IV. Interpretation and Discussion

IV.1 External Factors

SMEs Participants of the field study felt that their companies' initiative on knowledge management have been ignited by the tough competition and intensive competitive pressure in the market place and challenges from customers, who are demanding more value-for-money and expecting better services. Organizations exist within an “open” environment where external influences such as changes in the marketplace influences internal operation [24] [41]. Through fostering collaborative practices and knowledge sharing, knowledge management facilitates the learning about the external environment [17] and the implementation of a successful change management program responding to the external environment [24]. The organizations are implementing knowledge management to learn and respond to their customers better. Through effective knowledge management programs, businesses is also able to provide more enhanced or/ and new products and services. Literature, such as Alavi & Leidner 1999 [1]; suggest that knowledge about customer and customers are most important knowledge domains for businesses. In the mean time, 3 out 5 participants from large organizations also indicated the importance of Competition and Customer Demand.

IV.2 Internal Factors

Management Support

Management and leadership play critical roles in knowledge management [27], which is shared by both large and S&M businesses. Management provides vision and energy to stimulate and sustain effective knowledge management

practices and systems. Leaders have direct impact on the organization's culture and its knowledge management approaches. Without management's commitment and emphasis on knowledge management, people won't take it seriously [12]. Those at the top of an organization should have to find the knowledge needs of the business. Simply investing money in IT only can produce more examples of KM failures and waste of investment. Leaders have to take account issues such as culture, structure, process, training and development. More attention should be given to people since businesses make profits through selling and effectively using their knowledge (tacit knowledge) [19] [36]. One important challenge for leaders is how they can embed knowledge into people's day-to-day work to help them do their jobs more effectively and efficiently [20]. Besides being role models for learning and knowledge sharing, leaders are responsible for creating a climate of trust where people can share knowledge with confidence [27]. All the interview participants express the view that support from top management, i.e., understanding the importance of knowledge management, commitment, leadership, is crucial for the success of knowledge management s in organization. For example, the leadership process in General Electric (GE) is all about sharing knowledge and creating knowledge. The top management in GE has focused on the importance of sharing knowledge. The knowledge sharing practice starts at the top [19].

Organizational Culture

All the participants (both large and S&M businesses) of the field study share the importance of organizational culture, which influences the effects of other factors (i.e., technology, management practices) of knowledge management practices [39], in contributing to the success of knowledge management. Organizational culture has been increasingly recognized as a major barrier to knowledge management [13] [15]. Organizations have to create an environment where people feel comfortable and are willing to share their knowledge. A knowledge-oriented culture challenges people to share knowledge throughout the organization [10] [24]. In the mean time, the benefits of knowledge management need to be demonstrated, and knowledge-sharing practices should be rewarded with tangible (i.e., financial rewards) and intangible (i.e., recognition) incentives [12].

Organizational Structure

There is a general agreement among SMEs and large business participants that organizational structure facilitates the knowledge sharing and cross-boundary collaboration. Organizations with flexible and organic structure are more likely to achieve the perceived benefits of knowledge management than those organizations that are rigid and bureaucratic [15]. Organizations with a rigid structure must be prepared to re-engineer its organizational structure to facilitate effective knowledge management.

Benefits to Individuals

The factor, *benefits to individuals*, is perhaps most important for the success of KM. "What's in it for me" is always a popular comment by individuals when any new venture is initiated in an organization. Individuals will not buy into knowledge management if they can't identify clear benefits in using it. Although this factor was highlighted by all large business participants, it was not considered important by all SME participants.

IV. 3 The Role of Business Size in Knowledge Management

Past research has reported the impact of size in the adoption of technology. For example, Thong [40] reports that organizational size is positively related to the organization's adoption decision of information systems. Dasgupta et al. [9] report that larger organizations are more likely to adopt information technology. Sarvary [33] suggests that large firms with large customer base tend to perceive a KMS more useful and have a better chance to apply KMS to build sustain competitive advantage.

The results of this study basically indicates basically there is no major difference in significant factors of KM between large and S&M businesses across different industry. So does the concept of KM. In today's highly competitive market environment, all the companies have to practice knowledge management and it is quite impossible to survive the severe competition without managing knowledge in the knowledge economy. Perhaps larger companies are practising knowledge management more consciously and systematically than smaller businesses. And the former could also use more or more advanced IT technologies to manage their knowledge.

V. Conclusions and Future Study

This paper presents a comparison study of knowledge management between large and small & medium businesses. In doing so it takes a qualitative field study approach. Fifteen companies took part in the study, which resulted in eight interviews with key person(s) in the companies. The participating companies were in various stages of KM practices. The interviews were transcribed by the researchers and the contents were analyzed thoroughly using a structured process.

Three variables identified to be significant for KM success in both SMEs and large businesses were: "*Organizational Structure*", "*Organizational culture*", and "*Top Management Support*". These variables were mentioned by all the companies. Organizations planning to embark on KM or currently practicing some parts of KM should look into these variables carefully for successful implementation of KM.

This study contributes to the KM literature in the following ways. It used a qualitative research method to develop the factors, variables and comprehensive model. The research was thus exploratory in nature. It must be mentioned that most of the existing research in KM are

quantitative in nature, i.e., hypothesis testing confirmatory type. The comprehensive model can be used to undertake further research and thus add value to the literature on knowledge management. The paper elaborated on how the combined model can be used to undertake further research and how it can also be used for practical applications in companies which are embarking on KM.

The researchers' future plan is to develop a model of knowledge management success and test the moderating impact of size and other factors such as industry sector, business models, etc. This part of the research will use a quantitative approach, which will test a number of hypotheses and the model itself.

Information Technology Management at a Religious Organization

Albert Huang
Eberhardt School of Business, University of the Pacific
Stockton, California, USA 95211
EMAIL: Ahuang@Pacific.Edu

Abstract: Religious organizations face many of the same problems that business organizations face. The study describes information technology management issues facing a mid size religious organization, and the process it went through to organize its knowledge management efforts.

Keywords: Knowledge management, religious organizations, information systems.

I. Introduction

Religious organizations face many of the same problems that business organizations face. Administrators of religious organizations perform many functions business managers perform. Therefore, they face similar information technology management challenges faced by regular for profit businesses. This case study reports challenges facing a midsize religious diocese and its many parishes located in the United States and recommendations made by a team of external consultants.

II. Background

The diocese is located in a western state in the US. It comprises several counties and covers over 10,000 square miles. The total population in the diocese exceeds one million people. The number of members of the diocese is more than 200,000, almost twenty percent of the total population. There more than eighty priests assigned to various parishes in the diocese. In addition to a wide geographical coverage, the diocese is also ethnically diverse.

To facilitate management and administration, the diocese has adopted computer technology to help manage information. In the past decade, the diocese manages and supports an internal computer network with typical productivity tools to assist with the daily operations of the organization. The diocese has a website that provides a large amount of information to its members and the public. While the diocese is fulfilling its fundamental mission for the church, it has been challenged with growth and limited resources to

manage the information interdependency among its parishes, parishioners and its governing organizations.

III. Current Technology Status

Proper technology to facilitate better communication between the diocese and parishes is a high priority. Currently, a variety of communication methods are used. Most parishes rely on low-tech channels, such as postal service, telephones, and fax machines. Only a small portion use e-mail frequently.

Slightly more than 50 percent of parishes have their own Web pages. The majority of parishes own more than five computers. Two-third of the parishes has local area networks. A variety of software applications are used for various purposes.

IV. Initiative

The bishop of the diocese decided to employ an external consulting group to look into the technology infrastructure of the diocese and make recommendations to improve its information technology and information management. The consultants were brought in to meet with the top administrators and survey the parishes. The existing systems, users, and applications were analyzed.

V. Results

After detailed information gathering and analysis, the consultants made a series of recommendations:

1. Automation in parishes
2. Create a centralized file server at the diocese
3. User training
4. Establish a virtual private network between parishes and the diocese
5. Replace some existing applications with new ones that facilitate information exchange with other applications

Key Elements in an Effective Knowledge Management System: A Case Study Approach

Extended Abstract

Increasingly knowledge is acknowledged to be the most important resource in organisations. There is evidence in the literature that suggests that as organisations use knowledge effectively in their day-to-day operations they become more successful and therefore more valuable than their competitors who do not.

Knowledge management is important for several reasons. First, knowledge management literature argues that knowledge has become a significant competitive tool (Rowley, 1999). Many acknowledge that in today's knowledge-based economy, knowledge, rather than capital and labour, is the "only meaningful economic resource" (Drucker, 1993, Webber, 1993) or "their most valuable and strategic resource" (Zack, 1999). Second, managing knowledge is significantly different from managing other organisational assets. Stewart et al. (2000) argue that knowledge assets are different to physical assets with respect to three characteristics, namely, life, scope, and maintainability (Stewart et al., 2000). It follows that traditional physical asset management know-how may not be readily transferred to knowledge management. In addition, Sunassee & Sewry (2002) argue that the collective knowledge of an organisation's employees is a critical resource to an organisation and managers need to know how to manage it. Third, knowledge management is important because today's business environment is highly competitive. With an ever-changing customer needs and technology, organisations need to have the appropriate information and knowledge at the right time if they are going to make proper decision in a timely fashion (Sunassee and Sewry, 2002). However a review of knowledge management literature suggests that there are a number of issues where research is still at its infancy and which require further investigation. Some of these issues are highlighted in this section. Thus the aim of this paper is to identify the gaps in the literature and provide an agenda for further research.

To begin, knowledge can be defined as 'a symbolic representation built into basic primitives that can be manipulated by rules' and is based on the meaning of *data* and *information* (Spiegler, 2000). Information that is acted

upon and results in decisions and actions which add value to the organisation is knowledge (Kanter, 1999, Spiegler, 2000). The difference between information and knowledge is the same as the difference between *knowing-that* and *knowing-how* (Ryle, 1949). Taking one step further, knowledge management is a systematic process with the purpose of acquiring, organising, both tacit and implicit knowledge (Alavi and Leidner, 1999) to enable other employees to use the collected information in order to be more effective and productive (Alavi and Leidner, 1999). Thus, knowledge management is essentially creation and sharing of organisational knowledge, which is very important because it may determine an organisation's ability to establish and sustain competitive advantage (Grant, 1996).

In order for knowledge management to be efficient automated systems may be required. A knowledge management systems facilitates collecting, codifying, integrating and disseminating knowledge in an organisation (Alavi and Leidner, 1999). The main feature of knowledge management systems is that they can improve the capability of organisations to be more flexible and responsive to changing market conditions. In their survey of 109 respondents in several organisations in 12 countries around the world, Alavi & Leidner (1999) found that an "integrated and integrative technology architecture is a key driver for KMS [knowledge management system]" (p. 22). Specifically, this technology architecture consists of database and database management, communication and messaging, and browsing and retrieval (Alavi and Leidner, 1999). According to Alavi & Leidner (1999) the knowledge management systems are perceived to have a deep impact on organisational processes in terms of enhanced communication, and process efficiency leading to overall enhanced financial and marketing outcomes.

Knowledge management literature highlights that there are several important factors that need to be considered when knowledge management strategies are designed to ensure that knowledge flows effectively and efficiently within the organisation in order to carry out its vision and goals. First, knowledge management strategies should be consistent with the overall organisation business strategy if it is going to provide an organisation with a competitive edge (King, 2001.). Second, people and their contribution are seen as an important component in the knowledge management initiatives of an organisation (Bhatt, 2000). Specifically, top-

management support and employee commitment are key factors. Third, technology also plays an important role because it provides the means and the infrastructure necessary to accomplish knowledge management outcomes.

There appears to be agreement in literature suggesting that knowledge management initiatives should be people-rather than technology-centric (Vandenbosch and Ginzberg, 1997). This is because while technology can at the very best help convert data into information, only people can ascribe 'meaning' to that information turning it into knowledge. On the other hand, technology enables more effective knowledge management (Alavi and Leidner, 1999). In addition, different people in an organisation are likely to deduce different meanings from information. Therefore, over-emphasizing either people or technology or both may not be sufficient for knowledge management strategies to be successful. The interaction between people, technologies and the techniques people apply in exploiting these technologies may be one of the critical success factors of knowledge management strategies (Bhatt, 2001). The success of this interaction depends on organisational culture (Srinivasan, 2004) and will integrate different realities into a unique body of knowledge in the organisation allowing the organisation to act with a "collective mind" (Weick and Roberts, 1993). However a review of knowledge management literature suggests that there are a number of issues where research is still at its infancy and which require further investigation. Some of these issues are highlighted in this section. First, how can knowledge management effectiveness and benefits be measured. This is important because without effective measures it is difficult to conduct cost-benefit analyses and consequently determine the effectiveness of knowledge management investments. Yet, measuring knowledge management benefits can be a difficult task because often knowledge management outcomes are social and only impact organisational profits indirectly (de Gooijer, 2000). Second, given the importance of knowledge management and the need to cultivate a related culture,

organisations need to 'move beyond knowledge pull into knowledge push' (Ezingeard et al., 2000). This suggests that individual knowledge needs and knowledge profiling are important if individuals are to accept the new knowledge management culture (Ezingeard et al., 2000). Third, given that many organisations (e.g. Ernst & Young, etc.) are global, the pressing issue is how such organisations can globalise their knowledge management initiatives in order to gain competitive advantage. Further research is needed in these areas (Eriksson et al., 2000).

A Knowledge-Based Innovation for High Technology Industries and Applying to Cross Strait Marketplaces

Chen Te Fu

Lecturer, Cheng Shiu University, Taiwan

Ph.D. Candidate, School of management

University of western Sydney, Australia

Email: phd2004_05@yahoo.com

Abstract: The study discusses after China and Taiwan has finally cleared all the hurdles to gaining World Trade Organization (WTO) membership, joining in November 2001. However, foreign investors in China are increasingly embroiled in disputes with Chinese companies due to innovation barriers. Besides, after China and Taiwan joint WTO, high tech industrial competition faces globalization and digitalization two big problems. Therefore, this paper examines the notion that China's and Taiwan's entry into the WTO and their innovation reforms in line with globalization and digitalization have a significant impact on the entire system of knowledge-based innovation management.

Firstly, the study reviews innovation through a knowledge-based theory lens in the innovation supporting processes to construct a research framework. Internally, the supporting innovation processes include knowledge and technology innovation, Managing & organizing innovation. Externally, the supporting innovation processes include inter-organization networks, innovation networks and e-knowledge networks and cooperation innovation.

Secondly, the study through case studies critically investigates the supporting processes of innovation management in China and Taiwan in the context of their WTO entry, and puts forward exploratory ideas that may assist in creating a blueprint for deepening China's and Taiwan's innovation reforms. Under knowledge based and digital economy, how to overcome barriers of knowledge based innovation over the cross-strait and global markets are the most key factors for firm's survival. To answer these questions, in this paper, a more complete integrated innovation model and knowledge based innovation supply chain (KISC) for exploring and determining innovative supporting process in high tech industries and applying to cross strait (China and Taiwan) marketplace is presented. The results of the study will benefit not only the construction of knowledge based innovation framework, but also the business model transformation of competitive advantage.

Keywords: Knowledge management, innovation, high technology, ISC, WTO.

I. Introduction

I.1 Background and Motivation

Stepping into knowledge economy in 21 century, after almost fifteen years of lobbying and negotiation, China and Taiwan have finally cleared all the hurdles to gaining World Trade Organization (WTO) membership, joining in November 2001.

In response to the intensification of global competition, many firms throughout the world have developed international operation strategies to establish a worldwide production, distribution, and marketing network. Investments in manufacturing in China are frequently made due to the strategic benefits that they can bring. Fast economic growth, low labor costs, and a potentially huge domestic market have all led to significant increases in foreign investment in the People's Republic of China. Taiwan is the most investment country in China and its economy and high tech industries also is the most significant impact on cross strait (China and Taiwan) markets.

China has one of the world's largest untapped reservoirs of inexpensive labor, the importance of China's labor force is not just in its sheer size, but in its quality, which is improving steadily as a result of the training and educational reforms being introduced throughout the country. Over 14 million Chinese are employed in enterprises created by foreign investment, and more than one hundred Fortune 500 companies have operations in China. Dynamic technological advances and rapid economic globalization have changed China's international business climate to a significant extent. In future, China may influence the world as a source of raw materials, as an international manufacturing center, and as a major importer and exporter of consumer products, capital goods, and high technology. A new economic order in China – the globalization of business – has both shaped and been shaped by the advancements in knowledge and innovation management that have improved the efficiency and effectiveness between markets, manufacturing processing, and resources.

China's unprecedented economic growth and globalization have strained its knowledge-economy and innovation infrastructure to the limit. Knowledge-based innovation – the movement of technology, people, processes and information – has a significant impact on a society's standard of living. The innovative process affects every sphere of human activity and business strategy. Innovation is a significant component of the competitive advantage most enterprises incur, as life cycle of products is shorter and shorter and competing in marketplace is fiercely more and more, particularly in high tech industries. Efficient innovat-

ion management involves a successful integration of knowledge and technology that facilitates the innovative processes of products to the consumers at the right time and right place in accordance with consumer needs. As an increasing number of foreign manufacturers are establishing joint ventures in China, the demand for higher quality innovative management is growing tremendously. The reason for this growth in demand is simple: if foreign companies encounter too many innovative problems and barriers in China, to the extent that the total costs of utilizing China as a manufacturing base become too high when compared with other nations, then China will be excluded from a foreign firm's global manufacturing network.

However, foreign investors in China are increasingly embroiled in disputes with Chinese companies due to knowledge and innovation barriers. With continual innovation reforms, there are tremendous opportunities to fundamentally improve the knowledge-based innovation theory and practice. But the existing literature reveals very little systematic research in this area from the knowledge-based perspective.

In other side, during past twenty years, the most successful two high tech industries are IT industries and semiconductor industries. These two industries represent Taiwan's successfully turn around from labor intensity to capital intensity and technology intensity of high tech industries.

Nevertheless, Taiwan also faces three big problems:

1. The most industries move into China even though high tech industries.
2. Economic decline is increasingly
3. The jobless problems are serious increasingly. Recently, large volumes of industries were shifted out to China for survival even though high tech industries. The large markets and cheap labor cost is attracting for Taiwan's industries. But China this "resource black hole" will inhale how much Taiwan's industries and related resources is the big problem and dilemma for government and industries in Taiwan.

Facing the shifting of Taiwan traditional and high tech industries, the unique development of Taiwan's industries is to develop new domain just can create next wave's industrial survival space. Just like twenty years ago, Taiwan has used PC to replace calculating and game machine.

Taiwan's high tech industries have their advantage, if they could implement continue innovation, sustainable acquiring new knowledge, create new knowledge and applying new knowledge, the they must can sustainable develop successfully.

In these two years, many multinational corporations create innovation and R&D center in Taiwan. For example, there are Dell, HP, Sony, IBM and Microsoft and so on. Under fiercely competitive high tech industries environment, they have willing to invest in Taiwan are because Taiwan has many advantage of high tech industries as below.

1. Complete IT industrial supply chain. Industrial high "group gather degree" and own quickly logistics abilities, thus to form advantage of economic scale. It can decrease competitive cost.

2. Taiwan owns high quality R&D and production manpower and the advantage of lower R&D cost.

3. During past 30 to 40 years, many Taiwanese in USA are CEO or Boss of USA high tech industries. After their life and business are developed until mature term, many of them emerge minds to go back Taiwan.

4. The global main consumer markets is increasingly shift from northern America and Europe to Asia, Taiwan owns the advantage of nearing markets and it can provide integrated system services from designing, developing to manufacturing.

5. Taiwan government promotes supporting of industrial policy. It supply large R&D allowances and preferential of encouraging industries...and so on.

6. In 1990, USA has shifted out their production; this gave strong chance for Taiwan's high tech industries. Currently, USA starting to shift out R&D, Parent companies of USA focus on marketing and brand. This gives chance for turning around and upgrading for Taiwan's high tech industries again.

Base on above advantages, Taiwan's high tech industries need to start integrating design and R&D of USA and Japan and to create Taiwan as a "knowledge based innovation" center for supporting corporate innovation among cross-strait market. Furthermore, to extend Taiwan's high tech industries from "manufacturing style" to "innovation R&D style" and to develop value added of product even though to create own brand. Then Taiwan's high tech industries just can walk toward another milestone under large pressure of industrial shifting out to Mainland China.

1.2 Research Problems

Despite the attractive low cost environment, foreign companies and investors may still find it unprofitable to operate in China should there be serious problems in getting innovative sources to the factories and products to the customers in good condition and on time. Evidence from the literature reveals that foreign manufacturing operations in China do not find the innovative resources provided by Chinese enterprises satisfactory. Therefore, the most important issue will be which resources of innovation supporting processes are necessary to manage innovation in the knowledge intensive industry like high tech industries after China's and Taiwan's entry into the WTO?

According to abovementioned, the study assumed there are five research problems as follows:

1. How to through the advancements in knowledge and innovation management to improve the efficiency and effectiveness in cross strait markets, manufacturing processing, and resources?
2. How to acquire the supporting innovative resources from inside and outside of high tech industries?

3. How to through innovation supply chain to help Taiwan's high tech industries to maintain sustainable competitive advantage and reengineer from past manufacturing center to innovative research & development center.
4. Which resources of innovation supporting processes are necessary to manage innovation in the knowledge intensive industry like high tech industries after China's and Taiwan's entry into the WTO?

How to develop a complete integrated innovation model to reach above goals.

I. 3 Research Objective

In future, China may influence the world as a source of raw materials, as an international manufacturing center, and as a major importer and exporter of consumer products, capital goods, and high technology. A new economic order in China – the globalization of business – has both shaped and been shaped by the advancements in knowledge and innovation management that have improved the efficiency and effectiveness between markets, manufacturing processing, and resources. According to the best market place nearing position and large volumes of high tech talent, Taiwan should be changed from past manufacturing center to innovative research & development center. This strategy could help Taiwan and China to acquire win-win situation.

As one of the most important points of knowledge, innovation organizations should embody the ability to create, disseminate and transfer knowledge. Organizational innovation should be a major prerequisite for other innovations. This has special significance for innovation organizations. However, there is an urgency to study the best structure, management methods and functions of organizations in order to establish a healthy research atmosphere and create a new culture of innovation organizations.

The main objective of the study is to provide a complete and practical integrated model for high tech industries and applying to cross strait (Chinese and Taiwan) markets. The existing literature reveals very little systematic research in this area from the knowledge-based perspective. With continual innovation reforms, there are tremendous opportunities to fundamentally improve the knowledge-based innovation theory and practice.

Therefore, firstly, this paper will examine the notion that China's and Taiwan's entry into the WTO and their innovation reforms in line with globalization and digitalization have a significant impact on the entire system of knowledge-based innovation management. Secondly, this paper will critically investigate the supporting processes of innovation management in China and Taiwan in the context of their WTO entry, and puts forward exploratory ideas that may assist in creating a blueprint for deepening China's and Taiwan's innovation reforms and for supporting high technology industrial continues innovation.

Finally, for reaching above goals, the study will develop

an integrated innovation model to support internal and external innovative processes for high tech industries between China and Taiwan. The objectives of the study is to provide a more complete and practical integrated innovation model to link theory and practice for high tech industries and applying to cross strait (Chinese and Taiwan) markets.

II. Literature Review

II. 1 Sources of Innovation

The foremost management consultant of our time, Peter F. Drucker [52], promoted a provocative concept on how to make a profit: "Because its purpose is to create a customer, the business enterprise has two--and only two--basic functions: marketing and innovation. Marketing and innovation produce results: all the rest are 'costs'." He further taught that bright ideas are the riskiest and least successful source of innovative opportunities. Instead, he advised the systematic, managed, purposeful and organized search for changes and the systematic, managed, purposeful and organized analysis of the opportunities such changes might offer for innovation.

He said that to 'practice' innovation, we must be students of change, and suggested monitoring seven sources for innovation opportunities. Four of these lie within the enterprise and are primarily visible to people within that industry or service sector. Three involve changes outside the enterprise or industry. Here is a list of the seven sources, taken from his book, *Innovation and Entrepreneurship: Practice and Principles*.

1. The unexpected. The unexpected success, failure or outside event.
2. The incongruity-- between reality as it actually is and reality as it is assumed to be or as it "ought to be."
3. Innovation based on process need.
4. Changes in industry structure or market structure that catches everyone unawares.
5. Demographics-- population changes.
6. Changes in perception, mood and meaning.
7. New knowledge, both scientific and nonscientific.

John Stark Associates [35] in their innovation management articles assumed innovation sources in the future as follows (www.johnstark.com).

1. Customers' customers
2. The company's customers
3. In-house and external marketers
4. In-house and external R&D
5. The company's suppliers
6. The company's management
7. Engineering staff
8. Production workers
9. The company's competitors

II. 2 Knowledge-based Innovation

Towards a knowledge-based theory of the firm

Building on Polanyi [54] and Wittgenstein [70], Sveiby [63] [64] defines knowledge as a capacity-to-act (which may or may not be conscious).

Knowledge is dynamic, personal and distinctly different from data (discrete, unstructured symbols) and information (a medium for explicit communication). Since the dynamic properties of knowledge are most important for managers, the notion individual competence can be used as a fair synonym to a capacity-to-act.

People use their capacity-to-act in order to create value in mainly two directions; by transferring and converting knowledge externally and internally to the organization. The value grows each time a knowledge transfer or conversion takes place. The strategy formulation issues are concerned with how to utilize the leverage and how to avoid the blockages that prevent sharing and conversion. Activities that form the backbone of a knowledge-based strategy are to be aimed at improving the capacity-to-act both inside and outside the organization. (Karl-Erik Sveiby, 2001)

A knowledge-based theory for strategy formulation

It follows from the discussion above that strategy formulation should start with the competence of people. Inspired by McLuhan, Sveiby [45] [71] suggests that people in organizations create external and internal structures in order to express themselves. Most "things" in organizations are such relationships. People in an organization can use their competence to create value in mainly two directions: externally or internally. The external structure family consists of relationships with customers and suppliers and the reputation (image) of the firm. The internal structure consists of patents, concepts, models, and computer and administrative systems. These are created by the employees and are thus generally "owned" by the organization. The structure is partly independent of individuals and some of it remains even if a large number of the employees leave.

From an organizational viewpoint the knowledge has effectively doubled. Knowledge shared is knowledge doubled. The key to value creation lies in how effective these communications and conversions are and the major issue strategy for formulation is: how can the leverage be used to create value for the firm? The value creation is primarily determined by the tacit/explicit transfer of knowledge between individuals and in the conversion of knowledge from one type to another [50] as Figure 2-1. Knowledge transfer between individuals tends to improve competence of both individuals and teamwork tends to be a team co-creation of knowledge. However, it helps strategy formulation and action planning to distinguish directional components of the activities. Since knowledge cannot be managed the knowledge strategist looks at enabling [67] activities rather than command-control activities.

According to above, we can distinguish knowledge transfers, which create value for the organization. Enabling activities that form the backbone of a knowledge strategy are to be aimed at improving the capacity-to-act of people both inside and outside the organization.

The external transfer involves intangible relationships with customers and suppliers and forms the basis for the reputation (image) of the firm. Some of these relationships can be converted into legal property such as trademarks and brand names. The value of such intangible resources is primarily influenced by how well the company solves its customers' problems. The internal transfer relates to explicit administrative processes, internal networks, organizational culture and the competencies of individuals. [64]

Knowledge-based theories are the key to explain determined firms' behaviours such as:

1. Strategic alliances [32]; [37];
2. Mergers and acquisitions [6];
3. Firms' internationalisation [34];
4. Diversification [51]; or
5. Production plants' competitiveness [38].

The genesis of knowledge-based competition

Two intertwined strategic forces are compelling companies to reconsider fundamental business assumptions. These are, first, globalization and, second, digitization with connectivity brought about by revolutions in information processing, telecommunication (or infocom) and Internet technologies. These two forces - more aggressive global competition and accelerating technological change - translate into competition that is increasingly knowledge-based. This increasingly knowledge-based nature of competition is driving change in how value chains are being managed within and across firms. Managers will certainly have to augment their ability to manage diversity, complexity and ambiguity in employee, supplier and customer relationships in the New Economy.

The new management imperatives

Driven by these two forces, we are in the midst of an economic transition from an era of competitive advantage based on information to one based on knowledge creation. Today, intangibles such as customer service, innovation, speed, agility, etc. are more important than tangibles such as equipment, materials and hardware. To survive in the knowledge economy, new business models must be created, because many business axioms of the old economy are no longer applicable. Scarcity is a non-issue for digital assets. As such, the competitive dynamics of digital products differ greatly from that of physical products. In cyberspace, new economies of scales and economies of scope prevail [36].

A firm's performance depends on how much its managers can mobilize the knowledge resources individuals and teams in its value chain and how well they can turn these resources into activities that lead to value creation in hyper-competitive markets. Challenges presented by the knowledge economy make it necessary for organizations to harness the competencies of its knowledge workers, customers and suppliers, if sustainable competitive advantage is to be achieved as figure 2-1. [36]

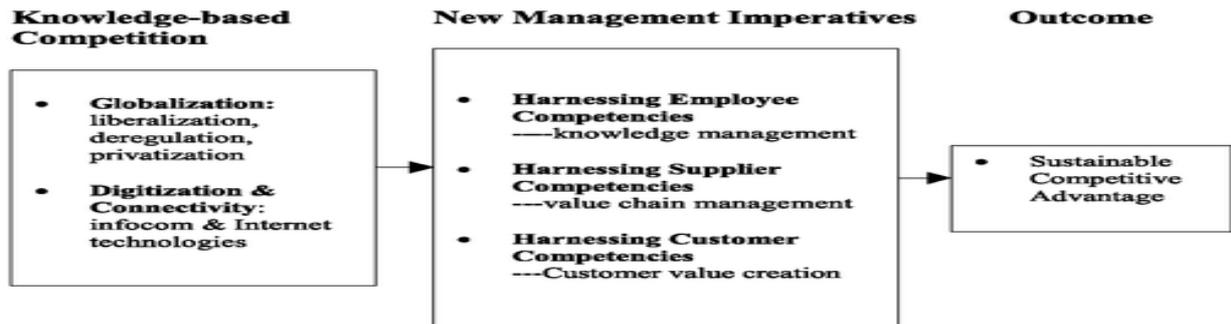

Figure 2-1: New management imperatives Source: [36]

Josephine Chinying Lang, [36] argues that there are linkages between aspects of the New Economy, including globalization and digitization, knowledge generation and competencies. Harnessing worker, customer and supplier competencies within the context of knowledge-based competition is the response called for.

The coming of globalized knowledge-based competition demands that management must attend to its knowledge workers, suppliers and customers in a new way. The real value of information systems lies in connecting people to people to enable them to share what expertise and knowledge they have at the moment, given that cutting edge knowledge is always changing. The solution is not to try to warehouse everything your workers ever knew but to connect questions to answers or to people who can help you find answers.

II. 3 Knowledge and Innovation in High Tech Industry

The study chose Markusen *et al.*'s [42] definition of high-tech, which is based on the percentage of high "human capital" jobs in an industry. High human capital jobs include engineers, technicians, scientists, mathematicians or some combination thereof. By this definition, there are 100% high-tech industries. One of the most important advantages of this definition over others is that human skills highly correlate with other indicators of "technological" performance, such as R&D [4], stock of capital, information intensity and, more importantly for the study, innovations.

In high tech manufacturing firms, the increasing importance of innovation in which knowledge turns into the main source of competitive advantage [47]. The importance of knowledge as a source of competitive advantage is still higher for those sectors on which innovations are being continually developed [18]; [53]. Also, knowledge management is crucial for successful launching of new products [40] and for the innovation process [56]. Therefore, organizations base competition on efficiency when acquiring [50], transmitting and integrating [71] and applying [62] knowledge.

Innovation in high tech firms is progressively turning into a systematic process, especially for determined high tech industries such as electronic products. Specific departments for management of R&D activities are created.

Also, a higher contact with customers increases the role that customers play in the innovation process [14]. Therefore, both R&D departments and customers become the main source of inputs for innovation.

However, innovation patterns in high tech manufacturing is for organizational and process innovations. The impossibility of patenting this kind of innovation and, therefore, protecting the returns generated out of these innovations shortens the life cycle of innovations dramatically [3]. Hence, the innovation process must be intensive because innovations are implemented and copied at such a speed that continuous innovation efforts are required to keep up with a determined degree of differentiation in order to support the firm's strategy [68].

Today, economic competition has become increasingly important in international commerce. High-tech dominates economic competition. Governments around the world realize that only by strengthening technological innovation, possessing their own intellectual properties and grasping high-tech resources can they take the initiative in economic competition. So, technologically advanced countries adopt various policies to protect their intellectual property rights. They try to achieve a market monopoly through a technology monopoly. It is spurring the public to place greater value on knowledge-technological resources. They realize that in the future world knowledge is the most important basis for economic growth. A country's "capability of creation, distribution and use of knowledge" will become the core of its competitive power.

In knowledge-based hyper-competitive markets, sustainability of competitive advantage will depend on a firm's innovative capacity. The rapid creation and diffusion of knowledge within and between firms have thus become a top priority for management, because it is now recognized that knowledge is the only real source of sustainable competitive advantage. That is, a firm's performance depends on how much its managers can mobilize the knowledge resources of individuals and teams in its value chain and how well they can turn these resources into activities that lead to value creation in hyper-competitive markets.

II. 4 Innovation Capacity Link between the Inside and Outside

Elson Szeto [22] assumed innovation capacity refers to a continuous improvement of the overall capability of firms to generate innovation for developing new products to meet market needs (customer needs). The capacity can be incrementally or radically increased through the participation of activities that triggers the supply of innovation resources and conversion of the resources as the knowledge base of the firm in an interactive environment [22]. The interaction is a process that provides stimulation to the firm from external sources that may be convertible into innovation resources.

Internally, a firm can further develop the innovation impulse as resources and apply it to new product development that will be turned into the knowledge base of a firm if appropriate codification is systematically implemented. Externally, inter-organizational network is an environment for the interaction and activities such as joint projects, collaborations or alliances for a specific R&D item and may benefit the participants in various degrees.

"What is unique about the way Japanese companies bring about continuous innovation is the linkage between the outside and the inside. Knowledge that is accumulated from the outside is shared widely within the organization, stored as part of company's knowledge base, and utilized by those engaged in developing new technologies and products" [50].

What "outside" environment is suitable for the development of innovation capacity of firms? Elson Szeto [22] assumed researchers of different perspectives still debate whether innovation can be generated from within firm hierarchy or from within a networked environment. Studies from a network perspective [5]; [23]; [2], inter-organizational network, becoming a new organization form, provides different stimulation through the collaborative activities with network members. Nohria and Ghoshal [49] find that the hierarchical structure of the conventional organization form was inadequate for the shift towards customization of product development and global linkages of product markets.

However, Drucker [20] suggests a systemic analysis of the possible sources to maintain "purposeful innovation" when entrepreneurs start their innovation processes within their resources and Whitley [69] looks for the governance systems that affect firm capabilities in performing various activities. The fundamental issue is how these organizational environments increase and support the firm's capacity of innovation for the continuous improvement of competitiveness, the answer is the internal and external supporting processes of innovation which reviewed as below.

II. 5 The Internal Supporting Processes of Innovation

II. 5. 1 Knowledge Management and Innovation

The innovative efforts are the right consequence of the investment in knowledge and knowledge workers. If KM is positively influenced by the search of innovations, the investments in the development of new knowledge may propel companies into new business in more rewarding

markets.

Innovative efforts have to be strategically combined with a competitive orientation and its consequent movements. This combination depends vitally on the highest level of individual knowledge and on its technological basis. Many companies are taking into account that new technologies and management approaches are changing the traditional perspective of managing intellectual resources. Knowledge acquisition, integration and application etc. knowledge management approaches can facilitate innovation, besides, we also need to consider competitors' knowledge when implement innovation. Improved techniques for knowledge integration lead to higher innovation levels [16].

KM, then, is about harnessing the intellectual and social capital of individuals in order to improve organizational learning capabilities, recognizing that knowledge, and not simply information, is the primary source of an organization's innovative potential [43]; [10]. The objective of KM can be to enhance exploitation (i.e. where existing knowledge is captured, transferred and deployed in other similar situations) or exploration (i.e. where knowledge is shared and synthesized and new knowledge is created [39]). The purpose of exploitation is to reduce problems of "reinventing the wheel" by using existing knowledge more efficiently. Although this is important for innovation, it is largely exploration through knowledge sharing that allows the development of genuinely new approaches.

However, the growing emphasis on innovation through "knowledge work" and "knowledge workers" and on the leveraging of "knowledge assets" suggests that the need to manage knowledge will endure as a core business concern, even if the label may change [20]. This is not to say that knowledge was ever insignificant - what is distinctive about the current period is that knowledge now acts upon itself in an accelerating spiral of innovation and change. Castells [10] summarizes this shift:

What characterizes the current technological revolution is not the centrality of knowledge and information but the application of such knowledge and information to knowledge generation and information processing/communication devices, in a cumulative feedback loop between innovation and the uses of innovation ... For the first time in history, the human mind is a direct productive force, not just a decisive element of a production system.

There are also clearly organizational trends which are aligned to this focus on KM in innovation. In organizational terms, the new "era" is typified by flatter structures, debureaucratization, decentralization, and co-ordination through increasing use of information and communication technologies (ICT). However, as businesses are stretched across time and space, reorganized along process or product lines, and restructured around virtual teams, they lose opportunities for innovation through the casual sharing of knowledge and learning induced by physical proximity.

Gibbons [25] notes further that "modes of knowledge production" are changing from the conventional disciplinary-based model, to a new model where knowledge is

produced interactively at the point of application among heterogeneous groups. In short, innovation processes are becoming more interactive - more dependent on knowledge which is widely distributed - therefore KM is increasingly central. Although the term "KM" may ultimately become another fad, the impetus for it is the profound problems posed by new kinds of organization and innovation.

II. 5. 2 KM, Innovation and Competitiveness

KM and the formulation of competitive strategies

In what concerns dynamic organizations, KM is a valuable strategic tool, because it can be a key resource for decision making, mainly for the formulation of alternative strategies. KM should be able to combine innovation efforts, updated IT, and knowledge development in order to achieve a set of capabilities to increase competitiveness. In fact, when this combination is adequately managed, the company can formulate competitive strategies, which integrate innovative products and new technological weapons to face its competitors [1].

In a fast-changing environment, the competitive advantage of many companies is based on the decision to exploit, to develop the power of knowledge development. To find out and exploit opportunities, companies need to establish the main orientations of KM in order to enlarge their growing possibilities based on innovation and competitiveness. If a firm is entirely aware of the vital importance of these factors, management decisions have to consider a complex background where the knowledge of the clients' needs and preferences and the competitors' strategies is decisively important. Practically, this means that a market orientation includes the concept of competitive orientation [61]; [17]. These considerations are already known and well accepted, but we need to extract from them the logical consequences. A competitive decision should be based on a wide and quite firm support, which shall integrate the different relationships among several types of knowledge. As a consequence, a comprehensive knowledge is the vital ground where competitiveness should be built.

II. 5. 3 Technology Innovation

In a study of 200 firms within the Norwegian IT sector, Johannessen, Olaisen, Bjørn [33] found that focusing on the use of IT might be a promising route for studying the relationship between IT and successful innovations, and between IT and performance. They also found a number of trade-offs between the various performance measures and between successful innovations and performance. Although they were able to find positive effects of IT they argue in favor of developing an information and a knowledge strategy prior to developing an IT strategy. Therefore, IT is only can be an enabler for innovation.

II. 6 Managing and Organizing Innovation

Based on in-depth interviews of 32 CEOs and top executives in leading European organizations, 40 people known

internationally for their ability to achieve and maintain a position among the top performers in their fields, and a "best practice study" of five leading international companies. Johannessen, Olaisen, Bjørn [33] in their innovation study pointed out, there are four entities: 1. Focus 2. Mastery 3. Intensity 4. Integrity in the management level, and four elements: 1. Process 2. Relationship 3. Commitment 4. Belonging in the organizing level. They have argued that creating the innovation-led company may represent a viable solution for coping with the turbulence and complexity of the knowledge economy. In doing so, it needs to focus both on the level of management and on the level of organising.

II. 7 The External Supporting Processes of Innovation

II. 7. 1 Inter-Organizational Network

Flows of knowledge on customers' needs increase the firm's degree of innovation. Need and experiences of customer is the most important source of innovation. Externally, inter-organizational network is an environment for the interaction and activities such as joint projects, collaborations or alliances for a specific R&D item and may benefit the participants in various degrees. When thinking of marketing knowledge, one should think of things such as competition, suppliers, customers, markets, target groups, consumers, clients, users, interested parties, sales, after sales, trade and distribution and relation management. [16]

Knowledge that is accumulated from the outside is shared widely within the organization, stored as part of company's knowledge base, and utilized by those engaged in developing new technologies and products" [50]. What "outside" environment is suitable for the development of innovation capacity of firms? Studies from a network perspective [5]; [23]; [2], inter-organizational network, becoming a new organization form, provides different stimulation through the collaborative activities with network members. The fundamental issue is how these organizational environments increase the firm's capacity of innovation for the continuous improvement of competitiveness.

II. 7. 2 Innovation Network

Innovation processes in a knowledge-based perspective

Due to the increased complexity of modern innovation processes a firm has to master a great number of different knowledge fields. In order to have the necessary access to external knowledge sources, firms, besides their specific competencies, have to provide for an additional broad knowledge base, the so-called absorptive capacity [11]; [8] or receiver competence [21] which allows them to flexibly react on external developments and external knowledge. In the computer industry, for example, the disciplines involved in the innovation process may range from solid state physics to mathematics, and from language theory to management science. So-called go-it-alone strategies or conservative strategies which mean that a firm relies only on its own R&D endeavours, cannot be successful in such a complex environment. Because of the systemic character [31] of

present-day technological solutions, technological development necessarily becomes a complex interactive process involving many different ideas, and their specific interrelationships.

Innovation networks in the knowledge-based approach

Obviously, the above characterisation of innovation processes has significant impacts on the analysis of innovation networks. These networks need to be understood not only in terms of transaction costs considerations, but also in the terms of learning, path dependencies, technological opportunities, and complementary assets. Networks do not only influence the co-ordination of resources but also insert a significant impact on their creation. This has to be seen in a twofold perspective: First, the pooling of different competencies in the network of firms of course enhances this process of resource creation by exploiting complementary effects. However, additionally, the co-operation in networks also creates a real surplus or synergy in this process [7].

In this light networks represent a mechanism for innovation diffusion through collaboration and the interactive relationship becomes not only a co-ordination device to create resources, but an essential enabling factor of technical progress [72]. Here it is not enough just to know what others are doing, but the firms also need to know how the respective technologies function and work together. And to support this inter-firm learning of often long-range cumulative, tacit and local know-how a stable and long lasting collaborative environment is necessary. This way innovation networks offer a possibility to overcome the restrictions of the irreversibilities and instead build on different specific knowledge-bases. With the fusion of different technological capabilities the exploration of new opportunities becomes possible - the cross-fertilization effects. In this respect, the essential dynamic properties of innovation networks become obvious.

Besides this creation of new so-called extensive opportunities [12] which constitutes the synergetic or surplus effect of innovation networks, above also the complementary effects were mentioned. In this respect, it is helpful to recall that the variety of assets and competencies which a firm needs access to in order to successfully commercialise a new technology is likely to be quite large even for only modest complex technologies [66]. Here, innovation networks show to be a promising alternative co-ordination mechanism which allows firm to have access to the complementary assets, which otherwise have to be built up alone - an extremely expansive and time-consuming endeavour, confronting at least small and medium sized firms with often insurmountable difficulties.

Successful innovation requires complex forms of business organisation. Innovating organisations must form linkages to others, upstream and downstream, lateral and horizontal. Advanced technological systems do not, and cannot, get created in splendid isolation. The communication and co-ordination requirements are often stupendous, and in

practice the price system alone does not suffice to achieve the necessary co-ordination [66]. Innovation networks represent such a flexible organisational device.

In summary, there are three major implications within the knowledge-based approach innovation networks: 1. Through accelerating and supporting the diffusion of new technological know-how, they are seen as an important co-ordination device enabling and supporting inter-firm learning. 2. The exploitation of complementarities becomes possible within innovation networks, which is a crucial prerequisite to master modern technological solutions characterised by complexity and a multitude of involved knowledge fields. 3. Through the amalgamation of different technological competencies, innovation networks constitute an organisational setting which opens the possibility of the exploration of synergies. By this, innovation processes are fed with new extensive technological opportunities, which otherwise would not exist, or whose existence would at least be delayed.

Functions and forms of innovation networks

National and regional systems of innovation

An important strand of literature focuses from a national angle on the institutional setting within which innovation processes and the specific interactions between the different actors involved take place. They coined the notions of national systems of innovation [41]; [48] and development blocs [15]; [9].

Formal and informal networks

The design of a specific innovation network can vary on a spectrum between formal contractual agreements and loosely coupled informal networks. Freeman [24], by surveying the empirical literature states:

Although rarely measured systematically, informal networks appeared to be most important. Multiple sources of information and pluralistic patterns of collaboration were the rule rather the exception.

In this respect, following Hakanson [28], also a dynamic component exerts influence: with an increasing duration of formal R&D co-operative relationships, they mutate to informal relationships as mutual trust and confidence between the partners is built up.

II. 7. 3 E-knowledge Networks

The universal adoption of the Internet has created the opportunity for firms and other organizations to establish collaborative networks of partners, with whom they may exchange strategic knowledge in order to achieve mutually beneficial objectives. This electronic commerce knowledge can be termed "e-knowledge" [29]. These "e-knowledge networks" could not have existed just a few short years ago because there was no widely-accepted platform for continuous and unattended exchange of information and knowledge about markets, customers, demand, inventories, and so forth. Today, such collaborative networks are

evolving in every economic sector in support of business-to-consumer commerce, business-to-business commerce, government-to-citizen interactivity, peer-to-peer exchanges, and internal connectivity through intranets [27]; [44] The technology of the Internet has become the greatest enabler of knowledge exchange within and between companies!

E-knowledge networks combine the positive benefits of knowledge management (KM) systems with those of inter-organizational systems (IOS). They also address some of the pitfalls of each, creating a powerful driver for advancing organizational objectives. Merrill, Ravi, Vijayan, [46] highlights some of the characteristics of e-knowledge networks. When firms engage in e-knowledge networks, they are able to share valuable knowledge, often created with emerging automated technologies such as data mining and intelligent agents, with their strategic partners, thereby enabling improved organizational effectiveness. Furthermore, entirely new business models are facilitated with the development and adoption of certain newer e-knowledge networks. Many of these emerging networks are characterized by automated exchange of rich customer knowledge by unattended computer systems, programmed to capture and evaluate knowledge with data mining algorithms, share it with strategic allies, and direct the operation of key interactive processes.

The keys to success in this evolving new economy are situational awareness and flexibility. These goals can be achieved by implementing electronic systems that generate immediate (real-time) knowledge about internal functions and processes, about customers and markets, about strategic partners, and about supply chain partners - suppliers, vendors, dealers and distributors. Such systems allow firms to be dynamic and flexible, thereby allowing rapid changes in their strategies and activities. Firms can use this knowledge to create new internal and external structures and relationships, leading to further improvements in knowledge, which leads to continuous strategy improvements.

Merrill, Ravi, Vijayan, [46] highlight the exchange of information and knowledge between e-knowledge network partners that are altering the implementation of B2B supply chain practices. These partners, in many cases, are altering their procurement practices to leverage the benefits of rich knowledge exchange for long-term success. They suggest that as the Internet expands its reach, along with ubiquitous and often automated information sharing capabilities, the ability to create knowledge-based networks of partners will be critical to maintaining competitive advantage. Firms will learn to rely on strategic partners for both core and peripheral functions, and will outsource significant processes to organizations who specialize in such functions and activities.

II. 8 The Innovation Supply Chain

II. 8. 1 What is Innovation Supply Chain?

According to the definition by Sciquest Company [60], the innovation supply chain is a methodology used to efficiently

integrate suppliers and research-intensive organization to ensure materials and information are made accessible and distributed at the right qualities, to the right locations, at the right time, in order to speed the process of innovation, reduce costs and improve quality. The ISC provide a framework for a seamless, streamlined approach to planning, sourcing and delivering products, As in manufacturing, optimizing the ISC is critical to maximizing throughput and enabling flexibility. ISC introduces intellectual capital, information management and regulatory compliance into tradition supply chain methodology. (www.sciquest.com)

II. 8. 2 How to Achieve the Goal of a Well-Managed Consumer Experience

The innovation supply chain

It is getting harder and harder to satisfy consumers in mature markets like C&EE (Consumer & Electronic Equipment) products, high tech manufacturing margins are being squeezed and competition on price is no longer a valid strategy. Increasingly, across many markets, the driving purchase criterion is the consumer's expectation of the overall experience a product will deliver. Those that do not offer a clearly differentiated experience risk being valued as commodities. A more effective strategy for manufacturers is to not only benchmark on price, or even command a small premium but also differentiates on the basis of consumer experience. In other words, behave like a successful service company. [26]

The use of outside supply may enhance an organization's ability, this focus on consumer experiences represents the ultimate challenge for manufacturers. New products are delivered into the economy by teams of professionals from different disciplines. In some of these - marketing and sales, for example - the knowledge focus is clearly on the consumer. In other disciplines - technical and creative in particular - the knowledge focus tends to be inward, that is, towards the specification of the product.

In the debate, poor knowledge flow, and entrenched uni-disciplinary attitudes emerge as the main barriers to the creation of better - higher margin - products brought to market in the shortest possible time. Shared goals, leading to collaborative effort and planning, seem to be the key to achieving reliable products with good functionality at a realistic price. However, to achieve the goal of a well-managed consumer experience a much higher level of knowledge transfer is needed, between consumer-facing disciplines such as marketing and design towards delivery disciplines such as engineering and manufacturing [26].

To achieve this higher level of integration, the innovation process needs to be seen as a knowledge supply chain - whose efficiency is measured by the extent to which a vision of the target experiences reaches each link in the chain. In parallel, other factors, such as intense price competition, are working to make integration even harder. To achieve maximum efficiency, professionals in different disciplines tend more and more to work for different

companies, often in different countries or on different continents. Commercial and cultural barriers abound. Information technology is helping information flow and is a parallel catalyst for change in the innovation process. However, to achieve any effective change, current underlying attitudes need to be understood and altered if they present an obstacle to progress. [26]

In practice, Gus Desbarats [26] assumed a framework namely "The Innovation Supply Chain" as follows: The problems involved when marketing to consumers in mature markets. Emphasises the need to build a direct knowledge of their consumers and to differentiate the service, product and brand from those of competitors. Asserts that small, distinct service experiences will combine to create a strong overriding impression of quality and value, and this mechanism is the foundation of achieving a strong brand. However, to be achieved in practice, these service targets need to be understood and communicated clearly up and down the innovation supply chain. This involves full co-operation between marketers, designers, manufacturers and distributors.

II. 8. 3 The Elements of ISC

In recent years, innovation supply chain (ISC) has attracted increasing attention as a comparatively mature organizational innovation mode, and this concept is still developing. The "ISC", has now become a common phrase in daily business life, similar corporations temporality joining together into meta-enterprises, and that of manufacturers, suppliers, distributors and even customers linking together in an enduring relationship built on mutual trust [26]. The innovation revolution is the defining business transformation of our generation." The *Taiwan Economic Daily* [65] held that though ISC can deal with production, sales, design, finance and other functions, enterprises have no such internal organization to carry out these functions. That is to say, the enterprise will not relinquish its key functions. Concerning the rest of the company's functions, due to limited resources and insufficient competitiveness, the enterprise must become a virtual company.

It must use every means to borrow strength from outside to increase its competitive edge. The target of this borrowed strength might be the upstream suppliers or the competition or the customer. Whatever the form, the guiding principles of ISC are to break the limitations of enterprises and extend the scope of the entity by using a strategy called "integration of external resources". This is a break from the former strategy - "selection of internal resources". In general, ISC is a type of dynamic union to respond quickly to market changes. There are 7 elements of ISC as follows [26].

1. The age of collaborative innovation
2. A necessary environment to integrate intellect through various fields for co-operative and inter-organization innovation organizations
3. The era of the knowledge economy, and the age of breaking the boundaries of the old research system

4. The flexible organization to facilitate free flow
5. A collective body to encourage people to learn from each other and share common knowledge
6. A parallel network-type organization and the new concept of "leadership"
7. Combination of relaxing environment and team spirit.

II. 8. 4 Summary

What needs to change and how each discipline helps the collective to deliver better consumer experiences? By examining attitudes along the innovation supply chain, we can see the use of outside supply may enhance an organization's ability to provide a wider product range and to diversify. Quinn et al., [57] pointed out: "Focusing on a narrower range of activities may allow core activities to be more easily levered to achieve a wider product range". In addition, the study proposed: "the total investment required to enter a new business area can be reduced and there can be easier achievement of optimum performance". Suppliers and collaborating partners can assist the innovation process through access to technologies, skills or information [19]; and through providing complementary expertise improve the speed to market of new product developments. In brief, an ISC meets the needs of innovation. It is the inevitable trend of social development.

III. Methodology

First of all, the study through literature review to develop a research framework. Secondly, the study through case studies to develop a more complete and practical integrated model and six researches propositions for practitioners of high tech industries and future researchers.

The data collection was through analysis of secondary data and interviews. The study interviews with top and middle level of directors who are related to innovation and knowledge management in 5 high tech industries. The interview questionnaires are sent out about 20, the response rate is 85%. The interview questionnaires are designed by informal and semi-structure, before send out to these high tech industries, the study have sent out interview questionnaires for pre-test to someone who are related with innovation and knowledge industries.

In summary, the study through literature review to construct a research framework, base on it, the study developed case studies to examine advantage and disadvantage of theories and constructed a more complete and practical model to link theories and practices for high tech industrial innovation.

IV. Case Studies and Discussion

IV. 1 Challenge 2008 - National Development Plan in Taiwan

After joint in WTO and for the new century, current problems facing Taiwan as below:

- Global competition
- Competition in the global economy growing more intense
- Global industrial chains being recognized
- Countries competing for talent and funds
- Mainland China's magnetic effect
- Cheap labor and land
- Vast market and preferential investment measures, luring global capital and technology, and creating industry clustering effects.
- Proposed ASEAN+3 FTA, accelerating the economic integration of China and East Asia.

Therefore, the Executive Yuan formally approved the National Development Plans for the new century on 9, May, 2004, which calls for a total investment of NT\$2.6 trillion over six years in the overall upgrading of Taiwan's living as well as investment and operating environments. The plan to develop a knowledge-based economy in Taiwan. This blueprint for socioeconomic development, with an equal emphasis on knowledge and innovation, economy and culture contains 10 key projects. The study reviews the goals and strategies of which are described below [13]:

- . Cultivation of E-Generation Manpower
- . Establishment of a Base for Innovation and R&D
- . Heightening of Industrial Value
- . Construction of e-Taiwan
- . Development of Operations Headquarters

Four major investments: Personnel, R&D and innovation, global logistics channels, living environment

Challenge Goals: Taiwan World No. 1 in 15 products or technologies, Doubling of tourist arrivals, R&D spending equal to 3% of GDP, Reduction of unemployment to under 4%, Economic growth rate above 5%, More than 6 million broadband households, Creation of 700,000 job opportunities. (<http://www.cepd.gov.tw/service/board/coun-dev.htm>.)

According to above background, motivation and the national development plan, in practice, the study adopts case studies to examine advantage and disadvantage of the integrated model (figure 2-4). After modification, the study constructed a more complete and practical integrated model to link theories and practices for high tech industrial innovation. Finally, the study developed six research propositions for practitioners and future researchers. The study summarizes the results of case studies, interviews and discussion as follows.

SWOT analysis

For comparing and finding out the advantage and disadvantage for these case studies, the study utilizes SWOT to analyze five cases: TK E-Business Corporation, SOYO Corporation, ELSA Technology, Radiant Innovation

company and Global View Corporation as table 4-1 to 4-5.

The results of interviews

The study summarized the results of interviews for case studies as follows:

1. All of firms for these case studies are knowledge-based companies.
2. All of firms for these case studies use technology innovation.
3. All of firms for these case studies are high technology industries.
4. All of f firms or these case studies are cross-strait (multinational) corporations.
5. All of firms for these case studies implement knowledge management and innovation orientation.
6. Some of firms for these case studies implement e-supply chain or knowledge (innovation) supply chain.
7. The ISC could guarantee reliability, flexibility, and scalability. ISC also can help high tech industries to get inter-connected with all relevant parties in the commerce process and extend the reach of business to the global market.
8. All of these firms throughout the world have developed international operation strategies to establish a worldwide production, distribution, and marketing network.
9. A new economic order in China and Taiwan– the globalization of business – has both shaped and been shaped by the advancements in knowledge and innovation management that have improved the efficiency and effectiveness between markets, manufacturing processing, and resources.
10. China's unprecedented economic growth and globalization have strained its knowledge-economy and innovation infrastructure to the limit.
11. Knowledge-based innovation – the movement of technology, people, processes and information – has a significant impact on a society's standard of living. And the standard between China and Taiwan is less and less.
12. A typical "innovation (knowledge) supply chain" may involve a variety of stages that include knowledge suppliers, manufacturers, wholesalers, distributors, retailers and customers. Innovation refers to the knowledge, and the management of the movement of knowledge and information, from one place to another as they make their ways from the beginning of the innovation (knowledge) supply chain to the customers' hands.
13. Efficient innovation management involves a successful integration of knowledge and technology that facilitates the innovative processes of products to the consumers at the right time and right place in accordance with consumer needs. The demand for higher quality innovative management is growing tremendously.
14. If foreign companies encounter too many innovative problems and barriers in China, to the extent that the total costs of utilizing China as a manufacturing base become too high when compared with other nations, then China will be

excluded from a foreign firm's global manufacturing network.

15. The innovation barriers identified in the interviews and case studies include high innovation costs, lack of knowledge integration and innovation infrastructure, the monopolistic nature of innovation management, and the poor quality of knowledge and information flow.

16. These obstacles have been recognized as the most common barriers that foreign and local firms have encountered in China. The integrated innovation model constructed from the case studies aimed at identifying innovation barriers and the solutions to those barriers from a knowledge-based perspective. The knowledge/innovation gaps should be filled in to map a more comprehensive picture of the proposition.

IV. 2 Discussion

IV. 2. 1 Knowledge Based Innovation for High Tech Industry to Fit Global Competition

Many firms throughout the world have developed international operation strategies to establish a worldwide production, distribution, and marketing network under the intensification of global competition. Fast economic growth, low labor costs, and a potentially huge domestic market have all led to significant increases in foreign investment in Mainland China as investments in manufacturing in China are frequently made due to the strategic benefits that they can bring. In near future, China may influence the world as a source of raw materials and an international manufacturing center. Moreover, as a major importer and exporter of consumer products, capital goods, and high technology.

The globalization of business – a new economic order in China has both shaped and been shaped by the advancements in knowledge and innovation management that have improved the efficiency and effectiveness between markets, manufacturing processing, and resources. China's unprecedented economic growth and globalization have strained its knowledge-economy and innovation infrastructure to the limit. Knowledge-based innovation – the movement of technology, people, processes and information – has a significant impact on a society's standard of living. The innovative process affects every sphere of human activity and business strategy.

Efficient innovation management involves a successful integration of knowledge and technology that facilitates the innovative processes of products to the consumers at the right time and right place in accordance with consumer needs. As an increasing number of foreign manufacturers are establishing joint ventures in China, the demand for higher quality innovative management is growing tremendously. The reason for this growth in demand is simple: if foreign companies encounter too many innovative problems and barriers in China, to the extent that the total costs of utilizing China as a manufacturing base become too high when compared with other nations, then China will be excluded from a foreign firm's global manufacturing network.

The innovation barriers identified in the study include high innovation costs, lack of knowledge integration and innovation infrastructure, the monopolistic nature of innovation management, and the poor quality of knowledge and information flow. These obstacles have been recognized as the most common barriers that foreign and local firms have encountered in China. The frameworks constructed from the literature review suggest that little research has been aimed at identifying innovation barriers and the solutions to those barriers from a knowledge-based perspective. The knowledge/innovation gaps should be filled in to map a more comprehensive picture of the proposition. The study through case studies, SWOT analysis and interviews to propose a solution includes knowledge innovation, integrating internal and external processes for supporting innovation to fill the knowledge/innovation gaps and to map a more comprehensive picture of the proposition.

IV. 2. 2 The Greatest Challenge and the Long-term Influence

There should be two aspects: the information condition based an electronic network and human relationships based on people and organizations in a complete foundation for the development of society, economy and technology should have. It is necessary for ISC systems to assist in the forming and improving of the latter basic aspect.

Changing a mindset is the greatest challenge. China has not yet formed the mechanism to invest in "men". Most people cannot accept the concept of ISC. When you talk about "virtual" organizations, many people, including those who are for so-called organizational innovation and advocate the concept of "advanced organizations", still pay first attention to the organizational scale, administrative ranks and the power and right. Their immediate consideration is not how many results that users or markets will adopt.

IV. 2. 3 Towards the Sixth-generation Innovation Process

The innovation supply chain is a methodology used to efficiently integrate suppliers and research-intensive organization to ensure materials and information are made accessible and distributed at the right qualities, to the right locations, at the right time, in order to speed the process of innovation, reduce costs and improve quality. The ISC provide a framework for a seamless, streamlined approach to planning, sourcing and delivering products, As in manufacturing, optimizing the ISC is critical to maximizing throughout and enabling flexibility.

In short, the study proposed a distinct from the 5G innovation process [59], to summarize the key aspects of the process for ISC and assumed a new KISC (knowledge based innovation supply chain) towards the sixth-generation innovation processes as follows:

- Integration (inside and outside innovation sources; virtual and physical; technology and knowledge; supply chain members; managing and organizing)

- Flexibility (organizational structures; decision making)
- Networking (inter-organization; innovation and e-knowledge networks)
- Cooperation and collaboration
- Quick response (Efficiency and effectiveness); real time information and knowledge processing
- Stability (information and products)
- Maximizing satisfaction (products and services)
- Minimizing cost (processes cost and communication cost)

V. An Integrative Knowledge Based Innovation Model for High Tech Industries

According above literature review, content analysis, case studies and discussions. The study develops an integrative knowledge based innovation model for high technology industries to fit the objectives of the study as Figure 5-1, and describe as follows.

The study integrated customer needs, knowledge-based and innovation networks related theories into a more complete and practical model for high technology industries. Customers (markets) needs are the most important innovation sources, according to customer (markets) needs and knowledge, high tech industries could develop innovation capacity. The core of the model is innovation capacity (supporting by internal and external processes). If high tech industries want to reach sustainable competitive advantage through innovation, it is necessary to integrate internal and external innovation supporting processes due to markets (customers) needs and finally through KISC (knowledge based innovation supply chain) to reach continue innovation and create sustainable competitive advantage for high tech industries.

V. 1 Knowledge Based Innovation Supply Chain (KISC)

KISC gathers people from different fields and technological backgrounds and organizes teams according to specific goals and systems to create superior environments for inter-organization innovation and integration of knowledge and intellect. For creating a more flexible, versatile, faster and robust innovation organization, the study integrated and presented an knowledge based innovation supply chain (KISC) model for integrating and determining innovative supporting process in high tech industries and applying to cross strait (Chinese and Taiwan) marketplace. High technology industries should use KISC perspective for easy and innovative knowledge sharing and flowing.

A new KISC (knowledge based innovation supply chain) as follows:

- Integration (inside and outside innovation sources; virtual and physical; technology and knowledge; supply chain members; managing and organizing)
- Flexibility (organizational structures; decision making)
- Networking (inter-organization; innovation and e-knowledge networks)

- Cooperation and collaboration
- Quick response (Efficiency and effectiveness); Parallel (real time) information processing
- Stability (information and products)
- Maximizing satisfaction (products and services)
- Minimizing cost (processes cost)

V. 2 Research Propositions of the Study

According this integrated innovation model, the study to integrate internal and external innovation processes, and through ISC to make corporate innovation capacity to reach real performances and to reach sustainable competitive advantage. Also, the study proposed one main research proposition and six sub research propositions for future researchers as follows:

RP: High tech industries increase innovation capacity and reach sustainable competitive advantage through linking corporate internal and external innovative supporting processes.

P1: High tech industries according to sources and flows of knowledge on customers' needs to increase the firm's innovation capacity.

P2: High tech industries improve techniques for knowledge management and use technology innovation can lead to higher innovation levels.

P3: High tech industries use managing & organizing approaches can lead to higher innovation levels.

P4: High tech industries apply cooperative innovation with suppliers, customers and partners to increase innovation capacity and lead to higher innovation levels.

P5: High tech industries apply KISC to cooperate with supply chain members, to cultivate innovation capacity and to integrate internal and external supporting process of innovation

P6: High tech industries combine internal and external supporting innovation processes to lead to innovation capacity and through KISC to reach sustainable competitive advantage.

VI. Conclusions

Under knowledge economy, which management approaches and technologies are necessary to support innovation in the knowledge intensive industry especially are high technology industries? It's necessary to integrate internal and external supporting innovative processes for high technology industries. The core is innovation capacities for reaching continue innovation, Internal supporting processes include the knowledge management & technology innovation and Managing & organizing innovation, external supporting processes include knowledge from customers, suppliers, partners and competitors and cooperative innovation. Knowledge management plays a fundamental role when managing processes innovation efforts. Process innovations remain a source of competitive advantage in the market for short periods of time. Knowledge management policies are the main drivers of process innovation. Design of new

processes innovation delivery system must take into account possible customers' behaviors and perceptions. Therefore, the more flexible and versatile knowledge management policies are, the faster and more robust innovation efforts are.

For creating a more flexible, versatile, faster and robust innovation organization, the study presented a knowledge based innovation supply chain (KISC) model for determining innovative supporting process in high tech industries and applying to cross strait (Chinese and Taiwan) marketplace. Such a model is developed under the knowledge-based theory lens. High technology industries should use KISC perspective for easy and innovative knowledge sharing. The study examines the notion that China's and Taiwan's entry into the WTO and its innovation reforms in line with globalization have a significant impact on the entire system of knowledge-based innovation management.

The study describes a complete and practical integrated innovation model. Such a model is developed under the knowledge-based theory lens. So, knowledge flows and knowledge integration capabilities of the organization's members are considered as crucial for the innovation processes to be successfully implemented. Final conclusions consider customers (markets) needs as the most important sources of innovation. And to integrate internal supporting innovation processes (knowledge management & technological innovation and Managing & organizing innovation) and external supporting innovation processes (knowledge and innovation from suppliers, partners, competitors and customers) and cooperative innovation as the main impellers of high technology industrial innovation. According this integrated innovation model, the study proposed one main research proposition and six sub research propositions for future researchers and practitioners. Whether which kinds of innovation are based on knowledge and people (knowledge workers). The winning companies of this decade will be those which provide their people with the best weapons with which to compete, that are knowledge and innovation. The results of the study will benefit not only the construction of knowledge based innovation framework, but also the business model transformation of competitive advantage.

Table 4-1: SWOT analysis of high tech industries (Case 1)

S	With the collective knowledge and resources of TK's experienced management team who worked for IBM [30], Andersen Consulting, McKinsey Consulting, Intel, Microsoft, Rockwell, Merrill Lynch and vertical industries. TK can acquire strong source of innovation and utilize their expertise of knowledge-based innovation into e-business markets.
W	The major shareholders include China Development Industry Bank, Ta-Jung Logistic Corp., the affiliate of the renowned Hsin Kuang Group, and many other key industry leaders. But lacks of professional marketing channel and supply chain will form a weak situation which let competitors easy to occupy market shares.
O	The large potential benefits between China and Taiwan e-business and e-supply (B2B2C) markets is TK's future opportunity to compete in cross-strait and global markets .
T	The threat for TK is global industries' competition, hard to overcome the block of current technology policy and law from Taiwan government and the lack of protection for intellectual and patent assets from China governments.

Table 4-2: SWOT analysis of high tech industries (Case 2)

S	In this competitive market place, SOYO's strategy to succeed is by continuing to innovate and always position SOYO ahead of the curve. SOYO's contract Research and Development team constantly searches for the latest technology and creative ways to integrate into their motherboards in order to meet the high demands of customers. Knowing their customers is the company's key strength. Launching the right product at the right time is what SOYO believes to be crucial in staying competitive. Best Overall Service. To service its valued customers and to support their needs, SOYO has built a worldwide network of offices. From prompt order processing, speedy and reliable delivery to after sales customer care, SOYO is with its customers every step along the way. The customers are the keys to SOYO's success.
W	SOYO's sales channel in China and Taiwan is still not enough to occupy the popular PC markets. Besides, though SOYO's strategic alliances partners include global famous corporation but SOYO can't get prompt technology transfer from them. This will cause SOYO's innovative product to be delayed time to markets.
O	The SOYO brand is synonymous with quality and creativity, and it is SOYO's goal to continue to grow in today's market place. Through constant search for the newest and the latest and SOYO's ability to deliver products at levels never seen before, SOYO continues to be the industry leader. Their flexible management structure allows SOYO to respond to the market demand quickly. SOYO's goal is to be the best at what it does and to always stay ahead of the curve!
T	<ol style="list-style-type: none"> 1. China and Taiwan's channel competitors. 2. Price's and quality's competition from the other motherboard's famous brand corporations. 3. Global industries' competition and hard to overcome the block of current technology policy and law for Taiwan government and the lack protection of intellectual and patent assets for China governments.

Table 4-3: SWOT analysis of high tech industries (Case 3)

S	ELSA not only benefits from this central location at the heart of Taipei, but also from the steady stream of highly qualified engineers from this internationally renowned university. Short development cycles and innovative products based on ATI and nVidia core technology remain the cornerstones of their continued growth.
W	Elsa has divided the product lines once again into individual business units directly in the heart of the technology hotbed, in Germany and Taiwan. But lack of China markets. As the link between the markets and the company, the business units are responsible for developing attractive product and marketing strategies tailored to the users within the given market segment in their respective regions. But no significant segment in their respective regions. ELSA also lacks of e-supply chain to link their branches and to link from users and distributors.
O	<p>ELSA's presence on international markets is one of the major factors which will determine their future growth. ELSA's presence in Wuerselen (Germany), Taipei (Taiwan), Seoul (Korea), and Beijing (China) play a key role in the development of international markets with their support in regions that are vital to the industry.</p> <p>ELSA regards the European and Asia as decisive markets not only with regard to procurement, but also for future sales and services. Therefore ELSA has been expanding their sales network and they are currently successful in the distribution business for graphics and multimedia products. ELSA Technology in Germany completes the goal of securing a pan-European presence for ELSA complete product range. ELSA expects to increase its support and services significantly. The existing and new relationships with distribution partners will also strengthened through the presence.</p>
T	<p>The existing and new other distribution partners will form threat to ELSA.</p> <p>Global industries' competition and hard to overcome the block of current technology policy and law for Taiwan government and the lack protection of intellectual and patent assets for China governments.</p>

Table 4-4: SWOT analysis of high tech industries (Case 4)

S	Radiant has obtained ISO 9001 and EN46001 certifications. The IR Ear Thermometer, their first product, has been EU CE and USA FDA certified. Radiant has two solid shareholders Sunplus a very experienced IC design company, and Global View, a leading palm-size electronic dictionary manufacturer. With the aim of providing better customer satisfaction, Radiant designs and creates uncompromised quality PHC products with competitive pricing.
W	Radiant lack of strong sales channel in China this most population markets. Also they lack of good channel relationships to promote their products.
O	The trends for aging society and quality living, PHC products have become necessities of life. Radiant will be continuously introducing a series of top PHC products in the near future. Through Radiant steady investments, innovative R&D, and the quality of production, they will become a world class PHC supplier.
T	Radiant are also seeking for ODM and OEM partners around the world. This will cause patent problems and other competitor's imitation. Global industries' competition and hard to overcome the block of current technology policy and law for Taiwan government and the lack protection of intellectual and patent assets for China governments.

Table 4-5: SWOT analysis of high tech industries (Case 5)

S	Ongoing Innovation, Contribute value to Society, Corporate Philosophy, Integrity Innovation Quality Service. Corporate Culture, Business and Customer Oriented, Speed and Simple, Respect, Team Work, Open-Mind discussion, Entrepreneurship
W	At present the company has subsidiaries in Mainland China, Korea, Taiwan, and Hongkong, with more than 1500 employees. But they lack of knowledge base innovation team. Also, they lack of strong marketing channels.
O	With their world-class high-tech know-how, they are committed to LINUX operating systems and GV OS Technology Platform in order to provide clients with powerful and economical overall solutions to software and hardware.
T	The low price competition from China and Korea. The high technology innovation competition from HK. And Taiwan. Global industries' competition and hard to overcome the block of current technology policy and law for Taiwan government and the lack protection of intellectual and patent assets for China governments.

Effective Knowledge Representation Through Data Modelling Approaches

Abstract: Data modelling can be seen as knowledge representation in terms of sharing the same philosophical assumptions. In data modelling process, the recognition of the philosophical background on human inquiry and the nature of knowledge pertinent for appreciating the problems is important as different ontological views lead to different conceptions about data models. Recognising and incorporating different forms of organisational knowledge are also important in the data modelling process as a formal representation of some subset of the knowledge, which the organisation needs to carry out its business. This paper discusses the two distinct philosophical foundations for the effective representation of organisational knowledge.

I. Introduction

Information systems with information technology have played an important role in capturing, storing, sharing and disseminating organisational knowledge. In the information systems development stage data modelling is an indispensable part of managing organisational knowledge in describing, organising and analysing data that are stored and manipulated in the information systems. Data modelling is an approach that is used to manage complex problems [6]. Data modelling approaches are divided into two paradigms. They are objectivism and subjectivism. Objectivism in data modelling follows the empirical analytical scientific method. It assumes that reality can be described by independent facts, which corresponds to the empirical base of observational statement in objectivist philosophy. A database captures these facts and data models provide the structure for organising all the facts into a consistent picture of reality. In accordance with this, objectivist data modelling approaches were called fact-based.

In contrast, subjectivism of data modelling pursues subjectivist paradigm. It assumes that that the domain of inquiry is not independent of the observer, and therefore reality cannot be described in terms of independent fact. Rather, what counts as reality are socially constructed images, which emerge in social interaction, in particular through communication in some language. The details of these images are not completely arbitrary, but depend on the grammar, the rules and meanings, which govern social communication. Accordingly, a data model attempts to formalise some of the informal social rules and meanings.

The subjectivist data modelling approaches were called rule-based.

As Klein and Hirschheim claim that “no data modelling approach can avoid philosophical assumptions because data modelling is a process of inquiry that has intrinsic similarities with classic scientific theory construction” [12, p. 8], understanding philosophical basis is essential to data modellers because different ontological views lead to different conceptions about data models. It is therefore significant for data modellers to be aware of different philosophical assumptions of conceptual data modelling. The purpose of this paper is to explore the implication of two different objectivist and subjectivist’s paradigms to conceptual data modelling process to effectively represent organisational knowledge. The organisation of the paper is as follows. First it discusses a philosophical perspective on data modelling in general. After that it moves to two sets of assumptions of data modelling in terms of ontology and epistemology. Following the discussion of the two assumptions, it examines objectivist-subjectivist data modelling. Then, it speculates the fact-based and rule-based of data modelling. Finally, it ends with conclusions and future work.

II. Philosophical Perspectives on Data Modelling

There is a slight difference between data modelling and conceptual data modelling. Conceptual data modelling is the phase of the development process that involves the abstraction and representation of the real world data pertinent to an organisation [2] whereas data modelling is the activity of creating a data model. Olle [14, p. 46] points out, “A data modelling facility has to be seen as functionally more restricted than a conceptual modelling facility”. He also points out that conceptual modelling is much less widely used and a data modelling facility is restricted to data and the processes. Although there are discrepancies, in this paper the term data modelling and conceptual data modelling is used interchangeably.

There are linkages between the concerns of data modelling and philosophy. One result of the philosophical debate on the meaning of language and hermeneutics is that it is impossible to capture knowledge simply in terms of articulable facts as the positivists had claimed. A broader concept of knowledge is relevant for understanding practical difficulties with determining the system or formalisation boundary in specifying computer applications. It is widely

recognised that data modelling should include the meanings and relationships among data that may be hidden from the users. It is for this reason that concern for the adequate recognition of the importance of tacit knowledge arises. Tacit knowledge is personal knowledge that is hard to formalise or articulate [15]. Hidden meanings and knowledge can be imperfectly represented during data modelling as it falls within the domain of tacit knowledge.

Moreover, just because users may know how to do their work, it does not follow that it is possible to capture their knowledge in explicit rules and descriptions [16]. This remains true even if some of the users are asked to participate the information systems design teams. In this sense it may be said that data modelling involves the design of a knowledge representation schema, which needs good techniques to decide what to include and what not to include, understanding the important role of tacit knowledge. In addition to the problem of hidden and tacit knowledge, data modelling constructs a formal representation of some subset of the knowledge, which the organisation needs to carry out its business.

Data modelling and knowledge representation can be seen essentially similar in terms of sharing the same fundamental assumptions. The existing approaches of data modelling with regard to the assumptions are about the nature of reality and the nature of the knowledge captured in a data model including the ways and means of how it is collected. That is the paradigmatic dimension of objectivism-subjectivism. The objectivist-subjectivist dimension of a paradigm raises two issues such as one dealing with ontology and the other with epistemology of data modelling.

III. Ontology V Epistemology

Ontology is concerned with the essence of things and the nature of the world. It subsumes two extreme positions of realism and nominalism. Realism postulates that the universe comprises objectively given immutable objects and structures [12]. These exist as empirical entities, on their own, independent of the observer's appreciation of them. On the other hand, nominalism is where reality is not a given immutable out there, but is socially constructed [12]. It is the product of the human mind.

The ontological question what is being modelled points to the fundamental assumption of data modelling approaches about the environment or modelling domain. That is about the nature of the Universe of Discourse (UoD). There are many forms of terminology for talking about the ontology of data modelling. Examples of terms used to describe ontology in data modelling are entities, relationships, facts and speech acts. The ontology of data modelling also includes some fundamental assumptions about the nature of the application domain. That is whether there is a single or several user systems or no system at all, whether the primary constituents of each user system are operations, roles, decisions, social action or speech acts.

In contrast to ontology, epistemology is the grounds of knowledge. The term relates to the way in which the world may be legitimately investigated and what may be considered as knowledge and progress. It includes elements concerned with sources of knowledge, structure of knowledge and the limits of what can be known. Two extreme positions are positivism and interpretivism. According to Klein and Hirschheim [12], positivism implies the existence of causal relationships which can be investigated using scientific method whereas interpretivism implies that there is no single truth that can be proven by such investigation. Different views and interpretations are potentially legitimate and the way to progress is not to try and discover the one correct view but to accept the differences and seek to gain insight by a deep understanding of such complexity.

The epistemological question why the result is valid points to the fundamental assumptions that are made on how one can obtain valid interpretations and knowledge about the UoD. Experimental modes of schema construction like prototyping can be compared with the blue-print specification approach as is associated with many versions of the so called waterfall model of schema development [9][3]. The question of how to cope with different types of uncertainty such as problem during data modelling is not the only consideration that is important in comparing experimental or specification approaches, but it is a good example to demonstrate that different methods imply different assumptions about knowledge and inquiry.

In the context of data modelling, ontological assumptions are concerned with the nature of the UoD to be modelled. Epistemological assumptions are concerned with the appropriate approach for inquiry regarding what one needs to know to create the data model and with the cognitive status of the result is a data model true or it is merely an imaginary tale. That is a simplifying design assumption presumed to be valid only for a particular system at a particular time. The existing approaches of data modelling with regard to the assumptions are about the paradigmatic dimension of objectivism versus subjectivism.

IV. Objectivism V Subjectivism

Objectivism postulates that the UoD is comprised of immutable objects and structures that exist as empirical entities. In principle, a model of the UoD ought to exist which is correct independently of the observers' appreciation of it. A data model is true if it accurately depicts the underlying reality of the UoD. In contrast, subjectivism in data modelling holds that the UoD is a subjective construction of the mind. A data model can best reflect peoples' conventions or perceptions that are subject to negotiated change. Important mechanisms by which subjective experiences take on an objective quality in the minds of individuals are the rules surrounding institutions, tradition as transmitted through artefacts and changing use of language and sedimentation [1]. Sedimentation refers to

the ordering of experiences, which is transmitted subconsciously by virtue of growing up in one segment of society as opposed to another or in different societies altogether [12]. From this view a data model is correct if it is consistent with the perception of the UoD as constructed by institutional programming, sedimentation and tradition. On the contrary, the objectivist view holds that language neutrally depicts reality, which is the same for all regardless of culture and individual perception.

Burrell and Morgan [4] describe the categorisation of assumptions on objectivist/subjectivist and order/conflict dimensions. According to them, the objectivist position is characterised by the realist ontology and positivist epistemology. The objectivist assumes that objects and structures exist as empirical entities independent of human observers and that the appropriate way of acquiring knowledge of the world is by observation and the identification of causal relationships. The subjectivist position holds that scientific method is not appropriate for explaining the social world as different people interpret the world in different ways and any agreement is intersubjective. The appropriate way to investigate the social world is to recognise multiple realities and to adopt an interpretivist stance. The order view of the world sees order, stability and integration while the conflict view sees coercion, disintegration, and places an emphasis on change.

The two classifications organise four particular positions such as functionalism (objectivism/order), radical structuralism (objectivism/conflict), social relativism (subjectivism/order), and neohumanism (subjectivism/conflict). The metaphors of doctor, warrior, liberal teacher, and emancipator respectively have symbolised these groupings. The doctor, technical expert sees data modelling as an objective use where entities and relationships can be said to exist independently of people. The data model is a value-free reflection of a singular reality and scientific method is the appropriate way of building a data model. The warrior also perceives data modelling as an objective use, but assumes that there are conflicting interests and is therefore concerned with whose requirements are being addressed. The difference is that the warrior considers data model as a reflection of real world structures but because of socio-economic factors the data model is not value-free which requires the data modeller's support in the struggle against the owners.

The liberal teacher, facilitator considers reality to be socially constructed and that there are as many realities as there are people involved in the development exercise. A good data model is one, which creates a shared understanding so the appropriate way to go about creating such a model is through participation and facilitation. The emancipator would also consider that reality is socially constructed, but recognises the presence of conflict and hence the exercise of power. The emancipator adopts a critical stance and seeks to initiate change that will improve the situation, recognising that there is unlikely to be a consensus and that any data model will be mediated through

the exercise of power. A good data model is one, which helps create a social reality that eases cultural domination via a rational discourse that is free from restrictions.

Under a more radical interpretation of the subjectivist approach, data modelling does not merely reflect social consensus perceptions, but it affects the very process of reality construction. This is so because socially transmitted concepts and names direct how reality is perceived and structured. The construction of reality varies with different languages and cultures. As data modelling typically introduces new concepts and ideas in the users world, it intervenes with the very definition of what counts as reality. It changes what is subjectively experienced as an objective reality and its appreciation what may at one point have been accidental or not even noticed may become very important and recorded in detail. In this sense, data modelling is a form of institutional representation and once a data model has been in use for some time it may become part of sedimentation and tradition. Accordingly, data modelling is never neutral, but rather a biased supporter of reality.

The framework of the categorisation suggested by Burrell and Morgan [4] illustrates that is but one way of approaching the world in assuming that a good data model is one that mirrors reality we are working within a positivist tradition. There are more frameworks proposed that show what the measure of a good data model is. Berger and Luckman [1] suggest a framework where subjective meanings become objective objectivation that then act back as they socialise present and future generations. Reality construction is the dialectical relationship of these three moments. Giddens's [8] proposal has advanced much complementarily from the paradigmatic conclusion of the Burrell and Morgan [4] by conceiving the objective and subjective to be present simultaneously, as represented in structuration theory. An important implication of structuration theory is that the objective/subjective distinction should be seen as duality rather than dualism, and that it is not possible to separate out objective components. This may lead to some inconsistencies in their conceptual base. Such inconsistencies are often not reflected, because technical work in the area of data modelling is often unaware of the deeper stipulations and assumptions on which newly proposed methods and tools rest.

Those assumptions are the principles on fact based, rule based, and frame based approaches. Objectivism in data modelling follows the empirical analytical scientific method. It assumes that reality can be described by independent facts, which corresponds to the empirical base of observational statement in objectivist philosophy. A database captures these facts and data models provide the structure for organising all the facts into a consistent picture of reality. In line with this, Objectivist data modelling approaches were called fact-based. Subjectivism of data modelling, in contrast, pursues subjectivist paradigm. It assumes that that the domain of inquiry is not independent of the observer, and therefore reality cannot be described in terms of independent fact. Rather, what counts as reality are socially constructed

images, which emerge in social interaction, in particular through communication in some language. The details of these images are not completely arbitrary, but depend on the grammar, the rules and meanings, which govern social communication. Hence, a data model attempts to formalise some of the informal social rules and meanings. The subjectivist data modelling approaches were called rule-based.

V. Fact-Based V Rule-Based Data Modelling

The fact-based approach is grounded on concepts that are related to given facts in the sense of existing state of affairs. The fact-based approaches to data modelling tend to follow the objectivist tradition. A fact is typically defined by associating a specific attribute or relationship to a given entity. Under this interpretation, a data model is like a mirror or picture of reality. Reality is a given and out there. Typical examples for such concepts are entity, property/attributes and relationship. Entities have properties or attributes. Both entities and their properties have an objective existence. Entity-based approaches implement von Wittgenstein's [17] picture theory of meaning. That is data correspond to facts and it is these that entity-based approaches seek to model. This is apparent when Kent [11] comments that by focusing on the facts, we obtain a methodology for data analysis and design which is at once simpler and more powerful than other methodologies for data modelling.

The fact-based approach represents the mainstream of the data modelling field. It has the longest history, and it has been intensively researched over the last two decades [5]. The approaches suggested within this approach have been widely applied, and there exists a considerable amount of application experience. Therefore, the fact-based approach is better understood than that of the rule-based approach.

In contrast, the rule-based approaches to data modelling are heavily influenced by the subjectivist tradition. Their proponents see the main task of data modelling as formalising the meaning of messages that are to be exchanged among a professional community such as managers and engineers. The expression of meanings must follow social determined rules, which facilitate the comprehension of what is communicated. They argue that meaning is created within the human mind and related to human purpose or intentions. The latter arise out of an understanding of reality, socially constructed. That is it emerges from social interaction conditioned by social conventions or rules. For example, all computer data ultimately have to be interpreted in terms of their natural language meanings. Hence data can at best convey meaning from someone, but they cannot have any objective meaning.

In the rule-based approach a data model describes rules which govern the uses of signs and symbols in organisational behaviours and thereby attach specific meanings to the organisational vocabulary. Therefore these approaches are largely derived from the concept of a rule. In general, a rule is regarded as a general prescription that

governs the generation, meaning and use of linguistic expressions both informal and formal as are included in the information system.

Rule-based approaches form a minority position in the data modelling field. It has been pursued by few researchers [8] and its history can be dated back to the late 1970s and early 1980s. Rule-based data modelling methods are much less developed than their fact-based counterparts. Moreover, these approaches have not been widely applied in their full form outside academia and experience of their usefulness is limited. One reason for this is their inner complexity and highly developed theoretical vocabulary which is difficult to adopt for practising information systems professionals. Data modelling in the rule-based is an important medium for organisations to learn about their communication practice helping detect distortions and inconsistencies in communication.

There is a third approach on data modelling which combines both objectivist and subjectivist principles of data modelling. The approach is also called frame-based because ideas can be captured in mental frames. The basic modelling construct of an object builds on the concept of an imaginary actor as originally proposed by Kay [10]. An actor in Kay's sense is any software object that behaves in predefined ways. Actors can be used to model real objects, but they can also be used to modelling imaginary objects that represent people's ideas, which exist only in Alice in Wonderland. An actor or frame view of data is based on the idea that a description of data with its permissible operations should be combined into an actor or knowledge frame. The frame-based approach is best viewed as a variant of objectivism in data modelling.

Similar to the frame based approach for the purpose of lessening the danger of one perspective only data modelling, an unbounded systems thinking approach as the application of multiple perspectives to data modelling has been proposed by Mitroff and Linstone [13]. The core three perspectives include organisation (O), technical (T) and personal (P). The T perspective is concerned with a scientific world-view, logic, rationality, modelling and analysis claiming of objectivity. The O perspective is concerned with social entities, politics and processes; and the P perspective is of the individual and concerned with power, influence, prestige, learning and beliefs. The flaw of the approach is associated with practical difficulties by realising different forms of knowledge, which requires different knowledge interests and thus need to be considered jointly. In other words, people with different background and tradition tend to follow one particular perspective over other perspectives for which there are no simple rules for balancing the requirements of different perspectives.

A central issue of data modelling is in assuming that data modelling must be either objective or subjective such that data modelling process can be based either upon the notion of an objective reality or upon the notion of a reality that is socially constructed. In other words, the problem is not whether to be objective or subjective but that one implies the

other and that any method that is based upon one of these ontological positions must accept and cater for the other. Both objective and subjective aspects are present at the same time. Objective methods can be said to be objective because they are not subjective. However, taking a strong objectivist position is difficult. We cannot demonstrate the existence of an objective reality. A strong subjectivist position is another danger for good data modelling. In addition, the failure of information systems development is caused by overlooking many different forms of organisational knowledge. That is beyond of technical aspects. Accordingly, data modelling process should be done by recognising and incorporating the different forms of knowledge, which may influence the success of the entire data modelling process.

VI. Conclusions And Further Study

Data modelling as an organisational knowledge representation is concerned with the fundamental assumptions. The existing approaches of data modelling with regard to the assumptions are about the nature of reality and the nature of the knowledge captured in a data model. In data modelling process the recognition of paradigmatic dimension of objectivism-subjectivism is important. However, it is not appropriate to consider the data modelling process as objective the notion of an objective reality, or as subjective the notion of a reality that is socially constructed. Without the notion of objectivity the notion of subjectivity is meaningless. It should be noted that the sharp distinction between fact-based and rule-based data modelling approaches is not necessary. Although the major emphasis in the information systems research community has been on the fact-based approaches, data modelling processes need to incorporate some of both fact-based and rule-based approaches and thereby engage in some middle ground between the extremes of fact-based and rule-based. For the effective representation of organisational knowledge, consideration should be given to casting both objectivism and subjectivism as a duality. In addition to taking the duality into consideration, data modelling process should also be done by recognising and incorporating different forms of organisational knowledge. The typical response to the problem of tacit knowledge is the modellers' purpose in applying a data model as a formal representation of some subset of the knowledge, which the organisation needs to carry out its business. Misunderstanding is connected to the failure to understand the important role of tacit knowledge. There is a need for good techniques to decide what to include and what not to include in the subset.

Further study should, therefore, include developing applicable techniques for decision making in selecting organisational tacit knowledge. It should also consider in the area of rule-based approaches of subjectivism, as the concepts of the subjectivist approaches are not well researched in comparison with the fact based objectivism. Moreover, although the fact-based approaches are a lot better researched there is more study needed in terms of

development of data modelling approaches that embed the philosophical assumptions.

The Building of a Knowledge Portal for Supply Chain Co-Evolving

Chian-Hsueng Chao

Department of Information Management, National University of Kaohsiung,
Kaohsiung, Taiwan, ROC
cchao@nuk.edu.tw

Abstract: Today, companies are demanding more than just access to data. They want processed and refined information that will help them to reach more effective tactical decisions. With the global deployment of computers, inter-connecting network, mobile devices, and information architecture, participants can work collaboratively by sharing networked resources, and exchanging knowledge in order to improve corporate performance. The collaboration/cooperation feature is especially important in today's supply chain practices. Under this paradigm shift, information-oriented productivity depends on the sharing of knowledge and skills among workers. Therefore, supply chain strategies can be driven by the collective intelligence and competence to meet today's business challenges that enable organizational learning. Management of organizational knowledge for creating business values and generating competitive advantages is critical for organizational development. In other words, it is related to the efficient integration of enterprise system, e-business application framework, and knowledge portal in order to achieve the goal of a learning organization and a supply chain. co-evolving This paper focuses on the design of an enterprise knowledge portal in a supply chain scheme for today's business. The ultimate goal is to develop a technological framework for a knowledge network that brings people, information, technologies, business processes, and organizational strategies together to better utilize knowledge in e-business. The benefits of knowledge portal in today's e-supply chain collaboration will not only expand the learning capabilities of workers. It will also help supply chain trading partners to develop a more concrete vision and strategy for enhancing their market values.

I. E-Business Supply Chain Knowledge Management

Traditional business partnerships are changing in response to technology advancements and business innovations. Companies can achieve a business advantage by leveraging networking technology and the principle of supply chain integration. With network connectivity, supply chain integration is now the core strategic competence that enables many companies to act as one. Supply Chain Management (SCM) evolved several decades ago from a simple set of logistics performance tools to an inter-enterprise, and even channel-wide, operating philosophy. SCM is now a bounda-

ry-spanning, channel-unifying, dynamic, and coevolving philosophy of inter-enterprise management. The major contribution of today's supply chain model is to improve the bottom line by enhancing collaboration between businesses and their trading partners [1]. This feature is very important for the every industry, because many participants need to cooperate/collaborate intensively throughout a project life cycle, which will change from one job to another.

Issues related to e-supply chain integration include the internal and external core business processes, the development of close linkages between channel partners, and the management of production and information as they move across organizational boundaries. The selection of processes and cooperations with supply chain partners is critical to the success of business. The selection of e-supply chain partners extends beyond choosing a trading partner or contractor and must include configuring the business-to-business collaboration among the partners. An increase in horizontal integration synchronizes the output of the entire supply chain. In today's e-business, competing for supply chain requires either aligning one's strategy to what the organization knows or developing knowledge management (KM) capabilities to support a desired supply chain strategy (Figure 1). Management of organizational knowledge for creating business values and generating competitive advantages is critical for organizational development. Knowledge management systems should support people to access and learn from past and present organizational business practices/strategies and to apply the lessons learned

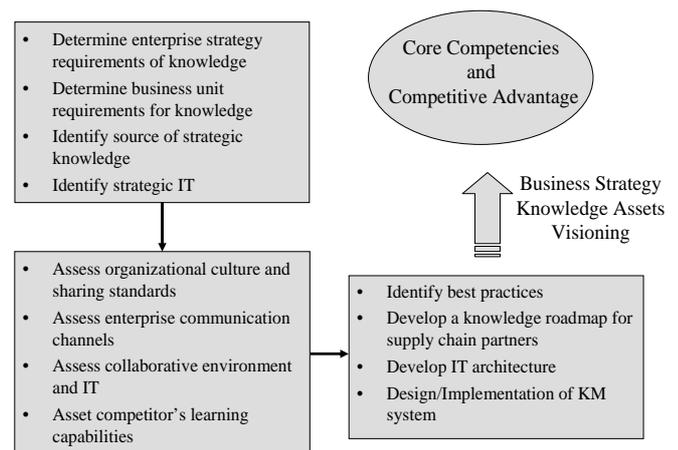

Figure 1 Aligning KM with Business Strategy

when making future decisions. Because supply chain strategies can be driven by the collective intelligence and

competence to meet today's business challenges that enable organizational learning. Based on the above discussion, a successful knowledge-oriented business for organizations should link supply chain management, relationship management, and knowledge management to function in an adaptive way and continue to thrive in the e-business era.

II. Portal of Storm: Knowledge Diffusion and Assimilation

Over the past few decades, organizations have constantly "reinvented" themselves through a series of business and technological innovations to fit into the global spectrum of business. An e-business supply chain knowledge management is a new business philosophy that drives enterprises to transform their business intelligence. Organizations are becoming knowledge intensive instead of capital intensive. This new business philosophy is an integral part of the knowledge economy for today's organizations to remain profitable, competitive, efficient, adaptive, and more intelligent.

The design of a KM portal needs to focus on the issues of data acquisition, information access/retrieval for knowledge utilization, communication, knowledge sharing, business process/information integration, document management, and most of all—collaboration. The focus on collaboration and collaborative support is perhaps one of the major distinguishing factors that differentiates knowledge support systems from other information systems. In business practices, collaborative problem solving, conversations, and teamwork generate a significant proportion of the knowledge assets that exist within a firm or entire supply chain. With network connectivity, the virtual teams can work collaboratively to share knowledge and best practices that enable supply chain "co-evolving." The enterprises will be able to better work together on a project across departmental and organizational barriers. Under this paradigm shift, intelligence and control are no longer concentrated in division offices. Empowered workers are actively engaged in their jobs, and they have the authority to form autonomous teams with self-defined roles and structures. The project members to form a "virtual team" can be from different divisions, departments, or even organizations. Those empowering workers will lead to radically different organizations that can cope with the ever-changing business environment. Interdependency between core knowledge workers will increase as the success of the enterprise becomes more dependent on how well they integrate their knowledge to produce innovative products and services [2]. This is the key issue of today's knowledge-enabled organization, and many of the concepts are brought into discussions of this paper. The objective is to develop a knowledge management framework that brings people, information technologies, business process, and organizational strategy together to better utilize knowledge in business practices in a supply chain scheme. KM portal systems should support people to access and learn from past

and present organizational business practices/strategies and to apply the lessons learned when making future decisions. The portal is also platform-independent that makes it possible to deliver business data and streamline business processes across heterogeneous business partners in the flash of a second. As mentioned before, the portal for knowledge management systems must to address the strategic visions of organization. There are several factors needed to consider in order to develop a successful KM system. The first is to recognize the organization's competence.

III. The Value Chain and Information Processing Network

Traditional managerial hierarchy is not addressed in the horizontal nature of collaborative or team-based communications, because of its vertical emphasis on communications and information systems. The shift from a division/functional organization to a matrix, and then to a network form arose from a desire to create organizations that utilize knowledge across processes and functions. Especially the rapid growth of the Internet brought about a reevaluation of the old supply chain philosophy and fostered the growth of new strategic alliance and business process integration across the border of organizations, thereby enabling organizations to more fully utilize the skills, knowledge, competences, and resources found in their supply chain network.

To design a supply chain solution, one must start by examining the basic framework of an enterprise's major business activities, which are considered competitive factors that are derived from Porter's value chain [3]. The value chain divides the organization into a set of generic functional areas, which can be further divided into a series of value activities. In the value chain, there are two distinct types of functional area: primary and support. Primary activities are concerned with the direct flow of production (such as inbound logistics, operations, outbound logistics, marketing, sales, and service), whereas support activities (firm infrastructure, human resource management, technology, and procurement) support the primary activities and each other. Starting with its generic value chain categories, a firm can subdivide into discrete activities, categorizing those activities that contribute best to its competitive advantage. The value is measured by the amount customers are willing to pay for an organization's product or service. Primary and support activities are called value activities, and an enterprise will be profitable as long as it creates more value than the cost of performing its value activities [4]. In this way, a value chain is defined and a better organizational structure and business process can be created around those value activities that can most improve an organization's competitive advantage [5].

The information processing view of an organization has been considered one of the most influential contributions to the contingency literature [6]. In this philosophy, information processing network provides the channels for exchange

and processing of information in a global system. The primary system objective of the information processing network is to provide a communication backbone for information exchange among its subsystem, the information processing nodes. The information-processing nodes within the network are responsible for receiving, using, selecting, producing, sending, and communicating (i.e. exchange information) with other information processing nodes (Figure 2). As a result, the lattice of channels between the various information-processing nodes forms a physical communication infrastructure called an information-processing network.

In value chain, Porter also recognized linkages outside the enterprise, as they relate to the customer's perception of value. This provides the possibility that one value chain could be linked to another value chain, because one business partner could be the other's customer. This interconnected value chain system can act as a supply chain or information processing network that encompasses the modern business world, and participating organizations can readily extend their technologies and knowledge to their partners. The "extended enterprise" aspect enables supply chain integration, more effective outsourcing, and self-service solutions for both internal and external stakeholders [5].

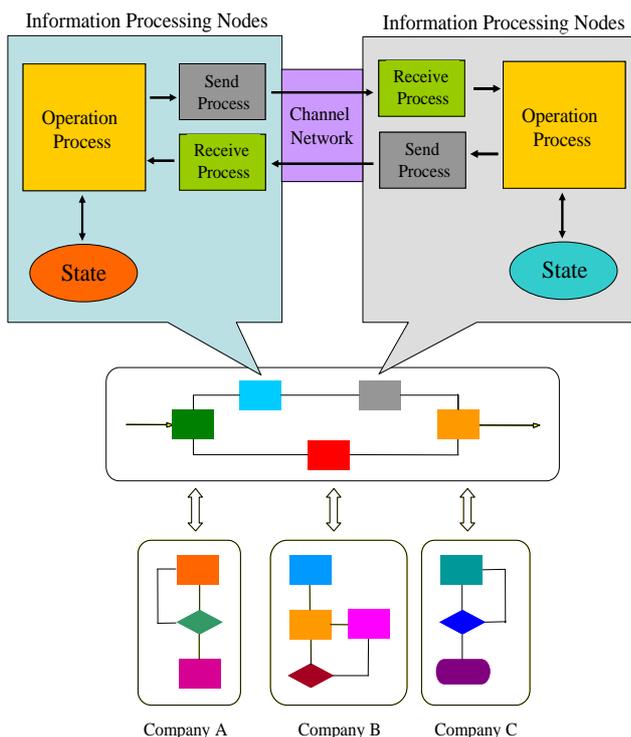

Figure 2 Information Processing View of Business Process Integration

This extended enterprise allows for the sophisticated interweaving of online business processes across trading partners and with other internal and external information sources. The usefulness of the integrated channels will be largely driven by new enterprise applications and KM portal that enhance the overall values. The following section will illustrate a typical integrated KM portal system for inter-

enterprise e-supply chain practices.

IV. The KM Portal System Architecture

The characteristics of information-processing nodes are much like the business components, but they conduct the actual exchange of information. The business components of the organization include people, processes, events, machines, and information that interact and combine to produce the products or output of the organization. People and information-processing machines, such as computers, are in this category. An enterprise operates as an information-processing system in a global information-processing network. Because it is an open structure, the network can be developed in a fractal pattern. The information-processing network can be expanded and connected to other organizations' information-processing networks. The information-processing nodes within each network in either organization can work collaboratively to achieve strategic goals in the newly joined network.

A typical enterprise KM portal is shown in Figure 3. In this figure, the KM portal act can like a groupware that supports not only several people working together on a task, but also their different and potentially changing roles. It has email and messaging functions, document management and information sharing, collaborative authoring, conferencing, time management, and some level of structured workflow support. Information can be managed only when it is embodied as content, which represents a specific combination of information and a manageable document [7]. Document management is a part of supporting IT, and it includes the ability to automatically develop and classify document databases.

Enterprise KM Portal		
Web Pages	To Do List /Calendar	Enterprise Applications
Conferencing/Chat /Discussion/E-mail	Search Tools and Directories	Document Management and Workflow
Project Management	Best Practices	Research
Database	Data Warehouse	News/Feedback

Figure 3 Typical KM Portal Components

In business practice, the project teams work collaboratively on the creation of documents and insuring that everyone has access to the latest updated version of the documents, which avoids working on the inconsistent versions of these documents. The KM portal is an integrated collaborative tool its database management ability organizes, stores, replicates, and provides shared access to documents by using a hypertext scheme. It has all the functionalities to

support basic business practices and knowledge management. The KM Portal system allows groups of users to interact and share information in an organized fashion and the documents can be posted on the Intranet or the Internet.

With the growing maturity of Internet technology, the KM portal can become more active. Applications can run on clients' browsers. The technological breakthrough makes the development of enterprise portal systems (utilizing corporate Intranet) easier in terms of communications and collab-

orations. The KM portal and Internet's hypertext scheme can easily profile different categories of business information for people working on the job site, or provide them with a "hyper-trail" for step-by-step operations. Behind the scene is a complex web that links different databases residing in the project team's organizations. With the aid of hypertext, an organization's information system becomes more accessible and adaptive, and the project data can be easily stored in archives for historical reference.

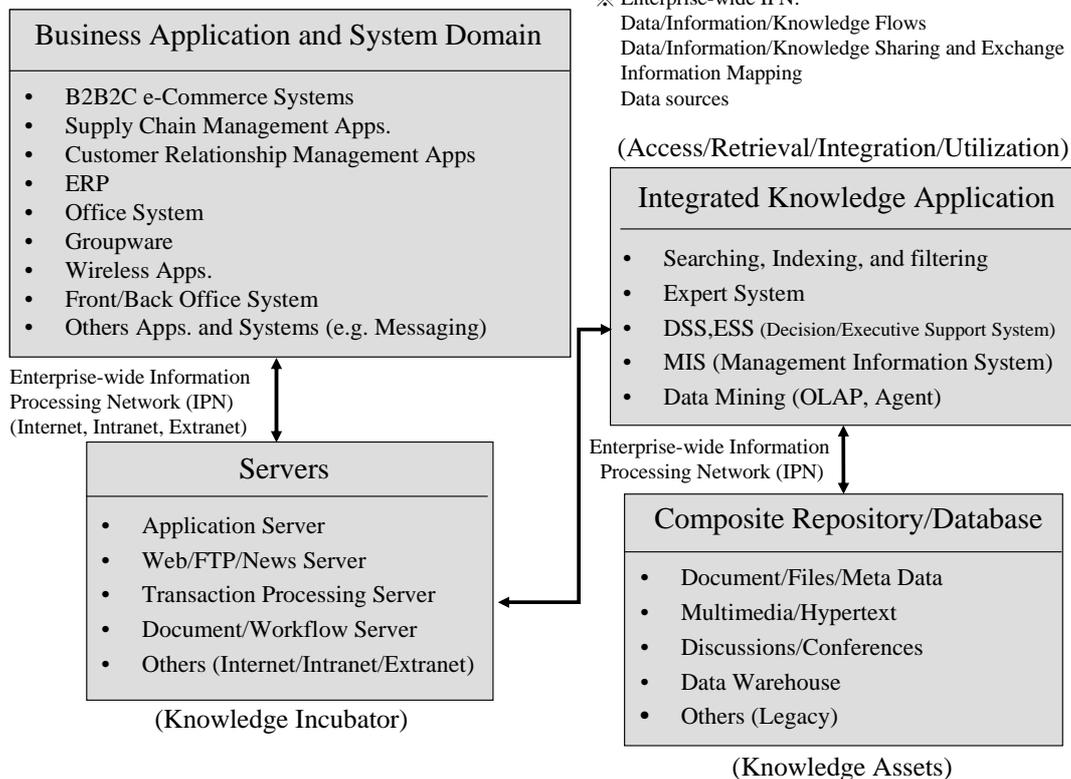

Figure 4 The KM Portal System Architecture

In this "knowledge portal" a dedicated knowledge server and database are required, because knowledge management must capture and retain in a central/distributed data repository the data and information that employees need. The technologies to facilitate these highly interactive communications are summarized in Figure 4. In this figure, for example, Internet/Intranet and groupware system are the most important ones for group communications and knowledge-sharing. For knowledge sharing, the architecture of IT in the knowledge management system is concerned with organizing and analyzing information in an organization's database so this knowledge can be readily available throughout a company. To help companies organize information residing in multiple locations and deliver it to prospective users, combinations of directory service, indexing, and searching are required in the KM system. Available groupware and document management systems do an excellent job in satisfying this requirement.

As mentioned, a central/distributed data repository that provides/captures the data and information for employees and executive decision-making is very important in a knowledge management system. The database is the core of a KM system, the decision-making support system is the driver that consolidates and directs the overall resources of the supply chain to the most mission-critical business activities to generate profits. It is believed that the next generation of knowledge management systems will be built on the Internet backbone with "agents" that flow through the net to gather business information and display it for decision-making purposes. On the other hand, the basic business applications are necessary to conduct daily business, such as word-processing, spreadsheets, accounting, and so forth. With the growth of the Internet, e-business is rapidly expanding into a complex web of commercial activities. Many organizations have recognized this competitive advantage and have shifted their focuses from process

improvement within an organization to process integration across their trading partners. This business-to-business practice transforms the traditional supply chain into a network that allows companies to work together and share knowledge. The key issue is the inter-enterprise processing. Therefore, this is the reason why knowledge management should include business processes integration.

V. The Learning Organization and Supply Chain Co-Evolving

In business practices, information is the glue that unifies businesses partnerships. Many organizations use their information processing networks and strive to become knowledge-enabled organizations to ensure that all employees are able to locate, access, and utilize the knowledge and skills they need to meet their individual and corporate goals. Senge in his thoughtful and provocative book [8] on system thinking described a "Learning Organization" as "an organization that is continually expanding its capacity to create its future." A knowledge-enabled organization is a learning organization, one where all employees are using their knowledge, skills, and learning to meet today's business challenges and to create new opportunities for the future. One thing important is that the organization also learns from customers, suppliers, and even competitors: from any and every relevant source within or outside the organization. An organization's value chain consists of all activities performed to design, produce, market, deliver, and support its product and service. Knowledge Management is introduced to enhance collaboration encourage innovation, boost productivity, achieve adaptivity, and increase the information system efficiency. The next generation of e-business will be built on an interconnected network which will help companies connect disparate systems, provide greater access to information, and more closely link employees and customers.

A successful knowledge portal and knowledge management system for today's new business must provide support for the capture and communication of users' demands, as well as enable these demands to automatically trigger business events and initiate process workflows. Indeed, a knowledge portal is integrated in terms of people focused on processes that ultimately respond to customer demand, but its success requires technology that can integrate and support every exchange of information across the entire supply chain. Data is the basic building block of information and ultimately of a knowledge-based business. A common data model is needed for the entire supply chain knowledge network, because the effectiveness of an e-business supply chain solution will depend largely on its ability to deliver an accurate and common view of customer demand data, as well as any subsequent events, plans, or other business data. Therefore, the enterprises are capable of quickly consolidating critical competencies and physical processes to gain competitive advantages easily.

VI. Conclusion

The explosion of strategic alliances and partnerships on a global scale has brought about the formation of inter-enterprise virtual organizations capable of leveraging the skills, physical resources, and innovative knowledge that reside at different locations in a supply chain network. The beauty of a supply chain knowledge network is that the true value of the information surpasses the conventional boundaries that often restrict employees' thinking [9]. The collaboration of people, processes, and technology is important, because companies can enhance customer satisfaction, improve operational efficiencies, and cut costs by leveraging a comprehensive, integrated, e-business suite of applications based on Internet technology. Information can be managed only when it is embodied as content, which represents a specific combination of information and a manageable document. A KM infrastructure combines automation, business rules, artificial intelligence, workflow, analytical tools and advanced messaging-analysis technologies to allow e-businesses to deliver information and to respond to customer requests rapidly and accurately [10]. In a successful "k-business" model, the sharing of information moves the supply chain closer to the desired goal of a demand chain. In this way, a true knowledge management system can be built and utilized by the entire supply chain community to generate profits. This adaptivity requires enhancing communication among all team members and aligning their actions toward a common project goal, and IT will be a key "enabler" for this transformation effort. Enterprises will need to learn that content communication is as important as technological infrastructure to the enterprise software application architecture. This new "e-supply chain" offers unlimited business opportunities when enterprises fully integrated their knowledge, processes, and technology. A well-designed and well-integrated knowledge portal will improve existing supply chain performance and provide organizational agility in the event of change.

Abstract: Knowledge management systems (KMS) are commonly tacit patterns practiced in Thai communities. Effective KMS is essential to successfully implement knowledge management (KM) and sustainable development organization. Appropriate model of total quality management (TQM) for Thai community's knowledge management systems will be designed. This study incorporated the concepts and theories of TQM models, KM and KMS in Thai communities. Index and standard of knowledge quality are analyzed and integrated concept of analytical TQM and Delphi technique are applied.

Keywords: Total Quality Management (TQM), Knowledge Management (KM), Community Development.

I. Introduction

The ability to manage quality of knowledge is becoming an essential core process sustainable development of today's organizations. Knowledge management (KM) theories and approaches have been adopted that they are the processes and strategies for continuing improvement [1], [2]. Knowledge management is large and complex issue includes management and operational practices and philosophies, technologies, strategies and human behavioral traits. Though they are different ways in working and results of KM implementations [3].

Creation, transferable, usability, storing and reusability of the knowledge are the most important notion of knowledge activities in knowledge management systems (KMS). An organization's KMS to provide competitive advantage needs both cognitive and social components, interconnected with individual member's cognition and social practices. The structural index which identify knowledge agents, evaluate knowledge sharing among organization members, and objectively assesses the contribution of knowledge agents are the benefits of KMS application [4].

Total Quality Management (TQM) is a mindset and a set of continuous and keeps on improvement processes for individuals, groups and whole organizations by understanding and discovering better process. Its major techniques provide a set of general governing principles; delight the customer, people – base management, continuous improvement, and managements by fact. And produces the excellence achieving results that delight all the organization's stakeholders (this includes employees, customer, suppliers, society in general and those with financial interests in the organization) [5].

Both KM and TQM are improving processes of the organizational qualities. The similarities of them include: result orientation, people base management, teamwork, leadership and delighting the customer. The differences are distinctive focus; approach of TQM is improvement base on fact, while KM is base on building a culture to support knowledge creation and sharing. Practical philosophy of TQM is "understanding and discovering" better process, while KM is "invented or identified" what people were doing and try to doing best practice and radical reinvention[5][6]. Though complement TQM with KM is possible and with properly TQM model planned KM process will be more effective and efficiencies.

Quality of life and sustainable of communities development, administrators as well as population will know what are the core value, core competency, and core knowledge of their living style and environment. They will know what critical knowledge of community is lacking or losing, and what are essential. These want suitable KMS, is powerful tool and important strategy KM implementation. This study is based on these concept (1) belief in community potential, (2) the TQM and KM theory which posits that tacit KMS has been in each communities, (3) concept of TQM can applied in public service organizations and (4) KM is effective in developing communities. Using TQM analytical techniques, knowledge of Thai community are identified and knowledge quality index and standard are established. By identifying the steps in famous TQM models, TQM model for KMS in Thai communities are designed. The model are tested and developed by integrated TQM and Delphi

technique. The model will serve as a theoretical framework and pragmatic foundations for identifying and categorizing knowledge qualities, management and measurement of community's knowledge assets; this assured the effectiveness of KM activities and KM feedback.

II. Literature Review

II.1 KM and KMS

Although knowledge and knowledge management concept is practice as early as 4000 years ago. Knowledge management systems (KMS), which involve the application of IT systems and other organizational resources to manage knowledge strategically, are a relatively recent phenomenon. It is generally accepted that knowledge comes from individual learning experiences and also comes from the meaningful organized accumulation of information through experience, communication, or inference. The adequate knowledge management processes is considered of a key factor for improving the organization's performance and long-term survival.

Definition of knowledge management means different in understanding of the term knowledge. In the past KM has been focus on information technology and information systems, but the new focus is on knowledge as distinct from the data-centric and information-centric. In perspective of process, the four basic activities: creating, storing, transferring, and applying are regarded, a complex mix of business processes, people, and technology is KM successful [7], [8], [9].

Adoption and diffusion of KMS are studied in the context of some Australian organizations factors and variables are identified, and they are found four major variables affecting KMS diffusion as: organizational culture, top management support, benefits to individuals, and dream of KMS [10].

In KMS 'Knowledge Management Gaps' that might occur when implementing the KM system. The reasons for these gaps and several fundamental approaches for avoiding them are the mismatch between the capability and greatly enhance the effectiveness of implementation of the KM system [11].

The KM development surveys using a literature review and classification of articles from 1995 to 2002 with keyword index in order to explore how KM technologies and applications have developed in this period. KM technologies using the seven categories as: KM framework, knowledge-based systems, data mining, information and communication technology, artificial intelligence/expert systems, database technology, and modeling, together with their applications for different research and problem domains. Some discussion is presented, indicating future development for knowledge management technologies and applications as the followings: (1) KM technologies tend to develop towards expert orientation and KM applications development is a problem-oriented domain. (2) Different social studies methodologies, such as statistical method, are

suggested to implement in KM as another kind of technology. (3) Integration of qualitative and quantitative methods and integration of KM technologies studies may broaden our horizon on this subject. (4) The ability to continually change and obtain new understanding is the power of KM technologies and will be the application of future works.

II.2 Quality and TQM

The success of quality management is based on several quality models. Much of perspective and popular literature on TQM subscribes that TQM is "universal" in its application ability. This appears on many levels the institutional, national and certification schemes (e.g. European Quality Award, the Malcolm Baldrige National Quality Award, QS 9000, IS 9000). The proposed TQM model can serve as a prototype for implementing quality improvement programs in manufacturing and service-sector settings.

II.3 TQM and KM

Research on Total Quality Management (TQM) and Just-in-Time (JIT) find that there is evidence supporting the compatibility of the practices in these programs and that manufacturing performance is associated with the level of implementation of both socially- and technically-oriented practices of the three programs.

TQM is an organizational culture dedicated to training, continuous improvement, and customer satisfaction. Empirical studies which have examined the relationship between TQM and organizational performance have investigated the impact of each dimension of TQM on performance separately. These studies have indicated that only a handful of the soft aspects of TQM (i.e., 'human factors' like commitment, team work and so on) contribute to organizational performance. Our contention is that soft TQM actually plays a number of roles. One is to create an environment where seamless dimension and implementation of hard TQM can take place, and the other is to directly aspect organizations' performance in the same way that traditional human resource management (HRM) practices can impact on an organization. The previous attempts to identify the relationships between elements of TQM are suggested. The first approach conceptualizes TQM as a limited set of technical tools (such as statistical process control and Pareto analysis) while the second approach views TQM as part of broader changes to human resource (HR) practices. Through examining computer, automotive, health care and banking industries in four countries, they found that the use of hard TQM tools tends to be more profound in companies that adopt strategies to increase stakeholder commitment and incorporate

III. Research Methodology

In this study, survey and analysis and Delphi Technique are integrated. Research processes are designed as following:

1) Documentary investigates on philosophical definitions, concepts, theories, and some examples of successful implementation on quality, TQM models, information standard, and measurement of knowledge assess, KM, and KMS.

2) Local Thai communities' structure, ways of public solving concept, wisdom and communities' life are analyzing for finding Thai communities' KMS framework. Survey and analysis Techniques are used.

3) In order to Thai communities' culture and environment, knowledge quality index and standard are settled. And the model of TQM for Thai community's knowledge management systems is designed and proved by Delphi Technique.

The model of TQM for Thai community's knowledge management systems is improved and then presented to public.

IV. Preliminary Results

Documentary investigation confirms possibility and usability of TQM application for Thai community' KMS. Preliminary results show that:

1) Knowledge is very important factor of community's potential growth. Each community has their KMS, which are different by community's way of life and environmental context.

2) Important factors of successfully organization in KM implement are knowledge sharing and innovative by nature of cultural organization.

3) There are a lot of tacit and explicit knowledge in Thai's communities, in difference forms such as tales, folk songs, literatures, way of lives, traditional curatives, home decoration style, and belief in religions ect. Most of them are not investigate in scientific methods. According to lack of dissemination systems mapping and suitable analytical tools, those knowledge are only garbage data and information.

4) TQM is philosophical and processes of organization quality investigation and improvement of inputs, processes and outputs. TQM techniques are assembly line, design of products for manufacture, and the end-to-end optimization of entire process. The improvement processes depended on collecting data and information, and analyzing, sharing codifying knowledge and discoveries. Usefully implementation technique will be suitable designed for organization circumstances, and successfully depended on having the knowledge people about individual parts of process work together in teams and share their knowledge that could be best decision made. So TQM could be integrated with KM and organized KMS communities effective able.

KM is the organizational behavior, knowledge sharing culture, and knowledge solution habit. Integrated Thai

communities' KMS with TQM model is needed to improve knowledge sharing, creating, and solving processes in society's value.

V. Conclusion

This study relation between KM, TQM model and quality definition are analyzed. The results confirm the importance and possibility of quality knowledge improvement in Thai communities by applying TQM to KMS. These results also confirm the relevance behind the management of both the technical and human aspects in knowledge quality processes, and potential of TQM and KM to generate competitive advantages. Thus, communities' knowledge index and standards will be designed and TQM model for Thai communities will be developed.

The Adoption of Mobile Short Message Services: Implications for Managing Value-Added Services in the Telecommunications Industry

Ziqi Liao

Abstract: This paper empirically explores several variables associated with the adoption of mobile short message services (SMS) from the consumer perspective. The results suggest that perceived usefulness, ease of use, behavioral control and reliability significantly explain the consumers' behavioral intention to use the mobile message services. The findings have practical implications for managing the value-added services in the telecommunications industry.

Keywords: Mobile commerce and business, value-added services, consumer behavior

I. Introduction

Emerging mobile commerce has great potentials because of its mobility and flexibility. It operates in the environment that is different from e-commerce conducted over the wired Internet. As one of the value-added services, the wireless SMS is increasingly popular. A key issue for the service providers is to appreciate the major factors of the SMS and consumer behavior in order to achieve the expected value of the services.

Existing studies in relation to the acceptance of information technology tend to explore attitudes, beliefs, and behavioral intentions of users. For instance, the technology acceptance model (TAM) was used to explore the acceptance and adoption of computer-based information systems [5]. Numerous studies were conducted to assess, validate and extend the TAM [1] [13] [16] [18] [19] [21] [22]. In addition, the theory of planned behavior (TPB) was emerged as one of the dominant social cognitive frameworks for understanding exercise motivation and behavior [2]. The TPB provides a parsimonious explanation of informational and motivational influences on behavior. The TPB could be considered as a deliberative processing model, which might be used to account for situations when performing a behavior was not entirely under the volitional control of the actor [2] [3]. Furthermore, Taylor and Todd [18] present the decomposed theory planned behavior (DTPB), in which attitude, subjective norm and perceived behavioral control contribute to behavioral intention. Further, they demonstrate that both TPB and DTPB can explain behavioral intention.

As a technology-based service, the adoption of the mobile SMS might be influenced by a number of demand-

side variables. Therefore, this paper aims to explore the use of wireless SMS from the consumer perspective. It begins with the description of several hypotheses followed by research methods. On the basis of the regression results, it discusses the key variables together with their impacts on consumers' intention to use the wireless SMS. Finally, the paper is concluded by highlighting the implications for managing value-added services in the telecommunications industry.

II. Hypotheses

Firstly, perceived usefulness affects individual attitude and intention to use a computer-based information system, which ultimately determines actual usage behavior [5]. It has been found that the acceptance of information systems is driven to a large extent by perceived usefulness [1] [7]. Other studies also show that perceived usefulness is positively associated with system usage [11] [12] [20]. It seems meaningful to test this argument in the case of the SMS. Therefore, H1 is proposed.

H1: Perceived usefulness positively influences consumers' intention to use the SMS.

Secondly, perceived ease of use could be a potential catalyst to increasing the likelihood of user acceptance [5] [7]. Perceived ease of use should be a quality attribute in IT-based services [4]. Perceived usability depends on ease of use [9]. This can be explained as stemming from a situation where the easier a technology is to use, the more useful it can be. As a matter of fact, perceived ease of use can directly contribute towards behavior [16]. In the case of the SMS, the message is entered through several keys and appears on a small display of a cell phone. It would be desirable if the operations were simple and user friendly. Therefore, H2 is proposed.

H2: Perceived ease of use positively influences consumers' intention to use the SMS.

Thirdly, social influence possibly affects the acceptance of a technology [8]. It may play a role in determining how users make their decisions about adopting and using a new technology [23]. According to [2], subjective norm reflects the degree to which referent others want the individuals to perform a particular behavior. The relative influence of subjective norm on intention is expected to be stronger for potential users, since they are likely to rely on the reactions

of others in forming their intentions [10]. In the technology domain, both peer and superior influences have been shown to be strong determinants of subjective norm [16] [19]. In order to test the impact of subjective norm on the SMS, H3 is proposed as follows.

H3: Subjective norm positively influences consumers' intention to use the SMS.

Moreover, the TPB incorporates a construct, namely perceived behavioral control, to account for a situation in which an individual lacks substantial control over the targeted behavior [2]. Perceived behavioral control refers to an individual's perception of the availability of requisite resources or opportunities that are necessary for performing a behavior. It can capture the perception about the skill and knowledge required to engage in a particular activity [2] [3]. It can also be measured by asking individuals about the potential barriers and costs of using a technology [14]. According to the TPB, perceived behavioral control has a direct effect on behavioral intention. Hence, H4 is proposed.

H4: Perceived behavioral control positively influences consumers' intention to use the SMS.

Lastly, perceived reliability is fundamental to product and service quality. In the case of service operations, reliability refers to the ability to dependably and accurately perform a service [15] [17]. The mobile SMS involves such risks as privacy and security, which may affect consumer behavior and dependability of the service. Therefore, H5 is proposed.

H5: Perceived reliability positively influences consumers' intention to use the SMS.

III. Research Methods

The research methods include survey and data analysis. Firstly, a questionnaire was designed to elucidate consumer feedback on the SMS. It consisted of a number of questions in relation to perceived usefulness, ease of use, subjective norm, behavioral control and reliability. The respondents were requested to provide their observations based on seven-point Likert-type scale ranging from 1 to 7. As a result, one hundred ninety five responses were received from mobile users at this stage. Based on the data collected, several procedures associated with the Statistical Package for Social Science were used to test the above hypotheses.

IV. Results and Discussion

The impacts of several attributes on consumer behavioral intention are examined using multiple regression analysis. In the present regression model, consumer behavioral intention is endogenous variable, while perceived ease of use, perceived usefulness, subjective norm, perceived behavioral control and perceived reliability are exogenous variables. Table 1 displays the regression results based on the data

randomly collected from different mobile users. The regression analysis suggests that perceived ease of use, usefulness, behavioral control and reliability significantly influence consumers' behavioral intention ($F = 43.309$, Sig. < 0.001). In addition, the value of adjusted R^2 indicates that the exogenous variables collectively explain 52.7% of the variance of consumers' behavioral intention to use the wireless SMS. Therefore, H1, H2, H4 and H5 are supported.

In general, service providers can strengthen the relationships with customers through encouraging the use of a particular service. If the individuals start to use a value-added mobile service, they might gradually appreciate the usefulness and tend to use the service in a more frequent manner. In other words, the impact of perceived usefulness on behavioral intention to use may increase over time. In addition, perceived ease of use considerably affects consumers' behavioral intention. It remains a primary concern in the case of the mobile SMS, which is similar to the case of the implementation of information systems. Therefore, the mobile service providers should improve the interface of the wireless SMS and enable more user-friendly operations.

However, the results indicate that subjective norm does not significantly affect behavioral intention. Hence, H3 is not supported. The link between subjective norm and behavioral intention may due to perceptions of the real consequences associated with use [18] [19]. It seems that the behavior of the other people has little impact in the case of mobile SMS. The mobile users are likely to have independent assessments and simply use the service from time to time.

Table 1 Results of Regression Analysis

	β	t	Sig.
(Constant)		3.956	.000
Usefulness	.201	3.242	.001
Ease of use	.319	5.054	.000
Subjective norm	-.012	-.217	.828
Behavioral control	.148	2.104	.037
Reliability	.298	4.819	.000

Note: Adjusted $R^2 = 0.527$

Furthermore, perceived behavioral control has a significant direct effect on behavioral intention. This is consistent with findings of prior studies [16] [18]. In this case, the consumers tend to use the SMS, if the service charge is very marginal in addition to the existing mobile service. This suggests that in order to encourage more consumers to use the SMS, the service providers should consistently reduce the cost of the service.

Finally, perceived reliability has a significant effect on behavioral intention. Consumers are concerned about the uncertainty and privacy when sending personal messages. Though the wireless SMS is useful for facilitating individual communications, individuals would not usually use the SMS to deliver sensitive personal data. However, the SMS has been widely used for promoting and advertising products

and services. It is not uncommon that the SMS has been abused to disseminate information for unacceptable commercial activities. Some may be frustrated by the receipt of many commercial messages. Therefore, the commercial SMS must be governed in order to enhance the confidence of the consumers in the mobile service providers.

V. Conclusion and Implications

This study examines the major considerations in relation to the use of wireless SMS. The results suggest that perceived usefulness, ease of use, behavioral control and reliability have substantial effects on behavioral intention to use the SMS. In general, consumers have appreciated the usefulness of the SMS. They are able to use the service because it requires limited expenses. More importantly, the mobile service providers should devote to develop more easy to use interface and user-friendly programs for the SMS. Moreover, they should further enhance the reliability of wireless communications. Even if individual demands and expectations may vary in different environments, the service providers must pay attention to the changing needs of the customers and continuously improve their existing wireless service operations and competitive strategies.

The findings of the study have practical implications for developing and managing different value-added services in the telecommunications industry. At present, the SMS is relatively popular to mobile users. However, other wireless applications such as mobile shopping and mobile banking are yet to be further developed, although the services are recently available. Moreover, there are various innovative value-added mobile services being developed by different service providers at present. Some applications are still at the early stage of development and relatively new to consumers. It is not uncommon that individual consumers may not be able to evaluate the usefulness of an innovative value-added service prior to implementation. The difficulty in measurement might be attributed to the fact that perceived usefulness is a measure that takes time to assess. It is also difficult for the service providers to quantify the value of a new value-added service before it has been extensively used by different customers. Therefore, the service providers in the telecommunications industry are suggested to consistently explore the determinants of an innovative value-added service in a particular social context in order to formulate appropriate business strategy for the service and realize the expected business value of the service.

Isomorphism and Mobile Commerce Strategy

Wenshin Chen

College of Business

Prairie View A&M University Prairie View, TX, USA

wechen@pvamu.edu

Abstract: Experts continuously predict that mobile technology would create new competitions in the business world and that all e-commerce would be on wireless devices in the near future. This technological trend indicates that M-commerce has been envisioned to be a major force of business competition. To any organizational member in an institutional field, a more comprehensive understanding of M-commerce strategy would thus become critical. Since conventional wisdom emphasizes economic aspects of technological strategy, a more comprehensive understanding of M-commerce would need to incorporate social/political aspects of strategic choice because such social/political backdrops in an institutional field often shape an organization's decision. Institutional theorists, for instance, argue that organization members' decisions are often driven by social/political pressures in an institutional field, particularly when the environment is surrounded by emerging technological issues. With its developing nature, M-commerce well fits into such an uncertain context. Institutional theory could thus help better understand how social/political forces in an institutional field influence an institutional member's decision. More specifically, this paper proposes that each of three isomorphic pressures, coercive, mimetic, and normative pressures, positively influences an organization's M-commerce strategy. These propositions encourage business and technology decision makers to consider social/political factors embedded in their institutional landscape and in turn better shape their organizations' M-commerce strategy.

Keywords: Mobile Commerce and Business, Isomorphism, Institutional Pressure

I. Introduction

As the Internet technology and the electronic market mature, emerging business competition beyond E-commerce has become increasingly significant in the business world [23]. Mobile commerce (M-commerce) has been predicted to become such a force to create new challenges and opportunities beyond the E-commerce market [13]. While the potentials of M-commerce have been extensively discussed by practitioners (e.g. [25] [46-47]), empirical studies that help understand and manage M-commerce strategy have not been parallel. The inadequate empirical studies of M-commerce might be due to the rapidly evolving

nature of mobile technology. However, as M-commerce creates a new competitive market and potentially transforms the manner in which business is conducted [12] [35], an insufficient understanding of such an emerging phenomenon might cause organizational inability to make an effective strategic choice. The purpose of this paper, thus, seeks to shorten the gap between practitioner's discussion and empirical research. It intends to examine an organization's strategic choice of M-commerce in an institutional field and in turn helps decision makers to better shape their M-commerce strategies.

Specific research questions of the study are mainly derived from the evolving nature and uncertainty of mobile technology. Research community has increasingly called for attention to issues and challenges of mobile technology [15] [19] [40] [44]. These technical challenges and standard issues of mobile technology prohibit an organization from fully envisioning the future of technological evolution. The rapid development of mobile technology could also exceed organizations' implementation capacity—before organizations fully comprehend the current technological capability, new devices or services might have appeared in the market. As such, high degree of technological uncertainty and complexity is involved in an organization's strategic choice of M-commerce, particularly in an institutional field where business competition is intense and social and political landscape is complicated. The paper thus asks: why does an organization adopt M-commerce strategy under such high uncertainty? What would an organization gain from the adoption of M-commerce strategy?

While conventional information technology (IT) strategy literature widely emphasizes economic aspect of strategic choice [26-27], the paper, in contrast, focuses on social and political aspects of strategic choice of IT in general and mobile commerce in particular. Derived from institutional theory, it specifically seeks to shed light on how isomorphic pressures influence an organization's adoption decision of M-commerce strategy. In the context of M-commerce, the discussion of isomorphic pressures could help better understand how an organization's decision making is driven by social and political landscape in an institutional field. The knowledge gained could thus encourage business and technology decision makers to consider not only economic but also social and political issues of M-commerce adoption and in turn better develop their M-commerce strategies.

I. 1 The Potential of M-commerce

This paper draws the definition of M-commerce from Tarasewich et al—"all activities related to a (potential)

commercial transaction conducted through communications networks that interface with wireless (or mobile) devices” [40, p. 42]. The reason of employing this definition is that it is one of better examples that specify the mechanism through which M-commerce is conducted. Such mechanisms—mobile devices—could include mobile phone, handheld computers, laptop computers, personal message pagers etc.

Practitioners have predicted that M-commerce could potentially turn a mobile phone into a retail outlet in a customer’s pocket [38] and change how firms sell and provide services for their customers [30]. It could also explosively influence particular industries such as financial services, travel, and retail businesses [35] and even more significantly, change firms’ business model [39] and IT strategy [31] [34]. Amazon.com founder Jeff Bezos even predicted that within ten years all e-commerce activities would be conducted through mobile devices [39]. In line with this view, Forrester Research reported that 90% of European companies intended to develop mobile Internet sites and 50% of them have already launched their development in the beginning of 2000s [8]. By the end of 2005, the US market will have more than 171.1 million mobile Internet users and 111 million consumers will access mobile Web on a monthly basis [12]. A survey in the US further indicated that mobile phones will become the second highest potential reach as an advertising medium only next to television [47]. The revenue that M-commerce will generate by the end of 2005 is predicted to be more than 100 billion worldwide [39].

However, all these predictions are mainly drawn from economic perspectives. If an organization’s decision making were simply based on such perspectives, the organization would then fail to understand social and political factors that play a significant role in influencing the success of technological adoption [1] [22]. With respect to an organization’s decision making, economic perspectives are derived from organizational voluntarism, which assumes that an organization’s strategic choice is simply a voluntary action so that it could be decided via an organization’s internal need assessment. Such a perspective neglects external factors such as environmental competition or institutional pressures. Zmud’s [48] push-pull model suggests that factors leading to an innovative action could be mainly categorized into push and pull forces. Pull forces stem from an organization’s internal evaluation of performance gaps or operations needs [7]. Push forces, on the other hand, result from a variety of external factors such as a promising technology, norms of the social systems [32], competitive pressures [21] or institutional influences [1]. In other words, an organization’s initiation of an innovation often results from both internal and external forces.

Institutional theorists further illustrate that one of external forces—institutional pressure—often leads to an organization’s isomorphic changes in a collective field. The organization tends to act in a similar fashion because of isomorphic pressures they face instead of their need to

obtain efficiency [9]. Such an institutional perspective provides social and political explanation of an organization’s behavior, extends traditional economic perspective, and in turn helps gain a more comprehensive understanding of strategic choice of M-commerce.

II. Institutional Theory

Institutional theorists argue that organizations act, not to increase cost efficiency, but to gain legitimacy [5] [18] [37]. Much of the ideas, values, and beliefs that an organization acts upon are influenced by institutional members instead of the organization’s needs of economic efficiency [28]. To survive, organizations have to first obtain institutional recognition; acting to accommodate institutional expectations, regardless of efficiency or cost benefits, would help to gain institutional recognition and in turn enhance survival opportunity [9].

Traditional wisdom of organizational voluntarism assumes that organizations make decisions based on their rational calculation of performance needs. In reality, however, institutional members would often follow the trend of institutional fashion and act collectively with other institutional members. An organization’s action in this pattern does not necessarily gain profit or efficiency. Instead, the result often lies in social recognition or political support [20]. Hiring a Nobel Prize winner, for example, would not be financially justified for a university; it could nonetheless attract better students or research opportunities and in turn gain better recognition for the university [9]. Such institutional actions have become common practice in the academia so that any university would highly sanction the legitimacy of actions. As a university acts toward the direction that is highly sanctioned, other universities would feel the urge or pressure to act in a similar fashion to gain institutional recognition. A university’s action thus does not necessarily result from internal, rational calculation of performance needs. Rather, it is highly influenced by institutional pressures resulting from common practice or collective action in the field. Such institutional pressures emerge to be powerful forces that cause institutional members act in an isomorphic pattern as illustrated by DiMaggio and Powell:

Once disparate organizations in the same line of business are structured into an actual field (as we shall argue, by competition, the state, or the professions), powerful forces emerge that lead them to become more similar to one another [9, p. 148].

These powerful institutional pressures could be due to institutional members’ dominant movement or governmental regulations. In relation to technological investments, an organization does not necessarily rationally evaluate its return of investment for the innovation. Instead, the motive for an organization to adopt an innovation often stems from standardized practices in the field [24] seeking for normative recognition [45], as illustrated by DiMaggio and Powell:

As an innovation spreads, a threshold is reached beyond which adoption provides legitimacy rather than improves performance... Strategies that are rationale for individual organizations may not be rational if adopted by larger numbers. Yet the very fact that they are normatively sanctioned increases the likelihood of their adoption [9, p.148].

In other words, an organization's technological adoption is often a function of institutional pressures—the fear of being different from other institutional members [2]. So long as an organization resides and competes in the field, it could not escape from these pressures. An organization's action, therefore, is often undertaken for considering other institutional members' action and result in a collective, isomorphic pattern [9], which seeks for social and political recognition and sequentially survival chances [28].

II. 1 Isomorphic Pressures

According to DiMaggio and Powell, the organization's collective action is mostly driven by isomorphism embedded in an institutional field. They specify isomorphism as “a constraining process that forces one unit in a population to resemble other units that face the same set of environmental conditions” [9, p.149]. These institutional theorists further contend that three sources that lead to isomorphism are coercive, mimetic, and normative pressures.

II. 2 Coercive Pressures

Coercive pressure is generally caused by governments or other powerful organizations in the same field. When governmental agencies enact industrial rules [22] or when powerful industrial leaders impose standardized practices [14], other organizations in the field would perceive an urgent pressure. This type of pressure rises from facing ‘must-have’ institutionalized rules or practices. Failing to cope with this type of institutionalized rules or practices could result in fatal failure. Adopting a new pollution control or prevention technology in certain fields where environmental issues are sensitive is one example that organizations respond to such coercive pressure [e.g., 36].

Since M-commerce has been predicted to be one of the most influential emerging technologies in changing a firm's competitive strategy [13] [31], a firm situated in a competitive institutional field will inevitably face strategic choices of M-commerce. Nowadays, a firm cannot compete against others if it does not well develop an E-commerce strategy. With increasing influences predicted by practitioners, M-commerce, similar to E-commerce, would soon become a “must-have” IT strategy; a firm without M-commerce strategy would then face difficulty in the competitive market in the near future. Failing to employ a clear M-commerce strategy, a firm could be excluded in the competitive market. In other words, a firm without M-commerce strategy would perceive high degree of coercive pressure. Such pressure would urge it to rapidly make strategic choice of M-commerce to compete at the same

level as other firms in the industry. As such,

P1: the greater the coercive pressures, the more likely a firm will adopt M-commerce strategy.

Two specific sources of coercive pressures could influence a firm's adoption of M-commerce strategy. First, the standard of mobile technology has not been well reconciled, especially in the US market [10] [34] [46]. This situation would encourage technologically leading firms quickly step in and standardize the practices for M-commerce. The more such leading firms are perceived as powerful and influential in the industry, the more likely other firms would be subjected to emerging mobile technological standard and subsequent coercive pressures. As such,

P1a: the greater power and influence of leading competitors, the more likely a firm will adopt M-commerce strategy.

Second, governmental agencies could also involve in the standardization of mobile technology. They could create a universal standard of mobile technology for the nation so that the technological compatibility across various vendors and devices could be achieved. Governmental intervention usually imposes coercive pressure directly on a firm so that certain standardized rules and practice have to be complied [22] [24]. With respect to mobile technology, such governmental intervention would also enable the compatibility of various standards. As such, it would, on the one hand, create coercive pressures on technologically leading firms and demand their compliance on the technological standards and, on the other hand, achieve higher technological compatibility, which would in turn ease the implementation and facilitate the adoption of M-commerce for other firms. Both situations would lead to more prevailing acceptance of M-commerce in the field. As such,

P1b: the greater the involvement of governmental agencies in the standardization of mobile technology, the more likely a firm will adopt M-commerce strategy.

II. 3 Mimetic Pressures

Mimetic pressure, in contrast, is primarily related to the uncertainty of environment and technology and the ambiguity of an organization's strategy. When the environment or technology is uncertain and an organization's strategy is ambiguous, an easier way for an organization to establish itself is to model after those who have been widely recognized in the industry [9] [24]. Following others' footsteps could minimize the risk due to high degree of environmental uncertainty or high cost of technological investment. For firms that are not widely sanctioned, the imitation of legitimate competitors becomes a voluntary but critical behavior to respond to the fear of being different [1] and help establish a firm's legitimacy [45]. Evidences have shown that in the context of EDI (electronic

data interchange) mimetic pressures perceived by an organization positively influence its adoption of the EDI systems [41]. In the context of M-commerce, issues involved in technological standard and infrastructure create both environmental and technological uncertainty [19] [40]. On the one hand, M-commerce is perceived as a significant strategic factor [34] so organizations inevitably perceive institutional pressures to adopt it. On the other hand, consumers remain unwilling to embrace M-commerce activities [25] because of the still uncertain stage of the technological development [34], the complicated mobile payment structure, and slowly developing wireless-telecommunication industry [46]. An organization might thus perceive that the investment could be costly and benefits might not be rewarding [25] [46]. Such context would then create mimetic pressures that encourage a firm to benchmark legitimate competitors and consequently adopt M-commerce strategy.

P2: the greater the mimetic pressures, the more likely a firm will adopt M-commerce strategy.

According to DiMaggio and Powell [9], mimetic pressures are mainly derived from two factors—external and internal factors. Externally, the significance of institutional practices and high uncertainty of the environment or technology constitute two major factors of mimetic pressures. More specifically, the significance of institutional practices stem from the prevailing usage of technologies and the perceived success of adopting firms [41]. In other words, an organization's decision to adopt emerging technologies is driven by the extent to which the technology is used in the field and the perceived success of firms that have adopted it. Enabled by mobile and relevant technologies, M-commerce thus cannot possibly escape from these effects in the institutional field; neither could it avoid environmental and technological uncertainty accompanied by emerging mobile technologies due to their developing and uncertain technological standard and infrastructure. Such uncertainty and the significance of institutional practices would unsurprisingly encourage an organization to model itself after other firms that have been successfully implemented M-commerce strategy.

P2a: the greater the uncertainty of mobile technology, the more likely a firm will adopt M-commerce strategy through imitating successful firms.

Internally, an organization's perception of mimetic pressures would be strengthened when it lacks of a clear strategy. The pioneers or early adopters of emerging innovations in the industry usually have a clearer vision with respect to adopting certain institutional practices or technologies to meet their organizational needs [41]. Other firms without a clear strategy, in contrast, would fear to be behind or to be different [1]. Such fear would encourage them to follow common and successful practices in the field so that the risk of technological implementation could be reduced [9]. In the context of M-commerce, technological

uncertainty would further push those who do not have clear business or IT strategy to model after firms that have successfully implemented M-commerce strategy.

P2b: the greater the ambiguity of a firm's strategy, the more likely a firm will adopt M-commerce strategy through imitating successful firms.

II. 4 Normative Pressures

Normative pressure, finally, is derived from the professionalization, the process through which the information is exchanged informally among professionals or formally through professional networks and associations [24]. Organizations in a collective field that consists of considerable amount of professional workforce will struggle to maintain prestige and resources, which are two major elements to attract professionals [9]. The professionalization process will encourage isomorphic behavior among organizations because organizations are inevitably inclined to demonstrate their capability to provide at least the same, if not better, benefits and services as their competitors do. Highly professionalized organizations (e.g., those who provide better benefits and services to their employees) will be recognized as more competitive and prestigious [24]. They will be more capable of not just retaining their employees but also attracting better workforce from the market. Their competitors, therefore, will face the pressures to model the benefits and service provided by these leading professionalized firms. In so doing, they could illustrate the willingness to maintain their employees and the desire to be recognized in the field [16].

Computer industry, where IT professionals generally share information rapidly and tend to identify themselves with their professions (e.g., programmers, system analysts) instead of with the company they currently work for, is one typical context in which normative pressures would emerge. Such normative pressures are positively related to an organization's adoption of an EDI system because the information of such systems is highly shared among professionals [41]. Predictably, in the context of M-commerce—a popular subject matter commonly shared by IT professionals, an organization member's decision making process of M-commerce strategy would be frequently discussed among IT professionals; their discussion would result in professionalization as aforementioned and in turn create significant normative pressures to any organizational members in the field. Consequently, the higher the normative pressure perceived by an organization, the more likely it will adopt M-commerce strategy.

P3: the greater the normative pressures, the more likely a firm will adopt M-commerce strategy.

While normative pressures generally stem from the professionalization [9], they specifically manifest themselves in two patterns: informal information exchange and formal professional networks and associations. Informally, IT professionals are likely to cross the boundary

of organizations and exchange professional information in various social settings. Such boundary-spanning individuals often bring in new ideas and help initiate an innovation in the organization [42]. As these boundary-spanning individuals exchange information frequently, they would be highly aware of any emerging technology newly developed and adopted in other organizations in the industry [42]. Such awareness would be increasingly prevailing within the organization. The management would thus inevitably sense the obligation to upgrade the professional practice and services to better retain its IT professionals. In the context of information technology, better professional practice and services often denote better technologies implemented. The state-of-the-art technologies used in the organization indicate certain challenges to IT professionals and the organization's willingness to compete with other organizations at the same level. As such, the degree to which boundary-spanning individuals informally exchange information among one another will create normative pressures for the organization and eventually influence its adoption decision of M-commerce strategy.

P3a: the more the informal boundary-spanning activities, the more likely a firm will adopt M-commerce strategy.

Formally, boundary-spanning activities could evolve through professional networks and associations. Such formal professional networks and associations often organize seminars or training sessions to help diffuse newly developed ideas or technological innovations. Professionals who frequently attend such activities would obtain knowledge and/or skills of concurrent practice or technologies in the industry. The managers involved in such professional affiliations would also eventually "view problems in a similar fashion, see the same policies, procedures and structures as normatively sanctioned and legitimated, and approach decisions in much the same way" [9, p. 153]. These boundary-spanning individuals would eventually become change agents or IT champions in the organization [32] to advocate the innovation in a similar fashion that other boundary-spanning professionals would do in their organizations. In the context of EDI, the extent of participation in professional associations denotes certain normative pressures, which in turn influences the intention of EDI adoption [41]. In the context of M-commerce, such formal participation of boundary-spanning activities would also help IT professionals and managers to realize the state-of-the-art mobile technology. Their realization would inevitably create certain degree of normative pressures that eventually urge an organization to adopt M-commerce so that the competitiveness could be ensured.

P3b: the greater the participation of professional network/associations among its professionals, the more likely a firm will adopt M-commerce strategy.

II. 5 The Effects of M-Commerce Strategy

Institutional theorists argue that an organization makes

isomorphic changes to pursue for social fitness [9], cultural support [20], or ultimately institutional legitimacy [24]. Such pursuit of legitimacy will reflect on organizations' external reputation. For example, as a firm makes isomorphic changes toward a popular management technique such as total quality management (TQM), it might symbolically create an innovative vision for the stakeholders. This innovative vision might be due to any form of isomorphic pressures. Once it is created, however, the organization has declared to its stakeholders that it intends to compete at the same level as other organizations do. The stakeholders would then better recognize the organization as a legitimate competitor in the industry. An organization's image and reputation would then be enhanced regardless of the actual performance [37].

Considering the tremendous potentials of M-commerce [31] [34], an organization's strategic choice of M-commerce would then demonstrate its willingness to create new competing opportunities and its desire to compete with other organizations in the field. Such demonstration could then help enhance an organization's innovative image and competing legitimacy—in another word, its external reputation.

P4: the adoption of M-commerce will be positively associated with an organization's reputation.

While the adoption decision of M-commerce would affect an organization's competing legitimacy through the heightened external reputation, it would also improve employees' recognition of the firms simultaneously. Empirical studies have shown that as an organization makes an innovative decision such as implementing a popular management technique—TQM, the organization gains not just the stakeholders' but also the employees' recognition [37]. Particularly, if such a decision stems from the strategic responses to normative pressures, it would denote an organization's enthusiasm to fully equip the employees with superior technology and the state-of-the-art practices. As the professionals exchange information about the current practice of the firms, the employees whose firms have adopted M-commerce would then feel more confident and comfortable to diffuse such information. Other professionals whose firms have not yet adopted M-commerce would then better recognize and appreciate the practice of the adopting firms. Such recognition and appreciation would reflect on the adopting employee's attitude toward their adopting firms. As such, the employees whose organizations have adopted M-commerce would tend to better recognize their firms.

P5: the firm's adoption decision of M-commerce will be positively associated with its employees' recognition of the firm.

These propositions and relationships among constructs are illustrated in Figure 1 below.

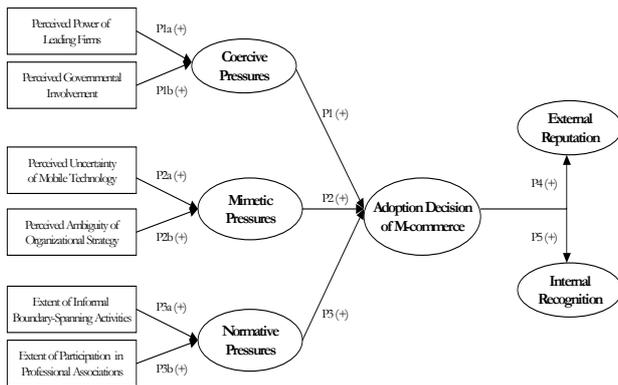

Figure 1. The Proposed Research Model

III. Methodology

The paper builds upon a theory testing approach. The purpose of such an approach is to obtain reliable statistical power and in turn generalize the results and allow replicability. To achieve these objectives, the survey method will be used to collect data because of the need of a large sample size across geographically distributed areas. In addition, structural equation modeling (SEM) techniques will be used to analyze data and test the proposed research model. SEM is best known for dealing with a theory-driven, confirmatory analysis of complex, multiple layers of relationships among underlying constructs [17], which suits the research model (Figure 1) that is strongly rooted in institutional theory.

The 1000 largest companies in the metropolitan area will be contacted as the potential participants. A solicitation letter will be first distributed to each of these companies' CIO or IT manager. An indication will be made in the letter to guide them fill out the survey online. Online survey allows autonomous and anonymous participation in a convenient fashion. It should better encourage the participation and facilitate the data collection process.

The Measures

Most items used on the survey are developed from conceptual definition because no existing instrument is specific enough to serve the purpose of the study.

Coercive pressures are measured by two sub-constructs: perceived power of leading firms (PPLF) and perceived governmental involvement (PGI). The former indicates the extent to which the leading firms impose coercive pressures on others. Such coercive pressures would particularly manifest themselves if an organization perceives that the leading firm possesses necessary technological and other resources to establish the standard or to well connect to governmental agencies and in turn lobby necessary changes in favor of them. As such, three seven-point scales will be

employed to assess a leading firm's technological, financial, and political resources (Appendix). Perceived governmental involvement, on the other hand, denotes the degree to which governmental agencies engage in the standardization of mobile technology, which is one of the main sources of coercive pressures. When a governmental agency regularly participates in industrial activities and/or promotes certain industrial or technological standards, coercive pressures would become more apparent. As such, two seven-point scales will be used to assess the degree of governmental agencies' participation in each of activities above (Appendix).

Mimetic pressures are measured by two sub-constructs: perceived uncertainty of mobile technology (PUMT) and perceived ambiguity of organizational strategy (PAOS). Perceived uncertainty of mobile technology mainly stems from technological standard and infrastructure issues [19]. Because many issues of technology and infrastructure development remain unsolved in the industry, an organization inevitably experiences difficulty to adopt M-commerce and tends to imitate other organizations. Perceived uncertainty of mobile technology, thus, would be measured by two seven-point scales assessing the degree to which the technology standard and infrastructure is perceived to continue to change in the near future (Appendix).

Perceived ambiguity of organizational strategy, in contrast, concerns an organization's business and IT strategy. While common business strategies are categorized as defenders, analyzers, prospectors, and reactors [29], IT strategy could be articulated by low cost and differentiation/innovation [33]. However, the concern of perceived ambiguity of organizational strategy does not involve the types of strategy but the degree to which the strategy is clearly illustrated in the organization. As such, the study would simply employ two seven-point scales; each of which assesses the degree of clarity of business and IT strategy, respectively (Appendix).

Normative pressures are measured by two sub-constructs: extent of participation in informal boundary-spanning activities (EPBS) and in formal professional associations (EPPA). Boundary-spanning activities could denote the contact through interpersonal relationships or with mass media [6]. The paper thus employs two seven-point scales to assess the degree of participation in each category of boundary-spanning activities (Appendix). In addition, the participation in formal professional associations indicates how much the professionals have been exposed to IT related professional activities. This notion resembles the construct of external participation in Brancheau and Wetherbe [6]. While these authors measure the number of networks and associations to which the professionals belong, this paper argues that a scale assessing the degree to which the professionals involved in professionals associations would be more appropriate because obtaining a membership is one thing, actively

involving in professional activities is another. The study thus employs one seven-point scale to assess the degree to which the professionals actively involve in professional activities (Appendix).

Adoption decision of M-commerce strategy is measured by the time of decision made (TDM) [6]. While some studies measure the adoption by intention (e.g., [41]), such measure is appropriate only when the action of adoption has not yet been undertaken. In the context of M-commerce, many large corporations might have implemented the technology and relevant competitive strategy [8]. As such, two seven-point scales that measure the past and the future decisions would better incorporate the decisions that have made and the intention to adopt (Appendix).

External reputation is measured by a firm's actual performance. The actual performance assesses a firm's changes in revenues. An increase of revenues indicates that the stakeholders have higher confidences on the firm so that the investment on the firm or the transactions with the firm increase. Such measure has also been used to signal a firm's reputation in the industry [37]. Rather than measured by the survey, the data would then be collected through public records such as the firm's quarterly or annual reports and/or financial performance in the stock market.

Internal recognition is measured by the turnover rate of employees. When the employees perceive that their firm could not provide equivalent practices or services as other firms do, they would be likely to leave for better opportunities. On the other hand, as they better recognize and appreciate the firm, they would tend to retain. The record of turnover rate would then be appropriate for the research context.

IV. Discussion

IT research has extensively applied economic-based theories such as transaction cost economics and resource-based view to explain the rationale of IT adoption (e.g., [3] [4] [11]). The former perceives IT as a tool to reduce cost while the latter views it as a valuable resource to provide competitive advantages. These theoretical perspectives stem from rational choice theorizing foundation in which an organization is assumed to be a rational actor who would act on rationally calculated purpose. Rational choice perspective, however, has been widely challenged because it fails to explain social and political factors emerging from the environment [18] [24] [37]. Social and political factors are important with respect to the technological adoption because they better explain environmental forces that lead to an organization's adoption decision [20] [22]. More specifically, this paper argues that isomorphic pressures help clarify an organization's action in adopting collective organizational practices in general [9] [28] and comparable technologies in particular [1] [41]. The findings of the study, thus, could

contribute to the organizational practice in the following ways.

First, since a regulated technological standard could create coercive pressures that force other firms to follow, developing and establishing a standard for mobile technology would become one of the most powerful weapons to help a firm compete in the emerging market. Organizations, thus, could seek strategic alliances or political cooperation to persuade governmental agencies to establish the standard of mobile technology. This could help dictate the institutional trend so that other firms have no option but comply with such standard. Second, the adoption of M-commerce needs to fit into an organization's strategy. Without a clear strategy, an organization would inevitably face mimetic pressures to imitate other firms' practices, particularly with many uncertain technological issues surrounding M-commerce. As such, to better compete in the emerging market and ensure survival chance, an organization needs to first develop a clear vision with respect to business and technological investments.

Third, an organization needs to renovate pressures into resources. Isomorphic pressures mostly result from institutional members in the field. If an organization could establish technological collaboration with these members or competitors, the competition resulting from isomorphic pressures could then be reduced. Such collaboration does not necessarily denote formal strategic alliance. Instead, it could imply an institutional network through which members exchange information and share experiences with respect to technological adoption. Finally, an organization might need to encourage its professionals and managers to actively participate in boundary-spanning activities. These boundary-spanning individuals could bring in new ideas and concurrent information of the field. Their informal interaction with other professionals in the field and formal involvement in professional associations could be developed into common practice in the firm. In the short term, such common practice could help an organization learn better approach of implementing M-commerce strategy; in the long term, it could further establish an innovative culture in the firm so that the organization would continuously improve its technological practice and establish an innovative legitimacy. Such legitimacy could, on the one hand, enhance an organization's survival chance and, on the other hand, help an organization to impose isomorphic pressures on other institutional members.

V. Concluding Remarks

While economic based theories such as transaction cost economics and resource-based view have been extensively applied, institutional theory offers a new dimension to examine IT phenomenon. Drawing from such a new dimension, the study seeks to examine an organization's adoption strategy of M-commerce in relation to isomorphism. Specifically, the paper proposes that each of isomorphic pressures would influence an organization's

adoption decision of M-commerce. Coercive pressures result from powerful organizations and governmental agencies' intervention in the standardization of mobile technology. Mimetic pressures are derived from the technological uncertainty and the ambiguity of organizational strategy while normative pressures rise from the professionalization through which boundary-spanning individuals involve in informal information exchange and formal experience sharing and training. These isomorphic pressures could motivate an organization to adopt M-commerce in a similar fashion as that of other institutional members.

Once the adoption decision of M-commerce is made, it denotes that the organization would join the competitive market much in the same way as other organizations do. The organization would then be better recognized by stakeholders as a legitimate player and by its employees as a better place for which they work. The heightened external reputation and internal recognition could consequently help enhance an organization's actual performance and retain its valuable professionals. To better compete and survive in the emerging competitive market, an organization would then need to pay strong attention to social and political landscapes of an institutional field so that a better strategic choice of M-commerce could be developed.

APPENDIX: The Survey Scales of Key Constructs

For all items: 7—strongly agree; 1—strongly disagree.

Perceived Power of Leading Firms (PPLF)

The leading firms possess powerful technological resources.
The leading firms possess powerful financial resources.
The leading firms possess powerful political resources.

Perceived Governmental Involvement (PGI)

The governmental agencies actively participate in the industrial activities.
The governmental agencies actively advocate certain standards for mobile technology.

Perceived Uncertainty of Mobile Technology (PUMT)

The standard of mobile technology will continue to change.
The infrastructure for connecting mobile technology will continue to evolve.

Perceived Ambiguity of Organizational Strategy (PAOS)

Our organization has a clear business strategy.
Our organization has a clear IT strategy.

Extent of Participation in Informal Boundary-Spanning Activities (EPBS)

I frequently contact other professionals in the industry for technological information.

I am actively exposed to mass media related to the technology.

Extent of Participation in Professional Associations (EPPA)

I actively participate in IT professional associations.

Time of Decision Made (TDM)

Our organization has adopted M-commerce for a long time.
Our organization intends to upgrade M-commerce soon.

The Multi-Channel CRM Application Framework for M-Business Practices

Chian-Hsueg Chao

Department of Information Management, National University of Kaohsiung,
Kaohsiung, Taiwan, ROC
cchao@nuk.edu.tw

Abstract: In every industry, customers' preferences are changing faster than ever before. Customers can no longer be categorized into well-defined market segments or homogeneous groups. They need to be treated as individuals each with specific needs. The information must be available to anyone from anywhere at anytime. Therefore, service quality becomes an important measure for both enterprises and customers. In real-time economy, sales and services have deep impacts on up/downstream decisions, as well as decisions related to supply chain trading partners. Thus, customer relationship management (CRM) has more transparency than ever, by shifting from a sales productivity tool to a technology-enabled relationship management strategy. Today's businesses are typical collaborative multi-enterprise multi-channel supply chain consisting of several specialists. Mobile technology and personalized customer care open the door to new opportunities by offering value-add services in CRM practices. The key to customer satisfaction and loyalty resides in the enterprise's core offering and efficient transaction management. This paper provides a broad discussion on the design of mobile-to-enterprise application framework for CRM practices. The purpose is to provide an overview and schematic to design an integrated mobile CRM suite. The ideal of this approach is to maximize the value of an enterprise's customer portfolio through more efficient and effective marketing, sales, and customer service and to put the customers in control, by providing self-service and solution-centered support. With the mobile CRM application framework, the enterprise is also extended to suppliers and trading partners so that when customers get in contact with the resources of an enterprise, they also touch the resources of the value chain. The customers who drive the entire value chain (or supply chain), determine what is to be produced, when it is produced, and at what price.

I. New Dimension of Channel Integration

Today, customers are in charge and make the rules. Consumers are demanding solutions customized to meet their specific needs. Consequently, the challenge is shifting from product-centric marketing to customer-centric marketing. Whenever an innovation is introduced, it brings both new challenges and business opportunities to enterprises. The e-business comes a long way from hype to mature. The mobile solutions will build on the top of the existing e-business investments. The m-business is facilitated by the

integration of the Internet, e-business, and the wireless world where customers can go online with any device at anytime from anywhere [1]. Mobile businesses open up new opportunities for innovated enterprises and give them new means of communications with inside/outside stakeholders. In a changing business landscape, mobile business addresses new customer channels and integration challenges. In order to compete in today's real-time economy, every business must be able to quickly identify and respond to the changing market conditions and customer needs. These sales challenges are made worse further by difficulties in pricing, promotion, and relationship-management. In real-time economy, sales and services have deep impacts on up/downstream decisions, as well as decisions related to supply chain trading partners. Thus, in m-business era customer relationship management (CRM) has more transparency than ever, by shifting from a sales productivity tool to a technology-enabled relationship management strategy in a global supply chain scheme. The CRM is a combination of business process and technology seeking to profile an enterprise's customers from different perspectives [2]. It contains call center service and support, customer contact management, and sales/marketing automation that help to acquire/retain customers and eliminate operation inefficiencies by streamlining and unifying customer information and other internal/external inter-enterprise process integrations.

Enterprises focus on how to use mobile technology to provide customers with rich service experiences and greater satisfactions. Mobile applications are beginning to play a central role in enabling real-time CRM. Enterprise must design a mobile application framework for both customers and their suppliers. The usefulness of the mobile channels will be largely driven by new enterprise applications that enhance the overall customer values. Seeing m-business processes in terms of a net value added chain is a good approach for visualizing current and future competitive advantages. The creation of these values depends on the enterprise's ability to coordinate and link those internal/external activities efficiently.

II. The Mobile Value Proposition

As the global economy shifts toward the mobile economy, enterprises need to be progressively more flexible and globalize. The mobile business strategies will focus on what "value" might be created for the customers and enterprises in the marketplace. To gain competitiveness and create values, the enterprise should target on redesigning their core

business processes in response to key competitive factors. These competitive factors can be derived from the Porter's value chain [3]. The value chain divides the organization into a set of generic functional areas, which can be further divided into a series of value activities. In the value chain, there are two distinct types of functional area: primary and support (Figure 1). Primary activities are concerned with the direct flow of production (such as inbound logistics, operations, outbound logistics, marketing, sales, and service), whereas support activities (firm infrastructure, human resource management, technology, and procurement) support the primary activities and each other. Starting with its generic value chain categories, a firm can subdivide into discrete activities, categorizing those activities that contribute best to its competitive advantage. The value is measured by the amount customers are willing to pay for an organization's product or service. Primary and support activities are called value activities, and an enterprise will be profitable as long as it creates more value than the cost of performing its value activities [4]. In this way, a value chain is defined and a better organizational structure and business process can be created around those value activities that can most improve an organization's competitive advantage [5].

Porter also recognized linkages outside the enterprise, as they relate to the customer's perception of value. This provides the possibility that one value chain could be linked to another value chain, because one business partner could be the other's customer. This interconnected value chain system can act as a supply chain that encompasses the modern business world, and participating organizations can readily extend their technologies to their partners. The "extended enterprise" aspect enables supply chain integration, more effective outsourcing, and self-service solutions for both internal and external stakeholders [5]. The usefulness of the mobile channels will be largely driven by new enterprise applications that enhance the overall customer values. A business that creates m-business applications can benefit from the first-to-market advantage.

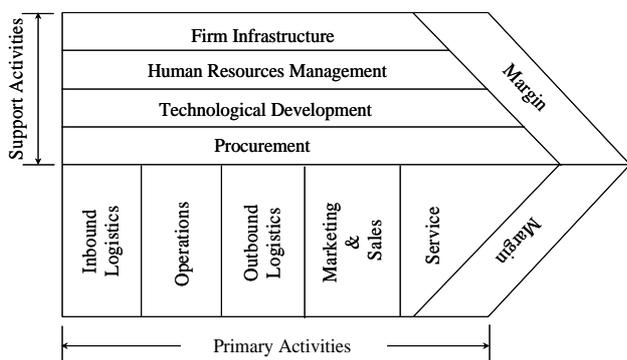

Figure 1. Porter's Value Chain (After Porter, 1985)

As the wireless Internet continues to expand, first-to-market organizations will have already secured a customer base. It can be foreseen that the m-business market value will be astronomical.

III. Customer Portal : One for All

As mentioned before, seeing m-business processes in terms of a net value added chain is also an approach for visualizing current and identifying future competitive advantages. In short, the creation of these values depends on the enterprise's ability to link and coordinate these internal/external activities efficiently [3]. This interconnected value chain system can act like a supply chain that encompass the modern business world, and participating organizations can readily extend their technologies to their partners.

Emphasis has been placed on the back-office integrations since the emerging of new supply chain practices in the mid-1990s. Today, there are many strategies on the enterprise back-office system integrations, such as enterprise resource planning (ERP) and enterprise application integration (EAI). These solutions are trying to create a unified communication channel that allows enterprise business processes to permeate different departments, divisions, and supply chain partners. In the meantime, there is a growing trend in the marriage of ERP with CRM [6]. The reasons are in two folds; (a) to maintain the integrity of business processes from production to sales automation and (b) the growing importance of customer care. With the combination of ERP and CRM, the enterprise will be more adaptive and flexible to engage customized services. In today's e-commerce, the customers are in control, and a business must realign its value chain around the customers to eliminate inefficiencies and customize information, products, and services. A set of CRM is not enough to handle diverse group of customers, especially when dealing with one-to-one relationship marketing. To maximize selling power and retain customers, CRM is becoming the central issue in gluing enterprise back-office business-to-business (B2B) and store-front (or front-end) business-to-customer (B2C) practices (Figure 2). The applications of CRM, by definition, must automate processes across multiple user types and functional areas. CRM is a broad set of sales/marketing solution that includes the following strategic areas: data acquisition and analysis (such as data mining and warehousing), marketing intelligence (such as business intelligence tools), sales force automation (SFA), customer services (such as CRM), product catalog and pricing services, proposal/quote/contract management, order management, fulfillment, and the integration of back-office system (such as ERP). The purpose of CRM is to build an adaptive marketing strategy such that the entire selling process will be more active and flexible than traditional 4Ps (product, price, place, and promotion) marketing approaches allowing sales teams to better handle any sales activities.

The IP convergence strategy will provide a solution that joins the two worlds of voice communications (telephony) and data traffic together. Technologies, such as interactive voice response (IVR), computer telephony integration (CTI), are beneficial to CRM. The fully interactive nature of the Internet changes everything in the world of self-service.

The blending of Sales Force Automation (SFA) with customer self-service brings new business opportunities. Relevant information and intelligence support processes all can be aligned and implemented in real-time at anywhere. This new dimension of channel integration strategy increases customers' value by satisfying customers' requirements and providing them with the best solution. With marketing intelligence, personalized customer care service will offer valued-added one-to-one relationship marketing to enhance individual purchasing experience and retain customer loyalties with enterprise. This effort can be achieved through the introduction of business intelligence in selling chain practices.

IV. Technological Framework

CRM suite, with an emphasis on purchasing process and customer care, represents a new shift in enterprise computing. This new dimension of channel integration brings both opportunities and challenges to enterprise to refine their business strategies and supporting information systems. The application of CRM includes technologies from initial customer contact to production and delivery of final goods or services. The scope also focuses on the gathering of customer data and information. Data acquisition is an important issue in CRM. The technologies to facilitate these highly interactive communications are summarized in Figure 3. In today's e-commerce practices, all business data are transmitted over a variety of communication channels because the essence of e-commerce lies in the communications of business data among organizations, supply chain trading partners, and customers. For a typical buying pattern, click-stream through an enterprise's web site, buttons pushed on a touch-tone phone, postal mail/email and faxes are all part of communication with customers. This information by now is not captured in meaningful way to maintain a comprehensive view of the attributes and patterns of customers. With the focus shifts from product-marketing to customer-centric marketing, business intelligence (BI) helps to coordinate information between brick-and-mortar and online initiates. It relies on integrated data from a variety of information sources: web site, call centers, customer profile and transaction log, operational database, ERP system, and even third party data. The BI analytical and segmentation applications offer tools for data mining as well as decision-making in enterprises. In CRM, data acquisition does not only capture customer preferences and patterns, but it also presents customers with personalized information in the purchasing process. The fully integrated CRM application has the ability to record and analyze all the activities of prospects and customers, whether the contact mechanism is via the web or a call center. This "automatically-collected" treasure of user behavior information theoretically gives the enterprise a huge advantage over brick-and-mortar competitors, who cannot easily record customer and prospect behavior.

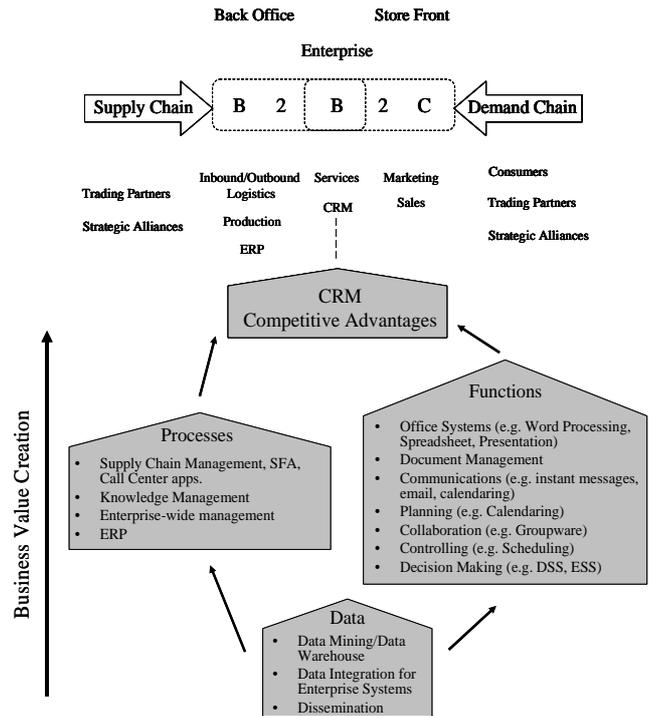

Figure 2. The M-business Value Proposition

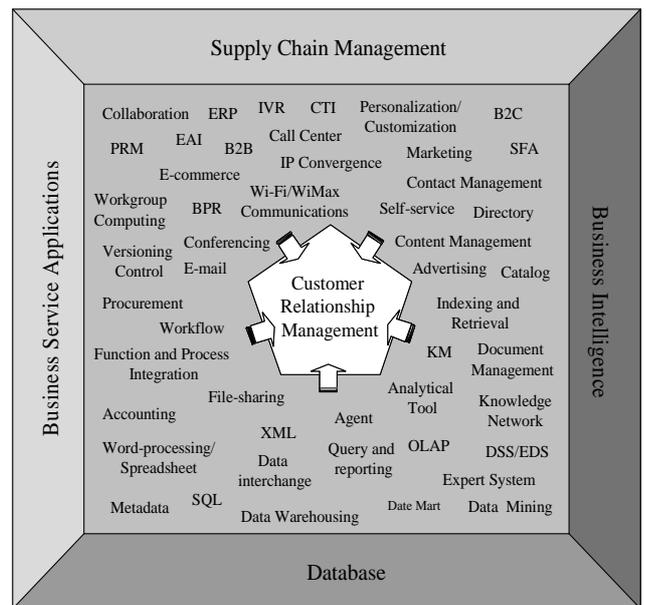

Figure 3. The CRM Technological Framework

The existence of an effective relationship management and click-stream/call-stream data warehouse is one of the most important long-term success differentiators in the e-commerce practices. Other technologies, such as interactive voice response (IVR), computer telephony integration (CTI), are beneficial to CRM. The fully interactive nature of the Internet changes everything in the world of self-service. The blending of SFA with customer self-service brings new

business opportunities. Relevant information and intelligence support processes all can be aligned and implemented in real-time at anywhere.

With the convergence of B2B, B2C, BI, and real-time relationship management, the personalization of customer information is now possible. A robust CRM suite for customer care applications enables new kinds of interactions, new kinds of information, and comprehensive access to all customers and enterprise portals. This customer care can foster joint problem-solving, convenient self-service, and self-selling. Given the information customers need in the purchasing process, they will sell to themselves and service their own information needs. In other words, customers can be an enterprise's best sales forces.

V. System Architecture

In today's m-business, competing for mobility requires either aligning one's strategy to what the enterprise agility or developing mobile computing capabilities to support a desired supply chain strategy. Mobile business systems must to address the strategic visions of enterprise. A successful mobile business application framework for enterprises should link supply chain management, relationship management, and knowledge management to function in an adaptive way and continue to thrive in the m-business era. The design of a m-business system needs to focus on collaboration. In the mobile CRM system architecture, several dedicated servers and databases are required, because enterprise must capture and retain in a central/distributed data repository the data and information that employees need (Figure 4). A CRM suite for customer care applications enables new kinds of interactions, new kinds of information, and comprehensive access to all customers and enterprise portals. This customer care can foster joint problem-solving, and convenient self-service. Given the information customers need in the purchasing process. The reasons to stress on 3G/4G and include in this framework are (a) it has wider bandwidths, higher bit rates, (b) it support interactive multimedia services, teleconferencing, wireless Internet, etc., and (c) the global mobility and service portability. For knowledge management issues, the architecture of IT in the knowledge management system is concerned with organizing and analyzing information in an enterprise's database so this knowledge can be readily available throughout an enterprise. A central/distributed data repository that provides/captures the data and information for employees and executive decision-making is also very important in a knowledge management system. The database system is the driver that consolidates and directs the overall resources of the supply chain to the most mission-critical business activities. As a result, an m-business CRM solution must provide supports for the capture and communication of customer demand, as well as enable this demand to automatically trigger business events and initiate process workflow. Transcoding contents and developing enterprise applications to work across several mobile devices and

browsers seem to be a complex problem. The key is to focus on the lowest common denominator: the XML (eXtensible Markup Language) and XSL(eXtensible Style sheet Language). The XML supports for developing mobile applications running on multiple devices and platforms [7]. Databases are also working with XML-structured data and tabular relational data. The ability to translate standard HTML/XML content into the various flavors of wireless content is based on the way that the XML/XSL standards operate. Because of these standards, XML is able to function as a meta language, flexible enough to recreate other markup languages and use them as subsets. Technologies such as Java Server Pages (JSP) and Active Server Pages (ASP) are also being extended to support multimode clients. Figure 5 illustrates some examples of transcoding systems and applications. Enterprises that provide HTML to wireless transcoding solutions translate standard content into XML that reflects all of the information flow and logic of the transcoded content, and by browser detection determines for each mobile user which subset of XML to translate content into [8]. Thus we see that a robust and active transcoding system goes a long way toward reducing complexity and maintaining consistency throughout the enterprise across multiple clients.

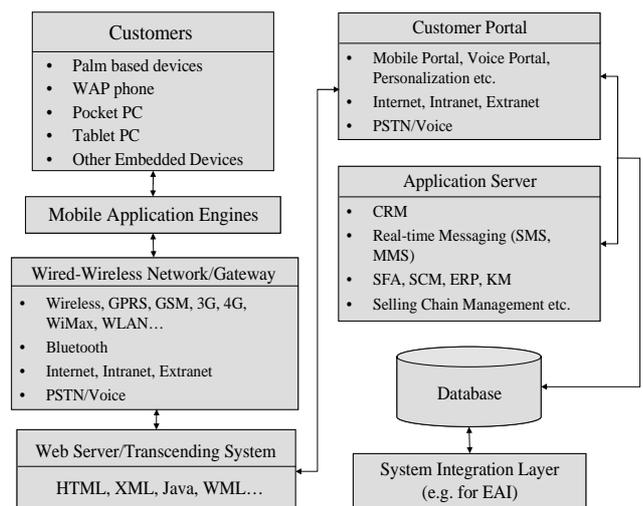

Figure 4. The Mobile Customer Portal System Architecture

Effective m-business supply chain solution will need to deliver an accurate and common view of customer demand data as well as any subsequent events, plans, or other business data. This new supply chain framework will offer virtually unlimited business opportunities in the alignment of technologies and processes. A well-designed and well-integrated supply chain for m-business will improve upon existing cost-responsive processes, and have organizational agility in the event of change.

VI. Conclusion

Multi-channel and multi-technology strategies represent the

next frontier of sales force integration. The mobile Internet will open an important new channel for commerce. Personalization provides value to customers by allowing them to find solutions that better fit their needs and saves them time in searching for their solutions. By interacting with customers electronically, their buying patterns can be evaluated and the services can be provided. To deliver the right product or service to the right customer for the right price via the right channel at the right time are the essence of CRM.

Content in XML can use XSL style sheets to dynamically render the content into:

- HTML for Desktop and PDA
- HDML or WML for mobile devices
- Specific XML for B-to-B

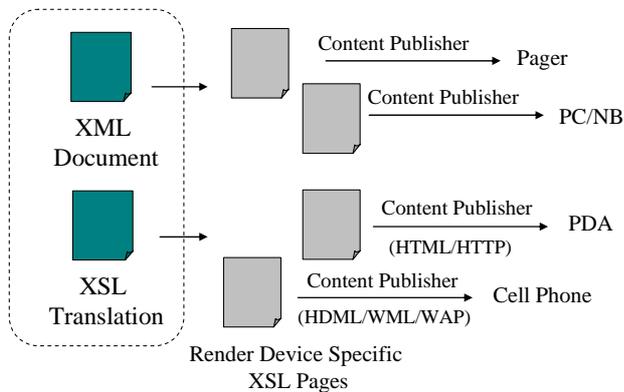

Figure 5 Content Transcoding and Delivery Scheme

This paper shows that the integration of sales, marketing, and customer service applications with business intelligence system will help enterprises to manage one-to-one marketing

and relationship management more effectively. This technological framework still hold promising with the coming era of mobile business. The IP convergence strategy will provide a solution that joins the two worlds of voice communications (telephony) and data traffic together. The integration of voice and data makes office solutions more flexible and easier to manage. Mobile Business opens up new paths to service-oriented information processing and optimizes internal and external communication.

With self-service applications in hand, customers will be able to touch the resource of an enterprise. The customer drives the entire value chain, determining what is to be produced, when, and at what price. The CRM that reinvented itself from traditional sales/marketing strategies will undoubtedly be the best solution to today's e-business Internet marketing.

Mobile Commerce Opportunities in the Airline Industry

Brian Masterson, June Wei
University of West Florida
11000 University Parkway
Pensacola, FL 32514

Abstract: Mobile commerce will provide opportunities to improve business values in the airline industry; however, it has been slowly adopted and has not been implemented widely. This paper develops a mobile commerce model for air travel companies that can be used to study features necessary to perform m-commerce using wireless devices. Twenty-eight interface features are identified based on this developed model. The implementation of these features for the existing web-based airline ticketing in the top ten airline companies are examined. These features are important to develop an efficient and user friendly mobile commerce for airline industry in the near future. The beneficiaries of the findings from the current research are the existing airline companies, future mobile commerce airline companies, and the developers of mobile commerce systems.

Keywords: Mobile Commerce, Electronic Commerce, Airline Industry, and Mobile Ticket

I. Introduction

Some might say that the U.S. domestic airline industry is on the brink of disaster. It is a complex situation, complicated by world events, economic forces, management and labor disagreements, national policy, intense intra-industry competition and consumer preference. The airline industry lost 15 billion in 2002 and 2003 and probably will lose 5 billion in 2004 (Will, 2004). Most organizations in the airline industry have attempted to respond to the financial turmoil through drastic evolution. Since the September 2001, the network or legacy carriers have scrambled to minimize losses by cutting jobs, eliminating routes, and decreasing infrastructure. Conversely, many of the low-fare airlines have increased routes, expanded hiring, and worked aggressively to gain market share by offering lower ticket prices. The low-cost carriers' share of the market has gone from 16 percent in the year of 2003 to 25 percent in 2004, and some analysts are predicting that they could account for as much as 40 percent of the market next year (Marks, 2004). The leadership at most airlines is now showing an understanding that despite the inability to control world events, positive results can be influenced through value chain analysis. By seeking ways to improve its value chain, the airlines have an opportunity to streamline production costs, improve customer service, and create a profitable market in spite of the global turmoil.

E-Commerce

Common to each of the above functional business areas is electric or e-commerce. E-commerce is as defined as the conduct of financial transactions by electronic means (Will, 2004). Essentially, e-commerce is about using the power of the Internet to make money. The airlines have all leveraged the power of the Internet to reach customers. In the past ten years, company websites have gone from an anomaly to a commodity.

Prior to the Internet boom, airlines relied heavily on ticketing agents and reservationists in order to sell and distribute tickets. Through company web pages, airlines are now able to sell and distribute tickets. Many airlines even offer discounts to customers who purchase their tickets online. "Today, airline tickets are one of the most popular items bought on the Internet worldwide, accounting for over a quarter of consumer online spending in the United States alone." (Hanke & Teo, 2003) Airlines utilize website technology to book passengers on flights, make reservations, check baggage, and expedite the boarding process. Through the expanded use of the Internet, airlines are able to reduce labor costs and in some cases eliminate commissions all together.

Technology and the Internet have been critical to the success of JetBlue. In 2003, 73% of all tickets were purchased through JetBlue's on-line website. Another 24.6% of tickets were booked through JetBlue's reservation agents (2003 JetBlue Annual Report). Unique to JetBlue is the fact that 100% of the company's reservation agents are part-time employees who generally work from home. To operate a traditional call center in the U.S. costs about \$31 per employee hour (including overhead and training). Conversely, home-based agents cost an average of \$21 an hour. "After wiring its agents' homes into its reservation system, JetBlue pays its agents starting wages of \$8.25 an hour plus benefits." (Whalen, 2004) The cost savings achieved by maintaining infrastructure (buildings, electricity, and employee benefits) are able to be passed along to the consumer in the form of lower fares.

The Internet also allows the airlines to reach new customers. Customer relationship marketing technologies are used to build customer relationships and improve profit margins. United Airlines launched United.com in 1997. In 2000, United created a separate e-commerce division within the organizational hierarchy that was "dedicated to maximizing the sale of travel products over the Internet and Internet-enabled devices." (Hanke & Teo, 2003) Many airlines currently use their own websites to market and sell

their use of technology to current and potential customers.

From E-Commerce to M-Commerce

Innovation and product differentiation through new products and services are critical in sustaining a significant competitive advantage (Hanke & Teo, 2003). The next opportunity for airlines to reach new markets, maintain low distribution costs, and enhance customer value can be achieved through the use of mobile or M-commerce technologies.

M-commerce can be defined as a transaction that takes place via wireless internet-enabled technology (through handheld computers, cellular phones, personal digital assistants (PDA), or palm) and that allows for freedom of movement for the end-user. Wireless fidelity (Wi-Fi), the transmission of short-ranged radio signals between a fixed based station and an end-user's mobile device, is the driving technology that facilitates m-commerce (Wireless computing, 2003). In 2003, 79 million users from around the world accessed the Internet via wireless technology. It was an increase of 145% from the previous year (Converging Markets, 2004).

II. Methodology

A Model for Web-based Mobile Commerce

The value chain as described by Michael Porter is an analytical tool used to identify and examine value-adding activities within the individual firm and between firms. The value chain is composed of primary and supporting functional business activities. Primary activities are those designed to bring the product, or service in this case to market. Primary activities include customer service before, during, and after-ticket sales. For the airline industry, typical five primary activities and their examples of IT adoptions value chain activities include (Huber et al. 2004):

Inbound logistics: passenger accountability, passenger security, etc. Examples of e-value chain for airline industry include Logistics Management Systems, Enterprise Resource Planning, and B2B E-Commerce

Operations: aircraft maintenance, aircraft availability, aircrew scheduling, etc. Examples of e-value chain for airline industry include Enterprise Resource Planning, and Computer Aided Manufacturing

Outbound logistics: baggage tracking, international and domestic passenger connection, frequent flyer mileage, etc. Examples of e-value chain for airline industry include B2B E-Commerce, B2C E-Commerce, Logistics Management Systems, Customer Relationship Management, Transaction Processing Systems, and Enterprise Resource Planning.

Marketing and Sales: Reservationists/travel agents, website management, promotions, fare pricing, etc. Examples of e-value chain for airline industry include B2B E-commerce, B2C E-Commerce, Customer Relationship Management, Transaction Processing Systems, and Enterprise Resource planning.

Service: Aircraft custodial care, customer support agents,

etc. Examples of e-value chain for airline industry include Enterprise Resource Planning, B2C E-Commerce, B2B E-Commerce, and Customer Relationship Management

The role of information technologies (IT) cannot be overstated as a key enabler of activities in the airlines' value chain. It demonstrates the functional areas that are influenced by effective IT.

Based on the analysis of the five primary activities of airline industrial value chain above, the current research analyzes the proliferation of tools designed to facilitate electronic and mobile commerce in the U.S. scheduled passenger airline industry. Specifically, the activities inside mobile airline ticketing system could be part of the primary activities inside airline industrial value chain described above.

Figure 1 presents a model for booking airline ticket using mobile devices that would be facilitated through the use of M-commerce technologies in order to increase business values in the airline industry. This model could all be accomplished while the customer is driving his/her car to the airport in order to catch the next flight. In Figure 1, there are eight steps:

Step 1. A mobile customer wants to book an airline ticket via a mobile device.

Step 2. The customer uses a wireless device to log onto m-commerce site of major airline that available.

Step 3. After evaluating the various flight options and their respective fares, the customer enters a personal identification number (PIN), credit card information (if not already on file), and selects his/her flight.

Step 4. The data is sent via encrypted signal to the respective airline to ensure that the seat remains available during the transaction process.

Step 5. The encrypted signal is simultaneously transmitted to the credit card company to ensure that sufficient funds are available and no account discrepancies are present.

Steps 6 and 7. Upon positive indication from the credit card company, the airline accepts the customer's travel request and issues a confirmation number.

Step 8. The confirmation number, m-ticket, m-receipt, and paper receipt are sent to the customer. A m-receipt is also sent to the credit card company. The customer can also get m-boarding pass through a wireless device.

Primary Features of Web-based Mobile Ticketing

Chun and Wei (2004) identified mobile ticketing features for air ticket agencies. In the current research, the focus is on mobile commerce in airline companies. The functional components in Figure 1 are mapped into features required for mobile commerce and presented in Table 1. Some of these features were modified and adopted from Chun and Wei (2004) for air travel agencies. By mapping the model developed in Figure 1 into features, there are twenty eight features developed in Table 1. In Table 1, there are four categories: basic attributes, customer relationship attributes, collaboration attributes, and m-commerce special attributes.

The customer relationship attributes depict features that are designed to increase customer value through convenience. The goal of these attributes is to build customer loyalty. Collaboration attributes imply the importance of strategic alliances and exemplifies the airlines' attempt to provide one-stop vacation shopping for prospective travelers. M-commerce special attribute depict possible characteristics and services offered to mobile customers.

Table 1 is also a compilation of the various features

available on airline web pages. They have been drilled down according to levels of sophistication and complexity. When selecting website content, it is critical that an airline chooses attributes are appropriate and that provide values to the customer served. Features in Table 1 contain basic or expected features that enable an end-user to view available flights and make a flight/fare selection. They are features designed to facilitate and simplify the transaction process.

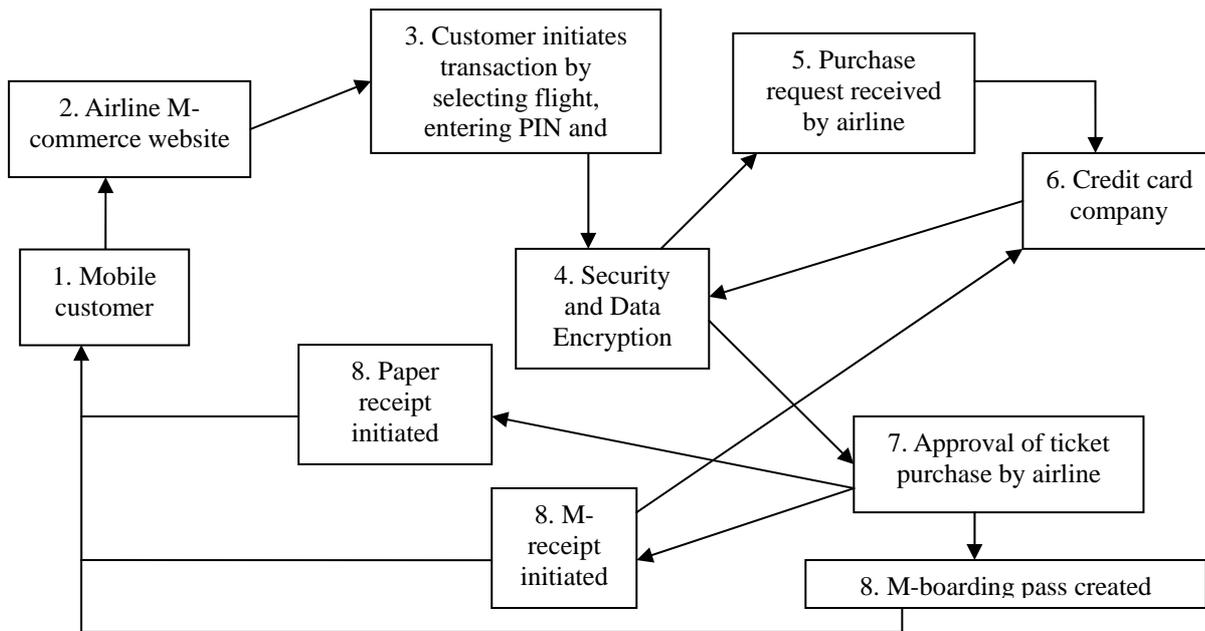

Figure 1. Typical M-Commerce Transaction

Table 1. Features for Mobile Commerce

Categories	Features	Feature Descriptions
Basic Attributes	A	Search begins at the homepage
	B	Dropdown menu available for the city code
	C	Dropdown calendar available
	D	Specific travel times can be chosen
	E	Both one way and round trip arrangements available
	F	Number of passengers traveling
	G	Point of contact phone numbers accessible within 1 click of homepage
	H	Domestic and International travel option
	I	Ability to select class of service (business, coach, etc.)
	J	Flights are sorted by price
	K	Both e-ticket and paper ticket offered
	L	Processing fee other than paper delivery charge is applied
	M	Source of credit card security is available
Customer relationship attributes	N	Membership is required to book tickets
	O	Memory function available to view "my account" information
	P	Redeemable coupons are available
	Q	Other options on similar schedules are available
	R	Frequent flyer miles from other airlines can be used

	S	Currency converter is available
	T	Travel itinerary e-mailed or faxed to passenger
	U	On-line check in offered
	V	Links available to destination weather forecast sites
	W	Airport maps/diagrams are downloadable
	X	Native language option available
Collaboration attributes	Y	Vacation packages available
	Z	Rental cars and hotel reservations links
	AA	Links to other websites (credit cards, etc.)
M-commerce special attributes	BB	Wireless ticket purchasing through wireless devices such as PDAs, cell phones.

Note: Some of these features are adapted from Chun and Wei (2004)

Table 2. Ranks of Airline Industry Leaders based on Market Shares (Corridore, 2004)

Rank	Year: 2004	Market Share (%)	Rank	Year: 1993	Market Share (%)
1	American	18.4	1	United	21.2
2	United	16.5	2	American	20.4
3	Delta	10.9	3	Delta	17.4
4	Continental	10.5	4	Northwest	12.2
5	Northwest	10.4	5	Continental	8.9
6	Southwest	7.5	6	US Airways	7.4
7	US Airways	5.7	7	TWA	4.8
8	America West	3.3	8	Southwest	3.5
9	Alaska Airlines	2.5	9	American West	2.4
10	JetBlue	2.3	10	Alaska Airlines	1.2

Data Collections

The U.S. Department of Transportation defines a major airline as one that has annual revenues over 1 billion. As of December 2002, the industry consisted of 83 large commercial air carriers. Of that total, 15 were major airlines (with annual revenues exceeding \$1 billion), 33 were nationals (\$100 million to \$1 billion), and 35 were mid-to-large sized regional airlines (\$20 million to \$100 million) (Corridore, 2004). Table 2 presents the airline industrial leaders based on market shares in 1993 and 2004, respectively.

The current study analyzes the features of these 28 features in the U.S. airline travel companies' websites that offer electronic airline tickets. M-commerce itself is a relatively new area and, undoubtedly, mobile airline ticketing is not yet available worldwide. As many scholars and industry analysts have claimed, mobile commerce is derived from electronic commerce (Coursaris et al 2003, Ozok & Wei 2003, Lee and Benbasat 2003); therefore, electronic airline ticketing that is more widely and popularly used should provide good guidelines on how mobile airline ticketing may be approached.

A total of twenty-eight features were gathered and tallied from the airline companies' websites, and the results are summarized in Table 3.

In Table 3, the websites of ten of the industry leaders in 2004 (Table 2) are examined. Almost unanimously from one company's website to another, the basic attributes are available. There is however several features that are used to help differentiate each website as well.

III. Findings

The findings based the features gathered from top ten airline companies' websites are tallied. First, the numbers of websites that provide each feature are tallied to find the most widely used features. Second, the numbers of features that various websites provide are tallied to analyze the versatility of those websites.

Website Features

In Table 3, the most widely used features are Features A, B, D, E, F, K, L, M, O, R, T, Z, and AA (80% or above) (thirteen features), which are usually found in the first search page, whether it is the homepage of the website or not. This observation clearly validates the importance of user-friendliness of the website's interface.

The least commonly used features are Features G, N, S, V, W, X, and BB (20% or below) (seven features). These features do not seem to be directly related to the immediate need of travel, explaining why those features are not very popular among websites studied. For example, Feature BB has been implemented by only one airline company, United Airline. Even though this feature is important and has potential benefits, it still not been widely adopted.

The rest of the other eight features are Features C, H, I, J, P, Q, U, and Y (eight features), which were implemented by some companies (between 20% to 80%). For example, Feature P, "Redeemable coupon" is not as ubiquitous as other features, but it may attract mobile customers, as both e-commerce and m-commerce get more popular.

Website Versatility

Ten airline companies' web sites are studied for the current research. In Table 3, out of these twenty-eight features available, all websites studied for these top ten airline companies have at least 11 or more of the features that are implemented. All these ten airlines have implemented above 50% for these twenty-eight features, except only one airline company, Alaska Airline, which implemented about 40% (lower than 50%) for these twenty-eight features.

Four companies that have implemented features more than the others (above 70%) are American, United, Delta, and Continental airlines. Out of these top ten airline companies, only the United Airline offers mobile ticketing.

IV. Discussions and Conclusions

The current research developed a mobile commerce model for the airline industry and studied the existing e-commerce environment, with a focus on web-based ticketing. The findings from the current research indicate that developing user-friendly m-commerce features is crucial to the success of m-commerce. There are some major findings from the current study.

First, it is not the number of features but the usefulness of the features that is critical to the success of the m-commerce. Thirteen features are most widely used features that were available at 80% or over of the websites, while seven web features were available at 20% or less than of the websites. All airline companies' web sites studied in the current research have at least 15 features, except for Alaska Airlines with 11 features. However, some airline companies streamlined the features better than others so that the users can get the information they want faster than they could have done on other websites.

Second, understanding socio-psychological aspects of m-commerce customers is essential to the success of m-commerce (Palen & Salzman 2002, Lee and Benbasat 2003). To coincide the speed and the ubiquity of m-commerce, the customers of m-commerce are almost always on the go and less patient than those of e-commerce. Therefore, the ideal m-commerce must be able to not only attract new customers but also beat the distractions that are also competing for the user's attention (Chun and Wei, 2004).

Third, the airline industry is just beginning to expand into the Wi-Fi (Wireless Fidelity) arena. United Airlines has recently made m-commerce features available to the general public. Among the m-commerce attributes offered on its website www.united.com, are the ability to book a flight, view personal itinerary, and receive electronic notification of flight status all via a web-enabled cellular phone or through wireless PDA. It even sends electronic boarding pass with bar-code identification. The bar code can be read directly from the passenger's PDA or cell phone using the same machinery currently in use to verify paper boarding passes.

To date, several airlines (Cathay Pacific, Lufthansa, and British Airways) offer passengers the opportunity to access the Internet while in-flight (Shifrin, 2003). Currently, the FAA has not approved the use of in-flight Internet onboard aircraft flying over the United States. However, many airports in the U.S. have established Wi-Fi "hotspots" that enable travelers within the airport to log on to the Internet without the need of a data port.

Despite the current legal prohibitions that restrict Internet access while airborne, m-commerce technology should be on an airline's radar. Business and leisure travelers

alike are rapidly becoming "tech savvy" and would achieve real value through the ability to purchase airline tickets without being tethered to a Local Area Network. In most cases, m-commerce capabilities are in line and consistent with current information systems infrastructure.

The next generation of the Internet enabled commerce is already here. Mobile commerce presents a multitude of opportunities for airlines to expand to new markets, reduce administration expenses, and lower operating costs. It affords airline passengers the freedom to travel effortlessly. No longer are passengers forced to wait in long lines at the airport. Passengers with on the go lifestyles can continue to travel while on the go and not miss a beat.

User Acceptance of Mobile Payments: A Theoretical Model for Mobile Payments

Jiajun Jim Chen, Carl Adams
University of Portsmouth, Portsmouth, PO1 3AE, UK

Abstract: Mobile payment refers to the use of mobile devices to conduct payment transactions. Users can use mobile devices for remote and proximity payments; moreover, they can purchase digital contents and physical goods and services. It offers an alternative payment method for consumers. However, there are relative low adoption rates in this payment method. This research aims to identify and explore key factors that affect the decision of whether to use mobile payments. Two well-established theories, the Technology Acceptance Model (TAM) and the Innovation Diffusion Theory (IDT), are applied to investigate user acceptance of mobile payments. Survey data from mobile payments users will be used to test the proposed hypothesis and the model.

Keywords: mobile payments, user acceptance, TAM, IDT, LISREL

I. Introduction

Recent developments in mobile/wireless communication technologies have changed our daily lives. For example, we have enjoyed a high penetration rate of use of mobile devices, and the growth of usage of mobile devices has had a positive impact on the promotion of mobile commerce applications [1]. This phenomenon has happened in e-commerce, when Internet use was increasing worldwide. Forrester Research predicts that the total revenue from European Online Retail will quadruple to €67 billion between 2004 and 2009 [2]. However, there are still many unresolved issues in e-commerce applications such as security, privacy issues, and usability. These have long been an obstacle for further business growth [3-5]. Thus, it is extraordinarily important for service providers to understand these issues from the consumers' perspective, when developing mobile commerce applications.

New wireless and mobile technologies offer various mobile applications. Mobile payment is one of the fastest growing services. The business applications of mobile payment include parking tickets, vending machines, points-of-sales, and digital content. Plenty of different industry sectors have become interested in mobile payments. At the moment, one of the problems with mobile payments is the lack of standards and regulations. Mobile payment can be implemented via different solutions, such as premium SMS, infrared, RFID and so on [6]. These solutions claim to offer easier, faster and more secure methods than do competing solutions, though this is arguable. There are still issues

concerning the roles and responsibilities of various market participations and their implementation. On the other hand, consumers and merchants have the potential to influence the adoption of mobile payment.

Mobile payment is a sub-set of mobile commerce, and it plays an important role in mobile commerce applications. From the consumers' point of view, service cost is one of the major concerns determining use of mobile payment. This principle can even be applied to any new services [7;8]. It is likely that cost will be one of potential factors influencing consumers' decisions regarding mobile payment usage.

As mentioned above, privacy is another concern for consumers' confidence regarding the use of e-commerce [9;10], especially in financial transactions. This concern will have a similar impact on mobile payment, because they share the same payment transaction method, non face-to-face payment transaction. Consumers will not feel safe, as they cannot physically view and examine the actual transactions [11].

The popularity of the use of mobile devices and the potential market for mobile payment applications, demonstrates a vital need to identify and understand the determinants of consumer acceptance of mobile payments. There is little empirical evidence and research into mobile payment adoption, such as what determinants influence user acceptance of mobile payments. It is beneficial to research mobile payment systems as new technologies are waiting for user adoption. Therefore, this research will propose an integrated model. The theoretical model adopted the TAM and the IDT in order to determine consumer acceptance of mobile payments.

II. Theoretical Framework

This research's theoretical constructs are based on the TAM and the IDT. Using these two well-established theories has helped in building a rigid theoretical foundation for this research. They are two of the most influential theories in clarifying and predicting users' acceptance and adoption in a new system.

II.1 Technology Acceptance Model (TAM)

Davis (1986) developed the TAM model to explain user acceptance of new computing technologies in the organisation context. This model was drawn from Theory of Reasoned Action (Ajzen and Fishbein, 1980). The model suggests users' behavioural intentions to determine actual system use, and users' attitudes toward using influence users' behavioural intention. Moreover, perceived usefulness and perceived ease of use have affected users' attitudes toward use. TAM is a powerful theory to predict user acceptance of

technology. Some empirical tests have demonstrated that TAM is a robust model for Information Technology [12;13]. Since then, TAM has been widely used to conduct technology acceptance behaviours regarding different aspects of Information Technology [14-17]. TAM could be a tool to analyse consumers' intentions toward acceptance of mobile payments. Furthermore, numerous of e-commerce related researches have adopted TAM, in order to investigate how to achieve consumers acceptance in e-commerce [15;18].

The TAM model includes two important factors, perceived usefulness, and perceived ease of use. Perceived usefulness refers to "the prospective user's subjective probability that using a specific application system will increase his or her job performance within an organization context," and perceived ease of use describes "the degree to which the prospective user expects the target system to be free of effort" [13]. The TAM model has been widely adopted and verified [13;19;20]; moreover, many researchers have customised the model, so that it fits for different contexts [21;22].

Perceived ease of use

A successful user interface design has potential implications concerning the perceived ease of use to the users. Can users pay easily and quickly? The system providers have to consider this question, in order to ensure users can use the systems effortlessly. Usability has been widely used to evaluate information systems [23-25]. For example, in software products, usability looks at operations, design, and layout to evaluate how easy software would be for users to use and make it do what they want.

Research in usability has been conducted for over a century. For mobile applications, it is important to understand and improve the usability of mobile device interfaces [26]. Moreover, mobile applications raise new challenges and issues for system developers. Mobile devices have unique characteristics, such as screen size, screen resolution, input methods and so on.

In e-commerce applications, there are established guidelines available concerning design and which implement several web components for e-commerce application. However, there is limited guidance for design in mobile applications, especially mobile commerce. Design and usability guidelines are for e-commerce applications that are not compatible with mobile applications [27]. Therefore, it is crucial to understand how users interact with mobile devices, and what is important to users when using mobile applications.

In order to design and implement an easy to use application, the characteristics of the systems need to be understood. An easy to use interface is important for any application, especially for mobile applications [28]. This is because of the unique characteristics of mobile devices, such as screen size, input mechanisms, battery consumption and so on. Systems developers have to give serious consideration to design guidance for mobile applications.

Perceived usefulness

Davis et al. (1989) have concluded that perceived usefulness may be defined as the way in which a particular system could enhance users' job performance. Within the mobile payment context, people are normally looking for convenience, speed, and other rewards for using the systems. A system classified as high in perceived usefulness would lead to a positive user acceptance relationship.

II. 2 Innovation Diffusion Theory (IDT)

Before an innovation can successfully appear in the commercial market, a lot work is required to convince the potential adoptors. Individual users will make a decision whether to adopt an innovation, and this is based on knowledge and on the performance of an innovation [29-31]. Moreover, the speed of the adoption is also affected by potential adoptors' knowledge and experience of an innovation, and the knowledge and experience of their close friends and family [30;32-34]. On the other hand, different adoptors have different approaches toward an innovation. Some adoptors will use new products or services as soon as they receive it. Other adoptors may wait and see; if they are not convinced by the services, they will not accept them until they feel comfortable with them [35].

Rogers (1963) presents IDT for user adoption. This is a well-established theory, and many researchers have adopted this theory for their research [36;37]. The theory identifies the innovation decision process, and it assists in the adoption rate of innovation. Users' acceptance and use of new technology or goods are two key elements in IDT (Zaltman & Stiff, 1973), and help achieve the likelihood of an innovation adoption and the process of innovation decision. Rogers (1995) concludes that five factors could explain new technology's adoption: relative advantage, complexity, compatibility, trialability, and observability.

Relative Advantage: the degree to which an innovation is perceived as better than the existing product.

Complexity: the degree to which an innovation is perceived as being difficult to understand and use.

Compatibility: the degree to which an innovation is perceived as consistent with existing values and experience of the potential adoptors.

Trialability: the degree to which an innovation can be experimented with before adoption.

Observability: the degree to which the results of an innovation are observable to others.

As stated above, these five attributes have been identified as innovation adoption rate's predictor [30;35]. Rogers (1995) concludes that these five attributes influence the potential adoptors' attitudes and intentions during the adoption process. However, Rogers (1995) also emphasises that the attributes are conceptually different. The following section presents more details of these five attributes for innovation diffusion.

Relative advantage

The potential adoptors' can gain an economic and social advantage, if an innovation is undoubtedly advantageous [30]. Unsurprisingly, the potential adaptors realise that the new products or services are more advantageous and useful than existing similar products or services, it can be predicted that they will accept it. Mobile payments are likely offer relative advantage services for consumers. For example, use of mobile phones is seemingly became part of our daily activities, where the device is not only a communication tool, but also an electronic wallet [6]. Mobile phone users can benefit from using wallet-enabled phones. If mobile payment is really advantageous for users, then mobile payment's relative advantage should have a positive effect upon users' intention toward mobile payments.

Compatibility

When an innovation provides alternative or supplementary products or services, and little effort is required to learn operations or behaviour change, potential adoptors are likely to accept it [30]. Using mobile payment systems only require understanding operation procedures and application areas, and it does not change users' behaviour with payment activities. Therefore, mobile payment compatibility should have a positive effect upon users' intentions toward mobile payments.

Complexity

When an innovation's design is sophisticated and complicated, the potential adoptors require more knowledge and instructions to operate or understand the products or services. If this happens, the adoption rates of innovation will probably be disrupted [34]. Mobile payment service is not a complex innovation, and it aims to provide an alternative and convenient payment service for consumers. Therefore, service providers have to consider system usability, and offer a simple solution. Subsequently, mobile payment complexity would have a negative upon users' attitudes toward mobile payments.

Trialability

An innovation allows users to try a product or service. If this innovation meets an individual's requirements, such as cost, quality of service and so on, then they are likely to adopt it. Otherwise, they will simply reject it. Mobile payment trialability, therefore should be related positively to individual users' intentions toward mobile payments.

Observability

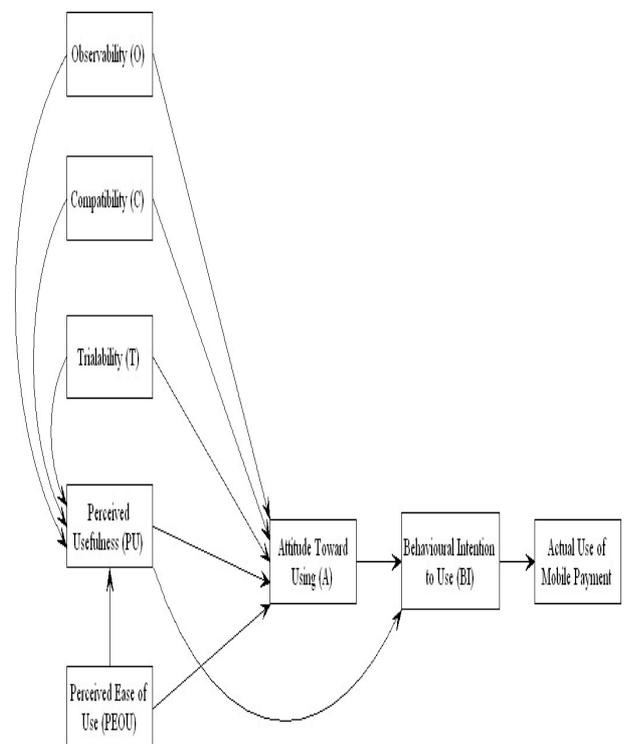

Innovations that are not easily observable have potential diffusion and adoption issues [35]. An innovation should attract the attention of the targeted user group, in order to make them aware of the service. Mobile payment is in a good situation as, when a mobile payment user uses the services in the public, it helps the service providers circulate services. This is because the potential adoptors can readily observe the innovation. Thus, the degree of mobile payment observability should have a positive effect upon users'

intentions toward mobile payments.

These attributes of IDT permit examination of the potential adoptors' decision making and are able to predict the future of innovations [30]. TAM and IDT have shown similarity in some constructs. Relative advantage is very similar to perceived usefulness in the TAM, and complexity is often viewed as the equivalent of the perceived ease of use construct in the TAM [38]. Previous researchers have combined these two theories, in order to offer a more powerful and acceptable model than the individual model [39], as shown in Figure 1.

In order to enhance consumers' enthusiasm for mobile payments, the mobile payment industry has to address the obstacles. For example, the European Central Bank has published guidelines for implementing mobile payment systems in Europe [40]. These potential factors will be incorporated as the antecedents of user acceptance of mobile payment systems as they have been considered relevant for mobile payment adoption.

Figure 1. A theoretical model for user acceptance model of mobile payments

III. Research Model and Hypotheses

A user's attitude has a significant impact on his/her behavioural intentions [41;42]. Previous research has suggested that, when conducting research into usage intentions, attitude will be accepted as a more accurate predictor in research, especially in studies on electronic, digital, and wireless channels (Bobitt & Dabholkar, 2001). Moreover, a user's actual use will depend on his/her

intention. These assumptions lead to the following hypotheses:

H1: A user's behavioural intention towards using mobile payment services has a positive effect upon his/her actual use of mobile payment services.

H2: A user's attitude toward using mobile payment services has a positive effect upon his/her intention to use mobile payment services.

In the TAM model, perceived usefulness can be interpreted as being the way a system could enhance a consumer's job performance [13]. Mobility is one of the main features that mobile services offer to consumers. In theory, consumers can access the services wherever they are. Perceived usefulness may have a positive effect upon the attitude towards mobile payment services [12]. Thus, in the context of a mobile service, perceived usefulness could be considered as how consumers' view mobile payments can be integrated into their daily lives [43]. If consumers gain a more positive view of mobile payment services, they will have a positive attitude and intention toward the services. Therefore, the following hypotheses are proposed:

H3: A user's perceived usefulness of mobile payment services has a positive effect upon his/her intention to use mobile payment services.

H4: A user's perceived usefulness of mobile payment services has a positive effect upon his/her attitude toward using mobile payment services.

Perceived ease of use is another key element in the TAM model and is concerned with the extent of users' belief that a system is easy to use, to set up, or to learn [13]. Mobile applications have different environments and contexts compared with e-commerce applications, and they can offer a complex service. Perceived ease of use may have a positive effect upon the attitude towards mobile payment services, and have a positive effect upon the perceived usefulness [12]. This leads to the following hypotheses.

H5: A user's perceived ease of use of mobile payment services has a positive effect upon his/her attitude to use mobile payment services.

H6: A user's perceived ease of use of mobile payment service has a positive effect upon his/her perceived usefulness of mobile payment services.

When an innovation provides alternative or supplementary products or services, and little effort is required to learn operations or behaviour change, potential adoptors are likely to accept it. Using mobile payment systems only require understanding operation procedures and application areas, and it does not change users' behaviour with payment activities. This assumption leads to the following hypotheses:

H7: Compatibility between a user using mobile payment services and a user's beliefs, values, and needs has a positive effect upon his/her attitude to using mobile payment services.

H8: Compatibility between a user using mobile payment services and a user's beliefs, values, and needs has a positive effect upon his/her perceived usefulness of mobile payment services.

An innovation allows users to try a product or service. If this innovation meets an individual's requirements, such as cost, quality of service and so on, then they are likely to adopt it. Otherwise, they will simply reject it. Mobile payment trialability, therefore should be related positively to individual users' intentions toward mobile payments.

H9: Mobile payment services' trialability has a positive effect upon a user's attitude to using mobile payment services.

H10: Mobile payment services' trialability has a positive effect upon a user's perceived usefulness of mobile payment services.

An innovation should attract the attention of the targeted user group, in order to make them aware of the service. Mobile payment is in a good situation as, when a mobile payment user uses the services in the public, it helps the service providers circulate services. Therefore, the following hypotheses are proposed:

H11: Mobile payment services' observability has a positive effect upon a user's attitude to using mobile payment services.

H12: Mobile payment services' observability has a positive effect upon a user's perceived usefulness of mobile payment services.

IV. Research Methodology

IV.1 Measure development

Survey has been selected as the central research methodology in this research. The multi-item scales measure was applied to this research in order to test the proposed research model. The statements are written for each item, and the participants were required to indicate whether they agreed or disagreed with the statements on a Likert scale. Many measures could be used in the TAM based research. For example, performance, productivity, effectiveness, usefulness, and time saving can be used to measure perceived usefulness. Moreover, ease of learning, ease of control, ease of understanding, ease of use, and flexibility of use can be measured perceived ease of use. Some of the items in the survey were taken from previously published scales with appropriate psychometric properties research, as shown in the following table; moreover, all of the items were adopted to fit the context of mobile payments. After an extensive literature review on the topic, new items were also developed.

This section will describe the development of the list of items by constructs.

Actual use of a mobile payment system. Consumers' frequency of use of a mobile payment system is considered a vital element for this research. Ajzen & Fishbein (1980) recommend measuring how often the system is used and approximately how many times it is used over a given time. Some researchers have employed this method ([12;13]. Applying this method to the research, the participants will be asked to record how frequently they use a mobile payment system on a 5-point Likert scale ranging from "Very

Frequently” to “Very Rarely”. The participants using services will then be asked how many times they have used it, based on 5-point Likert scale from “1-9 times” to “Over 40 times”.

Behavioural intention to use a mobile payment service. One question has been designed to ask participants the probability of their using a mobile payment system. This is because Ajzen & Fishbein (1980) identify that actual use is influenced by behavioural intention.

Attitude toward using a mobile payment service. Users’ attitudes can be deduced from their essential beliefs [41], and several research studies have used this principle extensively [13;44]. This research will follow this procedure to measure users’ attitudes. The items are adopted from previous research [12;43], and refined for mobile payment context.

Perceived usefulness of a mobile payment service. The items used to measure perceived usefulness are adopted from previous research with the contents having been refined to match mobile payment services [12]. Based on the findings of Davis et al. (1989) concerning perceived usefulness, this research argues that using the mobile payment will enhance users’ daily activities.

Perceived ease of use of a mobile payment service. The items for perceived ease of use are also developed from previous research [12]. Davis et al. (1989) conclude that perceived ease of use refers to whether a system is easy to learn or to use.

Compatibility. The items for measuring compatibility are adopted from Moore & Benbasat (1991) and Eastin (2002). Rogers (1995) concludes that identifying the compatibility of users’ needs, existing values, and beliefs with the new technological innovation is one way to evaluate the compatibility.

Trialability. A three-item scale is also adopted from Moore & Benbasat (1991) and REF. Rogers (1995) explains that an individual trying out an innovation is one way for a user to understand the system and how it works. The IDT suggests that trialability assists innovation to be adopted more rapidly than if the innovation does not have trialability [30].

Observability. Again, the items for measuring observability are adopted from Moore & Benbasat (1991) and REF. Rogers (1995) asserts that if the results of innovations can easily be shown, users are more likely to adopt the innovations. Mobile payment is a relatively recent innovation for most of the consumers, and it is probable that the systems’ observability will increase the adoption of mobile payment systems.

IV. 2 Data Collection

Mobile payment users are the target participants for this survey, which does not necessarily suggest that the participants have adopted the services. They are invited to participate in the survey online. In the survey, the participants have to consider one particular mobile payment scheme that they used during last three months.

The questionnaire collects two major types of information. The first part concerns participants’ demographic information, and the second part is about participants’ perceptions of each of the constructs in the proposed model. The demographic information includes gender, age, level of education, and occupation. The rest of the questionnaire asks for participants’ the opinions of each item.

In order to collect the data for this study, the survey signed up with an academic purpose survey organisation, which owns a mailing list of over a thousands users who occasionally participate in online surveys.

IV. 3 Data Analysis

Following the response from the online survey, the proposed hypotheses will be tested. SEM based analysis techniques will be used to analysis the data. First, the Confirmatory Factor Analysis (CFA) will be employed to assess the validity of the measurement for the model then the proposed model will be tested using the Structural Equation Modeling (SEM), so that the causal structure of the model can be evaluated. The research will use LISREL 8.7 to analyse the measurement model and the structural model.

V. Conclusion

This study is developing and investigating an in-depth understanding of consumer behaviours and motivations regarding mobile payments. Mobile payment is a new and emerging service in the market, and research in this area is required to identify the issues and opportunities for this service, in order to provide opportunities and guidelines for its diffusion.

Abstract: With the development on techniques of mobile communication, the daily activities benefit from these techniques more than ever. In order to make living more convenient, the mobile payment has been brought up in recent years. The consideration for carrying out the mobile payment is very different from that in the wired electronics payment scheme because of the characteristics of mobile device. In this article we develop a mobile payment scheme that is based on reducing the operation of the device, and furthermore achieves the demands of security. It can create the session key for each transaction by means of using the "Diffie-Hellman key exchange" protocol. The use of the Message Authentication Code (MAC) can achieve the integrity of electronic commerce. Both of them do not need a large number of operations and complex algorithm so it can achieve the purposes of this investigation: a secure, convenient and light-computation scheme for mobile payment.

Keywords: E-finance, Mobile payment, Authentication code, Key exchange

I. Introduction

Along with mature and widespread development of the internet technique, more and more people enjoy the convenience of the Internet. It also expands the consumer market rapidly expand, and many business services also have been brought on the Internet. These businesses activity working on the internet can be general named as E-Commerce.

Like many commercial services, the most important action is the payment after consuming on the internet. As a result, the electronic payment plays a very important role in the electronic commerce. Many electronic payment schemes have been implemented, and these electronic payments are not only adopted in the virtual store on the internet but also applied on the real store, such as CyberCash[1], Paybox[2], Mobipay[3], Sonera Shopper[4] and Paypal[5].

In the recent years, because of the rapid development of the mobile communication network, the mobile communication network is no longer limited by transmitting the traditional voice data, and the data transmission on the mobile communication network also has been carried out. In the technique aspect, the data transmission rate on the mobile communication networks also increases continuously.

Nowadays the data transmission rate in the 3G system also comes to 144 kps. Those techniques development make business activities execute on the mobile communication network. The business activities on the mobile communication network can be named for mobile commerce. People will be able to use the mobile device to purchase the product or service. However, in a business activity, payment is an essential process. It is no doubt that payment is also an essential process in the mobile commerce.

However, unlike wired environment, there are many restrictions in the wireless environment. First, in wireless environment, the bandwidth is lower than wired environment, and the transmission error rate is higher. It also makes long latency. Secondly, the power of mobile device is limited. The memory and operation abilities are much weaker than the desktop computer. If we transplant current e-payment scheme which has implemented on the wired environment directly to the wireless environment, undoubtedly there will be many problems.

In this paper, we propose an account-based mobile payment scheme applied in wireless environment. The purpose of this scheme depends on reducing the computing quantity of mobile device. Thus, it can match the characteristics of the mobile device which are addressed on the above section. In the security of transmission, we don't use the SET[6] or iKP[7] because of reducing the computation load and the communication overhead. Another reason is to overcome the restrictions of mobile device and reduce the influence of the high transmission error in the wireless network.

The organization of this paper is introduced as following. In section 2, we introduce the related technique using in our proposed scheme. In section 3, we will introduce proposing mobile payment scheme. In section 4 we will discuss and evaluate the security of our scheme from different points of view. In section 5 we gives conclusions.

II. Background

II.1 Public key and secret key cryptography

The cryptography in the communication can be classified into two categories. One is public key cryptography; another is secret key cryptography. The next sections will describe the features of them respectively.

The public key cryptography is also known as asymmetric cryptography. It uses difference keys to encrypt and decrypt the communication data. The private key is only known by the sender, and he uses this key to encrypt the data

which he wants to send. The receiver uses the public key which was published from the sender for everyone to decrypt the data encrypted by sender. Each user in the network needs to have two keys: a public key which is available for anyone; a private key which the sender will keep by her/himself. It also needs a trusted third party to manage the key and verify whether the key is valid or not. The drawbacks of this cryptography are time-consuming, and the computational overhead of device is heavy. There are many known public key cryptography, such as RSA[12], DSA[14] and ECC[13].

The secret key cryptography has also been known as symmetric cryptography. It uses the same key to encrypt and decrypt the communication data. All participants joining this system have to trust completely and each participant preserves a key copy of other participants. Sender and receiver have to share the same key before communication. In the process of generating the secret key, the relevant information of generating keys has to guarantee against eavesdropping. It can achieve through assigning the secure gateway. Once the secret key is obtained by the third party, the data of communication does not be protected and becomes very dangerous. The advantages of secret key encryption are that the encryption time of symmetric cryptography is shorter than public key cryptography and this cryptography suits for encrypting a large amount of data. There are many known secret key cryptography, such as DES[15], AES[16] and RC5[17].

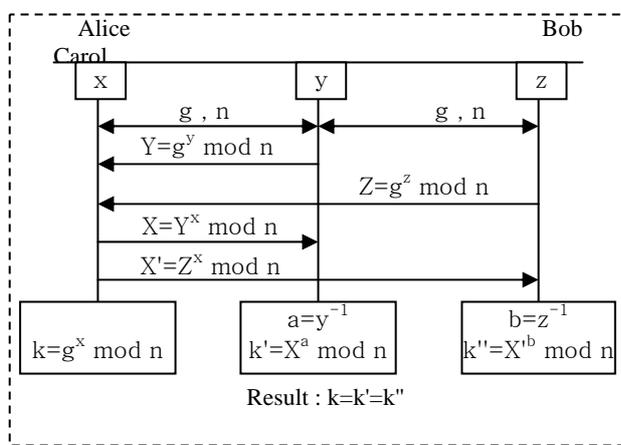

FIGURE 1. Process of three way exchange key

II. 2 Diffie-Hellman key change scheme

“The Diffie-Hellman key exchange scheme” is the first and well-known key distribution system invented in 1976, in which a common key could be established between two parties.[8] By using this key exchange scheme, communication parties can generate session key that needs to be used in the communication session. Generating a session key is very easy through this key exchange scheme, and can be completed without using complex algorithm. So it is suitable for using this algorithm in the small equipment

which only has low computation capability, like mobile device.

II. 3 Extension of Diffie-Hellman key exchange scheme

Based on *Diffie-Hellman key exchange* scheme, we can extend the two parties exchange key to three parties [9]. The Figure 1 shows the process of exchange key among three parties. The detail is described below.

First of all, Alice, Bob and Carol generate a number by themselves respectively.

Secondly, all of them coordinate two values, g and n .

Thirdly, Bob sends Y to Alice. The Y is counted by g , y and n . The equation is shown in (1).

$$Y = g^y \text{ mod } n \quad (1)$$

In this function, if the attacker eavesdropped the Y , g and n in the second step, he/she still can not compute the y .

The next three steps like third step. In step 4), Carol sends Z to Alice. The equation Z is shown in Figure 1. In step 5), Alice sends X to Bob. In step 6), Alice sends X' to Carol.

Finally, Alice calculates the value k . Bob calculates the value k' . Carol calculates the value k'' . The equation of k , k' and k'' shown in Figure 1. The result of this mechanism is that all of the values k , k' , k'' are identical. Therefore, Alice, Bob and Carol share the same session key.

II. 4 Message Authentication Code (MAC)

Documents which transmit in the public communication and computing environments are very dangerous, especially in the wireless environment. Documents may be hacked easily by anyone. It is very important to check the consistency of the document when a receiver receives this document. The Message Authentication Code is a scheme that can verify the consistency of document. [11] The process of *MAC* is as follows:

Step 1) Initial: Sender and receiver have the same authentication key

Step 2) Sender: $sMAC = MAC$ (original document, authentication Key)

Step 3) Sender \rightarrow receiver: $sMAC +$ document copy

Step 4) Receiver: $rMAC = MAC$ (document copy, authentication key)

If $sMAC = rMAC$ then

Document is correct

Else

Document may be modify and isn't valid document.

End if

In Step 1), both of parties need to obtain and know the same authentication key before communicating with each other.

In step 2), a sender uses an *MAC* algorithm which takes the original document and the authentication key into count to generate a message digest. The *MAC* algorithm often uses a hash algorithm to accomplish.

In step 3), the sender transfers the document copy and the message digest to the receiver.

In step 4), a receiver generates a message digest which is created by *MAC* algorithm by using the received document and his authentication key. Then receiver compares message digest received from sender with the one generated by receiver. If both of them are equal, the document is correct. Otherwise, the document may be modified by hacker. By using *MAC*, we can verify whether document is consistent or not.

III. Proposed Scheme

III.1 Abbreviation

The abbreviations of the relevant data used in following description are shown in Table 1.

TABLE 1. Abbreviations of the data used in the proposed mobile payment scheme

Abbreviation	Description
<i>PG</i>	Payment Gateway – a trusted third part. It is responsible for verifying the accuracy of transaction and transferring accounts
<i>TID</i>	Transaction Identification number
<i>M</i>	Merchant
<i>Ma</i>	Merchant account in the payment gateway
<i>C</i>	Customer
<i>Ca</i>	Customer account in the payment gateway
<i>OI</i>	Order Information
<i>P</i>	Total price of orders
$eK_i\{message\}$	Encrypt the message via the key K_i
$dK_i\{message\}$	Decrypt the message via the key K_i
$MAC\{message, K_i\}$	Run the <i>MAC</i> algorithm. The inputs are message and authentication key K_i
<i>Kcp</i>	Session <u>K</u> ey between <u>c</u> ustomer and <u>p</u> ayment gateway
<i>Kmp</i>	Session <u>K</u> ey between <u>m</u> erchant and <u>p</u> ayment gateway
<i>Kcmp</i>	Session <u>K</u> ey among <u>c</u> ustomer <u>m</u> erchant and <u>p</u> ayment gateway
<i>PIN</i>	Personal Identification Number

III.2 Basic assumption

- The customer's device can access the Internet, e.g. GPRS.
- Customers and merchants have an account at least in the payment gateway. And payment gateway maintains the accounts.
- The transmission is reliable in wireless environment. It means that it will retransmit data if errors occur.

- All of the keys – *Kcp*, *Kmp* and *Kcmp* – are generated by the use of *Diffie-Hellman key exchange* scheme.

- Payment gateway is a public's trusted third party.

- When customers and merchants login the payment gateway, both of them need to input account and password to authenticate.

III.3 Payment process

Our payment scheme idea is that customer and merchant send transaction information separately to the payment gateway. Both of customer and merchant can not get another part's information, because the information is hidden by the use of *MAC* which is a one-way hash function. When the payment gateway successful receives the transaction information from both customer and merchant, it will compare the information whether they are equal or not. If both of them is equivalent, we can say that the data is correct. Then the payment gateway will transfer an account. After accomplishing transfer, the payment gateway will send receipt to them. The process is shown in Figure 2 and the detail is described below:

Step 1) $M \rightarrow C : TID, OI, P$

Step 2) C : confirm the orders

Step 3) C : input *PIN* number on the mobile device

$M \leftrightarrow PG$:

generate *Kmp* (must login payment gateway)

$C \leftrightarrow PG$:

generate *Kcp* (must login payment gateway)

$C \leftrightarrow M \leftrightarrow PG$: generate *Kcmp*

Step 4) $M \rightarrow C : eKcmp\{MAC(Ma, Kmp)\}$

Step 5) $M \rightarrow PG$:

$eKcmp\{eKmp\{Ma\}, TID, OI, P, MAC(Ma, Kmp)\}$

Step 6) $C : uMAC =$

$MAC((TID||OI||P||Ua||MAC(Ma, Kmp)), Kcp)$

$C \rightarrow PG : eKcmp\{eKcp\{Ua\}, uMAC\}$

Step 7) $PG : rMAC =$

$MAC((TID||OI||P||Ua||MAC(Ma, Kmp)), Kcp)$

Compare if $rMAC = uMAC$

In step 1), after a customer shops at a real store or a web store, the merchant will transmit *TID, OI, P* to customer's mobile device. In a real store, it can be accomplished by point-of-sale system. In a web store, it can be done through wireless communication system as *GPRS*.

In step 2), the customer checks the *OI* and *P* shown on the mobile device's screen. If the information is correct, he/she starts payment process and goes to step 3). If not, he/she can cancel the transaction and restart again.

In step 3), the customer inputs a *PIN* number for first authentication. If the *PIN* number is correct, customer, merchant and payment gateway generate the keys – *Kcp*, *Kmp* and *Kcmp* – which are necessary in the payment process. Those keys are generated by the method of the extension of *Diffie-Hellman key exchange* scheme which is discussed in the sections 2.2 and 2.3.

In step 4), the merchant uses the *Kcmp* to encrypt

$MAC(Ma, Kmp)$ and transfers it to the customer. Only merchant, customer and payment gateway know the key, Kmp , and all communication data among merchants, customers and the payment gateway will be encrypted by Kmp . Consequently, the data are protected and under security.

In step 5), the merchant transmits order information, the merchant account which is encrypted by Kmp and $MAC(Ma, Kmp)$ to the payment gateway. The reason to send $eKmp\{Ma\}$ and $MAC(Ma, Kmp)$ is that the payment gateway can verify whether the merchant account is correct or not. Of course, the communications between them are encrypted by the key, Kmp .

In step 6), when the customer receives the data transmitted from the merchant, it generates $uMAC$. The equation of $uMAC$ is shown in (2).

$$uMAC = MAC((TID||OI||P||Ua||MAC(Ma,Kmp)),Kcp) \quad (2)$$

Because of using MAC , the size of the information will shorter than the one without using MAC . For this reason, it suits to transmit it in the wireless environment. Then the customer transmits $uMAC$ and Ua which is encrypted by Kcp to the payment gateway.

In step 7), when the payment gateway receives all information from the customer and the merchant, it first computes the $rMAC$. The equation of $rMAC$ is shown in (3).

$$rMAC = MAC((TID||OI||P||Ua||MAC(Ma,Kmp)), Kcp) \quad (3)$$

After the payment gateway calculates the $rMAC$, it compares with $uMAC$ which receives from customer before. If $rMAC$ is equal to $uMAC$, the payment gateway starts transferring an account.

IV. Analysis of Security

IV.1. Evaluation from the aspect of security criteria

When we talk about the security of e-commerce, we usually have to achieve the following security criteria of authentication, non-repudiation, integrity, and confidentiality. Because m-commerce is some kind of e-commerce, m-commerce has to achieve these four security elements to evaluate the system.

IV.1.1 Authentication

Customers need to key in PIN number on the cell phone, before using the cell phone to pay. Hence it can procure the authentication. In case the cell phone is stolen, it can not work without PIN code. In the payment gateway, customers and merchants have to login the system when they want to conduct a transaction. It needs account information and password when they login the payment gateway. Therefore, there are also ID identify in the payment gateway to ensure the security for the system.

IV.1.2 Confidentiality

In the proposed scheme, merchants transfer TID , OI , and other related information to customers without encrypting in the first step. While in other transferring steps, all

participants use $Kcmp$ to perform symmetric cryptography. Because there is no account information in the message of the first step, if some information is changed by illegal ways, customers can make sure whether the information is right or not and refuse the requirement. So there is not any influence in the confidentiality of the scheme.

IV.1.3 Integrity

When transferring information in the system, all information use MAC to ensure the integrity except for the first step. In first step, the customers check the transaction data shown on the screen of mobile device manually. In others steps, the computer will use MAC to check the integrity automatically. It is easy to use MAC to achieve the integrity. The output of MAC will be different if the input is different. In our scheme, the input data are composed of TID , OI and other related information. Most of them are difference in each transaction. It is hard to find that all input data is equal to old one. Therefore, we can ensure that the MAC can achieve the integrity in the proposed scheme.

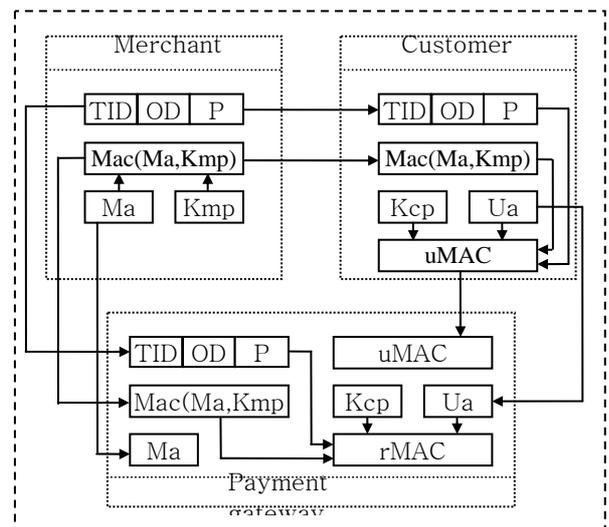

FIGURE 3. Data flow in our payment scheme

IV.1.4 Non-repudiation

Before dealing, customers and merchants have to login the payment gateway first and then they can proceed to go through the payment process. Customers and merchants use the Diffie-Hellman key exchange protocol to obtain keys, so that an account has a session key. The payment gateway will record the relationship between accounts and session keys. The system uses the method to achieve non-repudiation. When customers and merchants transfer their account, all of them use their individual session key to encrypt. Before producing the session key, customers and merchants have to login the payment gateway, and payment gateway is a public reliable third party. So based on the reason, the system can reach non-repudiation.

IV.2 Evaluation from the aspect of attacker's role

In our proposed scheme, we do not evaluate malicious payment gateway, because it is a public trusted third party. In this section, we only evaluate the aspects of malicious merchant, customer and other attackers.

1) Malicious merchant

First, a malicious merchant may fabricate a transaction. This action will make customer lost his money unknowingly. In our scheme, merchant needs customer's account to conduct a transaction. In Figure 3, when conducting a transaction, customer's account information is never transmitted to the merchant. When transmitting the Ua , it is also encrypted by session key " Kcp " and " $Kcmp$ ". For this reason, it has a very low probability to happen that the Ua is obtained by other one.

Secondly, the merchant will modify the price higher than original one when it transfers price to payment gateway. But the $rMAC$ will not be equal to the $sMAC$ which both of them need price information to generate.

Thirdly, malicious merchant may deny the transaction. In our scheme, transaction records will be recorded by payment gateway when conducting a transaction. As merchant logs in the payment gateway, he needs Ma and password. But both of them are not easy to obtain. All transmissions of the Ma are encrypted by session key " Kmp " and " $Kcmp$ ". It is very difficult to steal the Ma 's information.

2) Malicious consumer

In the first place, malicious consumer may modify the price lower than original one when it transfers price to payment gateway. Like above section, the $rMAC$ will not be equal to the $sMAC$ when payment gateway compares $rMAC$ with $sMAC$. Then the transaction will be canceled.

In the next place, malicious consumers may deny the transaction. In our scheme, customer will input PIN code in the mobile device first when performing the mobile payment. Transaction records also will be recorded by payment gateway. The information of Ua is encrypted by session key " Kcp " and " $Kcmp$ ". So it is very difficult to eavesdrop the Ua 's information.

3) Other attacker

All of transmission in our proposed scheme use $Kcmp$ to encrypt data. Because we use symmetric cryptography, the time of encryption is short. And each session key only uses one time. If anyone wants to modify transaction data, he must compute the $Kcmp$. But computing the $Kcmp$ is not easy. Even though he computes the $Kcmp$, the transaction has already been completed early.

V. Conclusions

With the development of communication network, there are more and more people enjoy the convenience of using mobile device. It does not like the traditional wired environment which is limited to a fixed place. It can be

worked at any time and any where. With smaller size and lighter weight, mobile devices can be a basic platform for many business activities in the future. But mobile device's electricity, memory and computation ability are not as strong as traditional PC, so these factors need to be considered in developing service in mobile devices.

When using asymmetric cryptography, it will consume much time and electricity of the device. In our proposed scheme, we use symmetric cryptography to save electricity and decrease computing time. In the way, we can extend the lift time of the device and decrease the waiting time when customers perform the payment process.

In the cryptography, the most importance thing is how to obtain the encryption key. In our payment scheme, we use Diffie-Hellman key exchange scheme to generate all the session keys we need. The process of key generation is simple and does not need complex operation. Hence, the method is appropriate to mobile devices which usually have low computing ability.

In the respect of security, the keys of conduct a transaction are different in each transaction. Therefore, there is useless to steal the keys, because all session keys only use one time. Another reason is that the transaction is accomplished when attackers obtain all session keys, because the time of conduct a transaction is short. If the keys is not easy to obtain, and most of the communication in our scheme is encryption, our scheme is secure.

In the respect of key management, we do not use public key infrastructure (PKI). In our scheme, we use "*Diffie-Hellman key exchange*" to generate session keys. The key management is done by payment gateway. Because there is no usage of PKI , the communication times will reduced. The less the communication times is, the more security the payment scheme is.

As above mention, our payment system offers a secure payment system and fits the characteristics of mobile device.

Abstract: Mobile Commerce is anticipated to be the next business revolution. Under the trend of mobile age, a person begins to realize the benefits of transaction by mobility operations. We can access information, shop and bank on line, work from home and speak and send messages via mobile appliances throughout all over the world. The research that is mobile transaction managing on database has begun since 1950 and skips the Link and Network Layer with support to improve mobile commerce. This paper focus on how effectually to make the new generation of mobile network protocol apply on mobile commerce and improve the mainly four properties required by mobile transactions. The four properties are respectively atomicity, consistency, isolation and durability. The purpose based on the mobile commerce environment and making mobile transactions complete and personal by means of the Destination Extension Header based on IPv6 and the Java Transaction Service. After experiment and testing, this paper verify that we improve the mobile commerce environment and make the mobile transaction more complete with the optimization of the Destination Extension Header based on IPv6 and the Java Transaction Service under the comparison with the environment on IPv4.

Keywords: IPv6, Destination Extension Header, Java Transaction Service.

I. Introduction

Mobile Commerce, or m-Commerce, is about the of applications and services that are becoming accessible from Internet-enabled mobile devices. It involves new technologies, services and business models. It is quite different from traditional e-Commerce. Mobile commerce is defined as the exchanges or buying and selling of commodities, service, or information on the Internet by using mobile handled devices such as PDA, cellular phone and laptop. It is estimated that 12 hundred million wireless device users in the global village will use their hand-held devices to authorize payment for premium content and physical goods. It is obviously trend that mobile commerce is more and more customary with the population of mobile handed devices. At the turn of the 21st century, the focus of telecommunication changed quickly, from traditional wired telephony-oriented services to data-based services; from homogeneous to heterogeneous networks; from non-intelligent devices to smart handhelds, personal digital assistants and mobile computers [23]. With the imminent

deployment of 3G and the the emergence of 4G mobile networks in the near future, it is expected that a sizable proportion of e-commerce traffic will move to mobile and wireless networks in the near future. To realize this above-mentioned potential, there has been some research in the field of mobile commerce including a three dimensional framework using four levels: applications, user infrastructure, middleware, and network infrastructure. With these advances in mobile commerce, it is expected that there will be an exponential surge in mobile commerce applications. In this paper, introduces the four standard attributes of mobile commerce transactions and identifies the requirements of mobile commerce transactions. More specifically, this thesis makes a sketchy investigation about the QoS requirements of mobile transactions and address how such transactions could be supported when the users of mobile commerce services experience a connectivity problem. As the existing IPv4 networks are not adequate to represent the quality for mobile commerce transactions, this paper makes it better then traditionally transactions management system to utilize the IPv6 packet header. IPv6 has a new way to deal with options that has substantially improved processing. It handles options in additional headers called Extension headers. This paper delves into one of six extension headers and it is called "Destination Option header" and a destination option header carries optional information that is examined by the destination node only. This thesis utilizes the IPv6 extension header and Java Transaction Service to improve four situations:

- All intermediate results must be kept hidden inside of the transaction
- To avoid inconsistencies due to conflicts of concurrent operations
- A transaction which access to some data must not know other transactions which concurrently access to the same data
- The produced output of a transaction must be visible and permanent as soon as the transaction commits.

II. Background

Mobile commerce systems often involve many activities and actors, which may work together to solve a given problem, or completely independent. In most of cases, different kinds of concurrent transactions are involved in complex applications, which require a mechanism for controlling and coordinating complex concurrent activities. Additionally, transaction models have been developed for database systems, ensuring fault tolerance properties in spite of concurrent access to the same data. Techniques have been proposed to deal with faults in complex distributed systems.

Therefore, this paper introduced the basic definition of mobile transaction and the four important properties a transaction must satisfy.

Transactions

Transactions were introduced to ensure the database systems integrity when concurrent programs work on same data. The transaction model is employed to prevent software or hardware failures and concurrent accesses to same data by different activities. Thus, a transaction groups simple operations together to form an indivisible set of operations with respect of concurrent transactions. A transaction must satisfy four properties, known as the ACID properties [18]: Atomicity, Consistency, Isolation, Durability; Classical implementations of a transaction model ensure transaction isolation by a locking mechanism. Data objects are locked if they are manipulated by a transaction, and until the transaction is committed or aborted. To achieve atomicity and consistency, the system orchestrates recovery in case of failure. Recovery is based on ensuring durability of the committed transactions' effects and discarding the effects of transactions that were being executed at the time of the failure and thus will be aborted. Logging is the principal service that is used to support recovery. Additional mechanisms are often used to ensure consistency and durability. In database systems we are interested only in data, whereas in distributed systems a resource is usually data together with related operations, often called a *transactional object*.

Mobile transaction models

Advances in wireless communications technology and portable computing devices have created a new paradigm, called *mobile computing*. Mobile computing is distinguished from classical, fixed-connection computing by the mobility of users and their computers and the mobile resource constraints such as limited wireless bandwidth and limited battery life. The model of a system that supports mobile computing consists of static and mobile components, where the only mobile component is the *Mobile Units*. Static elements are *Fixed Hosts* and *Base Stations*. A fixed host is not capable of connecting to the mobile units, while a base station is capable of connecting with mobile unit and is equipped with a wireless interface. Base stations act as an interface between the mobile computers and fixed hosts. They are also known as *Mobile Support Stations*. The geographical area covered by a base station is called a *cell*. To lessen the difficulty, this paper will represent the conceptual Figure 1 with the global view and it is formal to view not only mobile nodes as mobile units but also GSM as TCS in this framework. The disconnection of mobile stations for possibly long periods of time and bandwidth limitations requires a re-evaluation of transaction model and transaction processing techniques. There have been many proposals to model mobile transactions with different notions of a mobile transaction. Most of these approaches view a mobile transaction as consisting of sub-transactions

which have some flexibility in consistency and commit processing. In many of the models presented in the following sections, relaxing some of the ACID properties and non-blocking execution in the disconnected mobile unit, caching of data before the request, adaptation of commit protocols and recovery issues are examined [18].

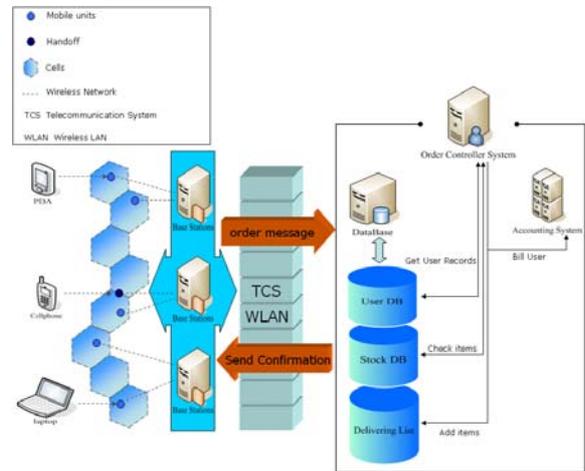

Figure 1: Conceptual Mobile Commerce Environment Framework

Advanced transaction models

a. Reporting and Co-Transactions Model

The Reporting approach [12] proposes an extension to the open-nested transaction model by addressing cell migration issues, in which a mobile transaction is structured as a set of sub-transactions (termed *component transactions*) and this model is shown in the Figure 2. The model is devised for mobile units constantly connected to the network, but moving through different cells. The model supports four types of sub-transactions that are expected to run on both mobile unit and fixed host:

- *Atomic transactions* with the classical ACID properties
- *Non-compensatable transactions* which cannot be compensated and therefore are not permitted committing their effect before its parent commits.
- *Reporting transactions* can report some of their results to other transactions at any point during execution. A report can be considered as a delegation of state between transactions.
- *Co-Transactions* are reporting transactions where control is passed from the reporting transaction to the one that receives the report. Co-transactions are suspended at the time of delegation and they resume their execution when they receive a report.

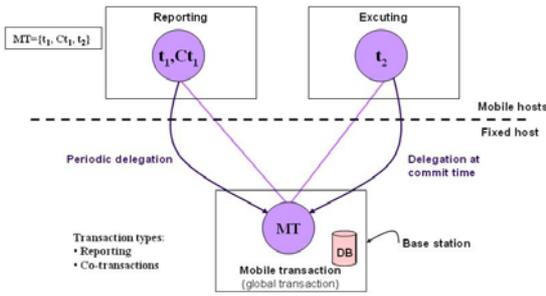

Figure 2: Reporting Model

However, mobile units are assumed to be always connected to the network, so disconnection handling is not considered in this model.

b. Clustering Model

A flexible, two-level consistency model has been introduced in [5] to deal with the frequent, predictable and varying disconnections and this model is shown in the Figure 3. It is also pointed out that, maintaining data consistency over all distributed sites injects unbearable overheads on mobile computing, and a more flexible open nested model is proposed. The model is based on grouping semantically related or closely located data together to form a cluster. Data are stored or cached at a mobile unit to support its autonomous operations during disconnections. A fully distributed environment is assumed where users submit transactions from both mobile and fixed terminals. Transactions may involve both remote data and data stored locally at the user’s device. The database is dynamically divided into clusters, and all data items inside a cluster are required to be fully consistent, while replicated data at different clusters may exhibit bounded inconsistencies. A cluster may be distributed on several strongly connected units. When a mobile unit is disconnected it becomes a cluster by itself. Therefore, clusters of data may be explicitly created or merged by a probable disconnection or connection of the associated mobile unit. Also, the movement of the mobile will cause the place of the mobile in the cluster, when it enters a new cell, it can change its cluster too. For every object two copies are maintained, one of them (strict version) must be globally consistent, and the other (weak version) can tolerate some degree of inconsistency but must be locally consistent. Weak transactions access only weak versions whereas strict transactions access strict versions. Weak transactions have two commit points, a local commit in the associated cluster and an implicit global commit after cluster merging. When reconnection is possible (or when application consistency requires it) a synchronization process, executed on the database server, allows the database to be globally consistent. Thus, weak operations support disconnected operation since a mobile device can operate disconnected as long as applications are satisfied with local copies. Users can use weak transactions to update mostly private data and strict transactions to update highly used common data.

Furthermore, by allowing applications to specify their consistency requirements, better bandwidth utilization can be achieved.

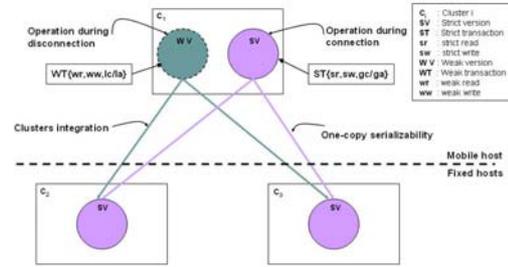

Figure 3: Clustering Model

c. Semantics-based Model

The Semantics-based approach [6] proposes the focus on the use of object semantics information to improve the mobile unit autonomy in disconnected mode. This contribution concentrates on *object fragmentation* as a solution to concurrent operations and to limitations of mobile unit storage capacity. This approach uses objects organization and application semantics to split large and complex data into smaller and manageable fragments of the same type. Each fragment can be cached independently and manipulated asynchronously. Fragment objects can be aggregate items, sets, stacks and queues. This model is shown in the Figure 4.

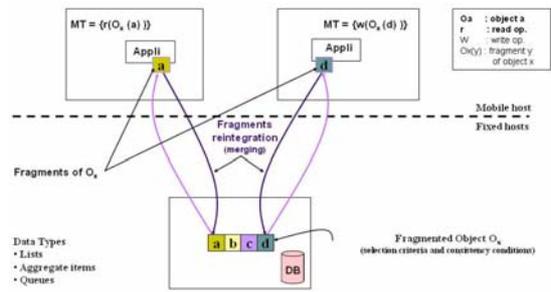

Figure 4: Semantics-Based Model

d. Pro-motion Model

The Pro-Motion approach [7] focuses on ensuring data consistency under disconnections and mobility and this model is shown in the Figure 5. Its fundamental building block is the *compact* which functions as basic unit of replication for caching, prefetching, and hoarding. A compact is an abstraction that encapsulates the caching data, methods for access of the cached data, current state information, consistency rules, obligations and interface methods to allow interaction between compacts and the mobile unit. It represents an agreement between the database server and the mobile host where the database

server delegates control of some data to the mobile unit to be used for local transaction processing. The database server is not aware of what the mobile unit will do with the compact data. It only receives back updates of those data when the computation on the mobile unit is ready to be reported. The mobile unit must comply with the methods and obligations specified in the compact. To improve autonomy and to increase concurrency, object semantics are used in the construction of compacts whenever possible. The main disadvantage is that the original fixed element called Base Station was modified in this proposal. Consequently, this shortcut will obstruct the implementation of the framework based on the mobile IPv4 network.

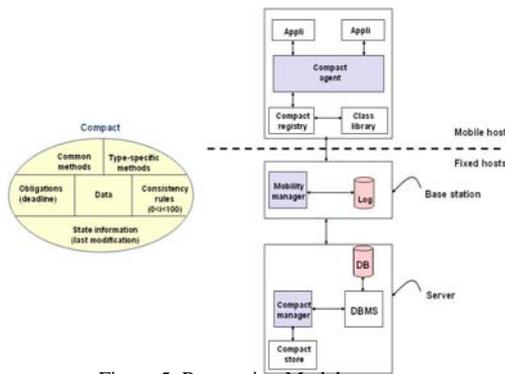

Figure 5: Pro-motion Model

The Communication Protocol Introduction

The success of a session in wireless networks depends on the link quality at the time the session is in progress. A poor quality link is possible to result in the disconnection of mobile commerce session. The disconnection of a session could lead to the termination of any on-going mobile commerce transactions, thus resulting in lots of effects such as loss of opportunities for the users on loss of revenue for the wireless service provider. Although it is not practical that all possible reasons for disconnection can be avoided, it is possible that some transactions could still be completed in such an environment. This paper utilizes the extension header based on IPv6 to construct the mobile environment and adopts the Destination Option Header, one of six Extension headers defined by the current IPv6 specification (RFC2460). Essentially speaking, IPv6 has a new way to deal with options that has substantially improved processing and handles options in additional headers called Extension headers. There can be zero, one, or more than one Extension header between the IPv6 header and the upper-layer protocol header. Each Extension header is identified by the Next Header field in the preceding header. The Extension headers are examined or processed only by the node identified in the Destination Address field of the IPv6 header. Consequently, this thesis introduces the basic operation of IPv6 and mobility support of IPv6 and makes some comparisons between IPv4 and IPv6 in the following subsections.

a. Mobile IPv6 Operation

We put the operation procedure of whole Mobile IPv6 sequentially as follows step by step, shown as Figure 6.

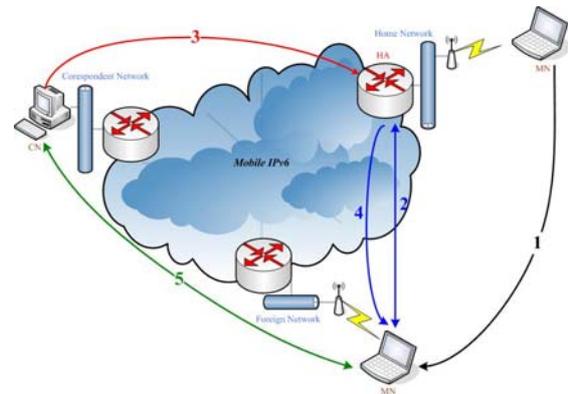

Figure 2.6: Mobile IPv6 Operation Sequentially

1. The MN travels to a foreign network and get a new CoA (Care of Address).
2. The MN performs a binding update to its Home Agent (HA) and the new CoA gets registered at HA. HA sends a binding acknowledgement to MN.
3. A CN wants to contact the MN. The HA intercepts packets destined to the MN.
4. The HA tunnels all packets to the MN from the CN using MN's CoA.

When the MN answers the CN, it may use its current CoA and perform a binding to the CN and communicate with the CN directly (optimized routing) or it can tunnel all its packets through the HA.

b. Mobility Support of IPv6

Mobile IPv6 allows a portable device to be move from one network to another network without changing its IP address and without its exiting connections. Additionally, no need to change its IP address makes it possible for mobile node to act as both client and server. The Mobile IPv6 solution presented here deals with macro-mobility mechanisms at layer3. This solution is the following:

- Keeping alive any communication between a mobile node and a correspondent node while the Mobile Nodes moves from an IP sub-network to another IP sub-networks. This innovative mechanism makes the action of a mobile node be as seamless as possible.
- Allowing a mobile node to be connected with the same IP address wherever the IP sub-networks the Mobile Node is connected to.

c. Compare IPv6 to IPv4

There are many significant differences between IPv6 and IPv4 and this section will examine the most significant difference. The most significant differences are:

- Streamlined Header Format

- Flow Label
- 128-bits Network Address
- Elimination of Header Checksum
- Fragmentation Only by Source Host
- Extension Headers
- Built-in Security

d. Header Comparison

IPv6 provides a more streamlined header than that of IPv4. Five fields are eliminated, including the variable-length IPv4 options field. Removal of the variable length field and other fields permits the IPv6 header to have a fixed format of 40 bytes in length. A comparison of the two types of headers is summarized in Table 1.

Table 1: Header Comparison Between IPv6 and IPv4

	IPv6	IPv4
Header Format	Fixed	Variable
Header Field	8	13
Header Length	40 bytes	20~60 bytes
Address length	128 bits	32 bits
Header Checksum	No	Yes
Fragmentation Fields	No	Yes
Extension Headers	Yes	No

e. Technology Comparison

Although Mobile IPv6 operated in coordination with the usability of IPv6, it was incompatible with Mobile IPv4. This paper delves into the evolution of the mobile network protocol.

1. The designation of Mobile IPv6 was penetrated in the IPv6:
 - a. Mobile IPv6 revoked the necessary existence of Foreign Agent (FA) based on Mobile IPv4 and embedded the original functions of FA in a router.
 - b. Mobile IPv6 revoked the designation of FA's CoA in order to support only the co-located CoA., because it considered the importance of End to End Security.
2. The utilization that transmitting packets as often as delivering Mobile IP messages improved the proceeding rate.
3. Mobile IPv6 was simplifying the mobile IP messages.
4. The route optimization and the smooth handover were the necessary support of mobile network based on Mobile IPv6.

III. Method

From the of Pro-Motion Model, this thesis recognized that what possible approaches this research can simulate and what possible disadvantages this research can modified. In

the section 「Usability Challenges of Mobile Services」, this thesis listed the crucial usability challenges of mobile services and the major issues about the mobile services based on Mobile IPv4 network. In the section 「Mobile Commerce Transaction Based on Mobile IPv6」, this thesis constructs the Mobile Commerce Transaction based on Mobile IPv6 and represents the Java Transaction Service Object (JTSO) in the Waterfall view. Finally this thesis proposes the Client-Server algorithm which ensures the Destination Option header to guarantee the connection End to End.

Usability Challenges of Mobile Services

When services are offered and transactions are operating via wireless connection to mobile users using handheld devices. Additionally, mobile user moved from Home Network to Foreign Network, crucial usability issues are [18]:

- How to facilitate the use of heterogeneous services
- How to adapt service interaction and display of content to the limitations of handheld devices, especially use the small displays.
- How to keep users' expenses for the wireless connection and use of services low and adequate to what they finally get
- How to deal with changing technical environments (e.g. changing quality of services for the underlying network connections)
- How to enhance the trust that users feels towards their service providers and how to protect user privacy

Most of mobile commerce system based on Mobile IPv4 network had not only lots of usability challenges but also many the basic layer problems. Via the Figure.7, this paper listed some major issues, the following are:

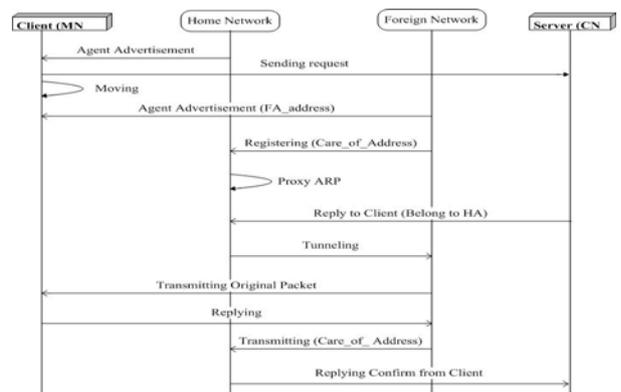

Figure 7: Mobile IPv4 Operation

- The existence of Foreign Agent made mobile commerce transaction time-consuming and risk-doubling.
- Most of Mobile IPv4 messages were complicated and especially in the Foreign Network.
- The mobile commerce environment based on Mobile IPv4 could not guarantee the connection End to End.

- The Mobile IPv4 was the lake of security and the disconnection would make the content of transactions stolen.
- The address space of Mobile IPv4 is running out.

Mobile Commerce Transaction Based on Mobile IPv6

This thesis proposes the sketch framework shown in the figure 8 and this framework is modified from the Pro-Motion model and constructed in the Mobile IPv6 network. In this framework, the Base Stations were moved out and the Java Transaction Service Object (JTSO) is abstraction that encapsulates the caching data and interface methods to allow interaction between JTSO and the mobile unit to fit the ACID properties. The mainly consideration about ACID is the following in the general view:

- Atomicity: Mainly actions/operations of mobile user
- Consistency: Mainly encapsulating transaction declaration of system
- Isolation: Mainly privacy mechanism and trusted system necessarily
- Durability: Mainly protecting mechanism of system

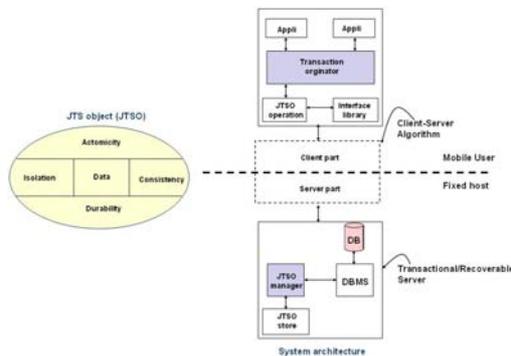

Figure 8: JTS Based on IPv6

In the Waterfall model, it is famous to make software in the process that is requirement, analyzing, designing and testing. To introduce the JTSO clearly, this thesis make the literal combination requirement & general view, analyzing & normalizing view and designing & engineering view.

Java Transaction Service System

The JTS provide an innovative mechanism across the elements of a client/server implementation. Furthermore, the external user will be added in the JTS and the analyzing model about the JTS is in the normalizing view. A transaction can involve multiple objects performing multiple requests. The scope of a transaction is defined by a transaction context that is shared by the participating objects. The JTS places no constraints on the number of objects involved, the topology of the application, or the way in which the application is distributed across a network. In the Figure 9, a client first begins a transaction (by issuing a request to an object defined by the JTS), which establishes a transaction context associated with the client. The client then issues requests. These requests are implicitly associated

with the client's transaction; they share the client's transaction context. Eventually, the client decides to end the transaction (by issuing another request). If there were no failures, the changes produced as a consequence of the client's requests would then be committed; otherwise, the changes would be rolled back. The JTS also supports scenarios where the client directly controls the propagation of the transaction context. For example, a client can pass the transaction context to an object as an explicit parameter in a request. An implementation of the JTS might limit the client's ability to explicitly propagate the transaction context in order to guarantee transaction integrity. The implementation supported by the JTS consists of the following entities:

- Transactional Client (TC)

A transactional client is an arbitrary program that can invoke operations of many transactional objects in a single transaction. The program that begins a transaction is called the transaction originator.

- Transactional Object (TO)

This paper shows the term transactional object to refer to an object whose behavior is affected by being invoked within the scope of a transaction. A transactional object typically contains or indirectly refers to persistent data that can be modified by requests. The Transaction Service does not require that all requests have transactional behavior, even when issued within the scope of a transaction. An object can choose to not support transactional behavior, or to support transactional behavior for some requests but not others. This paper uses the term non-transactional object to refer to an object none of whose operations are affected by being invoked within the scope of a transaction. If an object does not support transactional behavior for a request, then the changes produced by the request might not survive a failure and the changes will not be undone if the transaction associated with the request is rolled back. An object can also choose to support transactional behavior for some requests but not others. This choice can be exercised by both the client and the server of the request.

- Recoverable Object (RO) & Resource

To implement transactional behavior, an object must participate in a certain protocol defined by JTS Service and the protocol is MIPv6. The protocol is used to ensure that all participants in the transaction agree on the outcome (commit or rollback) and to recover from failures. To be more precise, an object is required to participate in this protocol only if it directly manages data whose state is subject to change within a transaction. An object whose data is affected by committing or rolling back a transaction is called a recoverable object. A recoverable object is by definition a transactional object. However, an object can be transactional but not recoverable by implementing its state using some other (recoverable) object. A client is concerned only that an object is transactional; a client cannot tell

whether a transactional object is or is not a recoverable object. A recoverable object must participate in the protocol provided by JTS. It does so by registering an object called a Resource with the JTS. JTS drives the commit protocol by issuing requests to the resources registered for a transaction. A recoverable object typically involves itself in a transaction because it is required to retain in stable storage certain information at critical times in its processing. When a recoverable object restarts after a failure, it participates in a recovery protocol based on the contents (or lack of contents) of its stable storage. A transaction can be used to coordinate non-durable activities not to require permanent changes to storage.

● Transactional/Recoverable Servers

On the one hand, this server is a collection of one or more objects whose behaviors are affected by the transaction, but have no recoverable states of their own. Instead, it implements transactional changes using other recoverable objects. This server when retaining a transactional object does not participate in the completion of the transaction, but it can force the transaction to be rolled back. On the other hand, this server when retaining recoverable objects is a collection of objects.

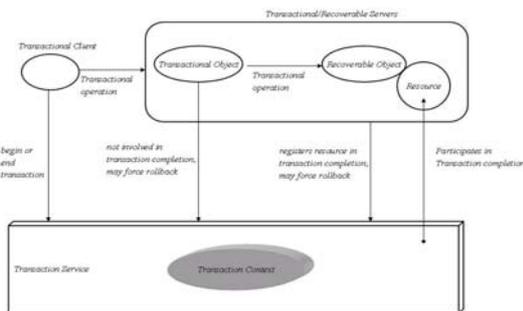

Figure 9: Java Transaction Service

Java Transaction Service System Architecture

Figure 10 illustrates the major components and interfaces defined by the JTS and Figure 11 illustrates the interfaces and methods operated by the JTS to satisfy the ACID properties.

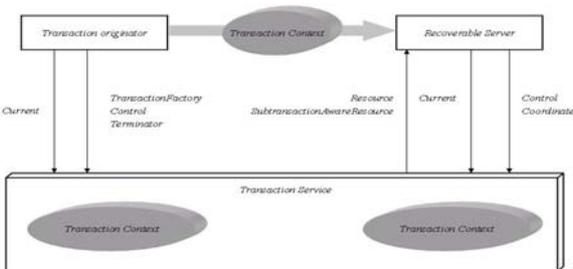

Figure 10: Major Components and Interface of the JTS

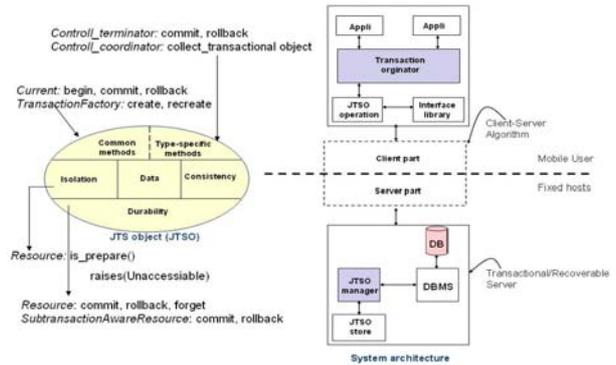

Figure 11: Engineering JTS Based on IPv6

The transaction originator is an arbitrary program that begins a transaction. The recoverable server implements an object with recoverable state that is invoked within the scope of the transaction, either directly by the transaction originator or indirectly through one or more transactional objects. The transaction originator creates a transaction using a *TransactionFactory*; a *Control* is returned that provides access to a *Terminator* and a *Coordinator*. The transaction originator uses the *Terminator* to commit or rollback the transaction. The *Coordinator* is made available to recoverable servers, either explicitly or implicitly. A recoverable server registers a *Resource* with the *Coordinator*. The *Resource* implements the two-phase commit protocol which is driven by the JTS. A recoverable server can register a specialized resource called a *Subtransaction Aware Resource* to track the completion of subtransactions. The interfaces for JTS are as follows:

● Current Interface

The **Current** interface defines operations that allow a client of the JTS to explicitly manage the association between transactions on the connection. The **Current** interface also defines operations that simplify the use of the JTS for most applications. These operations can be used to begin and end transactions and to obtain information about the current transaction. The **Current** interface is a locality-constrained interface whose behavior depends upon and may alter the transaction context.

```
interface Current {
    void begin()

    raises(SubtransactionsUnavailable);
    void commit()
    raises(NoTransaction);
    void rollback()
    raise(NoPermission)
    Status get_status();
    string get_transaction_name();
    void set_timeout(in unsigned long seconds)
    unsigned long get_timeout();
};
➤ begin
```

A new transaction is created. The transaction context of the

client is modified so that the original transaction is associated with the new transaction. If the client is currently associated with a transaction, the new transaction is a subtransaction of the original transaction. Otherwise, the new transaction is a top-level transaction.

➤ **commit**

If there is no transaction associated with the client, the `NoTransaction` exception is raised. Otherwise, the transaction associated with the client is completed.

➤ **rollback**

If the client does not have permission to rollback the transaction, the `NO_PERMISSION` exception is raised. Otherwise, the transaction associated with the client is rolled back.

➤ **get_status**

This operation returns the status of the transaction associated with the client.

➤ **get_transaction_name**

If there is no transaction associated with the client thread, an empty string is returned. Otherwise, this operation returns a printable string describing the transaction.

➤ **set_timeout**

This operation modifies a state variable associated with the target object and the target object affects the time-out period in number of seconds. Besides, this period is associated with top-level transactions. If the parameter has a non-zero value *n*, then top-level transactions will be subject to being rolled back if they do not complete before *n* seconds after their creation. If the parameter is zero, then no application specified time-out is established.

➤ **get_timeout**

This operation returns the state variable associated with the target object that affects the time-out period in number of seconds associated with top-level transactions created by the `begin` operation.

● **TransactionFactory** interface

The **TransactionFactory** interface is provided to allow the transaction originator to begin a transaction. This interface defines two operations, `create` and `recreate`, which create a new representation of a top-level transaction.

```
interface TransactionFactory {
    Control create(in unsigned long time_out);
    Control recreate(in PropagationContext ctx);
};
```

➤ **create**

A new top-level transaction is created and a **Control** object is returned. The **Control** object can be used to manage or to control participation in the new transaction. An implementation of the JTS may restrict the ability for the **Control** object to be transmitted to or used in other

execution environments. At a minimum, it can be used by the client thread. If the parameter has a nonzero value *n*, then the new transaction will be subject to being rolled back if it does not complete before *n* seconds have elapsed. If the parameter is zero, then no application specified time-out is established.

➤ **recreate**

A new representation is created for an existing transaction defined by the **PropagationContext** and a **Control** object is returned. The **Control** object can be used to manage or to control participation in the transaction. An implementation of JTS, which supports inter-position uses `recreate` to create a new representation of the transaction being imported, subordinate to the representation in `ctx`. The `recreate` operation can also be used to import a transaction that originated outside of the JTS.

● **Control** interface

The **Control** interface allows a program to explicitly manage or propagate a transaction context. An object supporting the **Control** interface is implicitly associated with one specific transaction.

```
interface Control {
    Terminator get_terminator();
    raises(Unavailable);
    Coordinator get_coordinator();
    raises(Unavailable);
};
```

The **Control** interface defines two operations, `get_terminator` and `get_coordinator`. The `get_terminator` operation returns a **Terminator** object, which supports operations to end the transaction. The `get_coordinator` operation returns a **Coordinator** object, which supports operations needed by resources to participate in the transaction. The two objects support operations that are typically performed by different parties. Providing two objects allow each set of operations to be made available only to the parties that require those operations. A **Control** object for a transaction is obtained using the operations defined by the **TransactionFactory** interface or the `create_subtransaction` operation defined by the **Coordinator** interface.

● **Terminator** interface

The **Terminator** interface supports operations to commit or rollback a transaction. Typically, these operations are used by the transaction originator.

```
interface Terminator {
    void commit(in boolean report);
    void rollback();
};
```

➤ **commit**

If the transaction has not been marked rollback only, and all of the participants in the transaction agree to commit, the transaction is committed and the operation terminates normally. Otherwise, the transaction is rolled back. The `report` parameter allows the application to control how long

it will block after issuing a commit. If the **report** parameter is true, the call will block until the commit protocol is complete and all outcomes are known. The JTS will report inconsistent or possibly inconsistent outcomes. If the parameter is false, the implementations of the JTS may make use of this fact to block only. When a top-level transaction is committed, all changes to recoverable objects made in the scope of this transaction are made permanent and visible to other transactions or clients. When a subtransaction is committed, the changes are made visible to other related transactions as appropriate to the degree of isolation enforced by the resources.

➤ **rollback**

The transaction is rolled back. When a transaction is rolled back, all changes to recoverable objects made in the scope of this transaction (including changes made by descendant transactions) are rolled back. All resources locked by the transaction are made available to other transactions as appropriate to the degree of isolation enforced by the resources.

● **Coordinator** interface

The **Coordinator** interface provides operations that are used by participants in a transaction. These participants are typically recoverable objects. Each object supporting the **Coordinator** interface is implicitly associated with a single transaction.

```
interface Coordinator {
    Status get_status();
    Status get_parent_status();
    Status get_top_level_status();
    boolean is_same_transaction(in Coordinator tc);
    boolean is_related_transaction(in Coordinator tc);
    boolean is_ancestor_transaction(in Coordinator tc);
    boolean is_descendant_transaction(in Coordinator tc);
    boolean is_top_level_transaction();
};
```

➤ **get_status**

This operation returns the status of the transaction associated with the target object: `Status_Active`, `Status_Prepare`, `Status_Commit`, `Status_RolledBack`, `Status_Unknown` and `Status_NoTransaction`.

➤ **get_parent_status**

If the transaction associated with the target object is a top-level transaction, then this operation is equivalent to the **get_status** operation. Otherwise, this operation returns the status of the parent of the transaction associated with the target object.

➤ **get_top_level_status**

This operation returns the status of the top-level ancestor of the transaction associated with the target object. If the transaction is a top-level transaction, then this operation is

equivalent to the **get_status** operation.

➤ **is_same_transaction**

This operation returns true if and only if the target object and the parameter object both refer to the same transaction.

➤ **is_related_transaction**

This operation returns true if and only if the transaction associated with the target object is related to the transaction associated with the parameter object. A transaction T_1 is related to a transaction T_2 if and only if there is a transaction T_3 such that T_3 is an ancestor of T_1 and T_3 is an ancestor of T_2 .

➤ **is_ancestor_transaction**

This operation returns true if and only if the transaction associated with the target object is an ancestor of the transaction associated with the parameter object. A transaction T_1 is an ancestor of a transaction T_2 if and only if T_1 is the same as T_2 or T_1 is an ancestor of the parent of T_2 .

➤ **is_descendant_transaction.**

This operation returns true if and only if the transaction associated with the target object is a descendant of the transaction associated with the parameter object. A transaction T_1 is a descendant of a transaction T_2 if and only if T_2 is an ancestor of T_1 .

➤ **is_top_level_transaction**

This operation returns true if and only if the transaction associated with the target object is a top-level transaction. A transaction is a top-level transaction if it has no parent.

● **Resource** interface

The **Resource** interface defines the operations invoked by the transaction service on each resource. Each object supporting the **Resource** interface is implicitly associated with a single top-level transaction. Note that in the case of failure, the completion sequence will continue after the failure is repaired. A resource should be prepared to receive duplicate requests for the **commit** or **rollback** operation and to respond consistently.

```
interface Resource {
    is_prepare();
    raises(Unaccessible);
    void rollback();
    void commit();
    void forget();
};
```

➤ **is_prepare**

If no persistent data associated with the resource has been modified by the transaction, the resource can return read only or not. After receiving this response, the JTS is not required to perform any additional operations on this resource. Furthermore, the resource can forget all knowledge of the transaction. If the resource is able to write (or has

already written) all the data needed to commit the transaction to stable storage, as well as an indication that it has prepared the transaction, it can call **commit**. After call the **commit**, the JTS is required to eventually perform either the **commit** or the **rollback** operation on this object.

➤ **rollback**

If necessary, the resource should rollback all changes made as part of the transaction. If the resource has forgotten the transaction, it should do nothing.

➤ **commit**

If necessary, the resource should commit all changes made as part of the transaction. If the resource has forgotten the transaction, it should do nothing.

➤ **forget**

This operation is performed only if the resource raised the exception to **rollback**, **commit**, or **prepare**. Once the coordinator has determined that the situation of the transaction's resource has been addressed, it should issue **forget** on the resource. The resource can forget all knowledge of the transaction.

● **Subtransaction Aware Resource** interface

Recoverable objects that implement nested transaction behavior may support a specialization of the **Resource** interface called the **SubtransactionAwareResource** interface. A recoverable object can be notified of the completion of a subtransaction by registering a specialized resource object that offers this interface with the JTS. The JTS uses this interface on each **Resource** object registered with a subtransaction. Each object supporting this interface is implicitly associated with a single subtransaction.

```
interface SubtransactionAwareResource : Resource
{
    void commit_subtransaction(in Coordinator parent);
    void rollback_subtransaction();
};
```

➤ **commit_subtransaction**

This operation is invoked only if the resource has been registered with a subtransaction and the subtransaction has been committed. The **Resource** object is provided with a **Coordinator** that represents the parent transaction. Note that the results of a committed subtransaction are relative to the completion of its ancestor transactions, that is, these results can be undone if any ancestor transaction is rolled back.

➤ **rollback_subtransaction**

This operation is invoked only if the resource has been registered with a subtransaction and notifies the resource that the subtransaction has rolled back.

The Destination Options Header Based on Mobile IPv6

This paper adopts the quotation about the header structure of

an IPv6 packet specified in RFC2460 in order to make a transaction complete possibly [1]. A Destination Options header carries optional information that is examined by the destination node only. The Next Header value identifying this type of header is the value 60. Figure 11 shows the format of the Destination Option header.

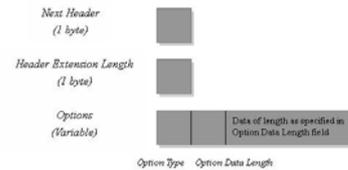

Figure 11: Format of the Destination Options header

The following list describes each field:

● **Next Header**

The Next Header field identifies the type of header that follows the Destination Options header.

● **Header Extension Length**

This field identifies the length of the Destination Options header in 8 byte units. The length calculation does not include the first 8 bytes.

● **Options**

There can be one or more options and the length of the options is variable and determined in the Header Extension Length field.

The utilization of Destination Option header to construct mobile commerce

Before the basic construction based on Mobile IPv6, this research makes some considerations listed in the following issues:

How well do it make each component of mobile network perform under realistic conditions to utilize the Destination Option header

How well should this research perform both before and after a new application is extended or a new priority scheme is introduced in the proposed methods listed in the background.

Is the highest priority of a transaction maximum throughput, or minimal response time for each type of network transaction

According the above considerations, this paper proposes the Client-Server algorithm that not only utilizes the Destination Option header to guarantee the connection End to End but also sets Time variable and parameter to measure both before and after a transaction. This algorithm is listed in Figure 12 and the description of variable value in this algorithm is listed in Table 2.

```

Client-Server Algorithm
Server (Correspondent Node)      Client (Mobile Node)
SLEEP                            CONNECT_ACCEPT
initial_delay = 0                destination_NextHeaderField = 60
CONNECT_INITIATE                 LOOP
source_NextHeaderField = 60      number_of_timing_records = 100
LOOP                              START TIMER
number_of_timing_records = 100   LOOP
START TIMER                       transactions_per_record = 1
LOOP                               SEND
transactions_per_record = 1       file_size = 999999
SEND                               receive_buffer_size = DEFAULT
file_size = 999999               send_buffer_size = DEFAULT
receive_buffer_size = DEFAULT     send_data_type = NOPRESS
send_buffer_size = DEFAULT        send_data_rate = UNLIMITED
send_data_type = NOPRESS          CONFIRM_REQUEST
send_data_rate = UNLIMITED       CONFIRM_ACKNOWLEDGEMENT
CONFIRM_REQUEST                   END LOOP
INCREMENT_TRANSACTION            END LOOP
END LOOP                           END TIMER
END TIMER                          SLEEP
transaction_delay = 0
SLEEP
END LOOP                           END LOOP
DISCONNECT                         DISCONNECT
close_type = Reset                 close_type = Reset
    
```

Figure 12: Client-Server Algorithm

Variable Name	Value	Description
initial_delay	0	Pause before the first transaction
number_of_timing_records	100	How many timing records to generate
transactions_per_record	1	Transactions per timing record
file_size	999999	How many byte in the transferred file
send_buffer_size	DEFAULT	How many of data in each SEND
receive_buffer_size	DEFAULT	How many of data in each RECEIVE
transaction_delay	0	Milliseconds to pause
send_data_type	NOPRESS	What type of data to send
send_data_rate	UNLIMITED	How fast to send data
destination_NextHeaderField	60	What option to use for MN
close_type	Reset	How connections are terminated
source_NextHeaderField	60	What option to use for CN

Table 2: Variable value description

IV. Conclusion and Future Work

As this thesis mentioned above, Mobile commerce will become the major tendency toward electronic business because of the benefits such convenience and instantaneous, etc. We also find the government is rapidly moving toward adopting the new Internet Protocol called "IPv6" to provide a standard mobile infrastructure for loosely-coupled large-scale distributed systems. Our thesis has suffered characteristics make developing efficient and effective scheduling algorithm for wireless mobile networks very challenging. The JTS has satisfied the following ACID characteristics that are first a transaction is atomic; if interrupted by failure, all effects are undone, second a transaction produces consistent results; the effects of a transaction preserve invariant properties, third a transaction is isolated; its intermediate states are not visible to other transactions and forth a transaction is durable; the effects of a completed transaction are persistent.

Recognizing that there are still many significant technical challenges exist in the development, deployment and management of such Java Transaction Service mobile commerce applications. The biggest challenge for such a service is the fragmentation of the security requirements. However, their standardized definitions are still evolving and we don't go deep into this issue too much. On the other hand, another future work is to increase data availability and reduce the load on a server by balancing the service access among the replicated transaction servers.

Exploring Customer Preferences on Mobile Services

Seung Baek, Jinwoo Kang & Woosuk Hong
College of Business Administration
Hanyang University, Seoul, Korea
¹⁾ e-mail: sbaek@hanyang.ac.kr
Tel: 82-2-2220-1062

Abstract: Designing mobile services is fundamentally different than designing online services. Not only are there differences in underlying technologies, but also in the way people use services. If these differences are not taken into account, mobile services are likely to fail. If mobile services do not deliver what people want, these services will fail no matter how excellent the underlying technology is. The user interface design that is commonly used in mobile services is based on multi-layered approach, which is not very user friendly. So a well designed single layered user interface will be more user friendly than the conventional one and it will be having edge over others. However, it is quite difficult to provide a single layered user interface in a small screen. This study aims at examining how user interface design attributes of mobile services affect customer preferences. In order to explore customer preferences to each design attribute, we measure customer's WTP (Willingness To Pay) toward different interface designs.

I. Introduction

In Korea, the phenomenal growth of ownership of cellular phones was not a government initiative, rather a private industry-driven one. As the user population of the high-speed Internet service is growing quickly in Korea, many users are more inclined to use the Internet for multimedia entertainment. With the rapid increase of the internet usage, the growing penetration of wireless devices, and the rapid technological innovation, wireless technology shifts the world of wired Internet to the wireless mobile Internet.

The Internet has provided an easy and effective way of delivering information and services to millions of users who are connected to a wired network. Evidently, this wired network addresses two major constraints: time and place. These limitations have raised the issue of the mobile internet, which enables users to access information from any place at any time. The mobile Internet is expected to deliver great time and place flexibility to individuals.

This study aims at examining how user interface design attributes of mobile services affect customer preferences. In order to explore customer preferences to each design attribute, we measure customer's WTP (Willingness To Pay) toward different interface designs.

II. User Interfaces of Mobile Services

The user interface and the size of mobile devices are the main concerns in design of mobile services. With the advancement in semiconductor technology, the size of mobile devices has reduced a lot. We can actually reduce it further by making a touch screen based user interface because it will avoid the need of physical keypad that takes a lot of space. The other important concern in the design of mobile devices is the User Interface (UI) because it is the one with which users have to interact all the time. The user interface design that is commonly used in mobile services is based on multi-layered approach, which is not very user friendly. So a well designed single layered user interface will be more user friendly than the conventional one and it will be having edge over others. However, it is quite difficult to provide a single layered user interface in a small screen.

III. WTP (Willingness to Pay)

To measure WTP, there are two methods: contingent method and conjoint method. In the contingent method, arbitrary goods or service are presented with specific prices, and then respondents take or reject the offers. While the contingent method asks respondents to evaluate real products, the conjoint method asks them to evaluate hypothetical products. The conjoint method allows researchers to presents respondents with a choice set that contains several alternatives that vary along several attributes, including price. Respondents decide the rankings among the alternatives. Based on the rankings, researchers can analyze the preferences and utilities of respondents for specific goods/service. The major objective of this study is to examine impacts of rich interaction design features of mobile services on customer preferences. To investigate customer preferences, it collects respondents' WTP to specific interface designs of mobile services. To analyze the WTP data, it uses the conjoint method.

IV. Research Methodology

The main purpose of this study is to explore the effects of design attributes of mobile services on WTP. In order to analyze relative impacts of interface design attributes on customers' preferences, this study employs conjoint analysis. A conjoint analysis is one of the most widely-used

methods which are designed to analyze consumer needs. This method shows relative importance of various utilities considered by consumers when they purchase service and a service that consists of the most ideal combination of those utilities. Conjoint analysis originates from mathematical psychology. Conjoint analysis is used to understand how consumers develop preferences for products or services, which encompass, as usual, multi-attributes and multi-attribute levels. Utility is a consumer’s subjective measurement of preference that is evaluated for each level of attributes. The utility values associated with each level of attributes are summed as the overall utility. Then, products or services with higher utility are assumed to be of a better choice for consumers. In order to apply the conjoint analysis into this research, we go through the following steps.

Step 1: Specifying Factors and Levels

Based on expert interview, we find that the interface design of mobile service is very critical to attract mobile customers. Wireless Application Protocol (WAP) phones are a growing relevant part of mobile services. In order to use WAP based services, users explore a menu hierarchy. The positions of specific mobile services within menu and the amount of their information within menu affect customer purchase decisions. Table 1 shows different levels of menu design attributes of mobile service. In this study, we examine how the menu design attributes affect customer’s WTP.

Table 1. Design Attributes of Menu Design in Mobile Services

Menu Design Attributes	Levels
Mobile service type shown in menu	Entertainment Service Information / Communication Service No Information about Mobile Service Type
Payment information of mobile service shown in menu	Cash Discount Information shown in menu Coupon Information shown in menu No Information about payment shown in menu
Menu position of mobile service	First Line Second Line Middle Line
Recommendation information about mobile services shown in menu	Log Data Based Recommendation User Evaluation Based Recommendation No Information

Step 2: Choosing a Presentation Method

Since this study has four attributes with three levels each, all possible hypothetical products are 81 (3*3*3*3). If we use a full-profile method, respondents would have difficulty in answering all 81 questions. For this reason, the number of questions is needed to be diminished to a proper level. As an alternative to a factorial design, we use a fractional factorial design. This approach is a way to reduce the number of questions. The number of initial questions (81 questions) is reduced to 9 questions (refer to Table 2). Based on the fractional factorial design, 9 hypothetical products are generated.

Table 2. Hypothetical Products

Product	Mobile Service Type	Payment Information	Menu Position of Mobile Service	Recommendation Information About Mobile Service
P1	No Information	No Information	First Line	User Evaluation Based Recommendation
P2	Entertainment	Coupon	Middle Line	User Evaluation Based Recommendation
P3	No Information	Cash Discount	Middle Line	No Information
P4	Information / Communication	Cash Discount	Second Line	User Evaluation Based Recommendation
P5	Information / Communication	No Information	Middle Line	Log Data Based Recommendation
P6	Entertainment	Cash Discount	First Line	Log Data Based Recommendation
P7	Entertainment	No Information	Second Line	No Information
P8	Information / Communication	Coupon	First Line	No Information
P9	No information	Coupon	Second Line	Log Data Based Recommendation

Step 3: Selecting a Measure of Consumer Preference

Based on 9 hypothetical products, we design a menu screen. In order to measure customer preferences to specific hypothetical products, the study employs the rank-order method, rather than the rating method. Respondents are asked to provide the maximum monetary amounts that they would pay to get these products. Based on the amounts, we investigate how much each menu design attribute of mobile services affects customer’s WTP.

Table 3. Part-Worths and Relative Importance

Attribute	Part-Worth			Relative Importance (%)
	1	2	3	
Mobile Service Type	Entertainment	Information / Communication	No Information	27.51
	1.74	0.32	0.94	
Payment Information of Mobile Services	Discount	Coupon	No Information	26.53
	1.54	0.96	0.50	
Menu Position of Mobile Services	First Line	Second Line	Middle Line	23.21
	1.20	0.48	1.33	
Recommendation Information of Mobile Services	Log Data Based Recommendation	User Evaluation Based Recommendation	No Information	22.75
	0.85	1.16	0.99	

V. Data Analysis

We interviewed 150 respondents, consisting of 86 males and 64 females. Since most of wireless internet users are

younger, most of respondents consist of 12-19 year olds in this study. In addition to portraying the impact of each level (entertainment, information/ communication, no information et. al) with the part-worth estimates, conjoint analysis can assess the relative importance of each design factor (information about mobile service type, payment information of mobile service, position of mobile service, and recommendation information about mobile service). Since the part-worth estimates are on a common scale, the greatest contribution to overall utility of preference, and hence the most important factor, is the factor with the highest range of part-worths.

In this study, we examine the relative impacts of menu design attributes of mobile services on customer's WTP. We try to find an optimal menu design of mobile services that high-valued by users. Table 3 reports the means of the part-worths and relative importance for 150 subjects. The greater the relative importance, the more an attribute influences your preferences for mobile services. If the information about mobile service types is shown in menu, there is the highest possibility that customers purchase mobile services (27.51%). In other words, customers utilize information about mobile service types as critical information in purchasing of mobile services. The second influential menu design attribute is the payment information

of mobile services shown in menu, (26.53%), the third is the positions of mobile services within menu (23.21%), and the last is the recommendation information of mobile service.

VI. Conclusions

One often meets the argument that due to the complexity of the service model and the convergence of technologies and services expected in mobile services, it is very little relevant research available to help us understand the mobile services and their users. The main purpose of the study is to explore attributes that influence customers' preferences to mobile services. To explore the relative importance of the attributes, the study uses conjoint analysis. It finds that the most influential attribute is the mobile service types. This finding supports the current phenomenon that the main usage of mobile services is concentrated on entertainment services. Although this study tries to understand customers of mobile services empirically, it has very limited contributions to theoretical development. In addition, regarding to the relationships between attributes of mobile services and customers' preferences, it does not propose a theoretical explanation.

Enterprise Resource Planning and IT Governance in Perspective: Strategic Planning and Alignment, Value Delivery, and Controlling

Edward W.N. BERNROIDER

Institute for Information Business, Vienna University of Economics and B.A., Austria, Email: bernroider@wu-wien.ac.at

Alexander HAMPEL

Department of Computer Science and Business Informatics, University of Vienna, Email: alexander.hampel@univie.ac.at

Abstract: This article assesses key aspects of IT governance comprising strategic planning especially alignment, value delivery, and control objectives through an empirical study of Austrian medium sized and large enterprises. Enterprise Resource Planning (ERP) systems are in general seen as key information systems supporting e-business processes. The findings show an underdeveloped IT governance competence in the Austrian market place in particular reflected through low levels of strategic alignment and strategic decision making, as well as missing ERP control procedures. Nevertheless, in term of value delivery a positive impact of ERP in a holistic, multi-dimensional assessment was observed covering ERP benefits, organisational performance effects, and key performance criteria used in an ERP balanced scorecard (BSC).

Keywords: Business Infrastructure Management, IT Governance, Enterprise Resource Planning, IT Controlling.

I. Introduction

Today's (e-)business requirements, in particular in terms of enhanced liability and accountability demands, have moved IT governance into the focus of attention. The core processes underlying effective and comprehensive IT governance are the same as those for enterprise governance [6]. IT activities have become critically important to all aspects of the enterprise. This in particular applies to enterprise resource planning (ERP) systems which are in general seen as key information systems supporting e-business processes. ERP is a fine expression of the inseparability of IT and business. As an enabling key technology as well as an effective managerial tool, ERP systems allow companies to integrate at all levels and utilise important extensions, in particular in terms of e-business functionality. They represent large, complex, computerised and integrated systems, which can strongly influence long-term business success. Although e-business is rapidly changing the basic paradigm under which businesses operate, the full potential of e-business can only be realized if e-business technologies (Internet, Intranet and WWW technologies) can be successfully integrated with backbone ERP systems. A review of the work published in the main information systems journals and conferences sho-

wed that research conducted in the area of ERP systems has concentrated on issues related to the implementation phase of the ERP lifecycle [5]. Work contributing to actual ERP operation comprised numerous factors that influence ERP usage depending on users-systems interactions over time based on structuration theory [13] and the behavioural-based theories, frameworks for classifying benefits [16], and barriers and challenges to the attainment of ERP benefits [7]. The latter article indicates that implementations do not live up to their expectations and do not provide the expected range of benefits. Another article on ERP performance indicates based on the sample of 50 companies implementing ERP packages from 1993 to 1997 a significant increase in costs as a percentage of revenue and a decrease in the number of employees as a percentage of revenue in the year after ERP implementation. It was reasoned that cost drivers connected to the ERP technology such as (external) ERP system engineers and on-going fixes and fine-tuning elevate costs.

This research project is concerned with the following three key aspects of IT governance [6, 11]:

- (i) strategic planning and alignment as well as top-level management responsibility,
- (ii) IT value delivery, and
- (iii) IT controlling (employment of criteria and standards for decision making and controlling for continuous improvement of IT enabled business processes).

Through an empirical study, it seeks to assess the levels of achievement in each category with respect to ERP system management. Motivated by the many critical perceptions of ERP system operation provided by research, a main goal of this article is to assess the organisational impact of system implementation through a holistic multi-dimensional approach. The framework draws on classifications of possible ERP benefits, on general firm level success measures, and on key performance indicators used in a balanced scorecard adopted to control ERP operation.

Due to the pervasive nature of ERP systems, our results should be of interest for a wide range of professional and scholarly communities apart from the information systems (IS) field. The results presented should assist business management facing the important task to monitor and control ERP system operation. At least, this work raises the awareness for relevant factors that need to be assessed in ERP environments.

II. Methodology

The methodology employed is an industry independent empirical survey undertaken in the years 2003 to 2004. The target group was defined as containing Austrian small to medium sized enterprises (SMEs) as well as large enterprise (LEs) allowing for controlling the size of the company in data analysis. Austria is an example for a well-developed country within the European Union. To avoid under representing the large enterprises in the sample, a stratified and disproportional sample with subgroups according to company size was defined. One thousand Austrian SMEs and LEs were randomly selected from firms listed in a comprehensive, pan-European database containing financial information on 7 million public and private companies in 38 European countries [2].

The questionnaire developed for this study was based on a previously undertaken ERP related study [1], on a review of the literature and on recommendations of a panel of ERP experts from two universities in Austria and the United Kingdom. Following an empirical design method, the panel was asked to critique the questionnaire for content validity [3]. According to their suggestions, the questionnaire was revised and used in Pre-Tests applied in the UK and Austria. Responses were examined to optimize the formulation of each question and ensure consistency in the way they were answered. The questionnaire contained a general section assessing the background information on the company especially IT/IS related and performance related questions. The assessed topics were structured in four sections following the ERP system lifecycle: adoption decision, acquisition, implementation, use and maintenance. Companies were contacted through a multi-staged procedure. A cover letter, the hardcopy questionnaire, and a self-addressed stamped return envelope were sent to business management of the 1000 companies. The package explained the purpose of the study, promoted participation in the survey, assured confidentiality, and offered an ERP-related collection of material on CD as well as a summary of the results together with an opportunity to engage in further research activities with our research department. The questionnaire was also provided in an electronic version to further strengthen the participation. Two weeks after the initial mailing, follow up calls were made to all companies that could not be identified as respondents, asking them for their interest in participating and if cooperative for an email address. Short after these calls, reminder/thank you emails were sent out. The next round of contact consisted in reminding 400 randomly selected companies via telephone calls that they had not yet responded, and again giving them the address and logins for the online questionnaire. Finally, 209 valid returns were registered, resulting in an above average response rate of 22%. Some companies could not be contacted, because they had ceased to exist, the address was wrong or could not be found, etc. These neutral dropouts (49 companies) were considered in the calculation of the

response rate and therefore did not decrease the return quota. To test for non-response bias, known distributions of variables available through the used corporate database were assessed. The analysis revealed no significant different characteristics between non-respondents and respondents. The data was analyzed using a statistical package offering the ability to work on complex samples.

III. Empirical Results

III.1 Sample Demographics

Following a commission recommendation of the European Communities concerning the definition of micro, small and medium-sized enterprises [4], this research classified as SME an enterprises which employs fewer than 250 persons and which has an annual turnover not exceeding EUR 50 million. Table 1 denotes the firm size and branch distribution of the data sample. The branch classification was based on the core codes given in brackets of the North American Industry Classification System (NAICS) which has replaced the U.S. Standard Industrial Classification (SIC) system in 1997 [12].

Table 1. Firm size and branch distribution

Size	No. of companies (rel. in %)	No. of companies (abs. unweighted N)
SMEs	92.8	129
LEs	7.2	79
Total	100	208
Branch		
Trade (42,44-45)	22.6	58
Manufacturing (31-33)	21.0	60
Construction (23)	20.5	20
Services (54)	15.7	30
Transportation and Warehousing (48-49)	7.6	8
Information (51)	4.5	8
Health Care and Social Assistance (62)	1.9	4
Management of Companies and Enterprises (55)	1.4	8
Other	4.8	12
Total	100	208

The observed distribution of management structure is given in Table 2. The traditional functional management structure was observed in 64.7% of the cases followed by the project/team structures in 16.1% of the enterprises.

Table 2. Management structures

Management structure	Rel. in %
Functional	64.7
Divisional	5.1
Geographic	1.0
Project/Team oriented	16.1
Matrix	7.6
Network (core and periphery)	0.8
Virtual	0.0
Other	4.7

ERP diffusion along the system’s lifecycle stages is denoted in Table 3. 15.5 % of all SMEs have already selected an ERP system, i.e. have reached at least the stage of implementing the system, comparing to 67.6 % of all LEs. As expected, the observed differences between SMEs and LEs are highly significant (χ^2 , $p=.00$). The company’s positions in the lifecycle correlate positively with organisational size ($\text{corr}=.16$, $p=.03$).

Table 3. ERP diffusion among SMEs and LEs

Stage	All companies		SMEs		LEs	
	%	cum. %	%	cum. %	%	cum. %
Consideration	6.6	6.6	6.6	6.6	6.4	6.4
Evaluation	.5	7.1	.3	6.9	2.0	8.4
Implementation	1.2	8.3	.4	7.3	10.5	18.9
Stabilisation	1.8	10.1	1.8	9.1	2.0	20.9
Usage and maintenance	13.4	23.5	11.4	20.5	39.0	59.9
Extension	2.9	26.4	1.9	22.4	16.1	76
No ERP	73.6	100	77.5	100	23.9	100

III. 2 Strategic Planning in Perspective

Business management has in only 25.8% of all cases explicitly defined their IT/IS strategy (regardless of their ERP utilization stage). Among LEs, the rate is 48.2%, still a remarkable low number. The mean rate of alignment of corporate respectively business strategies and structures with IT/IS strategies and infra-structures on a scale between 1 (very bad) to 5 (very good) is 3.13 revealing a slightly positive assessment. Selection criteria were derived from the strategic goals of the company in 65.3% of all cases. Again, the number increases among LEs, which in general are known to possess a better developed managerial competence. An indicator for top-level management responsibility is the inclusion of the CIO in the board of executives. In 41.9% of all cases, the IS/IT division is represented at board level.

Table 4. IT/IS strategic guidance

	All	SMEs	LEs	p (χ^2)
IS/IT division represented at board level	41.9%	41.8%	43.6%	-
Explicitly defined IT/IS strategy	25.8%	23.8%	48.2%	.00
Strategic Alignment ¹	3.13	3.11	3.51	.04
Strategic concept driving the choice of selection criteria	65.3%	63.7%	76.9%	-

¹ Rated on a scale between 1 (very bad) and 5 (very good), * $p<.05$, ** $p<.01$; N (SMEs) = max 39, N (LEs) = max 59

III. 3 ERP Value Delivery in Perspective

A comprehensive list of ERP decision making criteria were evaluated according to expectations/targets set prior to system implementation. The expectations of business management were most likely met in terms of the system related features “Y2K readiness”, “systems reliability”, and “EURO currency conversion”. The first and the third criteria were among the most important drivers for ERP software growth in the last decade. The expectations of ERP as technology enabler (including e-business, CRM, and SCM) were considered as the least successful aspects. According to the inquired list of all other remaining factors, expectations were at least met at the desired level in the mean case. The list of remaining factors comprised (given in the order of achieved success): “advanced technology”, “enabler for desired business processes”, “business process improvement”, “improved service levels”, “integrated and better quality of information”, “system interoperability”, “system usability”, “organizational fit”, “increased organisational flexibility”, “enhanced decision making”, “incorporation of business best practices”, “reduced cycle times”, “increased customer satisfaction”, “short implementation time”, “internationality of software”, “software costs (licenses, maintenance, etc.)”, “operating system independency”, and “improved innovation capabilities”. No substantive differences were detected in the perceptions given by managers of SMEs and LEs.

An often mentioned short term effect of large scale software introductions is a decline in process efficiencies, respectively organisational performance. This was confirmed by data analysis (see Table 5) and a significant difference was observed between SMEs and LEs (χ^2 , $p=.00$). While the majority of SMEs are faced with short term declines, only a minor number experience long term problems, and no SMEs has stated that the performance level prior to ERP were not recovered. The situation is different among LEs where a considerable proportion faced long term performance problems, while a minor, but nevertheless existing, proportion does not recover to past performance levels.

Table 5. Decline in organisational performance after switching to ERP

Decline in organisational performance	All (%)	SMEs (%)	LEs (%)
not noticed	30.7	25.1	52.2
experienced over a short period of time	60.6	69.3	26.8
experienced over a long period of time	8.3	5.6	18.8
experienced and not recovered	.5	.0	2.2

The question whether ERP is aiding to the organisation to gain a competitive edge was answered with yes by 83.1% of all enterprises. The view is clearly more optimistic in SMEs, i.e. the distribution is significantly dependent on the size of the organisation (χ^2 , $p=.01$). The rate increases to 88.1% for SMEs and decreases to 65% for LEs.

III. 4 ERP Controlling in Perspective

In terms of ERP controlling, only 3.4% of the enterprise in the survey have implemented an instrument to control ERP system operation. In evaluating the performance in the usage stage traditionally two different perspectives, the financial and the technical view, can be defined. The balanced scorecard (BSC) is a well known approach used for controlling based on multiple attributes aligned along four different perspectives. It was first proposed in 1992 [8] and soon after applied [9]. The BSC is a well established measurement method which links strategic objectives and performance measures. Its application promises strategy mapping between each of the perspectives. The idea of a BSC is to find a set of measures that maintain a balance between short- and long-term objectives, between lagging and leading indicators, between financial and non-financial criteria, and between internal and external performance perspectives [10, 14]. To assess the performance in system usage, this study has drawn on suggestions provided in academic literature, mainly on [15] where the BSC was developed for ERP controlling. denotes the four considered ERP controlling perspectives with attributed measures (see Table 6). Based on the gathered data, the overall conclusion is that ERP impact in terms of all measured dimensions provided positive effects in SMEs as well as LEs.

Table 6. Control variables in relation to the situation prior to ERP across balanced score card perspectives

IV. Conclusion

This article delivers an empirical overview of main components in IT governance with respect to ERP.

First, and often seen as most important, the rationale behind ERP was analysed in a strategic context. The main pre-condition of IT-governance – the alignment of business and IT strategy – is still underdeveloped in the Austrian marketplace. Only a minority explicitly defines their IT strategy. Approximately 25% of the large enterprise have evaluated and selected an ERP system without considering the strategic needs of their company. IT governance implies the IT responsibility of the executive board, but the data showed that CIOs are not regularly seen as members of the board (41.9%).

Second, ERP value in perspective shows that ERP in general meets and often exceeds expectations with respect to almost all assessed areas. Only in terms of enabling other applications such as customer relationship management (CRM) and supply chain management (SCM), ERP seems to fall short in terms of expected utility. This finding contradicts the critical perception of ERP success reported in academic literature given in the introduction of this article.

Organisational performance has declined in 60.6% of the enterprises shortly after implementation, but has recovered in almost all cases to prior levels (known as short dip in organisational performance after switching to ERP). A large majority (83.1% of the cases) believes that ERP is aiding to the organisation to gain a competitive edge.

Third, the quasi non-existence of ERP control procedures in the Austrian market place contradicts the need for IT-controlling (and –governance) mechanism, which is communicated in international IT/IS practice. Due to the documented importance of installed ERP systems respectively of the data and business processes they support, their omission in IS/IT controlling seems critical. This paper can help to introduce controlling in organizational practice through a BSC based approach by providing a list of reference with performance indicators. The empirical data revealed distinct positive effects of ERP in terms of all four BSC perspectives. The financial perspective showed that while IT/IS related costs have approximately remained unchanged, related costs in functional areas, e.g. procurement or logistics, have been reduced due to ERP. The positive valuation of ERP effects becomes more pronounced beyond a financial assessment, e.g., in terms of process efficiency and effectiveness gains.

To summarize, the main findings comprise the observed positive impact of ERP in a holistic, multi-dimensional perception and underdeveloped IT governance principles in Austria. The latter area constitutes a large market potential for consultants who deliver IT re-organisations especially based on new standards (COBIT, ITIL, ISO) or regulations (Sarbanes-Oxley, Basel 2). Future work will concentrate on compliance and substantive tests within case studies with regard to the mentioned frameworks.

Abstract: By June 2002, there were 17 grocers in the U.S. and Canada offering delivery services that allowed customers to order via the Internet or telephone. Within these grocers, some such as Peapod and FreshDirect offer services through the Internet without owning any retail store front while some supermarkets like Albertson's, Safeway, Publix and Tesco have developed their online grocery services as another shopping option for their customers. Studying the profile of online grocery shoppers and their behaviors can help businesses to develop and improve their strategies. This paper will discuss the findings from a survey (1516 respondents) on e-grocery in the United States. Responses to such topics as demographics & psychographics, shopping patterns, online shopping experiences, mental, physical and time related considerations, opinions about shopping and buying on the internet and order sizes are discussed.

Keywords: Operations strategy for e-commerce, e-grocery, consumer survey

I. Introduction

The Internet has become a viable way for conducting business. Its capability for communication between individuals without regard of geographic locations allows businesses to develop their markets worldwide. With the increasing number of Internet users and greater endorsement of customers for online shopping (Geissler 2002), the Internet can help businesses reach their customers in a shorter time and at a lower transaction cost (Kirkpatrick, 2002).

Among the growing number of online businesses, the online grocery market is a category that has been discussed widely for its suitability for e-commerce (Anckar et al. 2002). Despite the collapse of some high profile operators like Webvan, Streamline and HomeGrocer (Berning et al, 2004), recent research indicates continued growth in this e-grocery segment is slated to reach as much as \$11.3 sector (Kornum and Bjerre, 2005). By some predictions the Billion by 2006 (Berning et al, 2004). In the United States the

bigger trend is high value grocery items such as premium meats and seafood, and assorted fresh fruits (Singh, 2005)

II. E-Grocery

According to Berning et al, 2004, e-grocery may be defined as "a firm that uses the Internet to sell a full range of perishable items such as meat, fresh produce and frozen products and non-perishable food and drink items, such as breakfast cereals or canned goods. These products are ordered online for pick-up at a physical store or delivery to the customer's home, office or school".

Groceries differ from many other non perishable products, such as music and books, which are commonly purchased online. Many grocery products are perishable and therefore time-sensitive in terms of their delivery needs. The term "perishable" is used for those goods that are not pantry items and need to be stored in a refrigerator or a freezer. In addition, groceries are a replacement product, i.e., the same basket of products is more-or-less purchased on a regular basis (Kempiak and Fox 2002). Finally, some groceries are dependent on organoleptic (touch, smell, and sight) experiences, meaning that consumers like to inspect the quality of items they are purchasing. Even though the freshness and quality of the products can be guaranteed by the business, consumers still have difference preferences and acceptance standards for certain kinds of grocery products (Anckar et al, 2002). With these reasons, groceries could be considered as product category that is not suitable for online business. However, researches show that there are many factors for online groceries to thrive in the world of e-commerce. Many consumers dislike the chore of grocery shopping (Corral 1999) and many of them even have shopping stress (Aylott and Mitchell 1998). Thus, convenience and time saving can be dominant reasons for consumers to shop for groceries online. According to one survey report (Chiger 2001) 67% of the online shoppers agreed that convenience was the main reason they had bought via the Internet with 41% mentioning price as another factor.

E-grocery business models

Socioeconomic characteristics such as the ever growing demand on consumers' time, increased wealth, and

heightened levels of stress in consumers' everyday lives have influenced the growth of E-Commerce in general. The high total cost of E-grocers' picking and distributing items from a wide range of possible products and consumers learning to shop online may be delaying the wider adoption of such E-Commerce by grocers and consumers alike (Lim et al, 2004). As reported in June 2002, there were 17 grocers in the U.S. and Canada offering delivery services that allowed customers to order via the Internet or telephone (Geissler 2002). Slowly but surely, retailers are coming back with two basic business models — online ordering piggy-backed onto existing supermarkets, and the so-called pure-play approach, which seemed in danger of dying off after the Webvan conflagration, but now has resurfaced with a much more specialized way of doing business (Lempert 2005). Some large supermarket chains such as Albertson's, Safeway, Publix, Tesco, etc., opt for the first choice (i.e. store-based e-grocers). Examples of the pure-plays (i.e. grocers without physical store) are Peapod and FreshDirect.

Brick-and-mortar add-ons

Brick-and-mortar companies had been reluctant to fray into the e-grocery market for a long period of time. It is the entrance and the perceived success of the pure-plays that has caused them to reevaluate their strategy. The brick-and-mortar add-ons can be categorized as those that sell online themselves and those that establish partnerships with pure-plays (Lempert 2005). Despite its potential advantages, the pure-play model has its drawbacks.

1. Brick-and-mortar stores have established locations, brand names, and a large customer base.
2. A majority of consumers still prefer to buy groceries from a retail store. They may like to smell the vegetables and squeeze the fruit, or they may like to unwind from a long day by walking among the fresh breads of the bakery.
3. Consumers also trust the grocery stores they have known for many years, and like to shop where they feel assured the quality is consistent and the price is right.
4. Probably the biggest challenges for pure-plays are in order fulfillment and home delivery. Supermarkets aggregate demand by allowing customers to come to the stores, and therefore customers do the order picking and delivery. According to Procter & Gamble, traditional in-store shoppers who pick, pack, and deliver their own products now save the industry approximately 13 percent of the total cost of sales (Tapscott and Ticoll, 2000).
5. For e-grocers, the more deliveries in a given area, the lower the costs per delivery. Except for a few cities, Americans who can afford computers and Internet access are more likely to live in suburbs, which means more driving and fewer deliveries per hour for any company that offers home delivery.

Pure-play online e-grocers

Over the past decade the number of defunct e-grocers, including Webvan, HomeGrocer, Shoplink, and Kozmo, have far outnumbered the survivors. From a business perspective, the pure-play (no retail storefronts, only web ordering and delivery, and possibly one or more warehouses) e-grocer model has several advantages over the traditional retail grocery model (Hays et al, 2004).

1. E-grocers do not have the high costs associated with multiple retail locations, including rent, parking, and high property taxes.
2. By "pooling" their inventory in fewer locations, e-grocers can better manage their inventory, reducing inventory holding costs and increasing inventory turnover rates. This leads to less spoilage of products and shorter lead times from the producer to the consumer, key advantages in selling perishable products.
3. E-grocers can collect detailed information about their customers' buying habits and preferences, which can then be used for targeted marketing and personalized promotions. Such one-to-one marketing is what the traditional grocers are trying to do by using loyalty cards to track purchases.
4. E-grocers may generate incremental sales growth for the industry. Although many retailers and consumers believe that impulse purchases diminish online, some companies such as Amazon.com have been able to foster impulse selling quite well with innovative marketing.

III. Summary of the Survey Results

It is still not certain whether e-grocers would lead to successful businesses or not. Some online grocers such as Webvan, Streamline, and Homegrocer have failed to continue their businesses. However, some still survive and many supermarket chains are starting to offer online services as an option for their customers. Socioeconomic characteristics such as growing demands on consumers' time, increased wealth, and heightened levels of stress in many regular situations are among those factors that dramatically change many consumer markets. Ideal customer characteristics for the e-grocery segment of the Internet business have been studied by various surveys (Berning et al, 2004). Defining the ideal customer is intended to explain the low adoption rate within the e-grocery sector and if e-grocers are entering the correct geographic segments. Studying the profile of online grocery shoppers and their behaviors can help the businesses to develop and improve their strategies. According to one study (Berning et al, 2004), an ideal customer is a female aged between 25 and 44 years, likely belongs to a dual income household with income greater than \$50,000, has children and is likely to have a college education. The study also concluded that convenience was the largest factor for e-grocery customers.

This paper discusses the findings of a survey on e-grocery in the United States. This survey was conducted by

Survey International Inc. on the internet with customers in Chicago, IL, Boston, MA, New York, NY, Seattle, WA, and San Francisco, CA. Responses to issues such as demographics & psychographics, shopping patterns, online shopping experiences, mental, physical and time related considerations, opinions about shopping and buying on the internet and order sizes from 1516 respondents are discussed in the following section.

Respondent demographics and psychographics

- A majority of the respondents were females (77% of 1516 respondents).
- 32% of the respondents lived with 2 persons in the household and 62% had no children under the age of 16.
- Respondents were educated as 26% of them reported to finish short-advanced study (up to 2 years duration) and 25% finished medium-advanced study (up to 4 years duration).
- Major range of ages for the respondents was 30-55 years.
- The gross income of the household ranged between \$37,000 and \$49,000.
- 40% of them spent \$150-\$299 each month on groceries while 26% spent \$300-\$449.
- Most respondents lived in New York (36%) and Illinois (26%).
- Almost all of them (96%) had cars and of these, 42% had 2 cars in a household. 25% of them had bicycles and 4% had motorcycles.
- 65% of the respondents owned their houses.

Considering the internet experiences of the respondents, the results can be summarized as follows. Most respondents (95%) had access to the Internet at home, 53% had access to the Internet at work or educational establishment, 52% had access to the Internet at family, friends or acquaintances and only 19% had access to the Internet at other places than those mentioned before.

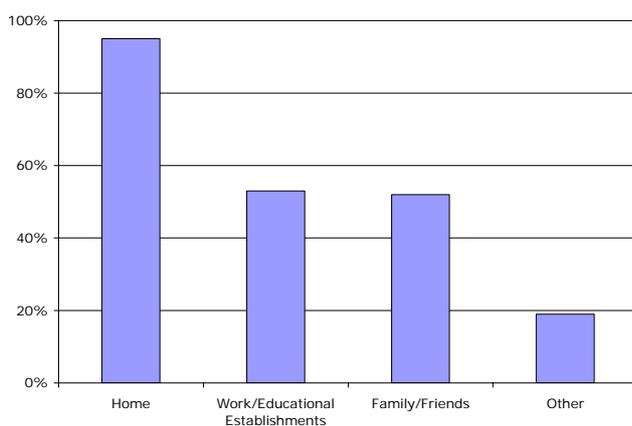

FIGURE 1: INTERNET ACCESS LOCATION FOR RESPONDENTS

Most of them never (73%) or rarely (18%) used the Internet at a library or at an Internet café. Most of them

(72%) used the Internet daily at home and 33% used the Internet daily at work or educational establishment. They rarely used the Internet at family, friends or acquaintances (46% answered “never” and 33% answered “less than 1 time per month”). Most of them (87%) never used the Internet at other places than those mentioned above.

Most of the respondents had used the Internet for more than 3 years. When asked about the first time the respondents had experienced the Internet, it had been more than 6 years for 40% of them, 5-6 years for 23% of them, and 3-4 years for 26% of them. More than half (54%) of the respondents spent more than 10 hours on the Internet during a normal week, irrespective of whether it is related to work, education or leisure. 54% of them considered themselves to have a moderate expertise in the Internet use, while 28% considered themselves to have a basic expertise.

Considering what the respondents found important to their lives, the following results are found from the survey. Values that were ranked most as “*extremely important*” to the respondents’ lives were - to obtain safety for their loved ones (70%), to have freedom of action and thought (65%), to enjoy life (61%), to have close friends (42%), to be competent, effective and efficient (41%), and to have a varied life (36%).

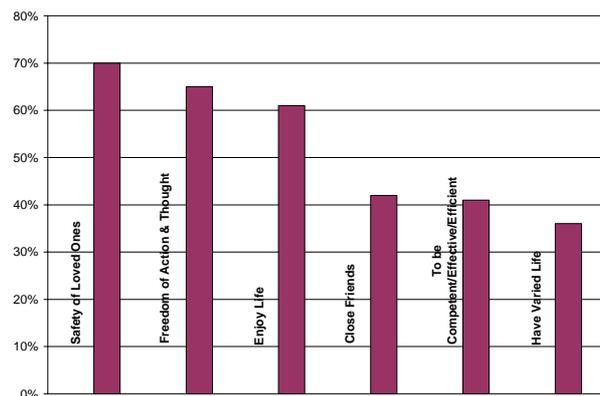

FIGURE 2: VALUES “EXTREMELY” IMPORTANT TO RESPONDENTS

Values that were ranked most as “*very to extremely important*” to their lives were; to have self-respect (60% extremely and 25% very important), to live a healthy life (53% extremely and 25% very important), to be polite (46% extremely and 26% very important), to be tolerant to different ideas and beliefs (43% extremely and 27% very important), to be helpful (39% extremely and 33% very important), to obtain pleasure in life (38% extremely and 29% very important), to have respect for traditions (33% extremely and 25% very important), and to have self-discipline and to resist temptations (30% extremely and 28% very important). More over, 26% of them ranked the value to protect the environment as “*very important*”.

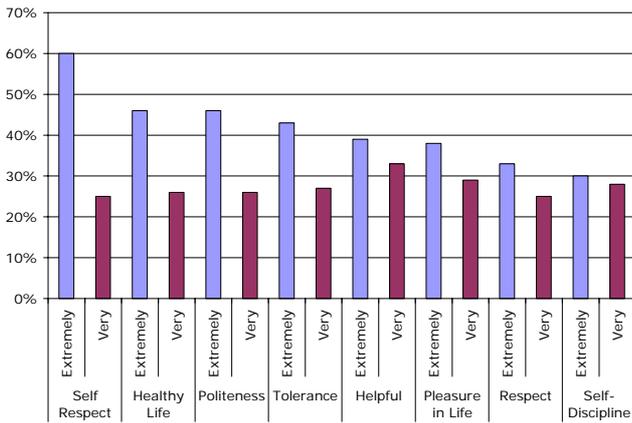

FIGURE 3: VALUES "VERY-TO-EXTREMELY" IMPORTANT TO RESPONDENTS

25% of the respondents ranked the value to have exciting lives as "quite important". For the value to have an impact on people and events, 26% of them ranked it as "quite important" and another 26% ranked it as "neither important nor not important". Values that were ranked most as "neither important nor not important" to their lives were - to obtain social recognition and respect (27%), to achieve material wealth (27%) and to avoid extremes of feeling and action (28%).

Shopping patterns

Concerning the responsibility for grocery shopping, more than half (52%) of the respondents did all of the grocery shopping, while 33% did most of the grocery shopping in the household. 55% of the respondents did main grocery shopping at the stores located within 0-3 miles from their houses. 68% of them reported to shop most often at other stores that are not listed in the survey. (Stores listed in the survey include Kroger, Safeway, Wal-Mart, Albertsons, Meijer, Shaw Supermarkets, Osco\Jewels, Aldi, Publix, and Ahold).

41% of the respondents normally bought grocery once a week and 34% bought it 2-3 times a week. Most of them wrote shopping lists before going grocery shopping as shown by the majority responses to this question as "always" (31%), "often" (28%) and "sometimes" (26%). Before going for grocery shopping, more than half of the respondents (61%) "never" looked for special offers on the internet while some of them "always" (36%) or "often" (30%) read special bargain or advertising folders. Half of the respondents (50%) "always" chose the store to shop in advance while 29% "often" did that. 39% "often" chose the product they wanted to buy in advance while 31% "always" did the same thing. About one-third (34%) "often" chose the brand they preferred to buy while 28% "sometimes" and 25% "always" did that.

Questions about how they combined their daily shopping with other activities revealed the following results. Activities that they rarely combined with grocery shopping were - going from workplace, doing grocery shopping and

collecting children (74% answered "never") and going from workplace, collecting children and doing grocery shopping (73% answered "never"). Combination of a trip from workplace, grocery shopping, and leisure activities as well as a trip from workplace, leisure activities and grocery shopping showed high responses for "never" (48%) however there were also significant responses as "sometimes" (27%). This is similar to the responses to a question about combining a trip from workplace to grocery as 33% answered "never" and 30% answered "sometimes".

The respondents "sometimes" combined grocery shopping with the following activities; leisure activities (43%), going to the post office, doctor, etc. (52%), shopping commodities e.g. clothes, CDs, books, PC equipment, etc. (49%). The respondents' answers ranged from "sometimes", "rarely" and "never" when asked about combining these activities with grocery shopping - visiting family (36% never, 25% rarely, 32% sometimes), visiting friends (34% never, 27% rarely, 34% sometimes), shopping permanent goods e.g. white goods, PC, radio/TV, etc. (25% never, 35% rarely, 33% sometimes), shopping in special shops e.g. cheese monger, fruits and vegetables, etc. (28% never, 27% rarely, 34% sometimes).

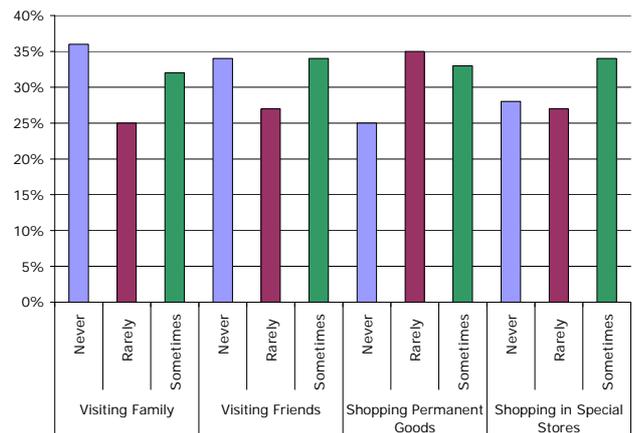

FIGURE 4: RESPONSES TO "SOMETIMES" COMBINING GROCERY SHOPPING WITH OTHER ACTIVITIES

Online shopping experiences

When asked which of the products/services the respondents had looked for information or bought via the Internet, the percentage of positive responses could be summarized in the Table 1 below.

TABLE 1: PERCENT OF THE POSITIVE RESPONSES FOR VARIOUS CATEGORIES OF PRODUCT/SERVICE

Products/Services	Never sought information or purchased online	Sought information on the Internet	Purchased Online
Groceries	54 %	40 %	11 %
Household goods	23 %	57 %	38 %

Products/Services	Never sought information or purchased online	Sought information on the Internet	Purchased Online
PCs	33 %	57 %	20 %
PC Supply (programs, etc.)	30 %	51 %	38 %
Furniture and housing equipment	39 %	54 %	14 %
Medicine	39 %	52 %	16 %
Travels and vacation	20 %	58 %	42 %
Pizza, Fast food (delivery)	76 %	20 %	6 %
Music/videos/books	10 %	53 %	68 %
Toys	30 %	44 %	44 %
Tickets (e.g. theater tickets)	36 %	43 %	36 %
Flowers, gifts for delivery	39 %	39 %	38 %
Personal care items	38 %	43 %	33 %
Accommodation	29 %	51 %	39 %
Insurance	54 %	43 %	6 %
Clothes	23 %	49 %	53 %

It can be seen that more than half (54 %) of the respondents had never sought information or purchased groceries online. However 40 % of them at least had sought information on the Internet and 11% had purchased groceries online. The products/services that were most purchased online based on this survey were music/videos/books (68 %), clothes (53 %), toys (44 %), and travels and vacation (42 %). The respondents sought information on the Internet mostly on these products - travels and vacation (58 %), household goods (57 %), PCs (57 %), and furniture and housing equipment (54 %). The products/services that the respondents less likely sought information for or purchased online were fast foods (76 % “never”), groceries (54 % “never”) and insurance (54% “never”). When asked about how long it had been since the first grocery purchase over the Internet, 80 % of the respondents answered that they had never shopped groceries on the Internet.

Mental, physical and time-related considerations in relation to buying groceries

The respondents ranked the importance of these considerations regarding grocery shopping as follows. They mostly agreed that when they bought groceries, it was important what they chose (51 % strongly agreed and 39 % agreed). It was also important to them that they made the right decision when buying groceries (28 % strongly agreed and 57 % agreed). Many of them (40 %) agreed that usually there is so much to do that they wished they had more time. When asked if they were often in a hurry when they bought groceries, 32% agreed and 28 % disagreed. 29% of the respondents agreed that grocery shopping was something to be dealt with and to finish the sooner the better, while 31 % of them neither agreed nor disagreed. Many of

them (42 %) neither agreed nor disagreed to the statement that there was a big difference between the groceries; however 27 % agreed to that statement.

Almost half of the respondents (49 %) disagreed that they often worried whether they made the right choices when buying groceries. Many (31 %) disagreed that the transportation of their bought grocery products was hard and 27 % neither agreed nor disagreed. 36% of the respondents disagreed that the transportation of their bought groceries was exhausting and 27 % neither agreed nor disagreed. About one-third (35 %) of the respondents disagreed that they liked to shop in stores they were unfamiliar with and another one-third of them (34 %) neither agreed nor disagreed. 37% of the respondents neither agreed nor disagreed that they liked to meet other people in the supermarket while 29 % disagreed. About the same number of the respondents disagreed (29 %) and neither agreed nor disagreed (29 %) that they really liked to visit different supermarkets, however, 25% of them agreed to that statement.

Opinions about shopping and buying on the internet

A majority of the respondents answered that it was *not important* that they could buy the following type of goods at an Internet grocery store; vegetables (73 %), fruit (72 %), meat (70 %), fish (76 %), fillings (73 %), dairy products (72 %), frozen goods (67 %), organic products (77 %). Even though a very small portion of the respondents answered “*very important*” to the above question, the results are shown here for comparison. The importance of the fact that they could find these products can be ranked as the following; fruits (11%), vegetables (11%), meat (10%), frozen goods (10%), dairy products (10%), fish (7%), organic products (5%) and fillings (5%). Figure 5 below shows these findings.

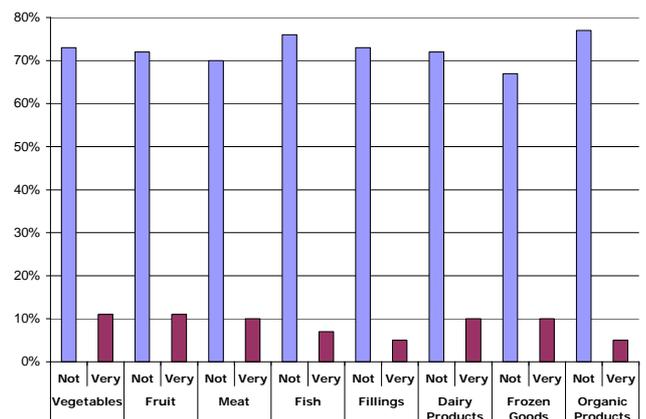

FIGURE 5: RESPONSES TO THE IMPORTANCE OF AVAILABILITY OF VARIOUS TYPES OF GROCERIES ON THE INTERNET

When asked about a reasonable minimum order value that included free packing and delivery when they bought groceries on the Internet, about one-third (31 %) of the respondents answered \$25-\$59. When asked what a

reasonable charge would be if they bought below the minimum order value that they selected, twenty-three percent of the respondents answered \$5-6, while 19% answered \$0-2 and another 19% answered \$3-4.

Most respondents *agreed* that the electronic shopping of groceries was complex because they could not feel and see the products (37% strongly agreed, 39% agreed). Almost half (46%) of the respondents agreed that a risk when buying groceries via the Internet was receiving low quality products or incorrect items. Most of them *disagreed* that buying groceries via the Internet was well suited to the way in which their households normally shopped for groceries (25% strongly disagreed, 34% disagreed).

The majority of the respondents *neither agreed nor disagreed* with the following statements:

- Shopping groceries via the Internet was favorable as it makes them less dependent of opening hours (28% neither agreed nor disagreed)
- Electronic shopping of groceries was easy to fit into their daily lives (31% neither agreed nor disagreed)
- It was hard to find the needed products when shopping groceries via the Internet (43% neither agreed nor disagreed, 26% no opinion)
- With electronic shopping of groceries it was difficult to order products (46% neither agree nor disagreed, 26% no opinion)
- It was easy to compare the prizes of grocery products on the Internet (36 % neither agreed nor disagreed)
- There was a lot of money to be saved when buying groceries on the Internet (45% neither agreed nor disagreed)
- There were too many untrustworthy shops on the Internet (42% neither agreed nor disagreed)
- Security around payment on the Internet was not good enough (33% neither agreed nor disagreed)
- It was difficult to receive groceries purchased via the Internet and to have them home delivered (37% neither agreed nor disagreed)
- There is too many of their preferred grocery products that they could not buy on the Internet (43% neither agreed nor disagreed, 27% no opinion)
- The groceries were often damaged when they received them at home (37% neither agreed nor disagreed, 47% no opinion)
- The cold and frozen goods were often inadequately cold/frozen when they received them at home (35% neither agreed nor disagreed, 48% no opinion)
- They often lacked room at home for returnable boxes (32% neither agreed nor disagreed, 38% no opinion)

The majority of the respondents answered *agree* and *neither agree or disagree* to the following statements:

- Electronic shopping of groceries was less exciting than buying in the non-internet shop (25% agreed, 36% neither agreed nor disagreed)

- Using electronic shopping of groceries saved much time (29% agreed, 34% neither agreed nor disagreed)
- Return and exchange opportunities were not as good on the Internet as in the supermarket/ non-internet shop (34% agreed, 25% neither agreed nor disagreed)
- Possibilities for advice were much too poor on the Internet (27% agreed, 36% neither agreed nor disagreed)
- Arrangement for payment on the Internet was just as safe as every other payment method (28% agreed, 29% neither agreed nor disagreed)
- To have groceries purchased on the Internet delivered at home was too expensive (26% agree, 36% neither agreed nor disagreed)

The majority of the respondents answered *disagree* and *neither agree or disagree* to the following statements:

- Electronic shopping was in general, very complex (30% disagreed, 36% neither agreed nor disagreed)
- Most of their friends and acquaintances thought shopping groceries via the Internet was a good idea (27% disagreed, 34% neither agreed nor disagreed)
- It was easy to compare the quality of groceries via the Internet (30% disagreed, 29% neither agreed nor disagreed)
- In general electronic shopping of groceries was problem-free (26% disagreed, 37% neither agreed nor disagreed)
- Members of their families thought that it was a good idea to buy groceries via the Internet (25% disagreed, 31% neither agreed nor disagreed)
- They often had difficulties at home in disposing of non-recyclable packaging (27% disagreed, 28% neither agreed nor disagreed, 29% no opinion)

When asked about how likely was it that over the next 5 years they would shop for groceries via the Internet, almost half of the respondents (46%) answered *not likely at all*. 41% of the respondents thought that none of their grocery shopping would be carried out via the Internet in 5 years from now while 22% of the respondents answered 1-10%.

Order sizes

In the brick-and-mortar stores, the frequencies that the respondents made large purchases can be summarized in Table 2 and Figure 6 below.

TABLE 2 FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE NON-INTERNET GROCERY SHOPS (N = 1516)

Stores	Frequency of shopping				
	Everyday	1-2/week	Every 2 weeks	1/mth.	Rarely or never
Kroger	1	25	24	25	1441
Safeway	2	55	61	71	1327
Wal-Mart	7	117	171	401	820
Albertsons	2	28	32	23	1431

Meijers	2	13	10	31	1460
Shaws	1	30	24	35	1426
Osco/Jewels	4	80	72	79	1280
Aldi	0	47	67	162	1239
Publix	1	2	9	10	1493
Ahold	0	12	20	7	1476
Other	21	452	341	199	502

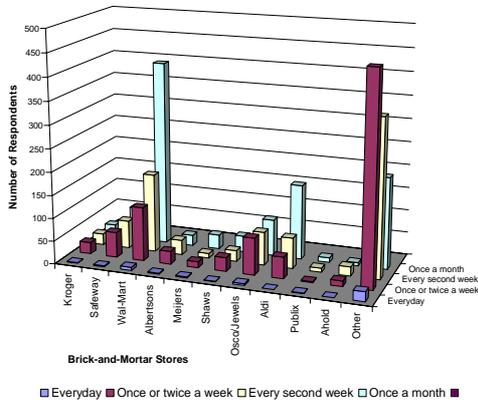

FIGURE 6: FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE NON-INTERNET GROCERY SHOPS (N = 1516)

In the pure-play stores, the frequencies that the respondents make large purchases can be summarized in Table 3 and Figure 7 below.

TABLE 3: FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE INTERNET GROCERY SHOPS (N = 1516)

Stores	Frequency of shopping				
	Everyday	1-2/week	Every 2 weeks	1/mth.	Rarely or never
Safeway	1	19	36	40	1420
Peapod	0	3	16	37	1460
Albertsons	0	12	12	12	1480
Other 1*	14	205	133	126	1219
Other 2*	4	83	78	86	1219
Other 3*	3	27	40	46	1309

* Names of pure-plays are not revealed intentionally

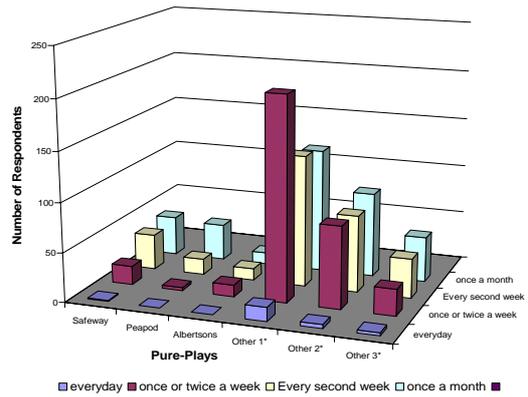

FIGURE 7: FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE INTERNET GROCERY SHOPS (N=1516)

In the Internet grocery shops that went out-of-business, the frequencies that the respondents made large purchases can be summarized in Table 4 and Figure 8 below.

TABLE 4: FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE CLOSED INTERNET GROCERY SHOPS (BASED ON 1516 RESPONDENTS)

Stores	Frequency of shopping				
	Everyday	1-2/week	Every 2 weeks	1/mth.	Rarely or never
Stream line	0	0	8	3	1505
Webvan	1	2	13	13	1487
Homegrocer	0	3	7	7	1499
Other	5	22	25	24	1440

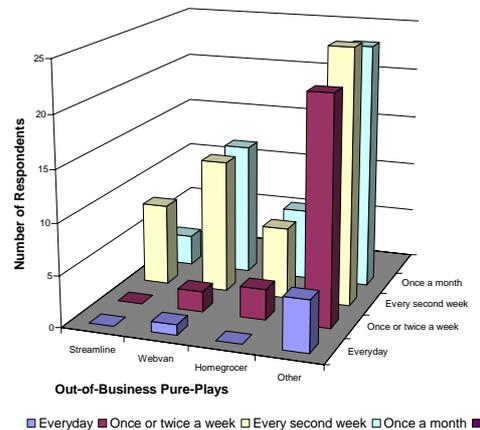

FIGURE 8: FREQUENCIES WITH WHICH THE RESPONDENTS MADE LARGE PURCHASES IN THE DEFUNCT INTERNET GROCERY SHOPS (N = 1516)

A majority of the respondents who made large purchases at brick-and-mortar stores shopped at stores other than those mentioned in the survey as can be seen in Figure 6, above. Figure 6 also shows that within the major stores (that have their names listed in the survey), the respondents made large

purchase most at Wal-Mart, Aldi, Osco/Jewels, and Safeway, in that order.

Even though the respondents did not often make large purchases in the Internet grocery stores, there were a significant amount that sometimes made large purchases from other stores numbered 1, 2, and 3 (names not revealed in the survey results), respectively. Among the 3 Internet grocery stores with their names listed in the survey (Safeway, Peapod, and Albertsons), the respondents bought their groceries mostly from Safeway, as can be seen from Figure 7.

In the cases of online grocery stores that were defunct, the most frequency with which the respondents made large purchases falls into once every other week. The store they shopped most was the store not listed in the questionnaire. For the stores listed, Webvan seemed to be the one they shopped most at, followed by Homegrocer and Streamline, in that order.

When asked about the amount of money the respondents typically spent all together for packing and delivery when they shopped for groceries via the Internet, the results can be summarized as follows. Among 27 respondents who had purchased groceries from Safeway, the amount ranged from \$0-1,500 with most frequencies at \$10 (3 respondents) and \$50 (3 respondents). Among 88 respondents who had purchased groceries from Peapod, the amount ranged from \$0-10,000 with most frequencies at \$100 (14 respondents). Among 9 respondents who had purchased groceries from Albertsons, the amount ranged from \$10-10,000 with varied frequencies. Among 188 respondents who had purchased groceries from Other Shop 1 (name not revealed in the questionnaire), the amount ranged from \$0-20,000 with most frequencies at \$0 (43 respondents). Among 21 respondents who had purchased groceries from Other Shop 2 (name not revealed in the questionnaire), the amount ranged from \$0-5,000 with most frequencies at \$30 (4 respondents). Among 15 respondents who had purchased groceries from Other Shop 3 (name not revealed in the questionnaire), the amount ranged from \$0-5,000 with most frequencies at \$0 (5 respondents).

IV. Conclusion

While the growth of E-Commerce buying and shipping for grocery products has been slow in the United States in the past five years, the trends are increasing. Most consumers

who are shopping for e-grocery are single or small family with relatively higher income levels. There is also a trend to have higher sales per shopping experience per individual customer as compared to in-store purchases. The successful e-tailers have offered this service of e-commerce purchased product with free delivery from their brick-and-mortar stores. The high value perishables are directly shipped to consumers from order-fulfillment centers or distribution centers.

Toward A New Operations Strategy in the Network Economy

Abstract: The rapid development of information technology has dramatically changed the dynamics of the market and altered the rules of competition. Inter-organization information systems make it possible for firms to achieve effective integration both in decision-making and operations processes, which brings enormous potential for supply chain cooperation. The scope of operations now is no longer confined to plant or strategic business unit (SBU) level. It has expanded to the whole supply chain.

In the network economy, almost every underlying assumption of old economy operations management comes into questions. Competitive advantages making firms success in the old economy may lose their utility in the new IT-based economy. New source of competitive advantages should be identified and cultivated. This study conceptually extends existing operations strategy models: (1) to reflect the substantial change brought by the network economy and the new characteristics of emerging operations mode; (2) by extending the unit of analysis from plant and strategic business unit to supply chain organization; (3) by adding new construct and at the same time extending the connotation of prior constructs used in traditional operations strategy models. A conceptual framework of the new operations strategy is recommended.

Keywords: operations strategy for E-commerce, supply chain, network economy

I. Introduction

Ever since Skinner (1969) pointed out the missing links between the manufacturing function and strategy [1], manufacturing strategy, or what is now called operations strategy, has received considerable attention both in academic world and business world. Manufacturing strategy is often advanced as a source of competitive advantage [2] [3].

The development of information technology has dramatically changed the dynamics of the market and altered the rules of competition. A key feature of present-day business is the idea that it is supply chains that compete, not companies [4]. Competitive advantages in the old economy may lose their utility in the new network economy. A key question that the operations management community needs to consider is whether the tools, models and concepts from the old economy can still serve operations management in

new economy organizations and their evolving business models [5]. Under this circumstance, a new strategic thinking is required in response to the challenge posed by the network economy. As Sampler and Short (1998) state, the new “information-driven competitive dynamics require researchers to develop new theoretical constructs and managerial perspectives to re-evaluate the firm and its extended set of relationships because failure to manage information and information-related resources can produce undesirable side-effects” [6].

This paper first examines the basic assumptions underlying traditional operations strategy. New factors and characteristics that should be taken into account in the formulation of operations strategy are then identified. Based on the work of existing literature, mainly the work of Hayes and Wheelwright, a conceptual framework incorporated the influence of new environment is presented.

II. The Impact of the Network Economy and the Limitation of Existing Operations Strategy Models

Hayes (2002) identifies five underlying assumptions of old economy operations management [7].

- (1) The organizational unit of analysis is an operating unit (e.g. factory, company, division or business unit of a company);
- (2) Operations management is primarily concerned with stable “products” and “processes”;
- (3) The dominant activity of the operations manager is to control the flow of materials (and/or information) through a sequence of process steps;
- (4) A major concern of operations managers is reducing the variable cost of production;
- (5) Your competitors are your enemies, and the key to prevailing against them lies in differentiation (e.g. through lower cost and superior performance, etc.).

Yet, in the network economy, almost all of these underlying assumptions come into questions. With the advent of inter-organizational information systems, and E-business in particular, electronic links between separately owned organizations could be established, which brings enormous potential for the supply chain partners to develop and enhance their cooperation. Therefore, within the context of the network economy, more factors should be taken into account in the process of operations strategy formulation.

(1) The network characteristics of the new operations mode should be incorporated. The scope of operations

strategy should be extended from a single operations unit to the whole supply chain..

(2) Besides “products” and “processes”, supply chain relationship should also be included as a primary decision area in response to the dramatic increase of reciprocal interdependencies between separate organizational units in the supply chain.

(3) Cooperation instead of competition should be emphasized.

III. Operations Strategy and Structure: A Brief Literature Review

Since Chandler’s seminal study in 1962 [8], the strategy/structure approach has been widely used in strategic management literatures. Review of the operations strategy reveals that structure decisions lies at the heart of traditional operations strategy field. Hayes and Wheelwright (1984) categorized the decision elements of operation strategy as structural and infrastructural. Structural decisions included those relating to capacity, facilities, production equipment and systems, and internal/external sourcing. Infrastructural decisions included human resource policies, quality systems, production planning, new product development, organization and performance measurement [2]. Nigel and Michael (2002) [9] held a different view. According to their analysis, all the decision areas have both structural and infrastructural implications. It is inadequate to categorize decision areas as being either entirely structural or entirely infrastructural.

The product-process matrix proposed by Hayes and Wheelwright [2] describes manufacturers’ choices about manufacture structure along two dimensions: process structure and product structure. Process structure ranges from the relatively unstructured job-shop environment to the highly structured continuous-flow production environment. The product structure dimension ranges from low standardization in product design (highly customized products) to commodity-like products that are highly standardized [10]. The underlying assumption of the product-process matrix is that the fit between process structure and product structure results in superior performance.

In their generic manufacturing strategy model, Kotha and Orne (1989) [11] defined manufacturing structure along three dimensions: process structure complexity, product line complexity and organizational scope. Process structure complexity in this model includes the traditional concept of process maturity [2] but has a broader scope. It has three sub-dimensions: (1) the level of mechanization of production processes; (2) the level of systemization of production processes and activities; (3) the degree of interconnection of production process tasks and stages. Production line complexity is a measure of the type and variety of product lines which could be represented by the complexity of end-products produced, individual product volumes and end-product maturity or experience. Kotha and Orne (1989) did not explicitly define organizational scope

but indicated ‘underlying variable’ of the third dimensions including geographic manufacturing scope, geographic market focus, vertical integration, customer-market scope, and the scale [10].

The scope of operations strategy evolves over time. The unit of analysis of Product-process matrix and generic manufacturing strategy model are two typical examples to reflect the evolution process. The product-process matrix was developed at the plant level, while the generic manufacturing strategy framework was developed at the strategic business unit (SBU) level. Yet most of the operations strategy models are developed in the context of old economy. Little work to date that integrates the characteristics of the operations in the network economy has been made.

IV. A Conceptual Framework of the New Operations Strategy

The authors agree with Nigel and Michael (2002) that the structural and infrastructural decisions in operations strategy are interwoven. Therefore, this paper does not distinguish the two concepts. Based on existing operations strategy literatures and relevant organization theories, this paper extend the traditional operations strategy frameworks by including aspects relating to inter-organizational supply chain management facilitated by the rapid development of information technology. Two core categories of elements of the new operations strategy are operations performance objectives and strategic decision areas. Figure 1 illustrates key elements of operations strategy and their interdependences.

IV. 1 Operations performance objectives

Objective reflects the state that a system is expected to achieve. The operations performance objectives reflect the aspects of operations performance that satisfy market requirements and therefore define what the operation is expected to pursue. Many authors on operations strategy have designed their own set of performance objectives. Similar constructs in the literature include “manufacturing task”, “competitive priority” and “competitive capability”. Though differences exist between definitions made by different authors, there are some commonly used categories. Four commonly accepted performance objectives are quality, speed, cost and flexibility. Quality refers to both product quality and service quality. Speed reflects how fast customers’ needs, also including product and service, can be met. Cost includes all the financial input required to satisfy customers’ needs. Flexibility indicates the ability to adapt to the change of customer requirement.

IV. 2 Strategic decision areas

The first strategic decision area is product structure. The structure of products manufactured is an important characteristic of manufacturing environments. According to

the product-process matrix, this reflects the maturity of the product life cycle stage [10]. The product structure construct here encompasses five sub-dimensions:

- (1) Primary product type or product life cycle stage;
- (2) Variety of final product;

- (3) Volume of each final product;
- (4) Customization/standardization of final product;
- (5) Compositions and modularization of key components of final product.

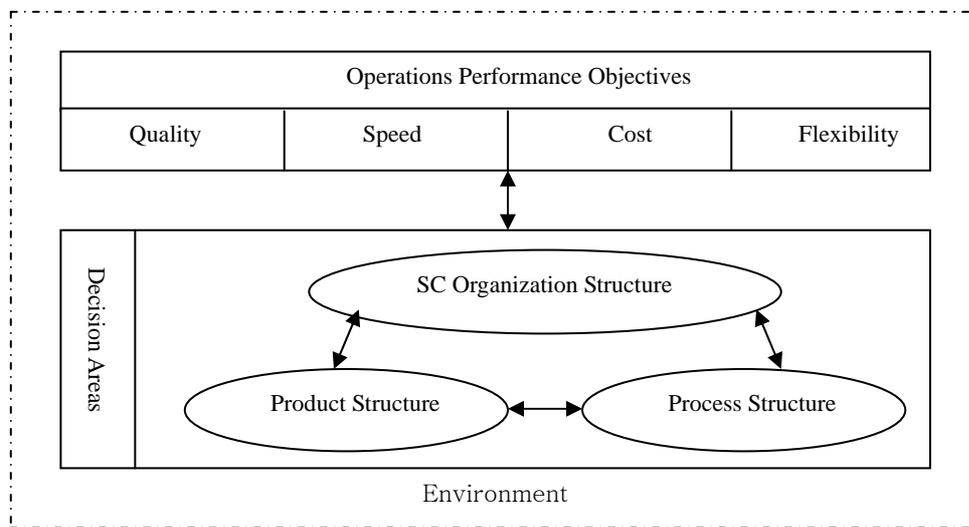

Figure 1 Key elements of operations strategy and their interdependences
Fig.1 Supply chain strategy analysis elements and decision areas

IV. 3 The external fit and the internal fit of operations strategy

The main tasks of operations strategy are identifying key elements of strategic operations decisions and integrating these elements in a pattern so that two kinds of “fit” can be achieved. The first fit is external fit or environmental fit. The external fit concerns how the operations strategy matches with the environment. The second fit is internal fit, including the fit among different structures and the fit between objectives and structures. Harmonized together, the whole of these mutually supportive elements can be a far greater source of competitive advantage than any single elements of the strategy.

V. Conclusions

Most of existing operations strategy models are developed in the context of old economy. Review of the operations strategy literature reveals that little work to date has been made to integrate the characteristics of the operations in the network economy. Our intentions in this paper are to extend the traditional operations strategy models in the context of network economy by incorporating factors enabled by the rapid advancement of information technology. A conceptual framework that demonstrates the elements of new operations strategy and their interdependences are proposed. This is just a nascent step toward the understanding of emerging operations management pattern. In the future, more work is required to refine and operationalize the constructs proposed

here as the basis of empirical research to further investigate and test the interrelationships among key elements of operations strategy as well as their links to performance.

Abstract: After researching various factors that influence the management and decisions on risk management of virtual organization, CBR based risk management for virtual organization is proposed in this paper. Relevant theories of fuzzy mathematics are utilized in the process of modifying the corresponding similar cases. Correct application of the new method is demonstrated substantially through instance simulation.

Keywords: Virtual Organization Management, risk management, case-based reasoning.

I. Introduction

Virtual Organization emerges recently as a new organization mode of enterprises. This mode has the properties of forming an interim economy of unified command of all enterprises of new product. It helps the enterprises to catch market opportunity and respond rapidly to certain market demand. Simultaneously, studies on strategies of risk management of virtual organization become popular. Successful virtual organization depends a lot on mutual cooperation and communication among enterprises of each partner, which increases greatly the number of factors affecting the risk management of enterprises. Of course, potential risk factors step up quickly as the institutional framework of the enterprises grows and the organization of virtual organizations becomes more complicated. The traditional risk management that works on the basis of regular procedures cannot cope with the new situation. Now, the new method Case-Based Reasoning (CBR) has evaded the bottleneck and solves the problem directly by making use of all existing case experiences for references. It offers an innovative direction in administrative decision of risk management.

II. Problem Description

In order to perform the enterprise's risk management harmoniously, scientific procedures are employed. The complete successive courses of risk management are risk identification, risk assessment, risk evaluation,

corresponding measure and effective risk control based on the risk evaluation, and appropriate handling of unfavorable consequence caused by the risk. In the first process of risk identification, the enterprise's overall goal and sub-goals that have to be accomplished for successful overall target should be clarified. That leads to the necessity of detecting out all risk factors that hinder the achievements of the goals, analyzing the influences of the risk factors, and identifying the existing risks of the enterprise [1]. It is then followed by the implementation of the corresponding measures on effective risk control after assessment and evaluation of the enterprise's risk. Thus the complete process of risk management is finished [2,3].

However, with constantly increasing potential factors that affect an enterprise's risk, the feasibility of the above-mentioned risk management has been queried due to its limitation to analyze and evaluation all risk factors. This paper suggests a new management decision method – CBR based risk management for virtual organization. In this method, every previous case of risk management is regarded as a study case. Through analyzing and comparing the data that correlate with risk factors, a case that is most similar to the present case of risk management is chosen.

Then the chosen case has to be modified under the risk control measures so that it can be utilized for the present one[4].

III. Case-Based Reasoning

The theory behind CBR comes from cognitive science, which states that mankind can retain and memorize information they have perceived. This retained information can be retrieved when similar scenarios appear and are lessons and references for problem solving. The basic thought of CBR is to imitate this human mode of thinking. It deals with present problem by directly retrieving the accumulated experiences and knowledge. Under the enlightenment of cognitive science, Roger Shank of American Yale University proposed the cognitive model and outlines of CBR theory for the first time in 1982, and began to work on the research and application of the field in artificial intelligence [5].

A working course of CBR system is shown in Fig. 1, It includes main steps like case representation, case retrieve, case organization, case revise, case reuse, case retain.

Existing research shows that the CBR is a kind of incremental type of problem-solving method. With the increase of cases and accumulation of experiences, ability of the system in solving problem is increasing constantly. Meanwhile, the continuous development in the technology of computer and artificial intelligence theory impels this method to maturity.

IV. Design of Case-Based Reasoning

Some key technologies that determine the efficacy of the CBR system are included when the system is applied. At present, these are the technologies that develop from the system, like the representation of the case, organization of case retain, retrieve of cases, and strategies of case revision. How to give a rational representation to the case is not a problem. Different ways of representation are designed for cases of different applicable areas. The main reference factors of the representation are integrity, rationality and good expansion performance. An effective case representation usually includes three parts of content: reason or background of the case, its characteristic details, solution and result. The multi-knowledge representation in the field of artificial intelligence is one of the usable examples. More ways of representation that gears at different areas are

available as a result of the rapid development in information technology.

Usually the CBR system uses a special case library to retain the cases. With the ever-increasing cases, it is not enough to rely only on good search algorithms to perform case retrieve. The organization and memory structure of the case become a basic problem. It concerns with search speed and successful case search. Nowadays, most CBR systems adopt either dynamic store models or the memory model based on semantic network.

Case retrieve and matching are the keys of the CBR system. Its main purpose is to search out the best case from the cases store according to the definition and description of the new problem and becomes the guideline for solving the new problem. Result of the case search determines the quality of the whole system directly. Nowadays, the commonly used tactics of case search are proximal tactics, derived tactics, knowledge-lead tactics, and template-search tactics.

Case revision is another important step. Its main job is to make appropriate revising and adjusting of the chosen similar case so that it is more applicable for the present situation. But due to diversities of different situations, there is no common tactics for case revision. Real problem has to be solved by concrete analysis. The focus of this paper is to provide guidance on tactics of case modification in risk management of virtual enterprises, utilizing theories in fuzzy mathematics and optimal algorithms. The concrete procedures are:

1) An evaluation performance for the enterprise's risk control tactics has to be listed. It includes data on the frequency of utilization of risk measure, risk expenses, occurrence frequency of the risk, and risk loss. Efficacy of the risk control measures is reflected by its occurrence frequency and the loss. Of course, when it comes to actual application, managers can add other meaningful and measurable performances according to their experience.

2) Statistical analysis on each risk control measure of the chosen case has to be done. Frequency of utilization of the risk measures, occurrence frequency of the risk, and risk loss are calculated. Usually, expenses on risk control measures are known and the risks of the corresponding solutions of each measure are fixed too.

3) Fuzzy intervals are assigned to each measurable performance according to experiences. Usually risk manager inclines to choose control measures of high frequency utilization, low consumed expenses, low occurrence frequency and small loss. Therefore a decision maker needs to define the membership degree of four performance as $A_i(x)$, $i = 1, 2, 3, 4$, to four fuzzy intervals: {Frequency of utilization of risk measure is high}, {Measure expense of the risk is low}, {Occurrence frequency of the risk is low}, {Risk loss is small}.

4) Manager, based on their experiences, establish the weight value w_i , for each performance in order to reflect the partiality.

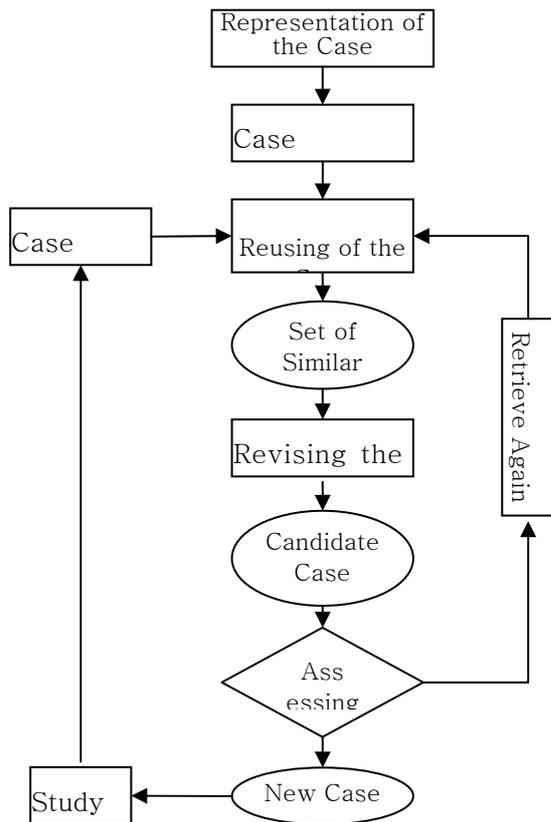

Fig. 1. The flow chart of the CBR System

Here, $\sum \omega_i = 1, i = 1, 2, 3, 4.$

5) To get an appraisal result of each risk control measure, the assumed weight values and the calculated membership degree are worked on with the weighted sum by the formula

$$\sum_{i=1}^4 \omega_i A_i(x)$$

6) Usually, an enterprise's risk management is constrained by the expenses of the risk measures. At this moment, not every risk is controllable. Therefore, under the condition of expense constraint, the best combination of risk control measure is selected. This is a typical kind of 0-1-knapsack problem. The method of optimizing can be applied to obtain the final combination of control measures.

V. Simulation Analysis

About 5,800 cases are stocked in the case library of the CBR system as emulation cases. Each case mainly includes contents of three parts. The first part lists 30 attributes that are ascribed to the characteristics of cases which are the data index that are related to the potential risk factors of the enterprise. Through comparison among these characteristic attributes, the case that is most similar to the present case is chosen as guidelines for decision-making. The second part is 8 attributes ascribed to risk control measure, with recorded

solutions adopted for the cases. The last part is 10 slots for recording the risks that have occurred and the subsequent loss in each course of risk management. These data reflect the efficacy of the adopted combination of risk control tactics.

As for the tactics of case retrieve, formula (1) is applied to choose a similar case:

$$sim(c_i, c_r) = \sum_{j=1}^n \varpi_j \times \frac{|c_i^j - c_r^j|}{c_i^j} \tag{1}$$

Among them, c_i and c_r express cases i and r respectively. ϖ_j shows the weight of the j th attribute. The degree of resemblance between the present case and the case in the case store is calculated through formula (1). A threshold value δ is the established. The degree of resemblance that is lower than δ will be elected and will be regarded as a guideline for present decision making.

Then the following modification method is carried out in order to confirm which risk control measure should be taken in the new case. The chosen case is examined under statistical analysis to confirm the following: frequency of utilization of the risk measure, measure expenses, occurrence frequency of the risk, and the corresponding risk loss. Usually, expenses of each risk control measure do not change. Statistical result is shown in table 1.

Table 1. Statistics of Cases

Control measure of the Risk	Measure 1	Measure 2	Measure 3	Measure 4	Measure 5	Measure 6	Measure 7	Measure 8			
Frequency of utilization of the measure	0.51	0.52	0.5	0.44	0.47	0.46	0.43	0.49			
Measure expenses	5	3.7	2.5	1.7	1.9	0.7	2	3			
Risk	Risk 1	Risk 2	Risk 3	Risk 4	Risk 5	Risk 6	Risk 7	Risk 8	Risk 9	Risk 10	
Occurrence frequency of the risk	0.52	0.45	0.41	0.47	0.5	0.48	0.52	0.51	0.52	0.53	0.52
Risk loss	2.9	3.28	2.1	1.8	8.9	6.71	2.93	2.75	2.9	2.52	3.5

As shown in Table 1, measures 7 and 8 are effective for two and three kinds of risks respectively. Other risk control measures address to only one kind of risk. In order to appraise each control measure of risk, a fuzzy set is formed to calculate the membership degree of the statistical results in Table 1. It includes the frequency of utilization of the measure, measure expenses, occurrence frequency of the corresponding risk and risk loss. In the fuzzy sets, only the

four significant elements are taken: frequency of utilization of measure is high, measure expenses are low, occurrence frequency of the risk is low and risk loss is small. Table 2 illustrates the membership functions.

Here, the trapezoid membership functions are chosen. Of course, other types can be selected according to the concrete problem. From the definition of the fuzzy set in Table 2, the membership degree of the fuzzy sets can be

calculated from the statistical data of Table 1. The result is displayed in Table 3.

Then, weight values are assigned to each elements of the set according to the different degree of emphasis. The four

elements are: frequency of utilization of the measure, measure expenses, occurrence frequency of the risk and risk loss. The maximum value to each element is 1 and they are illustrated in Table 4.

Table 2. The Membership Function of the Fuzzy Sets

Fuzzy set	Membership function
Frequency of utilization of measure is high	$A(x) = \begin{cases} 0 & x < 0.2 \\ \frac{x-0.2}{0.4} & 0.2 \leq x \leq 0.6 \\ 1 & 0.6 < x \end{cases}$
Measure expenses are low	$A(x) = \begin{cases} 0 & x < 2 \\ \frac{6-x}{4} & 2 \leq x \leq 6 \\ 1 & 6 < x \end{cases}$
Occurrence frequency of the risk is low	$A(x) = \begin{cases} 0 & x < 0.3 \\ \frac{0.5-x}{0.2} & 0.3 \leq x \leq 0.5 \\ 1 & 0.5 < x \end{cases}$
Risk loss is small	$A(x) = \begin{cases} 0 & x < 3 \\ \frac{9-x}{6} & 3 \leq x \leq 9 \\ 1 & 9 < x \end{cases}$

Through calculations of weighted sum on the data in Table 3 and 4, appraisals on each risk control measures are obtained and shown in Table 5. Here comes a typical solution of 0-1-knapsack problem. The best combination of risk control measure has to be selected under the constraints that the

measure expenses should not exceed the expenses of the new case, which is 9. {Measure 4, Measure 6, Measure 7, Measure 8} should be the best combination since it has achieved the goal of highest control efficacy. It is the solution of the new case.

Table 3. The Membership Degree of Statistical Data

Control measure of the risk	Measure 1	Measure 2	Measure 3	Measure 4	Measure 5	Measure 6	Measure 7	Measure 8			
Frequency of utilization of measure (high)	0.76	0.79	0.75	0.6	0.67	0.66	0.58	0.72			
Measure expenses (low)	0.25	0.575	0.875	1	1	1	1	0.75			
Risk	Risk 1	Risk 2	Risk 3	Risk 4	Risk 5	Risk 6	Risk 7	Risk 8	Risk 9	Risk 10	
Occurrence frequency of the risk (low)	0	0.27	0.45	0.13	0	0.11	0	0	0	0	
Risk loss (small)	1	0.95	1	1	0.015	0.38	1	0.239	1	1	0.92

Table 4. Appraisal Weight Value of Each Performance

Control measure of the risk	Measure 1	Measure 2	Measure 3	Measure 4	Measure 5	Measure 6	Measure 7	Measure 8
Frequency of utilization of measure (high)	0.3	0.2	0.58	0.39	0.45	0.3	0.5	0.4
Measure expenses	0.3	0.3	0.22	0.17	0.25	0.2	0.1	0.05

(low)											
Risk	Risk 1	Risk 2	Risk 3	Risk 4	Risk 5	Risk 6	Risk 7	Risk 8	Risk 1	Risk 9	Risk 10
Occurrence frequency of the risk (low)	0.1	0.1	0.1	0.21	0.1	0.2	0.1	0.1	0.1	0.1	0.05
Risk loss (small)	0.3	0.4	0.1	0.23	0.2	0.3	0.1	0.1	0.1	0.1	0.5

Table 5. Appraisal Results of Risk Control Measures

Control measure of the risk	1	2	3	4	5	6	7	8
Appraisal result	0.66	0.564	0.54	0.72	0.49	0.7	0.82	0.717
Measure expenses	5	3.7	2.5	1.7	1.9	0.7	2	3

The ten new cases, being chosen according to the above case selection and strategy modification, are tested. The final comparison between the derived risk control measure and the pragmatic risk control measure are listed in Table 6.

Moreover, the unanimous rates of the two combinations – measures of pragmatic case and measures based on CBR are statistically calculated. The average of unanimous rate of the ten cases is 72%.

Table 6. Comparison of Solutions

Case	Combination of pragmatic risk control measures	Combination of derived risk control measures	Unanimous number of measure	Number of actual measure	Unanimous rate
1	1, 6, 7, 8	4, 5, 7, 8	2	4	50%
2	2, 5, 6, 7, 8	1, 4, 6, 7	2	5	40%
3	1, 4, 5, 6, 7	1, 3, 4, 5, 6	4	5	80%
4	2, 3, 4, 8	2, 3, 4, 6, 8	4	4	100%
5	2, 3, 4, 7, 8	2, 3, 5, 6, 8	3	5	60%
6	2, 3, 4, 7, 8	2, 3, 5, 6, 7	3	5	60%
7	4, 5, 7, 8	4, 5, 7, 8	4	4	100%
8	3, 4, 5, 6	2, 3, 4, 6, 8	3	4	75%
9	2, 4, 5, 6, 8	4, 5, 6, 8	4	5	80%
10	3, 4, 5, 6	2, 3, 4, 6, 8	3	4	75%

VI. Conclusions

This article has proposed a CBR-based management decision method for virtual organization risk management. It uses the knowledge of fuzzy mathematics for the strategy of case modification, and develops a tactics of revising the case so that it becomes more applicable for the present situation. The new strategy integrates all considerations of the applications of risk control measures and appraisals on its control efficacy, so that the accuracy of getting the appropriate solution is enhanced. The method is elaborated in details through the emulation analysis.

Minimizing the Sum of Squared Errors in Seasonally-Adjusted, Trend-Enhanced, Exponential-Smoothing Forecasting

Henry C. Co

Technology & Operations Management
California Polytechnic & State University
3801 W. Temple Ave., Pomona, CA 91768
hco@csupomona.edu

Abstract: Every business seeks to correctly anticipate how much of which products it must manufacture, and where to deliver them, to satisfy the requirements of its customers, as well as its own requirements for growth and profitability. Since the forecast of demand is the cornerstone of all other, subsequent planning, errors become very costly very quickly. This paper presents an optimization model for determining the smoothing constants and initial estimates of level, trend, and seasonality indices in Winter's exponential smoothing forecasting model. The objective is to minimize the sum of squared forecast errors. An Excel template is available for download from the author's website. The template has built-in macros to perform all calculations. Instructions on how to use the template are included in the template.

I. Introduction

The forecast of demand is the gateway linking operations with the marketplace. Through that gateway, supply-chain managers hope to see clearly enough to plan (hire, buy, borrow, etc.), the better to reduce wastes, control costs, avoid conflicts, increase revenues and profits. Prior planning avoids fire-fighting, prepares for crises, and decreases the need for slack resources (capacity, inventory, staffing) to deal with unpredictable demand. In short, effective forecasting helps stabilize operations.

Every business seeks to correctly anticipate how much of which products it must manufacture, and where to deliver them, to satisfy the requirements of its customers, as well as its own requirements for growth and profitability. Since the forecast of demand is the cornerstone of all other, subsequent planning, errors become very costly very quickly. Accordingly, companies try hard to influencing the demand for their products, in the hope of exerting at least some control.

Forecasting models differ from one another according to whether they are qualitative or quantitative, simple or sophisticated. Qualitative forecasting methods rely on the subjective judgment and opinions of one or more individuals, about the likely course of future trends, tastes, technical changes, etc. These methods are useful in forecasting demand when there is little or no data to support quantitative methods (e.g., new products, new markets), and where it is believed that past relationships aren't good indication of the

future.

Quantitative forecasting methods, on the other hand, involve some kind of mathematical modeling. They have stringent data requirements – more data points, or numerical data measured in a way that allows meaningful calculations (e.g., using interval or ratio scales.) Time series analysis is a common forecasting technique in supply chain management. As their name suggest, time series analysis deals with time-based series of values of the attribute of interest, such as quantity sold. The method postulates that: (1) the observed series is the combined result of multiple phenomena; (2) the series therefore can be “decomposed” into its constituent components, i.e., level, trend, seasonality and cycle; and (3) the pattern in the past will continue into the future, thereby justifying extrapolation beyond the historical data.

Time series models include, among many others, the method of moving averages, exponential smoothing (e.g., the Winter's Model), Fourier series analysis, Box-Jenkins auto-regressive moving averages (ARIMA), and time series decomposition.

This paper presents an optimization model for determining the smoothing constants and initial estimates of level, trend, and seasonality indices in exponential smoothing forecasting. The objective is to minimize the sum of squared forecast errors. An Excel template is available for download at www.csupomona.edu/~hco/ManagementScience/00-Winters.xls. The template has built-in macros to perform all calculations. Instructions on how to use the template are included in the template.

II. The Winter's Model

The Winter's model is a seasonally-adjusted, trend-enhanced, exponential-smoothing forecasting model. Seasonally-adjusted trended forecasting uses historical data to derive a “base value L_t ,” a “trend value T_t ,” and a set of seasonal indices $R_1, R_2 \dots R_m$. Here m = number of periods that make up a complete seasonal pattern. For example, if we are dealing with monthly forecasts, then $m = 12$ months/year.

The demand forecast for period $t+p$ is $F_{t+p} = R_{t-m+p} [L_t + (p)T_t]$, for $p = 1, 2, \dots P$. P is the length of the forecasting horizon. R_{t-m+p} is the corresponding seasonal index estimated from the preceding year, L_t is the level of demand estimated at period t , and T_t is the trend component of demand estimated at period t .

For an average period, the seasonal index = 1. The index is greater than 1 if the demand for the period is above

average. On the other hand, an index less than 1 means that the demand for the period is lower than average.

To make seasonally-adjusted trended forecasts, we first have to find a way to derive the “base value L_t ,” the “trend value T_t ,” and the set of seasonal indices R . Then using the latest “base value,” “trend value,” and “seasonal indices” to generate our forecasts. For example, the forecast for month 1 ($t = 1$) is

$$F_1 = R_{-11} (L_0 + T_0)$$

Note that R_{-11} is the seasonal index estimate at $t = m-1 = 12-1 = -11$. L_0 and T_0 are the level and trend components estimates at $t = 0$ (the preceding month).

The Winter’s model consists of three revision equations, each equation for each of the three components of the time series:

Base value: $\alpha \left(\frac{A_t}{R_{-11}} \right) + (1-\alpha)(L_0 + T_0)$

Seasonal index: $\gamma \left(\frac{A_t}{L_t} \right) + (1-\gamma)(R_{-11})$, and

Trend component: $\beta(SA_1 - SA_0) + (1-\beta)(T_0)$

$0 \leq \alpha, \beta, \gamma \leq 1$ are the smoothing constants for the level, trend, and seasonality components of the time series.

In the following section, we will demonstrate the method of seasonally-adjusted trended forecasting. The process consists of the following steps:

1. Enter historical demand data.
 2. Assume values of the base, the trend, the seasonal indices, and the smoothing constants.
 3. Enter the revision and forecasting equation for the initial period. Copy and paste all the way to the row where the last demand data is.
 4. Compute some measure of forecast errors.
 5. Use Excel’s Solver tool to minimize the forecast error, by changing our initial assumptions about the base value, the trend value, the seasonal indices, and the smoothing constants.
- Use the latest “base value,” “trend value,” and “seasonal indices” to generate our forecasts.

III. Optimization Model

Supposed we have collected 60 months of data on demand for air conditioners. We want to forecast the demand for the next 12 months:

1	A	B	C
2		Data Range =	60
3			
4			Smoothing
5			Constants
6		$\alpha =$	0.200
7		$\beta =$	0.200
8		$\gamma =$	0.200
9			
10		Demand	
11		1,037	
12		1,070	
13		1,116	
14		1,173	
15		1,337	
16		1,369	
17		1,285	
18		1,438	
19		1,382	
20		1,248	
21		1,254	
22		1,170	
23		1,216	
24		1,390	
25		1,498	
26		1,469	
27		1,600	
28		1,800	
29		1,812	
30		1,769	
31		1,636	
32		1,591	

1. The first step is to decide the values of the smoothing constants α , β , and γ . Additionally, we need the initial values of the level, trend and seasonal components. Let us arbitrarily assume $\alpha = \beta = \gamma = 0.2$. We make reasonable assumptions about the initial values of the level, trend and seasonal components. This is shown below:

1	A	B	C	D	E
2		Data Range =	60		
3					
4			Smoothing		
5			Constants		
6		$\alpha =$	0.200		
7		$\beta =$	0.200		
8		$\gamma =$	0.200		
9					
10		Demand	Level	Trend	Season Idx
11					1.000
12					1.000
13					1.000
14					1.000
15					1.000
16					1.000
17					1.000
18					1.000
19					1.000
20					1.000
21					1.000
22			985	52	1.000
23		1,037			
24		1,070			
25		1,116			
26		1,173			
27		1,337			
28		1,369			
29		1,285			
30		1,438			
31		1,382			
32		1,248			

Notice that we have inserted 12 rows after row 10. We need 12 rows for the 12 seasonal indices (Column E). In the worksheet above, we assumed that all seasonal indexes are

equal to 1. The level component (cell C22) is 985 and the trend component (cell D22) is 52. Don't worry about making bad assumptions. Later, we will use an Excel tool called **Solver** to change them.

2. Write the Winter's Equations for the first period (i.e., for t=1). These are:

$$\alpha \left(\frac{A_t}{R_{t-m}} \right) + (1-\alpha)(L_{t-1} + T_{t-1})$$

$$\beta(L_t - L_{t-1}) + (1-\beta)(T_{t-1})$$

$$\gamma \left(\frac{A_t}{L_t} \right) + (1-\gamma)(R_{t-m})$$

The corresponding Excel formulae are:

$$C23 = \$C\$6 * (B23 / E11) + (1 - \$C\$6) * (C22 + D22)$$

$$D23 = \$C\$7 * (C23 - C22) + (1 - \$C\$7) * D22$$

$$E23 = \$C\$8 * (B23 / C23) + (1 - \$C\$8) * E11$$

The forecast for the first period is F23=(C22+D22)*E11, i.e., the sum of the level and trend component, multiplied by the first seasonal index.

The forecast error for the first period is G23=B23-F23

3. Copy all formulae and paste all the way down to the last row of demand (row 82):.

	A	B	C	D	E	F	G
1							
2		Data Range =	60				
3							
4			Smoothing				
5			Constants				
6			α =	0.200			
7			β =	0.200			
8			γ =	0.200			
9							
10		Demand	Level	Trend	Season Idx	Forecast	Error
11					1.000		
12					1.000		
13					1.000		
14					1.000		
15					1.000		
16					1.000		
17					1.000		
18					1.000		
19					1.000		
20					1.000		
21					1.000		
22			985	52	1.000		
23		1,037	1,037	52	1.000	1,037	0
24		1,070	1,085	51	0.997	1,089	-19
25		1,116	1,132	50	0.997	1,136	-20
26		1,173	1,181	50	0.999	1,182	-9
27		1,337	1,252	54	1.014	1,230	107
28		1,269	1,319	57	1.008	1,306	-63
29		1,285	1,357	53	0.989	1,375	-90
30		1,438	1,416	54	1.003	1,410	28
31		1,382	1,452	51	0.990	1,470	-88
32		1,248	1,452	40	0.972	1,503	-255

4. Enter formulae for sum of squared error and the average (Mean) error. Also, enter the formula for I4=AVERAGE(F11:F22); I4 is the average of the first 12 month's seasonal indices.

$$L24 = \text{SUMSQ}(G23:G82)$$

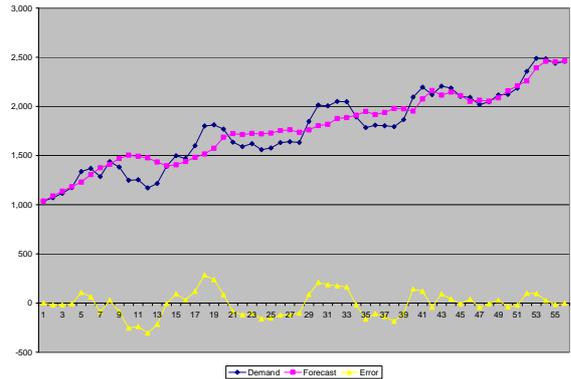

$$L25 = \text{AVERAGE}(G23:G82)$$

$$L26 = \text{AVERAGE}(E11:E22)$$

L24	H	I	J	K	L	M
22						
23						
24					917,831	
25					-11	
26					1.000	

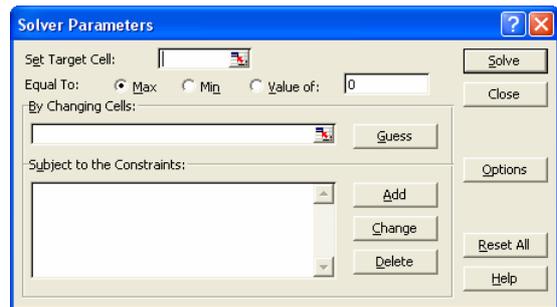

The sum of squared error is 917,831. The mean squared error (MSE) = 917,831/59 = 15556. Figure 1 below shows a

graph of the actual and forecasted demand:

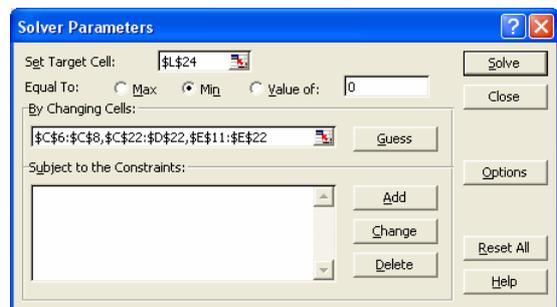

5. In step 1, we assumed, quite arbitrarily, the values of the smoothing constants, and the initial values of the level, the trend, and seasonal components of the time series. In this step, we will use a tool in Excel called Solver, to minimize the sum of squared forecast errors, by changing these assumed values.

Click Tools on the top of the Excel worksheet. From the Tools menu, select Solver, and the following Solver Parameter appears:

Starting from the top, enter L24 in the 'Set Target Cell' box. L24 is the sum of squared forecast errors. Next, click on the Min button to tell Solver that you want to minimize L24.

In the 'By Changing Box,' enter the cells where you find the values of the smoothing constants, and the initial values of the level, the trend, and seasonal components of the time series. These are: C6:C8 for the smoothing constants, C22:D22 for the level and trend components, and E11:E22 for the seasonal indices.

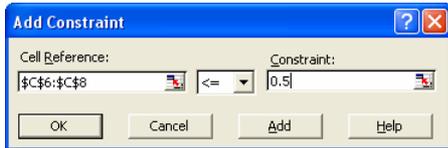

Note that Excel automatically add the '\$' sign to the cell references above.

Now, click Add to introduce some constraints. To make sure that the smoothing constants are non-negative, enter C6:C8 in the Cell Reference box, choose the greater-than-or-equal-to symbol \geq , and enter 0 in the constant box. This is shown below:

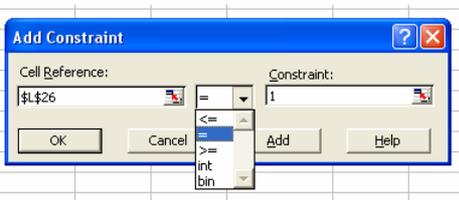

Note that instead of specifying 0 as the lower-bound for the smoothing constant, you may want to specify a small constant, say 0.01.

Similarly, we may want to specify an upper-limit for the values of the smoothing constant. Click Add to introduce another constraint:

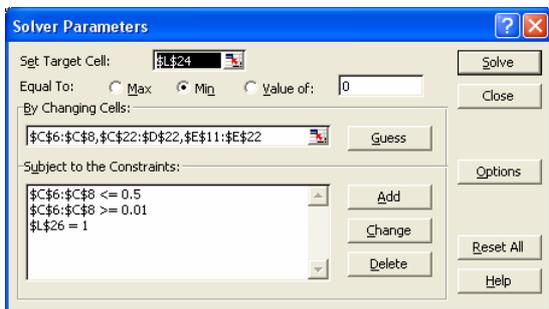

Here, we specify that the smoothing constants must not exceed 0.5.

Finally, add a constraint to make sure that the average of the seasonal indices =1. This is shown below:

The completed Solver Parameter menu is shown below:

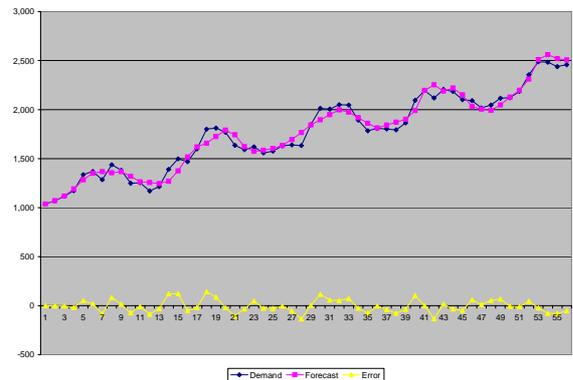

Here the lower-and-upper bound for the smoothing constants have been set at 0.01 and 0.5, respectively. Click 'Solve' to minimize the sum of squared forecast errors.

6. Optimized Worksheet

	A	B	C	D	E
1					
2		Data Range =	60		
3					
4		Smoothing Constants			
5					
6		$\alpha =$	0.446		
7		$\beta =$	0.010		
8		$\gamma =$	0.010		
9					
10		Demand	Level	Trend	Season Idx
11					0.927
12					0.939
13					0.961
14					1.004
15					1.070
16					1.084
17					1.071
18					1.071
19					1.033
20					0.976
21					0.940
22			1,095	23	0.922

Summary Statistics	
Sum of Squared Errors	233,257
Mean Error	-1
Average of Season Idx	1.000
Components of the Time Series	
The Level Component	2,456.2
The Trend Component	22.9
The Season Components	
	Period
	1
	2
	3
	4
	5
	6
	7
	8
	9
	10
	11
	12

The sum of squared error is 233,257. The MSE = $233,257/59 = 3954$. Using Solver, we were able to reduce the MSE by 75%. Figure 2 below shows a graph of the actual and forecasted demand:

The components of the time series shown here are the latest "base value," "trend value," and "seasonal indices" to

generate our forecasts. These values can be found at the bottom of the spreadsheet.

The forecasts are:

Jan	$[2,456.4 + (1) * (22.9)] * 0.927 =$	995
Feb	$[2,456.4 + (2) * (22.9)] * 0.939 =$	1.023
Mar	$[2,456.4 + (3) * (22.9)] * 0.965 =$	1.065
Apr	$[2,456.4 + (4) * (22.9)] * 1.004 =$	1.145
May	$[2,456.4 + (5) * (22.9)] * 1.070 =$	1.303
Jun	$[2,456.4 + (6) * (22.9)] * 1.085 =$	1.215
Jul	$[2,456.4 + (7) * (22.9)] * 1.071 =$	1.239
Aug	$[2,456.4 + (8) * (22.9)] * 1.071 =$	1.225
Sep	$[2,456.4 + (9) * (22.9)] * 1.033 =$	1.089
Oct	$[2,456.4 + (10) * (22.9)] * 0.976 =$	1.006
Nov	$[2,456.4 + (11) * (22.9)] * 0.940 =$	967
Dec	$[2,456.4 + (12) * (22.9)] * 0.922 =$	928

IV. Final Note

Using Solver, we were able to reduce the MSE by 75%. In the illustration above, we allowed Solver to change the smoothing constants, and the initial values of the level, the trend, and seasonal components. Sometimes, we are better off using our judgment to decide on the appropriate values of the smoothing constants.

Trends in the Delivery and Utilization of Enterprise ICT

Jiri Vorisek

Department of IT, University of Economics Prague
W. Churchill Sq. 4, 130 67 Prague 3, Czech Republic
Tel: +420 603 414848

E-mail: vorisek@vse.cz

Abstract: In this decade, we can expect changes in enterprise information systems that are even more dramatic than the changes in the last decade of the previous century. The changes will have an impact on end-user organisations as well as on suppliers of ICT products and services. They will also influence the number of graduates in ICT disciplines that will be needed and the type of qualification they will require. The aim of this article is to shed light on these changes and suggest how end-user organisations, ICT supplier organisations and universities can prepare for them.

I. Introduction

For the past two years G.Feuerlicht and I [6] [7] have been analysing the latest developments in information services worldwide. From this analysis we have concluded that the prevailing mode for supplying applications to users in the second half of this decade will be, with a high probability, outsourcing. In particular, one of the outsourcing variants "software-as-a-service" or ASP (Application Service Providing), is very likely to become dominant. Increasingly greater utilisation of externally supplied information services will influence the market in IS/ICT and the management of enterprise IS/ICT. During this year the author has carried out further interviews with leading Czech IS/ICT professionals - Martin Bednár, SAP ČR, Radim Hradílek, IBM ČR, Jan Kameníček, HP ČR, Jiří Polák, Deloitte&Touche. The main conclusion from these discussions and from the analysis is the prediction that in this decade we can anticipate even more dramatic changes than in the last decade of the previous century. These changes will affect both user organisations and organisations supplying IS/ICT products and services. The aim of this article is to shed light on these changes and indicate how the user and supplier organisations can prepare for them.

II. Significant trends in the utilisation of IS/ICT by enterprises

This section summarises the trends which in the opinion of the author will have a substantial influence on future utilisation of IS/ICT by user organisations and, consequently, on the composition of IS/ICT market.

Strategic importance of ICT has not ceased

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 672 - 680.

Less than two years ago Nicolas Carr published a provocative article in the Harvard Business Review "IT Doesn't Matter" [1] in which he declared that ICT is a commodity accessible to everyone. He compared ICT with railways and electricity and argued that it is no longer possible to use ICT to gain a strategic advantage against the competition.

Since this publication there have been many heated discussions on this theme in the Czech Republic and worldwide. Some debaters, including the author of this article, agree with much of what Carr wrote, but point out he makes a mistake of judging the influence and significance of ICT in isolation from entrepreneurial activities, business processes and company culture. The main difference between ICT and railways or electricity is that ICT has much greater influence on the business processes and the approach to management and production. Consequently, what can give a company (or a country) competitive advantage is not just ICT but appropriate integration of ICT with its entrepreneurial activities, its business processes and its culture. When this integration has a unique character that results in a product/service with higher utility value or lower cost then it will give the company a strategic advantage.

M.Bednár in an interview about the importance of ICT expressed it like this: "The deployment of ICT these days can be one of two types of applications:

- *applications that support business processes (back office, logistics, CRM etc.),*
- *applications that implement business processes, i.e. where the process exists only in an electronic form (electronic banking, mobile telephony, digital airline ticket etc.).*

For the first type of applications, it is possible to gain competitive advantage by combining ICT with an exceptional company culture and knowledge. This combination is unique for each company and enables the company to function effectively with flexibility and right priorities. The understanding of the importance and the potential of ICT is strategic because without ICT the assets of the company such as knowledge, culture and motivation will not be utilised. For the second type of application we have a product, its attributes and timely deployment to the marketplace – whoever gets there first gains a vital competitive advantage."

In support of the above claims, we can look at the success of Wal-Mart. In the Czech Republic, we can give an example published on www.ihned.cz in 2004: "The

company Czech Courier, operating a courier service eKurýr (www.ekuryr.cz) on the Czech and Slovak Internet, gained the representation of the international courier Sky Net Worldwide Express for the Czech Republic and Slovakia. Czech Courier was founded in 1999 to focus on express delivery of consignments with high added value. This added value lies principally in a unique electronic system eKurýr. As a result the deployment of this system the company has become a pioneer in utilising the Internet as a new commercial platform for courier services.”

For an organisation, not every new technology is important, but to miss some utilisation of the available technology can be fatal. For example, those suppliers of accommodation services who do not offer their services on the worldwide web are losing clients who are using only this communication channel. This could be a substantial part of the potential clientele.

The often accepted assertion, that using standard technology that is accessible to everyone (e.g. standard ERP or CRM) it is not possible to gain a strategic advantage, cannot not be right. The reason is that a unique integration of a standard ERP with business processes is very difficult to copy by the competition.

Interesting in this context is the view of J. Kameníček: “ICT still is not a 100% commodity. Hardware, operating systems and office applications have the characteristics of a commodity, but applications such as ERP, CRM and BI do not yet have them. Deployment, customisation and integration of these types of applications is complicated. Good integration of these applications with the business processes can bring a strategic advantage.”

Another factor that supports an argument for the strategic importance of ICT is the unremitting growth in the demand for timeliness and quality of information for decision making in the global economy from all levels of management. When it comes to the speed of reaction to important events, e.g. Gartner (2004) claims:

- in 2002 most goals had up to 2 months to be achieved,
- in 2004 it was only 1 month,
- in 2006 it will be 14 days,
- in 2008 it will be 7 days,
- and in 2010, it will be the same day.

It is not really a question of whether this forecast is accurate. The significant trend in the shortening of companies' reaction response time to external events cannot be doubted.

Conclusion number 1:

ICT still has strategic importance but different ways of ensuring this have to be found. Strategic advantage cannot be achieved by just deploying new technology. The prerequisite is a unique and effective integration of ICT with entrepreneurial activities, the company culture and the business processes. Such integration will enable the company to speed up its response to important events, reduce cost and increase

the quality, and help to provide new products or services to customers. Future ICT projects should focus on this type of integration.

Strengthening of the process orientation of an enterprise

In the end of the last century it was becoming clear that a functionally managed enterprise faces difficulties to solve problems (interests of individual departments can clash with organisational goals; an ambiguous, sometimes even an undefined process for customer orders; a difficult to predict time the enterprise will take to respond to important events etc.). The solution to such problems was to adopt process-management in the enterprise as depicted in Figure 1 [22]. With regards to the arguments in previous section, the

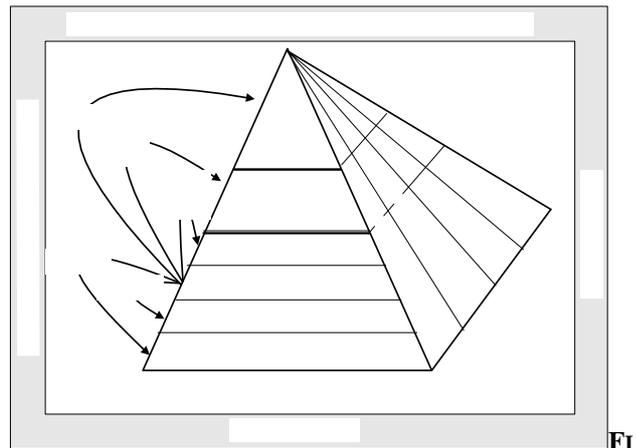

FIGURE 1: A process-managed enterprise

importance of process-management is still growing.

In a process-managed enterprise the key business processes are:

- business strategy formulation and implementation,
- new product/service development,
- production and supply processes definition and optimisation (methods, technological resources, personnel and know-how),
- supply-chain management (from integrating with suppliers to connecting with customers).

The aim of process-managed organisations is to achieve the state of so-called event-managed organisation and an organisation working in real-time. This means that the organisation has active sensors (usually using of IS/ICT) that indicate new events (arrival of an order, time to send VAT returns, production line failure, ...). As soon as the event happens, the process that guarantees the right response is activated. The response of the enterprise should be in real-time, i.e. in time that is optimal from the perspective of the supply chain, external partner, customer and the like.

This trend is affecting even enterprise ICT, i.e. many enterprises are adopting process-management of their own IS/ICT. ITIL and COBIT methods are de facto standards in

this area.

ICT marketplace has responded to the transition to process-management with a relatively wide choice of tools for business process modelling and for optimisation, monitoring and management of live processes. The Organization for the Advancement of Structured Information Standards [14] has been defining standards in this area. The success of process-management depends on a number of critical success factors. The most important of these are:

- change in the thinking of enterprise managers. Process-management requires other types of knowledge and skill compared to the classical functional-management; some managers do not have these and are not able to accept and apply new responsibilities and authority that are required,
- appropriately chosen detail of business process definition and its alignment with the knowledge of the employees undertaking the process [20]. A detailed definition of a process facilitates using less well qualified but well trained employees (consider e.g. workers on car assembly lines). On the down side, it prevents utilisation of employees' creativity and reduces the flexibility of the process (try, for example, to order a schnitzel in McDonalds),
- appropriately chosen process maturity. CMM [3] defines six levels of process maturity. The lowest level is for a non-existent process, the highest describes an optimizing process. However, it is not sensible to plan for the highest level for each process. This would be too expensive for processes that are not vital to the enterprise and happen rarely,
- appropriate utilisation of process methods and standards. When implementing process-management it is a good idea to use methods and standards designed for this - e.g. the above-mentioned ITIL and COBIT. Experience from process-oriented projects shows that it is very dangerous to apply the recommended standards mechanically. Each method must be tailored to the specific condition of the enterprise.

Conclusion number 2:

Enterprise process-management and process-managed ICT are now a necessity. Implementing process-management is a long-term activity that requires specific knowledge and skills, with success depending on specific critical factors.

Management of the relationship between business and ICT using ICT services

How to optimally link business and ICT is a problem that has eluded solution since enterprises first started to use ICT. For over 50 years, computer professionals and end-users have been looking for an optimal way to communicate with one another and for an optimum division of responsibility

for the costs and benefits of ICT projects. It seems like in this area things are looking up thanks to new methods for managing the relationship between business and ICT. These methods utilise the concept of ICT service, described using an SLA (Service Level Agreement), as a basic element on the boundary between the business and ICT. One of these methods - SPSPR - was described in [21]. One benefit of the SPSPR method is in that it defines the content of the communication between end-users and ICT professionals without undue use of technological concepts. Another benefit lies in the clear demarcation of responsibilities of different types of managers (TOP manager, owner of a business process, CIO, owner of an ICT process, manager of an ICT resource) for costs and benefits of ICT.

Similarly, to process-management the management of ICT services has a number of critical success factors. The most important of these are:

- the ability of the owners of business processes to define SLA for ICT requirements,
- the focus of ICT services. ICT services should be derived from the requirements of business processes, not from the interests of enterprise departments. I.e., the ICT services should be focused on improving performance of the enterprise, on bottlenecks in the business processes and on the business continuity. In the case where ICT services are not related to any business processes but to only to departments, the requirements for the ICT services are often inappropriate (e.g. the department requires a higher availability of the service than is absolutely necessary) and derived from particular interests of the department and not from enterprise goals.
- The ability of ICT managers to specify and manage ICT infrastructure that facilitates provision of agreed scalable ICT services.

Conclusion number 3:

Management of the relationship between business and ICT using ICT services has proved the best solution to the long-standing problem of communication between business and ICT professionals. However, this requires new knowledge and skill from both sides.

Emphasis on management of the returns on ICT investment

The ICT crisis since the beginning of this decade resulted in increased emphasis on the management of the returns on ICT investment. Progressively managed enterprises no longer invest into ICT without a thorough analysis of the return on investment and refuse to finance long-lasting ICT projects because they are very risky.

More and more TOP managers require that their CIOs ensure that any increase in the investment into ICT correlates with the increase in the turnover and that no projects are started unless an improvement in the performance of the enterprise can be guaranteed. The question is, how can

a CIO fulfil such expectations.

The first requirement needs a scalable ICT infrastructure and scalable ICT processes. When an enterprise operates its information systems on its own ICT infrastructure, scaling up or down may not be a realistic option. An enterprise has to plan its ICT infrastructure for the maximum anticipated required performance and incremental increases and reductions in capacity (e.g. disposing of surplus hardware, software licences and ICT specialists) are often impossible in practice. The solution to this problem is to buy external services; this will be discussed in the next paragraph.

The second requirement - guaranteed improvement in the enterprise performance - cannot be achieved by the ICT department alone. The requirement can be met only by an appropriate distribution of responsibilities of ICT and business managers - e.g. using the above-mentioned SPSR model. According to this model, the benefits of the commissioned ICT services will be the responsibility of the business process owner. The owner of the business process has to add the cost of each ICT service to other process costs and then evaluate the effectiveness of the process. If the cost of an ICT service is too high, the requirements should be reconsidered (e.g. reducing functionality, the number of users or availability). By contrast, the CIO is responsible for ensuring that the cost of an ICT service is competitive with similar ICT services on the market.

From the perspective of the current trends, the ICT market offers one good and one bad news. The good news is that thanks to the transfer of the development of a number of ICT products to China and India the cost will be coming down, perhaps even faster than the Moore's law would suggest. The bad news is that the requirements for the content, volume and quality of ICT services will be going on increasing, probably even faster than the decrease in the cost of ICT products. The reason for this are the trends mentioned above.

Conclusion number 4:

Well-managed enterprises want to control their ICT costs. The development of ICT has to reflect the growth in the turnover of the enterprise. Preconditions for success in this area are scalable ICT services and a clear allocation of responsibilities for the benefits and costs of ICT between the business and ICT managers.

Purchasing external ICT services instead of purchasing ICT products

The aspiration to concentrate enterprise activities on the core business of the enterprise and the consequent aspiration to outsource support business processes, together with the aspiration to buy scalable ICT services (based on the "pay as you go" principle), lead enterprises in the direction of ICT outsourcing.

In 2004, PMP Research carried out a survey into the scale of ICT outsourcing in end-user organisations. The results of this research show that more than a fifth of end-

user organisations spend more than half of their ICT budget on outsourcing and almost two thirds of organisations anticipate same or greater expenditure on outsourcing services.

Deciding about what to own and what to buy as an external services is not easy. An enterprise should have a sourcing strategy and use it to make such decisions. The development of a sourcing strategy as well as its use for decision-making is a complex process since a large number of variants with different critical success factors [6] needs to be considered. Some possible variants are:

- 1) BPO (Business Process Outsourcing), where the whole business support process is removed - e.g. accounting or transport - including ICT resources and their support,
- 2) total outsourcing of IS/ICT, where a selected external partner takes over all the ICT services, processes and resources,
- 3) partial outsourcing of ICT, where some ICT services, processes and resources are removed. Partial outsourcing has a large number of variants:
 - a) "classical ASP, where an external provider operates an application, used by many customers (companies) on its own infrastructure. An example is the service of Sales Force that currently provides CRM functionality for more than 100,000 users,
 - b) ASP operates single-customer applications (e.g. SAP R/3) on its own ICT infrastructure, but the infrastructure is shared by the applications. An example of such an ASP is the company Corio,
 - c) as b), but each customer has its own dedicated infrastructure,
 - d) the customer operates an application on its own infrastructure but the administration of the infrastructure is outsourced,
 - e) ICT infrastructure is outsourced by the customer operates and administers its own applications,
 - f) external administration of end-user workstations,
 - g) external operation of a Call centre,
 - h) etc.
- 4) outsourcing the development of an application.

The latest analysis [23] and predictions [2] show that the prevailing forms of outsourcing will be those described in 1), 2) and 3a) above.

For example, according to R.Hradílek, IBM is assuming that most of their customers (companies) will move to a complete outsourcing of their IS/ICT by 2010.

Just like in the case of the previous trends, effective utilisation of outsourcing depends on a number of critical success factors:

- choosing an appropriate variant of outsourcing,

- choosing an appropriate granularity of ICT services. At one extreme an ICT service can be all of the functionality of an ERP system, at the other extreme a service could be one transaction (e.g. ordering an airline ticket using a Web service),
- monitoring of ICT services to be able to carry out a detailed analysis of the cost of the services, processes and resources. Without good monitoring it is not possible to find out what is a better value - internal or external supply,
- quality of decision-making when deciding whether to outsource or not depends on the quality of information about the ICT market (services on offer) and on the quality of the sourcing strategy.

Another critical success factor in outsourcing has been proposed by M.Bednár: "An outsourcing contract can significantly complicate enterprise restructuring and attempts an ICT innovation. When an enterprise disposes of all of its ICT expertise, it can find itself in precarious position when it comes to the development in ICT.

Conclusion number 5:

It is highly probable that by the end of this decade outsourcing and particularly one of its forms - ASP - will be the prevailing means of acquiring ICT services.

Impact of the trends on end-user organisations

If the above-mentioned trends are realised, we can anticipate the following impact on end-user organisations:

- More and more decision about utilising ICT will be made by the owners of business processes and as a part of strategic management. This will require changes in the qualification required by these types of managers. Managers who understand how to use ICT to develop new product or service, or how to gain new customers, will become indispensable members of the top management team in most enterprises [17].
- Employees of an ICT department will have to know how to better demonstrate the value of ICT for the business and offer new ways of utilising ICT by the business. Wal-Mart is a good example. According to their CIO J.Carey the members of his team sit on all the top discussions about the company's strategy, as well as discussions about changes in the marketing and commercial activities.
- Because of outsourcing, the number of technologically oriented specialists (e.g. programmers, ICT administrators) in companies will decrease. However, the number of employees involved with the relationship between the business and ICT services (requirements definition for ICT, SLA specification, monitoring of the supply of services and the like) will increase. Not all of these employees will be working in the ICT department. In 2004 Gartner predicted that in the North American and European companies the fraction of employees

working in ICT will reach 8% in 2006 and in the "ICT driven industries", i.e. organisation such as banking, post, insurance, utilities and retail, it will be as much as 15-20%.

- The integrative and innovative role of ICT departments will grow. This is particularly the case for the "ICT driven industries". This is because ICT processes are not like standard support processes such as accounting or purchasing, they have an immediate impact of the effectiveness on most core business processes.
- The volume of ICT services will be scalable, and ICT costs will correlate with the level enterprise activities and the turnover.

Even though a number of ICT services will be purchased from external suppliers, the number of employees concerned with the utilisation of ICT will not decrease, but the structure of their qualifications will change. An enterprise must preserve the following key expertise:

- how to gain a competitive advantage using ICT, i.e. how to use ICT to create new product/service, gain new customers, speed up the response of the enterprise to external events and reduce process costs. In other words: how to support the business processes with appropriate ICT services - i.e. ICT services that provide appropriate functionality, quality and volume at a competitive cost.
- how to design the overall architecture for ICT services,
- which services, processes and resources should be owned and which should be outsourced,
- selection of the best supplier of an ICT service,
- monitoring and control of the supply of ICT services,
- monitoring of ICT services and measurement of the benefits of ICT for business processes.

III. Impact of the Trends on Supplier Organisations

If the above-mentioned trends are realised, particularly outsourcing of ICT services and stricter monitoring of the relationship between costs and benefits, we can anticipate the following impact on supplier organisation:

- The sale of new software licences to end-user organisations will decrease. The following tables confirm this trend. They were compiled using annual reports of large software houses. It should be noted that while the income from new licences decreased, income from maintenance and related services grew. Haber's research [8] came to the same conclusions. He found that currently 80% of software cost is for maintenance of applications and related activities. The increasing cost of maintenance could be another factor that will

contribute to the greater orientation of end-user organisations on outsourcing of their applications.

Oracle	1999	2000	2001	2002	2003
Licence					
annual growth		20	6	- 25	- 6
as a fraction of the total income	41	43	42	36	34
Support					
annual growth		27	20	8	8
as a fraction of the total income	27	29	33	40	44

PeopleSoft	1999	2000	2001	2002	2003
Licence					
annual growth		46	30	- 18	2
as a fraction of the total income	24	29	30	27	24
Services					
annual growth		5	23	3	22
as a fraction of the total income	74	64	65	72	76

SAP AG	1999	2000	2001	2002	2003
Licence					
annual growth		27%	5%	-11%	-6%
as a fraction of the total income	38%	39%	35%	31%	31%
Maintenance					
annual growth		44%	27%	15%	6%
as a fraction of the total income	23%	27%	29%	33%	37%

Siebel	1999	2000	2001	2002	2003
Licence					
annual growth		118%	- 4%	34%	31%
as a fraction of the total income	62%	61%	51%	43%	36%
Services, Maintenance etc.					
annual growth		126%	44%	- 8%	- 7%
as a fraction of the total income	38%	39%	49%	57%	64%

- Because of the decrease in the sales of new licences and the growth in outsourcing the number of software companies will fall. Those that do not adapt their business to these trends will fail.
- The key commercial article, instead of software and hardware products, will be scalable ICT services on-demand services, software-as-a-service...). Thus the hardware and software products will be "returning" to their makers who will use them to offer services on a large scale. In this context, F.Hoch – vice-president of the Software & Information Industry Association [19] declared "We believe that the software industry, as we know it, is passing away and a new industry is being born". Hamm and Ante [9] declare "Accenture, thanks to BPO, added 2.2 billion dollars to its revenue, 50% more than in the previous year, while IBM achieved an income of 3 billions from outsourcing and related activities, representing an increase of 45%!".

The gradual transition of large suppliers from products to services is illustrated by the following tables:

IBM	2000	2001	2002	2003	2004
% revenue					
servers	22,68	22,32	20,04	18,72	18,89
PCs	17,83	14,51	13,78	12,97	13,47
HW total	40,51	36,83	33,82	31,68	32,35
SW	14,81	15,58	16,10	16,06	15,68
IT services	38,96	42,08	44,79	47,83	47,99
Financial services	4,07	4,12	3,98	3,17	2,71
others	1,65	1,39	1,31	1,26	1,27

Hamm and Ante [9] have given some interesting facts about IBM: "The change is tangible. The number of employees focused more on the commerce than on pure technology has risen from 3,500 in 2002 to the today's more than 50,000 (in the total of 330,000 worldwide), and this represents a growth of over 10,000 annually. As a part of a painful process, other employees are leaving in their thousands - for example from the administrative and computer maintenance divisions.

With the sale of the loss-making PC manufacturing to the Chinese company Lenovo Group, Palmisano cut off a large part of the company's computer inheritance. At the same time he netted more than a dozen of companies in the area of support for entrepreneurial activities, including Daksh, an Indian customer relationship management company with six thousand employees."

HP % revenue	2000	2001	2002	2003	2004
servers	26,00	25,26	22,33	21,03	20,12
PCs	35,85	33,04	30,23	29,03	30,81
Printers, scanners	22,47	24,01	28,20	30,89	30,28
HW total	84,32	82,31	80,75	80,95	81,22
IT services	14,05	15,84	17,10	16,91	17,24
Financial services	2,00	2,62	2,89	2,63	2,37

SUN Microsystems % revenue	2000	2001	2002	2003	2004
Servers		67,88	59,19	54,60	52,34
Storage		14,39	13,58	13,56	13,42
Products total	85,37	82,27	72,77	68,16	65,76
Support services		11,99	20,31	24,87	26,81
Professional and Knowledge services		5,74	6,92	6,97	7,43

- The concept of a supplied ICT service is changing. It is no longer a question of supplying as much as possible for the highest price without considering the real needs of the customer. The aim of the best suppliers of ICT services will be to understand what the customer and the customer's customers require, and then plan and manage the supply of ICT services accordingly.
- There will be changes in the structure and company culture of supplier companies that respect the fact that supplying ICT services requires a different type of enterprise when compared to enterprises that supply products and licences.

Let us now look at the views of our interviewees on the probable consequences of the trends on end-user and supplier organisations.

M.Bednár: "From the perspective of ERP systems supplier the number of customer users is fundamental. The number of users and the number of dedicated servers are the basic metrics for calculating the cost of software. It therefore does not matter whether the users are supported via an ASP or directly. In both cases, the customer has to pay the cost of the licence. Positive effects can only be the result of quantity discount. Then it is a question of who benefits – is it the customer or ASP? The transformation from buying software up-front to renting it is only the result of financial engineering."

J.Kameníček: "HP – formerly primarily a product company, is increasing its focus on services. The classical ASP is not yet part of the HP's services portfolio, but outsourcing IS/ICT is our fastest growing service segment. Outsourcing services are offered as a part of the "utility computing" concept, i.e. the cost of services is derived from unit costs (per user in a particular category, per server etc.). The customer can thus easily change the volume of the

service as required and pay only for the actual number of users or supported servers in a given month. In the Czech Republic, the transfer to ASP will not happen quickly. The reason is the strong conservatism of customers and the distrust that leads to unwillingness to relinquish control of data and key ICT infrastructure."

J.Polák: "D&T has begun to offer ERP in the form of ASP – from January 2005 we are offering SAP and Peoplesoft in this way. It will be possible to rent individual modules as an application service. However, the difference from EDS and Accenture is that this is not a part of our core business."

R.Hradílek: "Recently, in the Czech Republic, there has been a decline in the demand for strategic and business consulting services, and an increase in the demand for ICT services and outsourcing. IBM has been strengthening its focus on supplying ICT services. We offer these under the label "On-demand Services" and "Managed Services". In the near future large ICT companies, as well as offering ICT services, will be offering other types of services that require ICT (e.g. collecting parking fees and fines, accounting etc.)."

M.Bednár: "I agree that the number of technologically oriented specialists in end-users organisation will fall. However, outsourcing results in new problems for which the customers should be ready."

J.Polák: "The increase in the required number of specialists who integrate business processes with ICT services will not affect just end-user organisations. It will be an opportunity for new consulting firms that specialise in this area. I do not think there will be less demand for developers. I can imagine that there will be several tens of new software houses, each with several tens of programmers. An example of what could happen is as follows: in England, a new company is started that bids for development projects. The actual development will take place in the Czech Republic and the English company will supply the software to the customer. Compared to China or India this form of outsourcing will have the advantage in the knowledge of cultural and legislative conditions in Europe."

J.Kameníček: "I agree that there is a trend in the decrease of ICT specialist in customer companies. However, this will not affect Czech economy in the next few years. Centralisation and remote administration of ICT may make the operation of ICT more effective, but thanks to cheaper labour, there is a significant trend in transferring of many companies from Western Europe to Central and Eastern Europe. These transfers are creating many new work opportunities in ICT so that the number of ICT workers has been increasing, particularly in Prague and other large towns."

M.Bednár: "The reduction in software implementation services is real. However, this is true more for financial and administrative process than for production and logistics."

R.Hradílek: "I agree that the coming market changes will affect the organisational structure and company culture of large ICT suppliers. Such changes have taken place in IBM

during the merger with PWC. ICT companies will have to train many new specialists in the sale of services – we shall be looking at new graduates for this type of role.”

J.Kameníček: “The important factors in the next development of the ICT market will be:

- labour costs. Therefore, service companies will not be just large global companies such as HP or IBM. Although these companies will have a large market share, there will be room for smaller, locally active companies, with lower labour costs and detailed knowledge of the customer. This will be most apparent in the SME market. The key problem for these companies will be whether they will get a critical mass of customers (users),
- the ability of start-up companies to enter new untried market segments and to offer more innovative as well as more risky types of services will ensure their success in the market.”

M.Bednár: “The return of hardware and software products to their makers is more relevant for hardware than software companies. The question of who is interested in this sort of business depends on whether the service is focused on the operation of ICT infrastructure or whether it also includes a responsibility for outsourcing of business processes. In the latter case, there will be room for specialist companies. For example, outsourcing of payroll and human resources has consequences well beyond ICT. The main expertise of such providers will be in human resources and social sphere, not in ICT.”

IV. Impact of the trends on universities

The changes in the focus of suppliers and users of IS/ICT will be reflected in the number of ICT graduates that will be required and the type of qualification they will need. The following changes can be anticipated:

- lower demand for purely technological professionals due to the decrease of such specialists in end-user organisations. However, technologically oriented graduates will continue to be in demand by suppliers. The knowledge required will not be just the development of new application but also deployment and management of secure and highly available operation of applications used by thousands of users.

The evidence for the lower demand for technologically oriented specialists comes from Australia. In 2004, the average Australian unemployment was 5.7%, but in ICT, it was over 10% and for programmer 18% [16].

The lower demand for technological professions will not be so marked in the countries of Central and Eastern Europe. The reason for this is the transfer of a number of development and operations centres of large suppliers to this area (e.g. the Sun Microsystems and CA development centres in Prague).

- high demand for specialists who are able to integrate ICT with business processes – the knowledge they require is described in section above. The graduates with two specialisations will be in very high demand – e.g. those who major in ICT and minor in production logistics.

V. Conclusions

The key trends that will be affecting utilisation of ICT in end-user organisations are:

- process-management of an enterprise and its ICT,
- endeavour for a unique and effective integration of ICT with entrepreneurial activities, company culture and business processes so that the enterprise can respond more quickly to important events, lower costs, increase quality and/or offer new products/services to customers,
- management of the relationship between business and ICT using ICT services,
- allocation of responsibilities for costs and benefits of ICT between business and ICT managers,
- utilisation of scalable ICT services,
- increasing proportion of externally supplied ICT services in the form of outsourcing or classical ASP.

A gradual development in the direction described here will have an impact on both the suppliers and users of ICT. These changes will be applicable to the core business of many companies, and thus the composition and qualifications of their workforce.

Abstract: Assessing use is very important for organizations selling and using customer services system in Internet environments. Based on a conceptual model, this paper is to empirically study individuals' assessments of a new customer services system in Internet environment. The model has three phases; pre-use, test and use. In relation to the three phases, the concepts of value and quality are discussed. The main contribution of this paper is the understanding of the difference between the concepts of value and quality being illustrated in the conceptual model. Customers' assessment of value and quality could have implications for companies developing new customer services system in Internet environments.

Keywords: Assessment, Customer services system, Quality, Value.

I. Introduction

Assessing use is of vital importance for organizations selling and using services in Internet environment (Davis et al., 1989; Philip and Hazlett, 2001). In the areas of information technology and management the introduction by Davis (1989) of the technology acceptance model (TAM), was in many ways pioneering in understanding the psychological factors influencing information system use. Davis emphasizes the role of the individual in the organization. Furthermore, Orlikowski (2000) puts forward that since most technologies can be used in a number of ways, users shape the meaning of technologies as they integrate them into everyday practice. Emphasized in this paper is the users' interaction with technology solutions in everyday practice in an organizational context.

Bobbit and Dabholkar (2001) share a similar understanding as Davis (1989) when they put emphasis on attitudinal beliefs to predict and understand use of technology-based self-services. Not entirely emphasized in the models by Davis (1989) and Bobbit and Dabholkar (2001) is a broader understanding of usage than attitudes and intentions of usage, because intentions predict use, but not usage over time (Chau, 1996). Karahanna et al. (1999), on the other hand, put forward the importance of studying technology adoption across time. Karahanna et al. highlight the importance of organizational issues and the affect on the individual, particularly for potential adopters of information technology. A framework is presented where they

combine innovation diffusion and attitude theories to study differences in pre-adoption and post-adoption beliefs and attitudes. The consciousness of the difference between adoption and usage is a critical factor when understanding adoption. The importance of different phases in time, by Karahanna et al. (1999) labelled pre- and post-adoption, is of equal importance in this paper.

In addition to the distinction, made by Karahanna et al. (1999), in pre-adoption and post-adoption, a middle phase is implemented in the conceptual model presented in this paper. The middle phase is labeled the test phase. The reason why assessment of usage of a new customer services system in Internet environment should contain an additional phase is users involvement in development processes and its affect on users' assessment of the service in Internet environment in the test phase. Therefore, when users are involved in the development process of a new service in Internet environment, the assessment of usage should be based on three phases (Figure 1). The purpose of this paper is to use a conceptual model (Figure 1) to empirically study individuals' assessments of a new customer services system in Internet environment over time.

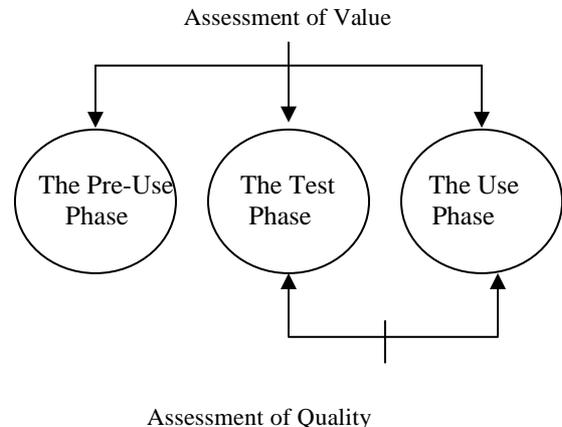

Fig. 1 User Assessment of Value and Quality of a New Service in Internet Environment.

In connection with these three phases, two concepts of great importance for user assessment will be discussed. The concepts are value and quality. McDougall and Levesque (2000) put forward that the concepts of quality and value are closely linked; "quality is just one side of the satisfaction equation." (p. 403). However, the difference between the concepts of value and quality is the main contribution of the conceptual model (Figure 1). The underlying principle of our model and the reason why the concepts of value and quality

are important is that users' ability to assess the value of a service in Internet environment is possible without usage. As for quality assessment, usage of the service in Internet environment is a requirement.

The structure of this paper is as follows; first, a brief introduction of the concepts of value and quality will be carried out. Thereafter, a discussion of the three phases will be presented with regards to the concepts of value and quality. In conjunction, early results from an ongoing study will be presented. Data collection in this study has been generated by the means of qualitative in-depth interviews over a period of two years. Interviews have been conducted with four pilot-customers of a new service in Internet environment in three different time phases, i.e. the pre-use, the test and the use phase.

II. Value

Perceived value is a difficult concept in that it is hard to define and measure (Zeithaml, 1988; McDougall and Levesque, 2000). Broadly defined, perceived value is the results or benefits customers receive in relation to the total costs. In other words, it is the difference between perceived benefits and costs (McDougall and Levesque, 2000).

According to Zeithaml (1988), customer-perceived value is the consumer's overall assessment of the utility of a product based on a perception of what is received and what is given. This can vary between people but also from occasion to occasion for the same person (Zeithaml, 1988). Caruana et al. (2000) state; "value is seen to be more individualistic and personal than quality and involves both a give and get component" (p. 1339). Raval and Grönroos (1996) suggest that customer-perceived value has to be related to different personal values, needs and preferences. In addition, they state, that the financial resources of the consumer must be taken into account.

III. Quality

Quality originates from Latin and means the attribute or the constitution of something. The ground of the competition is made up by the customers' experience of quality in relation to the costs (Edvardsson, 1996). Grönroos (2000) presents the concept of total perceived quality building upon the gap between expected and experienced quality.

Palvia et al. (2001) present a socio-technical framework for quality assessment of computer information systems. When assessing a system, the authors state; "the quality of an information system should be concerned with both the technical and the social subsystems. The technical subsystem covers the nature of the tasks to be accomplished and the technology that enables their accomplishment. The social subsystem involves the individuals who are responsible for accomplishing the tasks and the means whereby their work can be coordinated. In short, the assessment of system quality reflects the task, the supporting

technology, the people involved and the organization" (p. 238).

For individuals and organizations, value and quality are two important aspects. As a consequence, questions about how value and quality are perceived by individuals are essential when services in Internet environment are developed and assessed. Below, the concepts of value and quality will be discussed in conjunction to the three phases of the conceptual model (Figure 1). Based on a chronological order, the first phase, the pre-use phase will be presented, followed by the test phase and finally the use phase. The presentation will focus on theoretical as well as empirical findings.

IV. Empirical results

For individuals and organizations, value and quality are two important aspects. As a consequence, questions about how value and quality are perceived by individuals are essential when services in Internet environment are developed and assessed. Below, the concepts of value and quality will be discussed in conjunction to the three phases of the conceptual model (Figure 1). Based on a chronological order, the first phase, the pre-use phase will be presented, followed by the test phase and finally the use phase. The presentation will focus on theoretical as well as empirical findings.

IV. 1 The Pre-use Phase

The first phase in the conceptual model is the pre-use phase. At this point the potential user has a service present-at-hand, which means that information about the service and/or visual experience are the only sources available for the potential user to assess the service in Internet environment (Winograd and Flores, 1996). The importance of the pre-use phase is highlighted by Barki and Hartwick (1994), where they argue that it may be more easy to change users' "thoughts and feelings" before implementation. Early results from the study show an overall positive attitude towards the future service in Internet environment. Possible explanations could be that users perceive the service in Internet environment to be valuable or that users involvement in the development process has influenced users thoughts and feelings in a positive manner.

Davis et al. (1989) state that the most vital problem, when assessing user acceptance of IS in the early stages of development, is the difficulty to give users a clear picture of features and functions of the new system. Likewise, our study shows that although pilot-customers were given a short introduction in the early stages of the development of the upcoming service in Internet environment, they had difficulties in expressing opinions about the quality of the service.

Davis et al. (1989) discuss the importance of finding new methods for evaluation of acceptability of a system as early

as possible in the development of information systems. This could better help to decide if the system needs to be changed and decrease the risks of developing a system that is not going to be used. The overall picture in our study is that pilot-customers feel that they have had good opportunities to share opinions and concerns regarding the upcoming service in Internet environment. Pilot-customers concerns of missing features and functions in early presentations of the upcoming service in Internet environment were taken into consideration and later developed and implemented into the service. In line with the conceptual model (Figure 1), pilot-customers in the pre-use phase were able to express general opinions about quality issues, but not to make assessment of quality issues. However, assessment concerning values of features and functions of the upcoming service in Internet environment were possible to express opinions about.

IV. 2 The Test Phase

Emphasized by Davis et al. (1989) is the interest in the possibility to forecast and explain user behavior after a very short time of interaction with a system. In order for computer systems to improve organizational performance they must be used (Davis et al., 1989). As the users interact with the service in Internet environment in the test phase, it is possible to form a judgment about the quality, or excellence of the service (Zeithaml, 1988). After the pilot-customers had used the in Internet environment service for approximately a month, value and quality assessment were easier to express opinions about.

Orlikowski (2000) points out that technology users shape the meaning of technology as they integrate them into everyday practice. In other words, technology structures are not external from the user. In the test phase, the user repeatedly interacts with the service in Internet environment, which shapes their view about it and accordingly their use. Davis (1989) suggests that two determinants, "perceived usefulness" and "perceived ease of use", are especially important when people accept or reject information technology. Both variables influence users' attitude, intention and finally behaviour. In the test phase, as in the pre-use phase, the role of the individual is critical. It is of utter importance for the success of the application that the user finds it useful and easy to use. In our study, pilot-customers expressed difficulties in using the service in Internet environment for the first time. It was not obvious how to make an error-report in the service in Internet environment, although error-report is an essential function of the service. Pilot-customers assessments are important to take into consideration in the test phase since the determinant "perceived ease of use" (Davis, 1989) will have an influence on users behaviour in the use phase.

IV. 3 The use phase

In the test phase, but even more apparent in the use phase, the user gradually becomes more aware of the service in Internet environment not only in the own working tasks but

also in the organizational context. As Palvia et al. (2001) point out, when assessing a computer information system, a wider socio-technical view is important. Therefore, the quality of a computer information system should be concerned with both the technical and the social subsystems. A longer use of a service in Internet environment in an organizational context, "technology-in-practice" (Orlikowski, 2000), will have implications for users' judgment when assessing the service in Internet environment in the use phase.

Hu et al. (1999) state that the organizational context is new to IT acceptance and adoption research. Taylor and Todd (1995) argue for the importance in understanding determinants of information technology usage in organizations. Barki and Hartwick (1994:77) state that when new systems have been implemented and used, feelings and thoughts among the users were "likely to have greater impact on the use of new systems". In accordance with Taylor and Todd (1995), the importance of organizational issues and its affect on users' assessing services in Internet environment will be stressed throughout the use phase.

V. Conclusion

Our findings in the pre-use and the test phase indicate support for the conceptual foundation of the model (Figure 1) that is, the difference between the concepts of value and quality in relation to user assessment in three time phases.

Abstract: CIM (Computer Integrated Manufacturing) is like a strategic weapon that helps industries increase their capacity for competing. Case study by interviewing enterprise is the main technique applied in this research. Base on AST (Adaptive Structuration Theory) introduced by multiple case analyses, in the process of implementing CIM the interaction between CIM and organization of two TFT-LCD industries whose business operation characteristics are different will be discussed. The research result can be treated as a reference for enterprises to perform their CIM system more effectively and promote their core competency.

In the paper, some discoveries are found as follows: the enterprises that have higher degree of automation always pay more attention to the operation standard of manufacturing and system, and consider the correspondence between them for need of process automation. On the other hand, the enterprises that have lower degree of automation always pay more attention to the rationalization of production lines, the convenience of adjusting operation process after the system is implemented, division of labor among the related organizations and their responsibility as well. The reason why causes the difference is the former thinks both the system functions and information linking techniques are two most important key points in the CIM project, so the employee rate of the staff related with IT must be increased in the project organization.

I. Introduction

Many researches are proposed to mention about the successful key factors of introducing information technology system. In the recent years, however, observing the interaction between information system and organization in a view of sociology is one of academic research directions. The research motivation is to try to understand operation planning, introduction process, system performance and organizational performance of introducing information system through the interview analysis of the study case.

As information technology (IT) popularizes, in addition to semi-conductor industries, other high technology industries such as TFT-LCD industries, are also introducing manufacturing execution system (MES) gradually. In view of business owner, the introduction cost of MES is about

5~10% of whole plant construction cost. However, the success or failure of MES introduction deeply influences the operation condition of production lines. Therefore, most managers of manufacturing industries pay lots of attention to the MES introduction. Not only planning of automatic production lines has to be managed by MES, but also the case company introduced MES based on customer requirements.

Therefore, through the case study on the high technology manufacturing industry with different models of production operation management, this paper discusses the following questions to help enterprises with different planning of production lines introduce CIM related project.

1. Which factors will influence the selection consideration to the introduction of CIM in an enterprise organization? How?
2. How do CIM and the fitness of organization influence the process automation?
3. How does the introduction of CIM influence the performance of enterprise?

The research purposes is to use theoretical structure in Adaptive Structure Theory (AST) to observe the interaction between CIM system and organization in the introduction process of CIM, base on the case study on the different types of production operations. The discovered relations in the paper can help enterprises to effectively use CIM system to enhance the enterprise competence.

II. Literature Review

Roach [5][6] proposed the phenomenon of "Productivity paradox". Strassman [7] also stated there is nothing which can prove that his investment in 1980 had got returned. However, other researches such as Marri et al. [4], depicted the introduction of CIM could obviously raise production efficiency, quality of product, and lower inventory as well.

Giddens [2] proposed the duality of structures and in an agile point of view claimed individual activities are not only purely obeying rules or doing routines but also make social structure changed by the applications of knowledge concepts. Gregor and Johnston [3] thought that theory which can be applied in developing a cross-organizational information system should equip with the process of multiple-level analysis, be able to explain the organizational behaviors in different time, and support the theory of emergence.

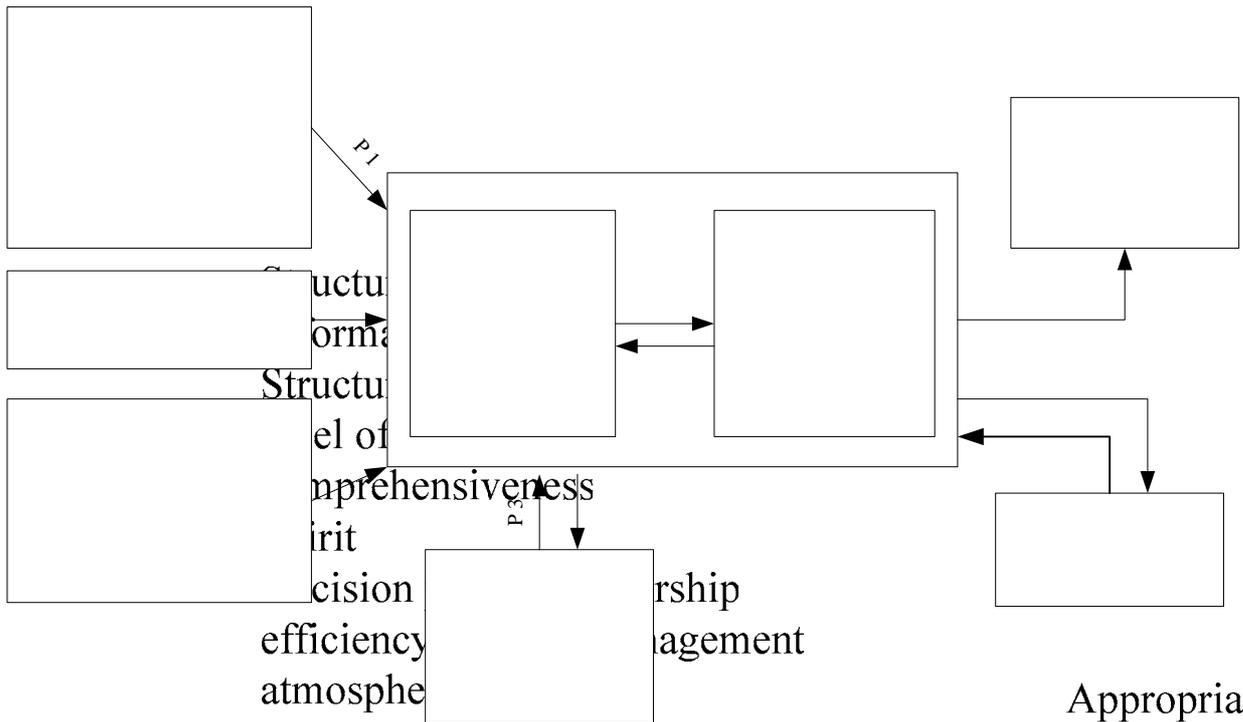

Fig. 2.1 AST theory architecture

(Source: DeSanctis and Poole, 1997)

Among these theories, Giddens' structural behavior theory is the most appropriate to be applied in the research on cross-organizational information system.

DeSanctis and Poole [1] proposed Adaptive Structure Theory: AST. It was used to discuss the interaction between the introduction of advanced information technology and organization in an enterprise. The structure is as the above figure 2.1.

The research implements the empirical study by making use of AST, and try to understand what the staffs think and their concepts in different organizations and enterprises while the information system is being introduced. Moreover, the difference of interaction among organizations in an enterprise will be discussed when CIM system is introduced.

III. Research Structure

III.1 Assumptions

The research adopts multiple-case-multiple-interview method to realize the concepts and the thoughts of all kinds of staffs in the organizations in the introduction process of CIM system through the comparison of interviewing information. In the paper, two TFT-LCD manufacturing companies with different degrees of automation are selected as the subjects of the case study. The introduction performance of CIM will be compared, base on the description of those staffs in the

organization.

There are seven assumptions proposed as follows:
The structural characteristics and the design concept of CIM system always influence the process of social interaction while introducing CIM system.

Because when the function and the information of CIM system have been upgraded, the system stability will be more important to production lines.

Assumption 1: system characteristics

P1b	The higher stability of CIM system and the higher instantaneity information processing will be more helpful to process automation.
------------	---

The operational characteristics of organization will influence the selection and introduction of CIM system. Once the system got sophisticated, it is easily found that there is a proportional relationship between the participation degree among information staffs to CIM system and the leading selection degree of system.

Assumption 2: organizational characteristics

P2b	The higher degree of production automation is, the higher leading selection degree of CIM system the information staffs have.
------------	--

The personality of users will influence the selection of CIM system. In the paper, the attitude of system users who take part in the project of CIM system was observed to realize whether the process automation is proportional to organization after the introduction of CIM system.

Assumption 3: characteristics of users

P3b The more positive attitude of system users who take part in the introduction of CIM system, the more possible the goal of the process automation will be achieved.

The assessment and selection of a system is a kind of interaction among systems and organizations. Moreover, the way to design the system is a key factor in the process of assessment and selection. The content of design should be followed the need of organization, and process automation is one of the main purposes in the introduction of CIM system. Hence, P4b also became another assumption proposed in the research.

Assumption 4: the assessment and selection of system

P4b If the design of CIM system is more fit to the need of organization, then the degree of process automation is higher.

The difference of the participation degrees and application methods of the project-related staffs will influence the project much.

Assumption 5: emergent structure

P5b The higher degree of process automation usually comes after a large portion of information staffs in the project of CIM system.

It helps on achieving the final goal of process automation.

The introduction of CIM system will affect the current organization, so the collaboration degree of organization in charge of the system maintenance will be higher.

Assumption 6: new organizational structure

P6b The degree of process automation and the collaboration degree of organization in the information department will be higher after the introduction of CIM system. The stability of CIM system can be maintained or increased through the maintenance operation of information department.

As managers demand the facilities be used effectively, a organism which increases the usage of facilities and production yield of production lines can be constructed through systematically monitoring management of production process.

Assumption 7: organizational performance

P7b The introduction of CIM can improve the performance of production lines; the higher degree of process automation will bring higher system efficiency.

Base on the above assumptions, the research structure is arranged as the figure 3.1 shows.

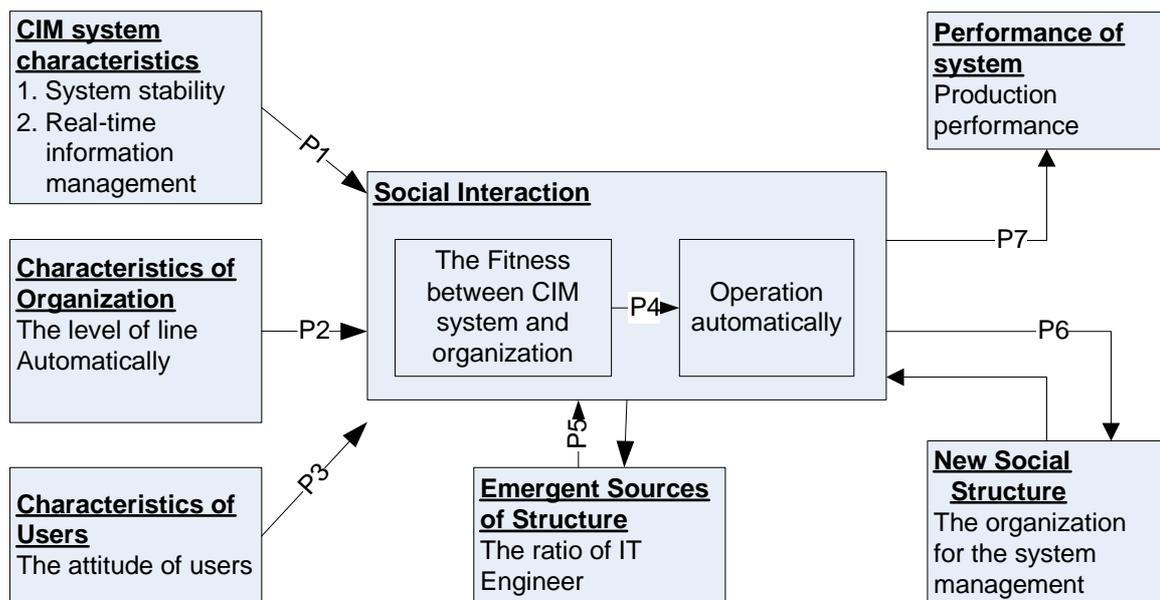

Fig. 3.1 research structure

III. 2 Planning of Interview Subject and Operation Model

To enrich the interviewing content of cases and collect the information of related research issues more completely, the interviewing subjects should be the most important roles really devoted to the introduction of CIM system, and they also can process the data collection in different points of view, such as the view of enterprise managers (Business unit managers, information system managers, production line managers), the view of system maintaineners (information managers, information system engineers), the view of system users (production line managers, production line operators). The occupational structure of the interviewing subjects is as figure 3.2.

IV. Case Study

The purpose of this research is to compare the processes and results of the introduction of CIM system in the two different operation-based companies. The comparison can be the following two ways:

☆ Assumption-based analysis:

The aim of is to investigate every occupational role in a company to know their idea and their thoughts of a series of assumptions, and then find out the same and the different depictions in these tow companies. Through the results of assumption-based analysis, it might be found the interaction among systems and organizations in the introduction process of CIM system in the different operational base companies.

☆ Occupation-based analysis:

The aim of occupation-based analysis is to ask every occupational role in different companies for knowing their idea and their thoughts of each question, and then analyze the reasons of these descriptions. Finally, the effect of every occupational role on CIM project will be known.

According to the arrangement of the interviewing content, some conclusions are found as follows:

(1) Which factors will affect the selection consideration of the introduction of CIM system in an enterprise? How?

This question can be illustrated from three aspects, namely, characteristics of system, characteristics of organization, and characteristics of users:

Characteristics of system:

The characteristics of CIM system are a series of processes of assisting the automation of production operations and the treatment of engineering data. Both the stability of system and the demand of real-time information processing are proportional to the degree of operation automation.

Characteristics of organization:

In the automated operation based enterprise, the information department is in charge of the CIM system project. Also, the first consideration for the system selection is mainly the information department, and the selection standard is based on the performance of system introduction.

Characteristics of users:

In the semi-automated operation based enterprise, the participation attitude of users is more positive, and they are the managerial core of operational process and system function.

(2) How CIM system and organizational fitness affect the process automation?

The case company A is based on operational automation, its organizational and operation process have had clear definition, and its system feature is to provide the managerial function of operation process; the main purpose of the case company B is to enhance the efficiency and the quality of operation, so the organization need to adjust or reconstruct the operation process during the process of system introduction.

As the cross-analysis of cases shown, the staffs in the enterprises with different degrees of automation have varied concepts and thoughts for CIM system so that the degrees of impact to organization are also different. For instance, the staffs in a production line with high degree of automation are more willing to pursue automation because of the standardization of production process and high unit price of each product. Therefore, the developing core tend to be placed on information department.

(3) After the introduction of CIM system, how it affect the performance of the enterprise?

Generally speaking, the introduction of CIM system usually helps enterprises to raise their performance. An enterprise with automated production operation will try to improve the level from operational automation to managerial automation, and implement more advanced appliance based on the data of CIM system. An enterprise with manual production operation will take advantage of the transparency of production data to make benefit from real-time management and quick response, especially for those who have more complicated manual production. The introduction of CIM system does affect the reconstruction of operation process a lot.

V. Conclusions and Future Works

Some conclusions are remarked here base on the arranged information of cross analysis of cases.

1. As the interview information shown, the interviewers all thought CIM system can improve the performance of production. The managers proposed the information

transparency of production lines will be helpful to managerial communication. Concerning about the benefit return of system, surprisingly, semi-automated operation based company B has more concrete cognition to benefit earning. Therefore, the research claimed the benefit return after the introduction of system is related with the profit-making business model but the degree of automation.

2. After researching the information of cases, we found the high portion of information staffs and what corresponds with the assumption P6b is high degree of process automation contribute mostly to the accomplishment of process automation. According to the observation of the case company's experience, the project staffs in the case company A evaluated a CIM system set-up for new factory always needs 20~30 information managers and information engineers. Among the different departments, the proportion of the users representatives employed to make sure the system requirements and senior engineers or senior managers in charge of projects is about one to five in the case company A but five to one in the case company B. If the time consumed in the project meeting is considered, the proportion difference between these two case companies will be ten times of the former.

3. For the enterprise with high degree of process automation, the connection operation specifications and standards between the production facilities and system in each production process should be noticed for successful introduction of CIM system. The other companies must notice the operation rationalization of production lines, the adjustment of operational process after introduction, and the confirmations of related organizational collaboration and responsibility. Briefly, there are three conclusions for related enterprises as follows

- (1) Raise the leading awareness of users will improve the introduction performance of CIM system.
- (2) For semi-automated operation based enterprises, they should consider the process reconstruction after the introduction of CIM system and the impact that the

proceeding schedule of project brings.

- (3) The higher degree of automation the case company has, the more stable system they should own.

The research verified the interaction between the advanced information system and organization depicted by the AST model through the case interview information. Moreover, the cross analysis is also applied to realize what enterprises and the system integration industries should notice while introducing CIM system under different degrees of automation of production lines. However, more advanced interview information and comparison analysis is required to extensively apply the conclusions to other similar enterprises and industries. Meanwhile, to obtain the intact interview content, it is a good way to make the assumptions under the AST models the question items in the questionnaire to verify the acquired information, that can increase the reliability of the information.

Managerial Use of Broad Scope MAS Information – A Function of JIT and ICT: An Exploratory Study

Lanita Winata, Lokman Mia
School of Accounting, Finance and Economics
Griffith University, Australia
Email: L.winata@griffith.edu.au
Ph: 61 7 5552 9083

Abstract: Is managerial use of the broad scope MAS (management accounting systems) information a function of JIT implementation and ICT? This study attempts to address the above question. The research propositions are developed following the relevant literature on MAS information, ICT and JIT. Seventy-six general managers, each in charge of one strategic business unit (SBU) within their respective organizations, participated in the study. Data was collected from the SBU general managers using a survey questionnaire. The results reveal that just-in-time manufacturing (JIT) implementation and managers' use of information and communication technology (ICT) are determinants of their use of the broad scope MAS information.

Keywords: JIT Manufacturing, Information Technology, MAS Information.

I. Introduction

Today's intensified global competition in the marketplace encourages firms to attain competitive advantage by offering greater range of quality products at competitive price and being customer responsive. (26) for instance, argue that organizations facing high competition ought to focus their alternatives on identifying and meeting customer desires, producing superior products and becoming more market orientated. These competitive pressures act as impetus for firms to employ strategies suitable to deal with their market conditions. The implementation of the JIT is one such strategy. There is also a body of literature (2) suggesting that broad scope MAS information provides necessary feedback on aspects of operations including cost, production, wastage, defect, inventory level, idle time, breakdown, stoppage, capacity utilization, market share and sales. Since a JIT implementation is aimed at controlling/improving the above aspects of operations, we posit that managers in JIT environments would use relatively more broad scope MAS information. JIT firms need to routinely communicate with all parties in the supply chain for effective management of the chain (18). Managerial use of the ICT improves efficiency of a supply chain management and integration through improved speed and flow of information and data exchange between the chain members. We argue that

managers' use of the broad scope MAS information in a JIT environment is augmented by their use of ICT as it makes availability and exchange of necessary information instantaneous, be it at the customer's site, at the production process or at the supplier's end. Following the above discussion we proposed and test the three hypothesis below:

H₁: Managers' use of the MAS information is positively associated with the JIT implementation.

H₂: There is a positive association of managers' use of the ICT with their use of the MAS information.

H₃: The interaction between managers' use of the ICT and implementation of JIT is positively associated with their use of the MAS information.

II. Method

II.1 The Sample.

Using the Dunn and Bradstreet 'Salescan' database, 360 firms were selected at random for the study from among the manufacturing firms operating in Australia and having annual sales revenue of \$300m to \$650m. In total, 79 SBU general managers completed and returned the questionnaire within nine weeks of mailing the questionnaire. Three of the questionnaires had to be discarded, as they were incomplete, leaving 76 cases in the final sample.

II.2 Measurement of Variables.

JIT implementation was assessed following Sakakibara, et al (39) on a six item scale arranging from 1 (very low) to 7 (very high).

Information Technology for Communication (ICT) was assessed using the 5-item instrument was adapted from (1) on a 7-point Likert-scale anchored at both ends. '1' represented a 'low use of ICT' and '7' represented a 'high use of ICT'

Use of the MAS Information was assessed using the 6-item instrument (adapted from (31) on a 7-point Likert scale ranging from 1 (not at all) to 7 (to a great extent).

III. Results

Recall hypotheses H₁ predicts that managers' use of the MAS information is positively associated with the JIT implementation and H₂ predicts that there is a positive association of managers' use of the ICT with their use of the

MAS information. Equation 1: $Y = \beta_0 + \beta_1JIT + \beta_2ICT + e$
 The results supported hypothesis 1 and 2, but not hypothesis 3.

IV. Discussion, Conclusion And Limitations

The significant and positive associations between the managers' use of the broad scope MAS information and their use of the ICT, and implementation of the JIT are encouraging. The significant and positive MAS - JIT association indicates that managers working in a JIT environment find broad scope MAS information are useful, therefore they use the information. The results support our argument early in the paper that managers in a JIT environment enjoy delegated authority for making decisions on the spot to ensure smooth running of operations, therefore they need to use a wide range of necessary information for decision-making. Broad scope MAS, by providing a wide range of quantitative and qualitative, financial and non-financial as well as ex-post and ex-ante information, is well suited to meet the managers' information needs. The study extends (31) by testing the relationship between JIT implementation and managers' use of the MAS information. Although (31) investigates the relationship between provision of the MAS information and SBU performance in JIT and non-JIT firms, managers' use of the MAS information in JIT environment is not tested.

The significant and positive MAS - ICT relationship supports our fundamental argument in the paper that ICT, through computerised network, assists managers in using broad scope MAS information. Since this type of MAS comprises a wide range of information as discussed above, managers using such information are faced with handling significantly large volume of data (cues) for decision-making. ICT, a computerised network with a capacity to handle voluminous data with lightning speed and unparalleled efficiency, assists managers' in using the MAS information and in carrying out interpersonal communication. Thus, the study extends research on ICT to financial information. Although there has been a significant amount of research on information technology for communication (see for instance Andersen 2001), none of the studies investigates the effect of ICT on managers' MAS information use in JIT environments.

Just like other studies conducted in field settings, the following limitations to the current study are worth mentioning here. First, the study was based on the manufacturing industry only, therefore, the results may be manufacturing industry specific. Given that JIT is applicable in service organizations and that cost structures in a service organisation is different from that in a manufacturing organisation, future research investigating the impact of market competition, JIT implementation and managerial use of the MAS information in service organizations will be beneficial.

Second, while considerable care was taken in selecting

the sample, participation of the SBU general managers in the study was voluntary. Thus, there is potential for self-selection (response) bias in the sample. For example, it is plausible that those companies which were successful in the JIT implementation and/or those that were performing well might have decided to participate in the study, whilst those that were not so successful in JIT implementation and/or not performing so well might have abstained.

Third, although considerable care was taken in devising measures for the variables in the model, there is still room for improvements. Future studies would benefit from taking care of this potential problem in formulating the research design. Although the current study pioneers the assessment of JIT implementation with respect to six key aspects, it did not collect data on the period for which each of these aspects had been in use by the respective SBUs prior to the study. Information on this issue might have made the results more informative. Following the relevant literature this study used perceptual measure to assess the extent of JIT implementation in the sample firms; using objective measures (where available and applicable) to assess the construct in future studies might make the results more informative. Consistent with its focus, this study assessed the extent of managers' *use*, not *usefulness*, of the MAS information (8). Incorporating measures of both managerial use and perceived usefulness of the information in future studies might produce more informative results.

Notwithstanding the above limitations, the results of the study have implications for theory and practice. The implication for theory is that the results provide empirical support for the prescriptive studies advocating use of broad scope information in just-in-time manufacturing environment. So far empirical research on JIT has been mostly prescriptive (39). Although prescriptive research is an important step towards developing theory, empirical research is a step forward to testing the theory in reality. Moreover, the study also provides empirical support for the view that organizations' manufacturing strategies like JIT create needs for managers' use of appropriate information systems such as the broad scope MAS and ICT helps the managers in making effective use of such systems.

One implication for practice is that an organisation which plans to implement a strategy like the implementation of JIT may perform better if it also upgrades/modifies concurrently its MAS and ICT. This implies that the organisation upgrades/designs its MAS to meet the managers' information needs; otherwise, realisation of the full benefits of implementing the strategy may be at least slow. Another practical implication for the results is that organizations that apply JIT could design MAS as such that the system has a built-in mechanism to identify and meet managers' information needs as they emerge, and thereby improve the system's relevance. The system's ability to meet the managers' changing information needs in an organisation is vital to the system's relevance; if it does not provide the necessary information, managers will ignore it, thereby making it irrelevant to their decision making process (23)

Abstract: Statistical process control (SPC) is a widely employed quality control method in industry. SPC is mainly designed for monitoring single quality characteristic. However, as the design of a product/process becomes complex, a process usually has multiple quality characteristics related to it. These characteristics must be monitored by multivariate SPC. When the autocorrelation is present in the process data, the traditional SPC may mislead the results. Hence, the autocorrelated data must be treated to eliminate the autocorrelation effect before employing SPC to detect the assignable causes. Besides, chance causes also have impact on the processes. When the process is out of control but no assignable cause is found, it can be adjusted by employing engineering process control (EPC). However, only using EPC to adjust the process may make inappropriate adjustments due to external disturbances or assignable causes. This study presents an integrated SPC and EPC procedure for multivariate autocorrelated process. The SPC procedure constructs a predicting model using group method of data handling (GMDH), which can transfer the autocorrelated data into uncorrelated data. Then, the Hotelling's T^2 and multivariate cumulative sum control charts are constructed to monitor the process. The EPC procedure constructs a controller utilizing data mining technique to adjust the multiple quality characteristics to their target values. Industry can employ this procedure to monitor and adjust the multivariate autocorrelated process.

Keywords: multivariate process, autocorrelation, statistical process control, engineering process control, group method of data handling, Hotelling's T^2 control chart, multivariate cumulative sum control chart

I. Introduction

Statistical process control (SPC) is a widely employed quality control method in industry. The objective of SPC is to monitor a product/process quality and maintain the process to a fixed target value. The best known tool of SPC is the control chart, which is used to detect the unusual variations in a manufacturing process. When the control chart declares a process out of control, it indicates a problem

with the process and the process engineer should look for an assignable cause and try to remove it. Traditionally, control chart is designed for monitoring single quality characteristic. However, as the design of a product/process gets complex, a process usually has multiple related quality characteristics which must be monitored simultaneously. When a process has multiple quality characteristics, it seems reasonable to use a separate univariate control chart for each quality characteristic instead of using a multivariate control chart since the univariate control chart is easily employed and interpreted. However, because each univariate control chart has its own type I error and these univariate control charts are aggregated to monitor multiple quality characteristics simultaneously, the overall probability of a type I error will be increased, in other words, the false alarm will be increased. Another reason that a series of univariate control charts cannot be used to replace the multivariate control chart is these univariate control charts neglect the correlation among the multiple quality characteristics. The consequences of neglecting the correlation among the multiple quality characteristics will increase both type I and type II errors. Therefore, many studies proposed multivariate control charts such as Hotelling's T^2 control chart [4], χ^2 control chart [3], multivariate cumulative sum (MCUSUM) control chart [12,16], and multivariate exponentially weighted moving average (MEWMA) control chart [8] to monitor several quality characteristics simultaneously.

Both univariate and multivariate control charts require that successive measurements from a process are independent of one another. However, due to the effects of tool wear or sampling frequency, the data assembled from a process may exhibit autocorrelation. When the autocorrelation is present in the data, it increases the chance that the control chart will indicate a process shift when the process has not shifted. A few multivariate control charts have been developed to deal with the process with autocorrelated observations. However, these control charts have some practical drawbacks.

The objective of control charts is to detect some unusual variations in the manufacturing process. When a process is out of control but no assignable cause is found, in this case, the process can be adjusted by employing engineering process control (EPC). EPC is a process adjustment technique for control engineers. The concept of EPC is not to remove the assignable causes of departures from the target but to compensate for the drift in process output by

continuously adjusting the process. EPC assumes that there is a dynamic model connecting the process input and the process output. When the model is correct, the EPC technique will minimize the process variability and keep the process output close to its target. However, if assignable causes occur that are outside the framework of a dynamic model, EPC technique cannot compensate the disturbance completely, and consequently, the variability will be increased [11].

Although many studies proposed multivariate control charts to monitor multiple quality characteristics or autocorrelated process, integrating SPC and EPC for a multivariate autocorrelated process is rarely seen. This study presents an integrated SPC and EPC procedure to monitor and adjust multivariate autocorrelated process. The proposed SPC procedure constructs a predicting model using group method of data handling (GMDH) to transfer the autocorrelated data into uncorrelated data. Then, the Hotelling's T^2 and MCUSUM control charts are constructed to monitor the process. The proposed EPC procedure constructs a controller utilizing GMDH to adjust the multiple quality characteristics to their target values. Industry can employ the proposed procedure to monitor and adjust the multivariate autocorrelated process.

II. Literature Review

This section first introduces the multivariate control charts, and then SPC techniques for autocorrelated process are reviewed. In the third subsection, the studies related to EPC are described. The method of GMDH is introduced in the last subsection.

II.1 Multivariate Control Chart

Hotelling's T^2 control chart was extended from the Shewhart control chart. It was the first developed multivariate control chart for monitoring several identically and independently distributed quality characteristics [4]. Hotelling's T^2 statistic to monitor several quality characteristics simultaneously is employed where assuming the covariance matrix of the quality characteristics is unknown. When the covariance matrix of the quality characteristics is known, the χ^2 statistic is used. Although the computation of Hotelling's T^2 control chart is more complicated than that of Shewhart control chart, when several correlated quality characteristics must be monitored simultaneously, Hotelling's T^2 control chart outperforms Shewhart control chart [4].

The MCUSUM control chart proposed by Woodall and Ncube [16] was extended from the univariate CUSUM control chart. Although the MCUSUM control chart is easy to employ, there may be a delayed reaction to a sudden large shift in the mean. Pignatiello and Runger [12] proposed two types of MCUSUM control charts which were designated as MC1 and MC2 control charts. Their study compared the effectiveness of the two proposed MCUSUM control charts with Hotelling's T^2 control chart and the MCUSUM control chart proposed by Woodall and Ncube. The results indicated

that the abilities of detecting small shifts in the mean vector from the MCUSUM control chart proposed by Woodall and Ncube and MC1 control chart are better than that of Hotelling's T^2 control chart. However, when there is a sudden large shift in the mean, the performance of Hotelling's T^2 control chart is better than that of MCUSUM control charts. Furthermore, the average run length (ARL) of MC1 control chart is more stable than the other three control charts.

Hotelling's T^2 control chart only uses the information gained from the current sample to determine whether a process is out of control, therefore, Hotelling's T^2 control chart is insensitive to small shifts in the mean vector. While MCUSUM control chart uses the information gained from the historical and current samples, therefore MCUSUM control chart is sensitive to small shifts in the mean vector.

II.2 Control Charts for Autocorrelated Process

In recent years, many SPC methods have been developed for monitoring the univariate autocorrelated data, such as the exponentially weighted moving average (EWMA) control chart [6], cumulative sum (CUSUM) control charts [2,13,14], and residual charts [1,9]. A few multivariate SPC methods for monitoring the autocorrelated process are also developed. Notably, Theodossiou [15] has proposed a CUSUM chart and Kramer and Schmid [7] have proposed a multivariate EWMA control chart to monitor the autocorrelated process. However, there are some practical drawbacks of using these methods. A prominent drawback is when evidence of an out-of-control situation is observed, and the above methods fail to provide the quality characteristic(s) responsible for the data point which falls outside the control limits.

II.3 Engineering Process Control

In mechanical, chemical, and electrical engineering applications, EPC are usually implemented to reduce process's variability. EPC assumes that a variable, which is called manipulatable variable, can be adjusted to compensate for the drift in process output to keep the process output close to the target. EPC assumes that there is a dynamic model connecting the process input and the process output. If the model is correct, the EPC technique will minimize the process variability and keep the process output close to the target. However, if the assignable causes occur that are outside the framework of a dynamic model, the EPC technique cannot compensate the disturbance completely; in that case, the variability will be increased [11]. Montgomery *et al.* [10] have demonstrated that the performance of an integrated SPC and EPC procedure is more effective than the EPC procedure alone.

II.4 Group Method of Data Handling

Group Method of Data Handling (GMDH) [5] is applied in a great variety of areas in data mining. Inductive GMDH algorithms aim to find interrelations of variables in a data set and select an optimal network or model structure. GMDH is an iterative method which successively tests models selected

from a set of candidate models according to a specified criterion. A general connection between the input and output variables can be found in the form of a functional Volterra series. A discrete analogue of Volterra series is Kolmogorov-Gabor polynomial which can be expressed as follows:

$$y = a_0 + \sum_{i=1}^M a_i x_i + \sum_{i=1}^M \sum_{j=1}^M a_{ij} x_i x_j + \sum_{i=1}^M \sum_{j=1}^M \sum_{k=1}^M a_{ijk} x_i x_j x_k + \dots \quad (1)$$

where $X = (x_1, x_2, \dots, x_M)$ is the vector of input variables and $A = (a_1, a_2, \dots, a_M)$ is the vector of summand coefficients.

The combinational GMDH algorithm has a multilayer iterative structure. The specific feature of GMDH is that the iteration rule does not remain consistent but expands with every new series. In the first series, all the models of the simplest structure are in the following form:

$$y = a_0 + a_i x_i \quad i = 1, 2, \dots, M \quad (2)$$

After sorting these models, select the best F models by a specified criterion.

In the second series, models of more complex structure are sorted. These models are constructed on output variables from the best models of the first series. The form of the models of the second series can be expressed as follows:

$$y = a_0 + a_1 x_i + a_2 x_j \quad i = 1, 2, \dots, F; \quad j = 1, 2, \dots, M. \quad F \leq M \quad (3)$$

In the third series, the sorting involves more complex structure form as follows:

$$y = a_0 + a_1 x_i + a_2 x_j + a_3 x_k \quad i = 1, \dots, F; \quad j = 1, \dots, F. \quad k = 1, \dots, M \quad F \leq M \quad (4)$$

The iterative procedure of the series continues until the criterion value stops increasing.

III. Proposed Procedure

This study develops an efficient procedure which includes two stages for monitoring a multivariate autocorrelated process. In the first stage, the SPC procedure constructs a predicting model using GMDH to transfer the autocorrelated data into uncorrelated data. Then, the Hotelling's T^2 and MC1 control charts are constructed to monitor a process to detect both large and small shift in the mean at the same time. If the process is out of control but no assignable cause is found, it can be adjusted by employing EPC to keep the multiple quality characteristics close to their target values. Therefore, in the second stage, the EPC procedure is proposed to construct a controller utilizing GMDH to adjust the multiple quality characteristics to their target values. The proposed two-stage procedure is described in Section 3.1 and 3.2.

III. 1 The Statistical Process Control Procedure

Constructing a multivariate control chart requires the analysis of a preliminary data set that is assumed to be in control and this data set is then used to construct a control chart for monitoring the process. Therefore, this section includes two phases. The first phase, designated as phase I, is to estimate parameters that will be used subsequently for on-going monitoring of the process. Phase I should utilize a very large sample of data so that the parameters and control limits are well-estimated for Phase II. Then, the second phase, designated as phase II, is to use the constructed control chart to monitor the process. The two phases are described as follows:

III. 1. 1 Phase I of the Statistical Process Control Procedure

This subsection presents a procedure to construct multivariate control charts for autocorrelated process. The procedure is described as follows:

Step 1: Collect and analyze the process data.

Assume that there are i input variables $x_1, x_2 \dots x_i$ and j quality characteristics $y_1, y_2 \dots y_j$ in the process. Draw univariate Shewhart control charts for the j quality characteristics to gain the information of the process data.

Step 2: Calculate the sample autocorrelation function of the data of each quality characteristic

Calculate the sample autocorrelation function for each quality characteristic and draw an autocorrelation function plot for each quality characteristic. If there is at least one quality characteristic exhibiting autocorrelation, go to Step 3; otherwise, go to Step 5.

Step 3: Construct a predicting model using GMDH

In order to eliminate the autocorrelation presented in the process data, this study utilizes GMDH as a predicting model to transfer the autocorrelated data into uncorrelated data to satisfy the assumption of independence of control charts. This study uses the observations of N periods before time t from the autocorrelated quality characteristic as the process input, and the process output is the quality characteristic of time t . After constructing the GMDH predicting models, the residuals can be obtained by subtracting the observation with the predicted value at time t . If the residuals satisfy the assumption of independence, they can be used to construct the control charts.

Step 4: Analyze the residuals

The residuals obtained from the GMDH predicting model must be checked whether the residuals satisfy the assumptions of normality and independence. If the residuals violate the assumptions, go back to Step 3 to modify the GMDH predicting model; if the residuals satisfy the assumptions, go to Step 5.

Step 5: Construct the multivariate control charts

Use the residuals to construct Hotelling’s T^2 and MC1 control charts. If one of the Hotelling’s T^2 and MC1 control charts reveals that the process is out of control, go to Step 6; otherwise, the Hotelling’s T^2 and MC1 control charts show that the process is in control, and the Hotelling’s T^2 and MC1 control charts can be adopted for constructing on-line statistical process control limits. Go to Step 1 of phase II.

Step 6: Deal with the out-of-control data points

Three ways to deal with the data points that fall outside the control limits are:

1. If one or two data points fall outside the control limits and the reason of the data points falling outside the control limits can be found and eliminated, then the data points can be eliminated, go back to Step 5 to construct new multivariate control charts.
2. If there are one or two data points falling outside the control limits but the reasons of the data points falling outside the control limit cannot be found, or the reasons can be found but cannot be eliminated, the data points will not be eliminated.
3. If three or more data points fall outside the control limits, it denotes that the process is out of control. The process engineer should find the problems and resolve them. After resolving the problems, go back to Step 1 and recollect the process data.

III. 1. 2 Phase II of the Statistical Process Control Procedure

This subsection presents a procedure to monitor a multivariate autocorrelated process. The procedure is described as follows:

Step 1: Record the information of the process data

Record the process number, machine number, the unit of quality characteristics, the name of operators, and the date of operation, etc. when using the control chart to monitor the process. If the data are recorded in details, the engineers can use this data to analyze the manufacturing process and then correct the process when the process is out of control.

Step 2: Specify the control limits of the control chart

Specify the lower and upper control limits of the Hotelling’s T^2 and MC1 control charts constructed in phase I.

Step 3: Sample the data and use the constructed GMDH model to predict the future values of quality characteristics.

Sample the data from each quality characteristic $y_{t-N}, (y_{t-N-1}, \dots, y_{t-1})$ as the process input and use the constructed GMDH model to predict the future value of each quality characteristic, \hat{y}_t .

Step 4: Calculate the residuals

Subtract the predicted value obtained from the GMDH predicting model with the actual value for each autocorrelated quality characteristic, the residuals can be obtained.

Step 5: Draw multivariate control charts

Use the residuals to draw the Hotelling’s T^2 and MC1 control charts. If there is any data point falling outside the control chart, go to Step 6; otherwise, the control charts denote that the process is in control and go back to Step 1.

Step 6: Diagnose the process and find the problems

If the Hotelling’s T^2 control chart reveals that the process is out of control, the MYT decomposition method can be used to find the quality characteristic that causes the process out of control. If the MC1 control chart reveals that the process is out of control, the regression method can be used to find the quality characteristic that causes the process out of control.

Step 7: Remove the assignable causes

According to the result of the diagnosis in Step 6, if the assignable causes can be found and removed, go back to Step 1. If no assignable cause is found, implement the EPC procedure to adjust the process.

III. 2 The Engineering Process Control Procedure

Before employing an EPC procedure to adjust the multiple quality characteristics to their target values, a controller utilizing GMDH must be constructed. This study uses i input variables $x_1, x_2 \dots x_i$ as the process input and j quality characteristics y_1, y_2, \dots, y_j as the process output to construct the GMDH controlling model. The EPC procedure is described as follows:

Step 1: Compute the value of the quality characteristic that is out of control

Subtract the value of the quality characteristic which is out of control from its target value, then the value of the process drifting away from its target, $e_t = y_t - T$, can be obtained.

Step 2: Compute the compensative value of quality characteristic

Compute the compensative value of quality characteristic, $\hat{Y}_{t+1} = T - e_t$.

Step 3: Obtain the predicted values of input variables

The predicted values of input variables $(\hat{x}_{1,t+1}, \hat{x}_{2,t+1} \dots \hat{x}_{i,t+1})$ can be obtained using the compensative value of quality characteristic, \hat{Y}_{t+1} , and the GMDH controller.

Step 4: Choose the appropriate input variable as the

controlling variable

There are two criteria to choose the input variables as the controlling variable for adjusting the process. They are:

1. The range of the adjustment of the input variable is the smaller the better. This study defines the index of evaluating the range of the adjustment of the input variable as the ratio of the volume of the adjustment of the input variable and the standard deviation of the input variable.
2. The influence of the input variables on other quality characteristics is the smaller the better.

The controlling variable not only influence the quality characteristic that is out of control, but also influence other quality characteristics that are in control. Therefore, when choosing an input variable as a controlling variable, the influence of the input variable on other quality characteristics must be considered to avoid that the controlling variable influences other quality characteristics.

Step 5: Use the predicted value of controlling variable as a set-point

Use the predicted value of controlling variable as a set-point to adjust the process and then go back to Step 1 of phase II to proceed to monitor the process.

IV. Conclusion

This study develops an integrated SPC and EPC procedure for a multivariate autocorrelated process. The contributions of the proposed method can be summarized as follows:

1. Because the predicting performance of GMDH is good and the application of GMDH is easier than that of time series and neural network, this study uses GMDH to construct a predicting model to transfer the autocorrelated data into uncorrelated data and construct a controller to adjust the multiple quality characteristics to their target values.
2. Engineers with little knowledge of Statistics can apply the proposed procedure easily. This procedure is very helpful in judging the real process conditions.

3. This study adopts the Hotelling's T^2 and MC1 control charts to detect large shift and small shift in the mean at the same time. Therefore, the proposed procedure has better capability to detect the out-of-control data points.

Discussions on the Environmental Strategies of SMEs

Sheng Li, Li Zhao, Haiying Zhang

Chengdu, 610074, P. R. China)

Abstract: Environmental issues have become the focal point of society. However, China enterprises have not paid enough attention to environmental issues, especially those of SMEs. In this paper, it points out that environmental issues of SMEs are imperative. By analyzing the restrictive factors, we put forward four environment strategies based on internal capability and the pollution degree of the enterprises and analyze each strategy in details.

Keywords: SMEs; environmental issues; environmental strategy

I. Introduction

The increasingly serious environmental problems have managed to bring people into reconsideration of their behaviors. Environmental protection is not only concerned with the sustainable development of national economies, but also closely related to the future of human beings. To protect our earth and turn sustainable development into true, various countries have been actively taking part in bilateral and multi-lateral co operations, signing international environmental conventions, and being devoted to solve global environmental problems. Environmental problems caused by enterprises have become a big concern of governments and the public. A survey of British SMEs by Hillary (1995) revealed that 70% of pollution in Britain is caused by SMEs. In China, with the rapid growth of SMEs, SMEs have increasing contribution to industrial pollution, which has, actually, become the emphasis of industrial pollution control. According to a survey by China National Environmental Protection Bureau, pollution caused by SMEs makes up 60% of the national total. Faced with such a serious situation, it is undoubtedly indispensable for SMEs to implement environmental strategies and strengthen environmental management.

II. Urgency of Implement Environmental Strategies in SMEs

In China, SMEs account for 99.7% of enterprises in number, employ 73.3% of the total industrial enterprises staff and produce 66.9% of the total output by all the industrial enterprises. All these facts speak for the decisive position of SMEs in China's economy. However, environmental problems are seriously blocking the further development of SMEs, and it is inevitable for them to put environmental

problems onto the agenda for the following two reasons. On the one hand, it is a prerequisite to avoid green trade barriers. With economic globalization and China's entry into WTO, enterprises in China are exposed to complicated international trade regulations and rules, and a lot of countries in the world, especially developed countries, have set non-tariff barriers in various ways, for example, SA8000 standards in the U.S.A, AVE standards in Germany, ETI standards in the UK and ISO14000 international environmental standards, and so on. In China, SMEs are playing a key role in export; therefore, greening their products and production process have become a necessity. On the other hand, it is a precondition to improve the competitiveness of enterprises. Resource-based theories (RBT) point out that environmental problems have already become a significant factor affecting an enterprise's competitiveness (Russo & Fouts, 1997). Due to various factors like small scales, backward technologies, insufficient capitals, and inadequate ability to take risks, SMEs are suffering from heavier environmental pressure than large enterprises, and, more seriously, they even become the victim of fierce competition among enterprises. Consequently, against the background of increasing attention to enterprises environmental problems worldwide, SMEs should have a clear profile themselves, correctly cope with the opportunities and threats brought by environmental problems, adopt proper environmental strategies to foster their own competitive advantage, and improve sustainable development of enterprises.

III. Restriction Factors of SMEs Environmental Strategies

Environmental strategies are the overall programs for enterprises to collaborate all the production and operation activities with eco-environment. In this sense, enterprises' environmental strategies are restricted by two types of factors. Proper analysis of these factors is the precondition of working out counter measurements, and is beneficial to integrate their competitive factors and build environment-oriented competitive advantage. Generally, the restriction factors of SMEs are as follows.

The first factor is government regulation. At present, majority of enterprises take environmental protection actions with the purpose of influencing Government's environmental regulations. Increasing perfection of environmental regulations and rules has become an essential external condition to promote enterprises to strengthen environmental management. Due to the worsened environmental conditions, all the Governments have enhanced their intervention into the environmental problems, and promulgated relevant

regulations, for instance, the U.S.A has managed to issued a series of regulations like CAA (the Clean Air Act), CWA (the Clean Water Act), RCRA (the Resource Conservation and Recovery Act), CERCLA (the Comprehensive Environmental Response, Compensation and Liability Act), TSCA (the Toxic Substances Act), SARA (the Superfund Amendment and Reauthorization Act) and EPCRA (the Emergency Planning and Community Right-to-Know Act). Japan and some developed countries in Europe and even some developing countries have also issued some acts, which tend to be increasing strict. China has also issued a series of acts to protect water, atmosphere, and resources and eliminate solid waste materials, for example, Environmental Protection Law of the People's Republic of China, Atmosphere Pollution Prevention Law of the People's Republic of China, Water Pollution Prevention Law of the People's Republic of China, and so on. Usually, Government's intervention to the market would apply different effects on the enterprises in the industry; that is, this intervention would result in some winners and losers, namely, some unqualified enterprises forced to withdraw from the market, and others actively taking part in environmentally friendly practices and obtaining competitive advantage. China has started to handle the pollution problems of SMEs since 1995, and a special pollution rectification is carried out once a year. By 2004, the 10th rectification has been held, and approximately over 1,000,000 SMEs have been closed as a result of pollution problems.

Secondly, market acts as another factor. Pressure from consumers is the major restricting factor SMEs are facing. With speeding of the course of industrialization, deteriorating of global environmental pollution, existence and development of human beings are threatened, which has contributed greatly to the growing consciousness of environmental protection, and even the big turn of the people's way of thinking, values, consumers' psychology and behavior. Consumers gradually turn to green food, pursuing eco-health. They tend to pay a high price for the products of some environmental protection features, and refuse those enterprises and products with low environmental performance. Compared to the large scaled enterprises, SMEs could not produce products with high environmental performance, which, as discussed above, implies great threats to the further expansion of the enterprise, especially those exporting SMEs: without improvement of their products and collapse of the green barriers, they could hardly obtain any long-term development. Besides, pressure from the public, green competitors, green suppliers and potential green entrants to the market would also become the realistic threats to the enterprise, and therefore, they have to change their conventional environment-blind views and behavior to obtain a position in the market.

Thirdly, internal factors of the enterprise could also play a role. Plenty of factors existing within the enterprise also affect their environmental strategies. As a complicated organization, an enterprise is composed of staff, managers,

shareholders, and the board et al. These stakeholders have different interests, and consequently, bear different environmental pressure. Managers' environmental consciousness is crucial, and their tasks in directing environmental strategies include defining enterprise's prospects, mission, operating philosophy and targets, formulating innovative strategies, fostering environmentally friendly culture, setting up environmentally friendly organizational structure and training staff, and so on. Only under the guidance of managers' environmental consciousness, environmentally friendly organizational structure and environmental protection culture could be built up to realize environmental organization management and root environmental consciousness into the mind of staffs. Managers should make full use of opportunities to protect or improve environment, positively instill the concept of environmental protection into every department, and build an environmental culture. However, a survey has been delivered among the Chinese managers, and it illustrates that less than 1/3 of the managers think that they have a full understanding of relevant environmental laws and regulations, and majority of them have very weak environmental consciousness, especially SMEs managers. In addition, organizational structures also play a significant role in enterprise environmental strategies. Russo and Fouts (1997) argue that bureaucratic enterprises usually react passively to environmental problems, while organic enterprises tend to adopt positive preventive environmental strategies. Study of SMEs by Castka and Balzarova (2004) points out that the system structure of an enterprise (e.g. ISO 9001:2000) is an effective tool to assign the social responsibilities to the individual enterprises. Some domestic research also proves that enterprises with standardized management system like ISO 9000 are more positive in implementing environmental strategies. In China, organizational structure and system of SMEs are still incomplete, which, inevitably, seriously undermines the implementation of environmental strategies. Moreover, an analysis by a research group of Beijing Normal University implies that SMEs are still faced with plenty of barriers in the process of carrying out environmental strategies. Firstly, financial inadequacy is the most serious problem. Due to their small scales and limited strength, SMEs has seriously inadequate input to environmental protection. Secondly, backward technical support is another barrier. Lin Hanchuan et al (2001) have carried out a survey of among SMEs in Hubei and Guangzhou, and it reveals that the most of them still stay at the technical level of 1980s or even earlier. In recent years, new technologies with environmental consideration are seldom applied in majority of SMEs. The third barrier is related to incomplete policies and social service system of SMEs.

Enterprise environmental strategies are mainly restricted by the three factors stated above. Undoubtedly, these three factors are interactive and dependant to one another, which is shown in Figure 1.

IV. Selection of SMEs' Environmental Strategies

Comparatively speaking, factors like government regulations and market are uncontrollable for enterprises, while their internal factors are controllable. Since enterprises could hardly change their situation and behavior by working on the uncontrollable factors, the internal factors become crucial in implementing environmental strategies. However, it is still undeniable that pressure from both the government and market also affect the strategic choices of enterprises, although the former acts in a more direct way than the latter. Petts et al (1999) mention that scholars have already reached an agreement on the driving factors of business environmental performance, and point out further that

abiding by the relevant regulations and laws is them most essential one. For SMEs, controlling and managing power is far more influential than market power and social power. Due to the incomplete market economic system in China, SMEs are usually lack of long-term consciousness, and, as a result, have a slow reaction to market pressure. Furthermore, influence of Government regulations is decided by the pollution level of the enterprise and related industry, and in this sense, using enterprise strength and its pollution level as two dimensions, we have built up a matrix, which could have some implications for SMEs in selecting environmental strategies.

According to Figure 2, SMEs could adopt four strategies for their environmental management: sustainable development, proactive, compliance and adjusting.

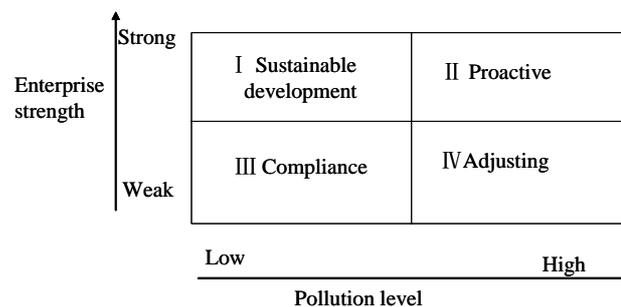

Figure 2. Environmental Strategies of SMEs

IV. 1 Environmental Strategy of Sustainable Development

Some SMEs with features of clear organizational structure, competitive products, advanced technologies and sufficient fund usually have strong enterprise strength and low level of pollution, and they are recommended to adopt environmental strategies of sustainable development. Thanks to the advanced technologies and environmental friendliness of their products, environmental protection standards of these businesses usually outperform the regulatory standards of government. These businesses are usually of high competitiveness, for example, clothing industry, and they are faced with no external environmental pressure, and it is a wise decision for them to concentrate on improving competitive advantage by their existing green advantages, and constantly expanding.

IV. 2 Proactive Environmental Strategy

Some other SMEs are characterized as having clear organizational structure, competitive products, but these products have relatively serious pollution due to some their specific properties or some technical factors. These businesses enjoy rapid development and certain scale, however, their development is at the price of consumption of resources, for example, chemical industry, and result in serious environmental pollution. Therefore, they are at the top list of government control. Due to the uncontrollability

of government regulations and market factors, these businesses are required to work on their internal factors, for instance, adopting new technologies, eliminating backward technologies with serious environmental effects, or relocating factories in the sparsely populated areas, and control their environmental effects to the minimum. This kind of strategy is "proactive environmental strategy". On the other hand, enterprises should be active to communicate and collaborate with the government, and obtain political support by political tactics. This strategy is tailored for those with strong strength but poor environmental performance, and with implementation of it, businesses could not only reduce their damage to environment, but also lower the unit cost of product, enhance internal strength and competitive advantage.

IV. 3 Compliance

Due to various individual strengths, environmental strategies of different SMEs businesses should have different emphasis. Without strong market power, advanced technologies, and large scale, some SMEs are at the beginning stage of development and of little negative environmental effect, such as small high-tech companies. Although Government's regulations have limited impacts on these businesses, they still should strictly comply with these rules, and then devote to expand and upgrade their strength. This is "environmental strategies to comply with". This kind of businesses should focus on solving bottleneck problems like financing,

shortage of human resources, featureless products and weak research ability.

IV. 4 Adjusting

Those with backward technologies, uncompetitive products, small organizational scale, and serious environmental pollution are the emphasis of government's control, such as some small paper mills. This kind of SMEs is at the edge of life-and-death, and they must positively adjust themselves, close some production lines with serious environmental effects, and introduce new technologies. However, in the case of lack of cash and human resources, they could consider cooperate with other large companies, and seek for further development. This is what we call "environmental strategies to adjust", which is usually accompanied by the integral strategic adjustment of the company, covering organizational structure adjustment, production technology adjustment, staff adjustment, and product type adjustment.

IV. 5 Benefits From Implementing of Positive Environmental Strategies

According to Bichta (2003) and Russo & Fouts (1997), implementing of positive environmental strategies can bring the following benefits to the company:

(1)Economic profits. Pollution means waste. Investments on new technologies can result in effective reduction of raw materials, improved operating efficiency of equipments and facilities, effective recycling and reuse of waste and reduction of operating costs, which would inevitably upgrade the economic profits of the organization.

(2)Reputation. Businesses could positively publicize their environmental policies to win reputation, which is undeniable competitive advantage. Therefore, SMEs in China should be aware that there are no conflicts between implementing environmental strategies, and positively shoulder the social responsibilities and economic profits.

Here, we propose four types of environmental strategies for SMEs: sustainable development, proactive, compliance and adjusting. However, it can not be inferred that a SME could have only a choice for these four environmental strategies to be applied in its environmental management practice. Moreover, in fact we think that these strategies can be utilized in the same SME during its life cycle, and the tactics contented in a strategy and their portfolios should be a continuous pedigree.

V. Conclusions

Environmental issues have become the focus of society. However, China enterprises have not paid enough attention to environmental issues, especially those of SMEs. In this paper, it points out that environmental issues of SMEs are imperative. On the basis of analyzing the restrictive factors, we puts forward four environmental strategies based on internal ability and the pollution degree of the enterprises and analyze each strategy in details. It should be pointed out that each environmental strategy has its corresponding

strengthens and weaknesses, and the tactics contented in a strategy and their portfolios should be a continuous pedigree. The further studies should focus on the structure and distribution of continuous pedigree of environmental tactics and its effect direction and intensity with respect to SMEs.

John Naisbitt, author of *Mega trends*, et al has raise the theory that the lager the world economic scale is, the more powerful SMEs are economically. A number of economists also state that with full potential, SMEs will play a main role in 21st century's economic development. At present, China's economy is at the turn of transformation, and SMEs are all faced with the problems of improving their ability to start a second undertaking as soon as possible, and to make full use of resources. However, increasingly rapid development of technologies and globalization of environmental problems do provide a perfect opportunity for SMEs, which requires that SMEs to get rid of their traditional short-term concepts, grasp opportunities, fulfill their social responsibilities, correctly work out and carry out environmental strategies, so that further development and growth could be achieved in the fierce competition.

Abstract: What are future requirements for ERP solutions in small and medium-sized enterprises (SMEs)? The following research paper focuses on identifying interfacial areas between banking services and financial processes of SMEs. It should be possible for these services to be embedded into the information systems of SMEs in order to support their financial processes such as cash management, reconciliation, customer management and asset management in an automated, seamless manner. In this paper, we develop a framework and a methodology for our empirical explorative research, which are intended to be the foundation for investigating both financial processes within SMEs, as well as firms' willingness to adopt new services offered by banks. Furthermore, first results from four case studies indicate some promising results. But they also show particular problems from granting banks access to SME-internal systems.

I. Introduction

B2B integration of applications within the supply chain management has been a necessary requirement to stay in the market even for small companies in particular branches (e.g. the automotive industry) for many years. While similar trends could be observed in the financial services industry (such as outsourcing of IT and business processes as well as the inter-organizational integration of processes, which formerly were in the same firm), we want to turn around the perspective and to ask which financial processes can be insourced by banks (or other financial service providers) from small and medium-sized enterprises (SMEs). Which added-value services could a bank additionally deliver to SMEs, due to its position and competencies? These scenarios alike require a seamless integration of SMEs' business processes with a bank's service. Therefore, the investigation has to get an overview about the actual IS maturity of SMEs with the main focus on willingness and readiness to inter-organizational integration.

Presently, the financial services industry is intensively working on process optimization and modularization of processes, which leads to encapsulated services that cannot only be used within the financial firm but can also be offered to customers. A simultaneous investigation of existing or potential so-called value chain crossings (VCCs) on both sides (suppliers and customers: banks and SMEs) could give substantial insights into the future layout of an integrated market-oriented inter-organizational financial value-chain network.

One of our research goals is the identification of financial business functions (i.e., parts of business processes)

within business processes of SMEs, which can be more efficiently carried out by specialized financial service providers such as banks. The driving vision is that firms – especially SMEs, which typically lack specialized resources in certain financial domains like cash management – may profit from a bank's experience by integrating certain functions, which are offered and executed by the bank, within their own business processes. We refer to this linkage as *Value Chain Crossing* (VCC), i.e., a (financial) service provider's service seamlessly embedded within an industry partner's business process.

An old existing example which almost represents a VCC, but is not finally integrated in a seamless manner, is the EDI transmission of payment runs. Another example is the integrated Electronic Bill Presentment and Payment (EBPP).

The VCC definition matches with the service-oriented paradigm, where services can be plugged in and out within a modular business process landscape or may be even replaced by services from external vendors.

Our research questions thus are:

1. Which financial processes of SMEs offer the possibility for VCC with banks?
2. How do perceived factors like benefits, risks, external pressure, and technological readiness affect a SME's willingness to adopt new financial services, by integrating their systems with those of financial service providers?

For the first research question, we are developing scenarios for VCC between financial service providers and SMEs. Through explorative case studies, we examine whether or not these scenarios are regarded by managers of SMEs as viable.

For the second research question, we develop a theory-based framework of factors which might influence the willingness of SMEs to integrate with banks. We use this framework as a theoretical foundation for our explorative research of the VCC scenarios.

The remainder of the paper is structured as follows: after a short literature review in the following section, we depict the application domain of our explorative research and introduce our research framework. We describe the methodology for the empirical investigations before outlining the case studies we have conducted. In the last two chapters, we briefly discuss the results obtained so far, draw a conclusion and outline the further research.

II. Literature Review

VCC requires the appropriate enabling support on the technical layer. The set of technologies which carry out the integration between two or more organizations are referred

to in literature as Inter-organizational Systems (IOS). Cash and Kasynski [4] simply define IOS as “an automated information system shared by two or more companies”. Johnston and Vitale [19] refer to IOS as systems which are “built around information technology, i.e., around computer and communications technology that facilitates the creation, storage, transformation, and transmission of information”. In other words, IOS are the technological means by which application and, implicitly, business process integration of two or more firms are carried out.

Inter-organizational cooperation through IOS may occur in several forms [3]. For example, from the point of view of the participant's position relative to each other, horizontal cooperation takes place between organizations that act on the same level of the supply chain, i.e., between potential competitors. In contrast, vertical cooperation occurs between organizations that act on different levels of the supply chain. Finally, lateral (or diagonal) cooperation takes place between organizations that have neither a vertical nor a horizontal relationship [3]. In lateral cooperations, the use of IOS facilitates the appearance of electronic “links between industries that were formerly separated” [16].

VCC is a form of lateral cooperation. As Williams [26] states, “advances in the use of IOS entail greater interdependence between, and deeper systems penetration into, organizations”. According to him, “when [IOS] are used to alter the division of labor and to develop new forms of coordination and control between organizations, they penetrate more deeply into the affairs of each organization, as when one organization requires information via an IOS about work in progress in another organization” [26].

Large parts of literature discuss the issue of innovation adoption and diffusion within organizations. For example, the Technology Acceptance Model (TAM) [7] investigates technology adoption on an individual level, where users are free to choose whether they use the new technology or not. This theory identifies two perceived attributes as key indicators for the adoption of innovation: perceived usefulness and perceived ease of use of the new technology. The usefulness is a measure of “the extent to which an application contributes to the enhancement of the user's performance”, while the “ease of use relates to the effort required by the user to take advantage of the application” [7]. This model has been validated in many studies about technological innovation “where individual autonomy is permitted to adopt or reject an innovation” [15].

More suitable with the context of our research is Gallivan's Organizational Acceptance Model [15]. He criticizes about the TAM that in certain situations, where its underlying assumptions are not met, the TAM is likely to “produce findings that are weak, unstable, or open to question” [15]. Such a situation would occur when users of a certain technological innovation are mandated to use the new technology, which is adopted at organizational level.

There is a literature stream which focuses on process and stage research models, attempting to understand organizational-level implementation of innovations. In these

research models, the matter of interest is how extensively the innovation is used and how deeply the firm's use of the technology alters processes, rather than the user adoption and use of the technology per se [15]. The best-known model which describes technology implementation in organizations [15] is the six-stage model [5] [20]. The six stages of implementation are: (1) initiation, (2) adoption, (3) adaption, (4) acceptance, (5) routinization, and (6) infusion.

Our research concentrates on the first of the six stages named above. During the initiation stage, “active and/or passive scanning of organizational problems/opportunities and IT solutions are undertaken”. As a result, “a match is found between an IT solution and its application in the organization” [5]. For this phase, we investigate how the factors that we use in our research framework influence the willingness of decision-makers to adopt new financial services, by integrating their systems with those of financial service providers.

III. Research Domain and Framework

III.1 Research Domain

Our objective is to get an insight into the actual EAI and B2BI maturity of German SMEs as well as into the actual and possible integration of banking services into the financial processes of SMEs.

Cooperation is evaluated to be the most adequate strategy to ensure the survival of the German SME segment [3] [2] [25]. Nevertheless, many studies show that small companies use cooperation much less than larger firms. As (SME specific) cooperation inhibitors, insufficient ability and low willingness to cooperate were identified [3]. Helm et al. show that this low willingness often originates from the company's legal form [17]. Many SMEs are led by their owners, who set their primary goal on ensuring autonomy. Furthermore, this governance mode leads to a more risk adverse attitude, fearing the possibility of cooperation failure. Empirical studies showed that 30-50% of all cooperations fail [13]. Additionally, the lacking strategic orientation of SMEs is a reason for missing willingness to cooperate. Additionally, SMEs often are more risk adverse and fear the possibility of cooperation failures. Empirical studies showed that 30-50% of all cooperations fail ([13] (studies mentioned there)).

The first large empirical survey on internet-based cooperation of SMEs in Germany was conducted in 1999 [10]. The authors prescinded from particular business processes and investigated general cooperation activities and their impact on external business performance.

Due to increasing industrialization tendencies in the financial services industry, the aim of our study is to focus more dedicatedly on the cooperative support of the particular area of financial processes. These will not be part of the core business in most cases and might be a possible area of outsourcing (as a particular form of cooperation). Earlier surveys, which analyzed cooperation opportunities in the

SME segment, focused almost only on cooperation within the firms' value chains, and not on financial processes [10].

An empirical survey on large German firms showed rather high outsourcing potentials and even BPO activities in financial processes [23]. It has to be investigated whether this result can be transferred to the SME sector, or if SMEs' financial processes occupy only a minor fraction of the firm's resources, so that outsourcing will not lead to significant advantages.

Financial processes in our definition do not only cover the process of funds allocation and controlling, but also include all financial aspects involved with a firm's value chain, such as procurement and sales.

For our study, we developed a financial process map (see Figure 1), which structures an SME's financial functions into the process groups of Financial Trade Enablement & Settlement [23], Finance Management and Transactions Management. The Financial Trade Enablement & Settlement covers procurement and sales of goods and services, supported by managing the transactions infrastructure, while Finance Management embraces administrative financial functions.

For all financial processes, we investigate whether or not there are any VCC potentials, i.e., which process steps can be outsourced to banks.

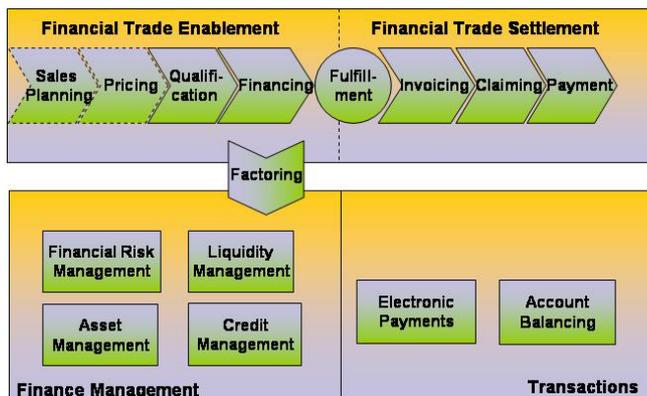

Figure 1. Financial process map of an SME

For example, during the enablement phase, banks could take over parts of the financial risk management, liquidity management, asset management, or credit management. During the settlement phase, opportunities for VCC could be offered by electronic payments or the account balancing.

III. 2 Research framework

Based on the EDI adoption framework of Iacovou et al., we have developed a framework of factors which we think have an influence on SME's willingness to adopt a VCC in the financial chain. Iacovou et al. [18] propose three factors which explain the EDI adoption behaviour of small firms: perceived benefits, organizational readiness and external pressure. We adapt this framework to our research domain, which is the VCC between SMEs and banks and add a further factor, "perceived risks", which might have an

important influence on the willingness of SMEs to adopt new financial services and thus to integrate with banks through IOS. The reason for considering this additional factor lies in the fact that, unlike EDI integration, as analyzed by Iacovou et al., where information is pushed to the integration partner, VCC implies the possibility for the bank to extract (pull) data out of SMEs information systems. SMEs might fear that, by adopting VCC, banks might get insights into the company's internal data that the company is not prepared to reveal.

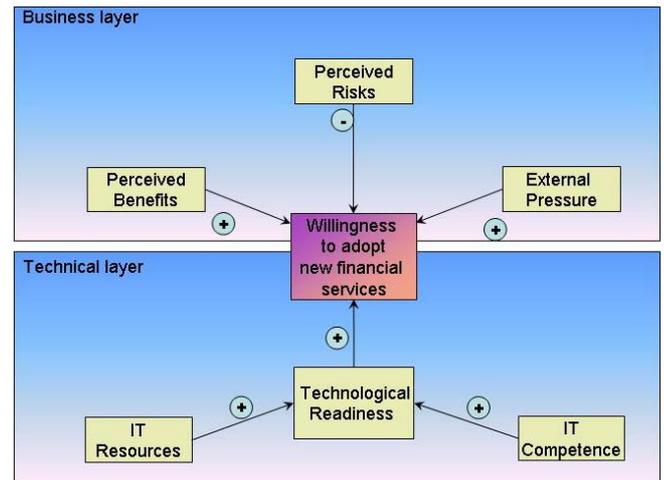

Figure 2. Research framework

Our framework is composed of the following factors:

Perceived benefits. The perceived benefits of adopting new IOS can be grouped into two categories. Direct benefits are "mostly operational savings related to the internal efficiency of the organization" [18]. The second group includes indirect benefits, like the improving impact that the implementation of new services might have on business processes and relationships [18].

Within our framework, perceived benefits refer to the benefits which decision makers within an organization believe will be generated by the integration of their own financial value chain with the financial chain of banks. While direct benefits of integration could be for example operational savings, indirect benefits could translate into a better rating of a SMEs creditworthiness and thus into better credit granting conditions, since the bank now has automated access to relevant data.

Because the framework offers an ex ante view of financial services adoption, the notion of perceived benefits refers to manager's expectations before any system implementation. They are thus "anticipated benefits" [18] and, as Iacovou et al. state, may differ significantly from the list of obtained benefits, provided by an ex post view.

A related term, "perceived usefulness", which also stresses out the ex ante character of this notion, is defined by Davis as "the degree to which a person believes that using a

particular system would enhance his/her job performance" [7].

Mehrtens et al. [22] also use the notion of perceived benefits to develop their model of factors which influence the internet adoption behaviour by SMEs.

We anticipate that firms that expect and recognize the benefits of optimizing their financial chain through integration with banks will be more frequently willing to adopt new financial services, than firms that do not expect benefits form such integration effort.

External pressure. In a study about IOS based on EDI, Crook and Kumar [6] identify three types of causal conditions for the adoption of EDI, where the first two terms can be subsumed under the notion of external pressure:

1. Customer-initiated EDI can be observed in vertically integrated industries, where large customers can force a firm to adopt EDI as an IOS.
2. Reaction to competition at organizational and industry level.
3. Organization-initiated use of EDI.

The notion of external pressure is also part of the framework developed by Iacovou et al., referring to "influences from the organizational environment" [18]. He sees the two main sources of external pressure to be (1) competitive pressure and (2) imposition by trading partners.

For our object of research, the imposition by trading partners or, using the terms of Crook et al., "customer-initiated" adoption, are not relevant, since we investigate the relationship between financial services providers (e.g. banks) and SMEs, with SMEs being the customers. But the external pressure as a "reaction to competition", or "competitive pressure" might play an important role as a determinant factor for the willingness of SMEs to adopt new financial services and thus to integrate with financial service providers. We believe this, because we think that the increased competition German SMEs have been facing in recent years will ultimately lead to optimization efforts even in secondary processes like financial processes.

Thus, we expect those SMEs that encounter external pressure from their competitors to optimize their financial chain will more frequently be willing to integrate with financial service providers, then those who do not encounter such pressure.

Perceived risks. Perceived risk is the "*felt uncertainty regarding possible negative consequences of using a product or service*" [12] and may possess several facets. Featherman identified seven facets of perceived risk for individuals, when confronted with the question whether to adopt new e-services, or not.

Decisions about VCC adoption on organizational level are taken by individuals and therefore, several of the seven risk facets described below also apply within the context of VCC. The seven risk facets identified by Featherman are:

1. Performance risk is "*the possibility of the product malfunctioning and not performing as it was designed and*

advertised and therefore failing to deliver the desired benefits" [2]. For VCC, performance risk means the possibility of malfunctioning IOS which would result into possible opportunity costs.

2. Financial risk is "*the potential monetary outlay associated with the initial purchase price as well as the subsequent maintenance cost of the product*" [19]. The current financial services research context expands this facet to include the recurring potential for financial loss due to fraud.

3. Time risk. Consumers may lose time when making a bad purchasing decision by wasting time researching and making the purchase, learning how to use a product or service only to have to replace it if it does not perform to expectations.

4. Psychological risk. The risk that the selection or performance of the producer will have a negative effect on the consumer's peace of mind or self-perception. Especially lack of trust is a very important matter when giving banks online access to company information.

5. Social risk. Potential loss of status in one's social group as a result of adopting a product or service, looking foolish or untrendy. We do not expect social risk to play a significant role in a B2B environment, since vanity is not a matter of interest when adopting VCC.

6. Privacy risk. Potential loss of control over personal information, such as when information about you is used without your knowledge or permission. In the case of the integration of SMEs with banks and granting them online access to firm data, managers of SMEs might feel that they are giving up control of the amount and the time of delivery of information to the bank.

7. Overall risk. A general measure of perceived risk when all criteria are evaluated together.

We expect all risk facets except for the social risk to influence directly managerial decision-making about the adoption of VCC.

Technological readiness. This term is derived from Iacovou et al.'s notion of "organizational readiness". In their view, the organizational readiness has two dimensions: the technological and the financial readiness. For the adoption of new financial services we assume the latter to have a rather insignificant relevance, because this kind of services would never justify huge investments. Financial efforts instead are captured in the construct of perceived benefits.

The technological readiness itself has, again, two dimensions: the level of IT competence within the organization (in terms of people and know-how) and the IT resources (in terms of hardware and software). The more knowledge, IT specialists and IT resources a company possesses, the higher its "level of sophistication" [18]. Iacovou et al. state that "*sophisticated firms usually are less likely to feel intimidated by the technology, possess a superior corporate view of data as an integral part of overall information management, and have access to the*

required technological resources (i.e. hardware, expertise, and a competent project leader)".

In the case studies, we addressed the factor of technological readiness by asking managers if they have ERP, EAI, and CRM solutions implemented within their organizations and what types of IOS, if any, they use when exchanging data with business partners.

We expect firms with a higher technological readiness to be more willing to adopt new financial services than firms with a lower technological readiness.

IV. Methodology

Our research is divided into two phases with different objectives. The first step consists of conducting multiple interview-based case studies with a mainly explorative orientation. Objective is to get an insight into the actual EAI and B2BI maturity of German SMEs as well as into the actual and possible integration of banking services into SMEs' financial processes and the associated benefits and risks. The relationships between IT-based integration readiness and already existing VCCs should be explored. Further, the interviews will be used to identify possible new VCC scenarios, i.e. which additional financial services could be offered by banks and therefore should be integrated into the SME's process landscape.

In the second step we will conduct a questionnaire-based survey to validate the results and to evaluate the potential benefits and risks which are associated with the VCC scenarios that have been identified in the case studies. The questionnaire will not only focus on SMEs but also incorporate banks as supply-side.

The research questions given in the introduction are of a *what* or a *why* type¹. Case study methodologists suggest exploratory case studies to answer this kind of questions and to develop theories which can be validated in a following step by other research methods [8] [27]. Our case study design considers the attributes which Dubé and Paré identify as evaluated necessary by most of the case study methodologists [8] such as Benbasat [1], Eisenhardt [9], Lee [21], and Yin [27]. They claim for a clear a priori definition of the research questions, the constructs, and the unit of analysis. Further, a pilot case as well as a multiple-case design are recommended and realized. The attribute of literal replication logic is only partly met, because on the one hand the research domain is quite broad and unexplored and on the other hand the primary goal of the first phase (= case studies) is to collect information about the current state of B2BI readiness in different branches and to develop possible VCC scenarios.

Interviews have been the primary data source of our case studies. Besides that, company reports were consulted. From the framework development we derived an interview guideline which captures the constructs which have to be

instantiated to each of the investigated financial processes (Figure 1). For the first ("pilot") case, the interview was conducted by three researchers (instead of two in later interviews) and the interview guideline was partially redesigned based on these first experiences. Furthermore, the guideline has been marginally refined after every of the following interviews.

The interview guideline consists of two parts. In the first part, we are asking for general information about the company and the interviewee, as well as about the company's information systems infrastructure and its relationships to banks (how many bank relationships, how many accounts, etc.) and other financial service providers. In the second part, for a subset of the financial functions presented in Figure 1, six VCC scenarios have been developed, in which a bank could take over the whole or a particular part of each function by integrating his service with the SME's information systems. For each of these scenarios, we discuss the potential benefits, involved interaction and integration efforts as well as potential risks and external pressures that might affect SMEs to adopt the VCCs. These constructs represent the upper part of our framework, while the technical layer would form the same prerequisite for all scenarios.

For collecting the cases, we used a regional SME database and selected 50 firms which fulfilled at least 2 out of the 3 "medium size" criteria of the European Union in 2004. Medium-size companies are defined as companies which have between 50 and 249 employees, a turnover between 10 and 50 Million EUR, and a balance sheet total between 10 and 43 Million EUR. The reason why we only chose medium-size companies in the first step (instead of small *and* medium-size), was that for developing hypothetical VCC scenarios, a quite well developed and (more or less) process-oriented IS infrastructure should be present within the company, which would allow the embedding of external services offered by a financial service provider.

The main branches we focused on during the selection process were Manufacturing, Trade and Repair Services, Real Estate/Renting, and Construction (following the NACE classification of the EU [11]). These four branches cover 88% of the German medium-size enterprises [14].

After the list was finished, the companies were called by phone and the managers responsible for the majority of financial processes were identified. Because SMEs have a quite small management, each time this person could be identified clearly and easily. After an initial mailing which explained our aims, these managers were called and asked for participation. Six out of the 50 managers agreed in taking part in a 2-3 hours interview. Up to today, four of these case studies have been realized – unfortunately only in the manufacturing sector, so far. The first results will be presented in the following chapter. After collecting at least six further cases, the case study results will build the base for the design of the next phase of our research, which will be a questionnaire-based survey for evaluating the VCC

¹ Even the 2nd question actually is of a *what* type (reformulated: "what is the present state of maturity...")

scenarios with 700 SMEs as well as with about 300 banks.

V. First Cases

V.1 Case Study Participants

In this section we describe the firms which took part in our first case studies. To ensure anonymity, we chose fictive names.

PlastiCo is a private limited company with a family-owned majority of shares. It produces finished and semi-finished plastics goods (plastic in primary forms, plastic plates, sheets, tubes and profiles) and sells them to 800-900 established business customers located worldwide. The company has 110 employees, out of which about 75% work in the production while 25% work in the administration. The company's turnover in 2004 was about 23.5 million EUR.

In 2004, PlastiCo was forced to start insolvency proceedings that could finally be solved through consolidation and recapitalization measures. Due to this episode, the company's explicit strategy in the financial field is to maintain its independency from banks. Also because of this incident, PlastiCo currently has to pay most of its suppliers in advance, while it usually grants payment targets of 30 to 90 days to the customers. For this reason, PlastiCo's liquidities usually oscillate around zero. Our interview partner is head of IT and controlling with PlastiCo.

LacquersCo is a family-owned enterprise founded in 1917, which produces lacquers for the interior. It serves customers that range from wholesale customers to big retail store chains to craftsmen to do-it-yourself customers. In the B2B sector, the company counts about 1000 business customers. LacquersCo has 240 employees out of which about 55% work in the production while the rest works in the administration. Business figures like the company's annual turnover were not communicated by the interview partner. He occupies the position of a controller, factually responsible for all financial processes, reporting directly to the board of directors.

VacuCo was founded 1994 and is currently owned by an equity fund. It produces huge vacuum equipments for the metallurgic and automotive industry. Due to the nature of their product, they only sell about 60 to 70 complete installations each year. For the spare part business, the company has about 2,000 to 3,000 worldwide customers, all of them being big metallurgic or automotive companies. VacuCo has 268 employees and has achieved in 2004 a turnover of 74 million EUR. Our interview partner is head of the finance division, responsible for all financial processes at VacuCo.

CosmetiCo is a cosmetics company owned by a large corporation. About 85% of its products are sold to the owning corporation; the rest goes to about 7 to 9 worldwide customers, all being large companies. CosmetiCo has 230 permanent employees, out of which about 100 work in the production while the rest is working in the administration. Each year, the company hires about 80 to 160 additional workers for the Christmas season. In 2004, the company has

reached a turnover of 67 million EUR. Our interview partner was the chief of administration at CosmetiCo, in charge with all financial processes.

V.2 Units of Analysis

As units of analysis we chose six different (potential) VCC scenarios, which are linked to different financial functions in the process map (Figure 1). As mentioned before, goal of the case studies was to get first evaluations of these scenarios and to develop new ones, together with the interviewees, which have a huge expertise on SMEs' financial processes. The six VCC scenarios are shortly summarized in Table 1. Some of them do not represent new business models. Nevertheless, they are still not realized by VCCs according to our definition, i.e. by an inter-organizational integration of the relevant information systems.

The IT infrastructure of the case study participants, which would form the foundation for implementing a VCC, is briefly described in Table 2. During the case studies, the focus was on the use of inner-organizational and inter-organizational systems.

V.3 Case Study Results

In the following, we restrict the presentation of our first results to the two VCC scenarios of customer management (CM) and liquidity management (LM).

VCC scenario Liquidity Management (LM). The LM scenario describes the transfer of cash balancing tasks between multiple accounts (and possibly between multiple banks) from the SME to a bank.

The four study participants have between 2 and 21 bank accounts at 2 to 4 banks. All firms check their accounts manually at least once a day. VacuCo uses a cash pool account to manually balance its 21 accounts each day, based on liquidity requirement analyses.

VacuCo stated that outsourcing the liquidity management would be possible and very interesting. The same was assumed by the other firms for the hypothetical case, that they would have more accounts. Presently, these firms spend quite little efforts on cash balancing. Risks from granting one bank access to all of the firm's accounts were seen as low, except by PlastiCo, which made some bad experiences with banks before and during its insolvency phase.

A capital club between different firms is seen partially as interesting and partially as not practicable due to security reasons. Nevertheless, both firms that are subsidiaries of a corporate group (VacuCo and CosmetiCo) take part or will take part in a corporate cash pool program, where the corporation balances the liquidity of the different members, using an internal interest rate for allocation. The results are summarized in Table 3.

VCC scenario Customer Management (CM). The CM scenario describes outsourcing of customer-relevant financial processes, such as qualification, payment control, dunning, and customer portfolio analyses. By granting the bank access to customer-relevant data the bank can apply its

capabilities of rating etc. and use its information about the SME's account transactions to control incoming payments etc. The scenario was only discussed with three of the case study partners, because CosmetiCo makes most of its business with its parent company and has only very few customers. None of the firms mentioned problems with bad payment behavior and all wanted to protect their customer relationships. Following, no firm would outsource dunning and only one firm would perhaps grant a bank access to customer data for portfolio analyses while the interviewee could not believe that the customers would agree with releasing data about them. The results are presented in Table 4.

Beside a first evaluation of the six initial scenarios, a major issue was to identify new scenarios, which could be evaluated in further case studies and in the questionnaire-based second phase of the project. A first scenario which was developed during an inter-view was a firm's need to get Basel II support, i.e. SMEs would open their systems to banks for getting better ratings and for getting advice to optimize their business figures when applying for loans.

VI. Discussion

The presented results of our first case studies show only preliminary findings of our research. Nevertheless, they indicate potential VCCs, as well as the problems involved. It was not goal of this paper to show a representative picture of the German SMEs' attitude to adopt VCCs, but to present the research approach and to discuss its appropriateness for answering the research questions introduced in the first section. The choice of a research domain which rather does not exist in practice, yet, was the main motivation for adopting a two-phase approach (case studies and questionnaire). Our first case studies may not be representative for the German SME sector and even for their particular industry, but they helped to get first insights into the feasibility of the developed VCC scenarios and the problems involved with them. When acquiring the next case study partners, we will more strongly focus on branches which have not been included so far (esp. trade and service companies). Nevertheless, case studies are never the appropriate approach to provide a representative picture in such a broad research domain and are even less appropriate to do explanatory research. The case studies showed that, besides the type of industry, there are a huge number of factors which might influence VCC adoption within the different financial processes (e.g. the firm's liquidity situation, governance mode, type of customers, geographical operating range on supplier and customer side, prior experiences with banks etc.). An explanatory research model would have at least to cover all of these parameters as control variables, while an exploratory research approach uses the model to structure the search for concrete drivers and inhibitors.

The case studies also neglected the supply-side view. The question how feasible a VCC scenario would be from a

bank's point of view again will be part of the questionnaire-based research. Of course, the step from determining the basic possibility of implementing a VCC to designing an effective business model, which will lead to bilateral adoption, is critical. Nevertheless, the competitive pressure in Germany enforces banks to look for new business opportunities and markets. Following Porter, innovative and sophisticated products are a possible strategy to achieve competitive advantages [24].

VII. Conclusion and Further Research

Main goal of this paper was to develop a research framework and a methodology which allows investigating the interfacial area between banking business and SMEs' financial processes. Additionally, some first case study results, which finally will form the first part of the research project, were presented.

The research framework interlinks the constructs of technological readiness, perceived benefits and risks, as well as external pressure regarding the adoption of novel embedded banking services into an SME's application landscape.

First results show some promising VCC scenarios, but also uncover the problem of granting a bank access to internal data, esp. if customer information is involved.

As a next step, we will conduct more cases in other branches (esp. trade), following the proposed methodology. After this, phase II will follow, which comprises an empirical survey with 700 SMEs and the German Top-300 banks (for also evaluating the developed scenarios from "supplier side"). Afterwards, a more technical part of the project will make sample implementations of promising VCC scenarios, together with partners from the banking industry, from the software branch, and from the SME sector. In this manner, we will hopefully be able to make a theoretical (assessment framework for embedded financial services) and a practical contribution (prototype implementation of VCCs) to the emerging domain of value chain crossings between banks as financial service providers and the SME sector.

This work was developed as part of the sourcing framework of the E-Finance Lab (www.efinancelab.com). We are indebted to the participating universities and industry partners.

Table 1. First VCC scenarios

VCC scenario (abbr.)	Related financial function	Description
Bank reconciliation (BR)	Invoicing, payments	The bank takes over all tasks for digitally mapping bank vouchers to internal accounting vouchers.
Liquidity management (LM)	Liquidity management	SMEs often hold multiple bank accounts for different reasons. If one bank has access to all accounts and at the same time is granted access to particular internal systems of the SME, it could take over liquidity balancing. By considering planning data, liquidity balancing could be done more effectively and future-oriented. The scenario could be extended to a capital club, where the liquidity balancing could be done over the accounts of multiple small firms, which trust each other (e.g. within a regional context).
Customer Management (CM)	Qualification, claiming	The account holding bank has information about incoming payments from the SME's customers. By granting the bank access to additional customer and invoice data, it could control incoming payments, perform dunning, check creditworthiness as well as perform customer profitability and portfolio analyses (customer-based business intelligence)
Factoring (FO)	Factoring, liquidity management	Factoring means an ongoing purchase of receivables through a financial institution. These institutions adopt the risk of default and all collection and dunning issues. At present, factoring is mainly offered by specialized companies. The VCC scenario includes a factoring community under the patronage of a bank, where different companies join to sell/purchase receivables to/from each other. The bank provides claim rating, control, and mutual trust.
Financial risk management (RM)	Financial risk management	If the bank is granted access to particular systems of the SME, it can provide financial risk management capabilities to the bank, much more easily. Depending on the SME's kind of business this could be factoring risks, interest risks, and currency risks.
Asset management (AM)	Asset management	Because a bank possesses superior knowledge regarding different types of asset products and of the capital market, it could overtake all tasks related to asset management, if a SME had sufficient cash funds to do sophisticated asset management (more than overnight money).

Table 2: Information systems infrastructures of case study partners

		PlastiCo	LacquersCo	VacuCo	CosmetiCo
Enterprise Resource Planning System (ERP)	Product	SAP R/3	TWS	SAP R/3	ABAS ERP
	coverage of all processes	80-100%	Unknown	40-60%	80-100%
	coverage of financial processes	60-80%	Unknown	80%	80-100%
Customer Relationship Management System (CRM)		Covered by R/3	None	Covered by R/3	None
Internal systems integration (EAI)		None	None	SAP connectors	None
B2B integration		EDI covers 20% of all communications with automotive customers.	EDI covers about 30-40% of total business document exchange.	No integration. Only classical media (fax, mail) and email.	No integration. Only classical media (fax, mail) and email.

Table 3: Case study results on VCC scenario "Liquidity Management"

		PlastiCo	LacquersCo	VacuCo	CosmetiCo
Demo graphics	Number of bank contacts	3	3	4	2
	Number of accounts	3	3	21	2
Perceived benefits	Actual efforts, which could be reduced by outsourcing.	Rather low efforts; manual transfer of data into ERP; accounts are checked 3 times/day. Scenario was evaluated as interesting for more accounts	Rather low efforts, once per day accounts are checked. For more accounts, this scenario was evaluated as interesting.	High efforts; cash pool account is used for manual cash balancing, based on liquidity requirement analyses.	Low efforts, but in the past it was planned (but not realized) to create more accounts for foreign currencies and to outsource the balancing over those accounts.
	Integration and interaction efforts	Perceived as low	Perceived as low	Perceived as low	In the past, the VCC scenario could not be realized due to incompatible systems between the banks.
Perceived risks	Risk from granting one bank access to all accounts	Medium, due to own experiences before and during the insolvency phase	Low, would be no problem	Low, would be no problem	Low, would be no problem
	Risk from granting a bank access to additional planning data, etc.	Too high	Too high	Medium, would be realizable	No problem
	Risk from joining a capital club	Medium, a committee would have to be implemented	Rather high	Too high	Rather high, but will be implemented within the corporate
External pressure	Competitive reasons for outsourcing	None	None	None	None
	Others			Corporate forces subsidiaries sometimes to grant credits to other subsidiaries (bilateral contracts)	From Aug 2005 all subsidiaries will take part in a corporate-wide capital club, where liquidity is balanced daily

Table 4: Case study results on VCC scenario "Customer Management"

		PlastiCo	LacquersCo	VacuCo	CosmetiCo
Demographics	Number of customers	800-900 established clients, 3,000 customers in total	1,000	2,000-3,000	8-10
	Number of outgoing invoices	12,000 per year	62,000-84,000 per year	3,150-4,150 per year	1,500-2,000 per year
	Customers' payment behavior	<1% of all invoices are not paid, a few customers claim every invoice for stretching the payment target	Almost no problems	0.03% of all invoices are not paid, <1% reclaimed	No problems
Perceived Benefits	Actual efforts, which could be reduced by outsourcing.	Customer management (<i>qualification and portfolio analysis</i>) is already outsourced to a specialized service provider which offers an extensive added value. <i>Dunning</i> is done internally, outsourcing would not make sense, because there are no scale effects.	<i>Qualification</i> is done internally. External information is requested manually. <i>Portfolio analyses</i> are done internally. Benefits from outsourcing are estimated to be rather low. <i>Dunning</i> is done internally.	<i>Qualification</i> is done internally. External information is requested manually. <i>Customer portfolio analyses</i> are not needed (one-off business). <i>Dunning</i> is executed automatically by R/3.	Scenario was not discussed, because 85% of CosmetiCo's business is done with its parent company.
	Integration and interaction efforts	Perceived as rather high. Too high for outsourcing dunning.	Perceived as very high.	Perceived as very high.	
Perceived Risks	Risk from granting a bank access to customer data	High, but controllable	Too high	Too high	
	Risk from outsourcing dunning	Too high	Too high	Too high	
external pressure	Competitive reasons for outsourcing	None	None	None	

The Impacts of Liberalization and Privatization in Taiwanese Electric Industry

Ming-Yuan Cho Jung-chin Chen Jong-ching Hwang
Electrical Engineering Department
National Kaohsiung University of Applied Sciences, Taiwan
a092304104@cc.kuas.edu.tw

Abstract: Taiwanese electric industry with liberalization has been a rapid change in the management style and the working environment. The change of the working environment has made a notable impact on the working conditions and the job security of the employees. This paper presents a brief literature review of the influences of liberalization and privatization on workers attitudes and proposes six overarching factors of importance to workers. These factors are: (1) the safeguarding of workers' rights and interests (2) compensation of potential loss (3) communication (4) leadership trusts and employee consultation (5) participation of employees and the labor union (6) encouragement to learn and to cultivate a second specialty. These factors are developed as a framework which could serve to help decision-makers and leaders with useful strategies in the privatization process.

I. Introduction

Liberalization is occurring very quickly in many countries throughout the world. In contrast to decades ago, when privatization was discussed but only a few industrialized countries were actively promoting the concept of privatization, the rationale for privatization is now widely accepted. It is perceived that State-owned enterprises (SOEs) have not met consumers' needs well and the records of SOEs have become worse and worse [18].

Privatization, in short, is the process of transferring productive operations and assets from the public sector to the private sector. Broadly defined in this fashion, privatization is much more than merely selling an enterprise to the private highest bidder. Privatization includes a wide range of approaches like contracting out, leasing, private sector financing of infrastructure projects, liquidation, and mass privatization [22].

Taiwan Power Company (TPC) face the great impacts and organizational change (OC) brought by privatization, liberalization and globalization. Privatization inevitably entails significant changes in the management style and the working environment and hence has a masked impact on the working conditions and job security of the employees. Clearly, privatization policy has many social and economic impacts. Thus, even though privatization of SOEs has become the major trend of development for many countries in the world, the promotion of privatization can easily incur strong resistance.

In Taiwan, in view of the great changes in the domestic

economic environment, the policy goals of the government's privatization efforts have been reset to put emphasis on building competition across all industries and promoting the allocation efficiency of social resources. Despite the slow progress of privatization in its first several years, the government has set privatization as one essential part of its current deregulation drive, and there is no doubt that the government will fulfill its privatization commitment and introduce competition into all markets [3].

Although the strategic policy of privatization is clear, it is to beneficial to everyone involved that the process can be undertaken without disruption and disharmony.

II. Liberalization and its Pproblems

II.1 Delay in Deregulation

Liberalization and privatization in industrialized countries has generally centered on denationalization or privatization in a narrow sense. In the UK privatization and deregulation has occurred more widely, linked to broad micro-economic reform. Generally in the developing world and in East Asia privatization has made very slow progress.

This does not mean that deregulation is not necessary in other countries or that the regulated part of the economy is small in other countries. It is said that 40.9 percent of all industries in Japan were regulated by the Government in 1993, while in the USA sectors subject to regulation were reduced from 28.9 percent in 1980 to 23.3 percent in 1992 in terms of their contributions to total gross domestic product [10].

There are number factors that can give impetus to deregulation. First, conditions for the Government to take leadership for deregulation must be present. For example, deregulation must be made an issue of policy during elections. Second, managers in regulated industries must change their dependence on government regulation and be encouraged to do business on their own account. They must recognize that this is for their own interest in the long run, that there will be expansion of business under deregulation. Third, there must be a deregulation principle law to give a legal basis to the idea or principle of deregulation and to prevent its mutilation in implementation.

For a long time, TPC has been operating in a bureaucratic fashion and workers' rights could be considered to have been overprotected and generous compared to other parts of society. When facing the impacts of privatization, employees feel that their working capability is threatened and thus reject organizational reform. They do not believe in the commitments of the owner [1]. A management crisis is

precipitated by privatization of SOEs.

Reflecting the public consensus reached at the National Development Conference (NDC) held at the end of 1996, the Taiwanese government vowed to expedite the privatization of SOEs. Accordingly, the CEPD completed a review of the timetable set for 47 SOEs to be privatized by 2003, and steered through modifications of the regulatory legislation to facilitate the privatization process. However, the government has encountered some delays in the course of privatization due to: (1) Legislative logjam (2) Labor opposition (3) Resistance from Taiwan's Provincial Governments.

There are four main reasons why the privatization program of Taiwanese public enterprise is often behind schedule [3].

1. Workers and labor union resistance change.
2. Political interference in the privatization process.
3. Legal restrictions on business scope.
4. Financial restrictions in public enterprises.

In Taiwan, privatization cannot be viewed as a pure economic policy or a policy option [3]. Instead, it contains substantial social meanings and consequences.

II. 2 Effects of Liberalization

As has already been mentioned, privatization has meant a change in management style and working conditions. The distinctions are summarized under six headings, and it is in terms of changes in these characteristics that privatization or quasi-privatization can be expected to impact on performance [14]. The six characteristics are: goals, management, labor, communications and reporting systems, organizational structure and nature and location of the business. The change of the working environment has made a notable impact on the working conditions and job security of the employees.

The Taiwanese experience has several practical and theoretical implications. First, there should be clear policy objectives of what privatization is expected to achieve. Given Taiwanese economic and technological context, liberalization and privatization were implemented to prepare SOEs for global competition and technological challenges, and to stimulate the stock market. In other countries privatization may be carried out due to fiscal and efficiency considerations. As in general it is important that efficiency improvements should be the primary goal of privatization [7].

Second, the approach to privatization should reflect the policy objectives of the state. In Taiwanese case, there was a well-planned, phased approach which involved gradual liberalization, as well as increased regulation to ensure high levels of quality and service, within an approach described as "managed competition" [16]. In other contexts, "shock-treatment" and further deregulation may be desirable.

Third, the Taiwanese experience is consistent with the proposition that privatization is more successful if it is carried out within a well-developed institutional and regulatory context. Privatization of both competitive and

noncompetitive SOEs is easier to launch and more likely to yield financial and economic benefits in countries that encourage entry and free trade, offer a stable climate for investment, and have a relatively well-developed regulatory and institutional capacity [7]. The existence of such a context in Taiwanese has aided SOE's privatization and subsequent performance.

Fourth, the state should give its full commitment to the privatization process within a well-planned framework for action. Political authorities gave their complete commitment and support to the privatization effort, ensured the integrity of the process, maximised transparency and reduced discretionary decision making by individuals involved, all of which are deemed as key success factors in privatization programmes [4].

Fifth, the SOE should receive prior preparation for privatization. The means to do so vary, and should depend on the industry context and the state of the enterprise. In Taiwan, for example, the gradual introduction of "managed competition" was deemed necessary, while in other contexts efficiency improvement measures may be warranted, such as bringing in private managers who should be given autonomy as well as held closely accountable for performance [4].

Finally, the dominant view that government ownership leads to inefficiency should be reconsidered, in the light of the Taiwanese experience. Clear government policies relating to the pursuit of globally competitive standards of quality and service, a civil service recognised for its efficiency, meritocracy and pragmatism [5], as well as clear competitive strategies and focus on efficiency at the SOE level have led Taiwanese SOEs to world-class performance.

It can be argued that the Taiwanese context is not typical of other countries' situations. Taiwan is a small, resource-lacking island-country, but has exhibited clear long-term development strategies at the national level as well as an efficient civil service and a highly skilled workforce. Taiwanese experience with SOEs, however, does indicate that it is possible to achieve world-class performance under government ownership, given certain contextual conditions. The gradual privatization and liberalisation processes, coupled with "managed competition" used in SOEs, moreover, have significant practical implications for the implementation of privatization programmes which may be useful in a variety of contexts.

Government's sales policy in stock market

In the UK, the Government gave favorable treatment to buyers of shares and assets which were state-owned. Consumers buying BT shares in 1984 were offered a choice between vouchers to reduce their telephone bills or one bonus share for every ten still held by the end of November 1987, three years later [15]. The Housing Act of 1980 in the UK gave people who live in state-owned houses the right to buy them at a radical discount. But in Japan there was no favorable treatment to buyers at all. The Government thought it unfair to treat buyers of shares of privatized assets favorably because the assets were national property

originally. The telecommunication market in Germany, there is no special rights for the government as stockholder, no "golden share".

In Japan privatized enterprises did not give any favorable treatment to their shareholders, while in the UK, for example, BT shareholders were given bonus shares or reduced telephone charges, as mentioned above. The Nippon Telegraph and Telephone Corporation (NTT) shareholders were given 0.02 bonus share for every one in November 1995, but this is far from favorable treatment because of the small quota and a severe slump in the stock price [18]. There has been no reduction of the telephone bills for shareholders.

In the UK, privatization led to a high degree of worker participation and workers have obtained shares at a discount or with the assistance of interest-free loans [19]. The same can be seen in social denationalization in West Germany in 1959-65 [8]. But in Japan employee loyalty is high, so there seemed no need to try to enhance it with employee share schemes.

Employee Resistance Organizational Change

When facing changes to the *status quo*, some people perceive that the proposed is against their vested interests, others are afraid of the uncertain consequences; both groups will therefore resist the reform. Employees' psychological reaction and attitude depend on their understandings of the reform, their experience and their current social relations. Although likely to be more complicated in reality, reference [17] categorized responses to change into three categories:

- Aggressive support,
- Neutral observation and
- Resistance.

It is the latter of these responses that is the focus of the work in this portfolio, although doubtless their some mutual dependence among them. Reference [11] had noted that resistance is commonplace, thus workers' attitude is one of the keys for organizational reform. In [17], define resistance as the actions taken by members of an organization to reject the objective or policy of the organization. Members refuse to achieve the objective, or try to avoid carrying out requests from the organization. Reference [1] believes that it is vital to find out why workers resist against organizational reform during the process of privatization. On the basis of research he concludes that workers usually resist against organizational change for the following reasons:

1. Potential economic loss.
2. Potential social loss.
3. Adjustment.
4. Lack of Respect.
5. Misunderstanding

Reducing Resistance from Workers

Guidance for the implementation of change comes from many sources. Reference [2] found that the following approaches can reduce resistance against reform:

- the initial introduction of small-scale, modest reform,
- the extensive use of education and demonstration,
- the planning and implementation of staff participation.

In an overlapping set of suggestions, which importantly identifies specific attention to dealing with the emotional status of participants, Reference [20] suggested:

1. When participants of reform are familiar with the values and ideals of the plan of reform;
2. Allowing affected personnel to participate in the plan of reform;
3. Full support from the high-level managers;
4. When participants of reform believe that the reform can reduce their workload;
5. When participants are interested in the plan of reform;
6. When participants of reform do not need to worry about their independence and security;
7. When participants have consensus towards the importance of reform;
8. Let participants act together;
9. Understand the feelings of the participants and reduce unnecessary fear;
10. Full communication and question clarification;
11. Establish mutual trust among participants and
12. Increase usefulness by public discussion.

A condensed but wide ranging set of practices was also suggested by [9]. These approaches to resistance reduction should be used concurrently and intelligently. That is, managers should use various strategies; understand the advantages and limitations of each method and to communicate according to the actual situation.

(1) Communication

Consultation has various functions that include emotional relief, advice, reassurance, negotiation, clarification, and re-education. Communication can help to let workers understand the necessity of reform and to reduce their resistance. Leaders can use one-on-one discussion, group briefing, education and training to communicate with workers and to publicize the notion of reform. Participants in organizational reform should inform as early and as clearly as possible about what is involved. Effective communication allows workers to receive relevant information, and also gives them opportunity to raise questions and receive satisfactory answers. A feedback system is thus established.

(2) Participation and Involvement

The involvement of potential rejecters in decision-making can not only reduce potential resistance but also increase the quality of policies. In [21], also holds that in organizational reform, participation of workers is vital for the morale and for the relations between workers and the management. Moreover, participation is a form of communication, by which workers can understand why reform is needed. Reference [13] believes that recognition, emotion and action are the three important features of participation that can

create active reaction for observation and judgment. Through participation in the decision-making process, workers feel that their comments are respected and hence their resistance to organizational reform can be reduced. Participation and involvement can take many forms and may include the use of team and group process to involve worker at all levels in planning the future. As well, reward schemes for positive suggestions about improved processes can work.

(3) Facilitation and Support

Reform promoters should use various supportive activities to reduce resistance from workers. When employees feel worried or anxious, leaders can use employee consultation, psychological consultation and new skill training to assist workers adapt to the new situation.

(4) Negotiation and Agreement

Certain rewards are needed to reduce resistance, such as to include certain employees who have influence.

(5) Manipulation and Cooperation

Manipulation means to reduce the impacts of reform, to twist the resistance and to set up a favorable environment. Cooperation refers to comprehensive strategy and multiple military tactics, which is related to controls and participation. By giving the leader of the resistance party an important role to play, members who reject reform would participate in the decision-making process and thus are involved.

(6) Explicit and Implicit Coercion

Put pressure on the rejecters to force them to accept the decision.

The above-mentioned six methods should be used simultaneously and intelligently to ensure successful reform of the organization.

In summary, six dimensions emerge a crucial to the privatization change process. Briefly again, a number of studies have suggested that *safeguard of workers' rights and interests* have a significant impact on workers in privatization [1] [15]. Also studies have indicated that *compensation of potential loss* have positive effects on workers' commitment [1]. In relation to *communication*, it has been found that the effects of workers were positively correlated with successful organizational change [1] [9] [21]. In most previous studies, measuring effects of change on *leadership, trust and employee consultation* has been used [1] [9] [13] [21]. Previous studies have all related *participation of employees and the labor union* with successful privatization [1] [13] [21]. The relationship between reducing workers' resistance and *encouraging the learning of a second specialty* has been examined by [1] [9] [13] [21].

Notably, the research which provides the foundations for the establishment of these six dimensions to managing resistance is drawn from research down in western societies and it is not clear how these relate to the situation which exists in modern day Taiwan which has a Chinese but also

has important Japanese and American influences as the result of occupation and strategic alliances. The intent of the remainder of this paper is to develop an instrument which effectively taps these dimensions within a Taiwanese organizational context in which the threat of privatization is real.

III. Research Methodology

A survey instrument encompassing the six dimensions described above was developed. This contained 30 items taken from various appropriate sources. Twelve items on workers interests were drawn from a survey instrument developed by the Taiwan Power Company. Thirteen questions were drawn from a privatization questionnaire developed by the Taiwan Council for Economic Planning and Development (CEPD). The remaining five items addressed the regulation of workers' rights.

Each item required a response on 5 point Lickert scale from strongly disagree to strongly agree.

The instrument was trialed with workers and representatives of a labor union of a large scale SOE in Taiwanese electric industry. Of the total 490 questionnaires mailed or e-mailed, 251 were completed and usable responses returned, yielding a 51.2 per cent response rate. The demographic sample characteristics of respondents are shown in Table I.

TABLE I
Sample Characteristics

Item	Variety	Sample (N)	Sample (%)
Gender	Male	222	88.4
	Female	29	11.6
Age	25 below	2	0.8
	25-34	25	10.0
	35-44	81	32.3
	45-55	110	43.8
	55 above	33	13.1
Level of education	Junior school	4	1.6
	Senior school	30	12.0
	Polytechnic Diploma	105	41.8
	University	93	37.0
	Post graduate above	19	7.6
Level of position	Top manager	1	0.4
	Mid manager	8	3.2
	Grass-roots cadre	90	35.9
	Worker	152	60.6
Years of experience	5 below	5	2.0
	5-15	29	11.6
	15-20	74	29.5
	20 above	143	57.0

Analysis of item responses consisted of factor analysis and the application of the Cronbach's alpha statistic to ascertain factor, reliability and validity. Factor analysis is a statistical technique, which is used to condense many variables into a few underlying constructs [6]. It reduces a large number of attributes by combining them into meaningful groups or factors. Before factors analysis can be used as a data reduction method, it must satisfy the underlying assumption of sampling adequacy [12].

IV. Results

The reliability of the scale was tested using Cronbach's alpha coefficient. Each construct was tested for unidimensionality, reliability and convergent validity using Cronbach's alpha coefficient.

Factor analysis suggested six factors. These have been labeled: Safeguard of workers' rights and interests (factor 1); compensation of potential loss (factor 2); Communication (factor 3); Leadership trust and Employee Consultation (factor 4); Participation of employees and the labor union (factor 5); Encourage the employees to learn and to cultivate a second specialty (factor 6). The Cronbach alpha coefficients for the six factors (see Table II) were between 0.78 and 0.93. The analysis for each factor is presented below.

TABLE II
Cronbach's alpha reliability estimates of six factors

Factors (six constructs)	Eigenvalue	Alpha
Safeguard of workers' rights and interests (factor 1)	16.93	0.93
Compensation of potential loss (factor 2)	2.72	0.89
Communication (factor 3)	2.12	0.85
Leadership trust and Employee Consultation (factor 4)	1.71	0.78
Participation of employees and the labor union (factor 5)	1.46	0.88
Encourage the employees to learn and to cultivate a second specialty (factor 6)	1.28	0.79

V. Discussions and Conclusions

At the outset of this study it was unclear what might be the dominant issues perceived to be affecting workers during the process of privatization of State owned enterprises in Taiwan. Taiwan has a mixed history of Spanish, conquest, Japanese occupation, the Chinese revolution and still ensuing friction with the mainland, a defensive reliance on the United States, and so on. Until recently, Taiwan has been much more prosperous than mainland China and more 'western' oriented. Yet Taiwanese society is still very Chinese. Traditional ceremonies and holidays are still marked. So it was reasonable to establish what factors were perceived important by workers faced with privatization and to understand whether these were effectively the same in research conducted in the west. As it turned out, the factor groupings effectively mirrored the findings from research in the west with the following labels given to the factors identified:

- (1) Safeguard of workers' rights and interests;
- (2) Compensation of potential loss;
- (3) Communication;
- (4) Leadership trust and Employee Consultation;
- (5) Participation of employees and the labor union and

- (6) Encourage the employees to learn and to cultivate a second specialty.

The immediate practical implication of this validation process is to provide general guidance to the Taiwanese government in terms of what it needs to do to hasten its privatization reform process. The findings obviously fall short of being specific as to what actions the government might take. However, the message that better communication is required is obvious and that each the factors identified need attention in practical terms.

The approach taken to data collection was via survey and subsequent factor analysis of responses. The findings are relatively clear cut. However, and without detracting from the findings presented, it is recognized that a different and more qualitative approach may have been used to collect data. Such approaches would have meant that the responses of participants would not have been constrained, or bounded, by the items in front of them on the survey form. These approaches, such as interviews or focus groups, might also have allowed the gathering of data which provided understanding into the value bases of the responses.

There are many factors that might influence support or resistance to privatization of Taiwanese electric industry. Some of these will relate to efficiency arguments with the prevailing pedagogy predominantly being that public enterprises are less efficient than privatized ones. This, of course, is disputable but the tide of opinion is currently against SOEs. It is not known how much this belief has taken root in individual SOE workers and hence the importance of efficiency arguments in relation to resistance to privatization has yet to clarify.

Likewise, it is generally argued that TPC has not met consumers' needs well, with the operational and service performance record of SOEs becoming worse and worse over time. This may be because Taiwan is experiencing a period of rapid and important social and economic change. Accession to the World Trade Organisation, democratic reforms and the general processes of globalisation are bringing about great changes in the domestic economic environment. In Taiwan, the policy goals of the government's privatization efforts have thus been changed to put emphasis on building competition across all industries and promoting the allocate efficiency of social resources. Despite the slow progress of privatization in its first several years, the government has marked privatization as one essential part of the current deregulation drive. There seems little doubt that the government will fulfill its privatization commitment and introduce competition into all markets [3]. The important role of SOEs and former SOEs (after privatization) are closely related to the life and social welfare of the general public. In Taiwan, most basic services are provided by SOEs or former SOEs. The success or failure of the Taiwan economy and society is thus linked with the success of these organisations and it is thus extremely important, among many other factors, to cultivate leadership ability of managers in advance in order to

successfully promote privatization. Development of a deeper understanding of the factors described in this study is a starting point.

Some further research is suggested. In the following papers of this portfolio, the effects on workers in the privatization process in Taiwanese electric industry will be explored. Of interest is the relationship of these variables with workers commitment on six factors, such as gender, age, salary, level of education, level of position and years of experience.

Abstract: The healthcare (medical) industry is the one that needs highly intensive knowledge and know-how. In other words, health professionals' knowledge is the largest part of intellectual capital within this business. While facing new disease or advanced medical knowledge doctors and healthcare professionals have to update these new medical information to provide quality care. Considering the working schedule of medical staffs, E-library turns to be the best channel of learning. The Department of Health (DOH) then established an e-library system on the internet to support its hospitals.

In this study, ISS Model The purposes of this study are to survey the users' satisfaction and intension to use of the e-library and to identify the critical after exploring factors for users' intense to use and satisfaction. The information system success (ISS) Model modified by DeLone & McLean in 2003 is adopted as research model. of this survey are medical professionals from 25 DOH hospitals exclude their branches and those under outsourcing management. 342 questionnaires are distributed

intention to use, satisfaction level, information quality, system quality and service quality resp-ectively. Finally, the frequency of using the e-library is rather low. It reveals that promotion of the e-library to the DOH staffs is needed. The results of this study serve as a reference for hospitals that intend to adopt e-library for enhancing their medical staffs in updating medical knowledge.

Keywords: ISS MODEL, e-library, healthcare industry .

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 718 - 718.

and 248 ones are returned which gives a 72.5% of response rate. However, 7 copies among them are ineffective. ANOVA and Structural Equations Model are used to investigate the correlation among variables.

The results show that DeLone & McLean's ISS Model is useful in investigating the usage and satisfaction of DOH e-library system. The subjects all have positive affirmation of using the e-library system. The variables of information quality, system quality, and service quality have direct impacts on the intention to use the e-library. Factors that influence the net benefit of using the e-library system are

The Need for Business Law Co-Ordination in the Global Marketplace

Abstract: E-mail is regarded by some companies as a mainstream marketing option. Legislation that prohibits unsolicited electronic messages of a marketing nature is a basis to stop the growth of spam. The ideal solution would be an international framework of legislation and law enforcement, but, legislation around the world has been diverse. New Zealand has taken a wait and see attitude to spam legislation. Its discussion paper "Legislating Against Spam," which was issued in May 2004, made considerable reference to the Australian approach. This paper considers the proposed New Zealand legislation in light of the Australian Spam Act 2003 and the New Zealand and Australian Memorandum of Understanding (MoU) on business law co-ordination. Does the proposed legislation go far enough? Legislation is a positive move. Without legislation, there is no basis from which New Zealand can address spam on a global basis. It is also a move to ensure sound business e-marketing practices which are essential as the Internet increases in importance for business communications. Spam is a global problem and reference is also included to the diverse approaches of the United Kingdom and the United States.

Introduction

E-mail is an important business tool as it is low cost and effective. Increasingly consumers use technology to access information. Related to this has been a significant growth in spam via the internet which threatens the growth of the internet and the information society as a whole.

On July 25, 2005, the New Zealand Commerce Minister, Pete Hodgson, announced that New Zealand and Australia would review their Memorandum of Understanding (MoU) on business law co-ordination. "Better co-ordination has been called for by the business community on both sides of the Tasman and we are interested in their views on the MoU and how it could be improved." Two days later, the Unsolicited Electronic Messages Bill was tabled in the New Zealand Parliament. The Australian Spam Act 2003 was the outcome of the review by the Australian National Office for the Information Economy (NOIE). New Zealand's discussion paper which was issued in May 2004, *Legislating Against Spam*, made considerable reference to the Australian approach.

The Unsolicited Electronic Messages Bill

The explanatory note to the Unsolicited Electronic Messages Bill states that the legislation is part of a multi-tiered strategy to combat the growth of spam along with self-regulation in the form of industry codes of practice, education and awareness campaigns, improved technical measures, and international co-operation. Generally, it is a positive move as it will ensure that New Zealand is no longer a soft target for spammers. However, it should be noted that New Zealand has been slow to introduce legislation and its response is not innovative but rather a weak response to the problem.

Australian Spam Act 2003

The Australian Government website of the Department of Communications, Information Technology and the Arts outlines its "multi-layered strategy to address spam as recommended in the *Final Report of the National Office for the Information Economy (NOIE) review of the spam problem and how it can be countered*. This strategy involves the following elements designed to complement and reinforce each other:

- national legislation (the *Spam Act 2003* and the *Spam (Consequential Amendments) Act 2003*);
- international cooperation;
- information and awareness-raising;
- industry codes of practice; and
- technical solutions.

The Australian Spam Act 2003 and the Spam (Consequential Amendments) Act 2003 were passed by Parliament in December 2003 and both came into effect on 10 April 2004.

Is the Australian Spam Act the best model for New Zealand?

Cheng suggests that "[t]he 2003 [Australian] enactments should be seen as a major step on a long road, rather than arrival at a final destination." This is particularly the case when the Spam Act is considered in light of global developments, legislation in other jurisdictions, such as the United States and the European Directives. It was announced on 2 July 2004 that the Australian Competition & Consumer Commission (ACCC), and the Australian

Communications Authority (ACA) were signatories to a Memorandum of Understanding between the US Federal Trade Commission, the UK Department of Trade & Industry, the UK Information Commissioner and UK Office of Fair Trading for mutual assistance in the enforcement of spam laws. The UK Department of Trade and Industry website outlines the effect -

“It will mean for the first time that:

- Enforcement authorities in the UK, United States and Australia will work together to investigate spammers in those countries;
 - * enforcement authorities across all three countries will take part in joint training initiatives to combat spam;
 - * international solutions and strengthening capabilities will be developed to trace and convict spammers; and
 - * cross border enforcement against spammers will take effect.”

United Kingdom

UK spam is covered by a set of regulations. The Directive on Privacy and Electronic Communications (2002/58) was adopted by the European Commission and it was implemented in the United Kingdom via the Privacy and Electronic Communications (EC Directive) Regulations 2003 which came into force on December 11, 2003. The Regulations prohibit the sending of unsolicited emails for direct marketing purposes without the recipient's prior consent (opt-in) unless one of three exemptions applies:

- (a) that person has obtained the contact details of the recipient of that electronic mail in the course of the sale or negotiations for the sale of a product or service to that recipient;
- (b) the direct marketing is in respect of that person's similar products and services only; and
- (c) the recipient has been given a simple means of refusing (free of charge except for the costs of the transmission of the refusal) the use of his contact details for the purposes of such direct marketing, at the time that the details were initially collected, and, where he did not initially refuse the use of the details, at the time of each subsequent communication. (Regulation 22(3))

The sender of all marketing messages must not conceal his or her identity and must provide a valid address for opt-out requests.

The Information Commissioner is responsible for enforcing the regulations, which is one of the major criticisms of the Act outlined by Munir as the Commissioner is “overworked and under-resourced.” Munir also criticises the low £5,000 fine for breaking the Regulations and its application. Spam to private email addresses is prohibited but it is permissible to send spam to the employees of businesses. Regulation 22 (electronic mail) applies only to transmissions to individual subscribers (the term “individual” means “a living individual” and includes “an unincorporated body of such individuals”). Motion concludes his summary of the regulations: “A laudable effort

all round on the part of the UK Government, but it is doubtful that any of this is going to make much difference in isolation.”

United States

The United States “Controlling the Assault of Non-Solicited Pornography and Marketing Act,” otherwise known as the CAN-SPAM Act 2004 took effect as from 1 Jan 2004 and only applies to spam messages which are commercial. Section 2 of the Act outlines twelve Congressional findings and policy, the first of which states: “Electronic mail has become an extremely important and popular means of communication, relied on by millions of Americans on a daily basis for personal and commercial purposes. Its low cost and global reach make it extremely convenient and efficient, and offer unique opportunities for the development and growth of frictionless commerce.”

The Act defines “commercial electronic mail message” as “any electronic mail message the primary purpose of which is the commercial advertisement or promotion of a commercial product or service (including content on an Internet website operated for a commercial purpose).” Excluded are “transactional or relationship messages,” which facilitate existing commercial exchanges or provide information necessary to existing commercial relationships.

A major criticism of the Act is that it is an opt-out regime. The recipient must be told that he or she will receive messages unless advice is received they do not want them. Commercial messages must contain opt-out provisions and the sender’s physical address. Some recipients would take the view that spammers include an opt-out to validate e-mail addresses which could mean more e-mails.

The Act prohibits the use of deceptive subject lines and false headers. In the case of unsolicited email, the marketer must label the email as an advertisement by ADV or other comparable identifier in the subject line. To amount to actionable spam there must be multiple unsolicited commercial emails that do not comply with the provisions of the Act.

The CAN-SPAM Act provides criminal penalties and unlike the UK Regulations the penalties are steep (fines up to 2 million). Zhang notes that some critics consider the possible penalties are disproportionate to the crime.

The CAN-SPAM Act does not allow a private right of action. Parker Baxter asserts that the theory behind allowing an individual private right of action against spammers in small claims court is that a rash of small lawsuits can create significant costs for the spammer that are normally shifted to the recipient of an unsolicited communication and can thereby cause a reduction in the amount of spam sent.

Subsection 12 of the Congressional findings and policy states: “Many States have enacted legislation intended to regulate or reduce unsolicited commercial electronic mail, but these statutes impose different standards and requirements. As a result, they do not appear to have been successful in addressing the problems associated with unsolicited commercial electronic mail, in part because,

since an electronic mail address does not specify a geographic location, it can be extremely difficult for law-abiding businesses to know with which of these disparate statutes they are required to comply." Spam regulation has been removed from state regulation to the federal government and in some cases imposes a softer regime.

Australia

The underlying principle of consent was emphasised on the Second Reading by the Minister for Communications, Information Technology & the Arts -

"The Spam Bill 2003 has as its cornerstone the principle of consent. Has the recipient asked for this communication—which constitutes explicit consent—or is there implicit consent? Implicit consent would exist where there is an existing business or other relationship. Drafting the bill has been a delicate balancing act. We must balance the legitimate needs of business and the concerns of the community."

The Spam Act is divided into 6 Parts – five of which contain a section headed "simplified outline."

Part 1 Introduction s3: Simplified outline

It states: The following is a simplified outline of this Act:

This Act sets up a scheme for regulating commercial e-mail and other types of commercial electronic messages.

- Unsolicited commercial electronic messages must not be sent.
- Commercial electronic messages must include information about the individual or organisation who authorised the sending of the message.
- Commercial electronic messages must contain a functional unsubscribe facility.
- Address-harvesting software must not be supplied, acquired or used.
- An electronic address list produced using address-harvesting software must not be supplied, acquired or used.
- The main remedies for breaches of this Act are civil penalties and injunctions.

The basic definition of spam is in S6. For the purposes of the Act, it is a commercial electronic message. The Australian Communications Authority (ACA, a government regulator of telecommunications and radiocommunications is responsible for enforcing the Act. Its website defines spam as "unsolicited commercial electronic messages regardless of their content". The provisions relating to consent, allow

the sending of legitimate commercial messages. Bulk spamming is covered by penalty provisions rather than in definition.

An electronic message becomes a "commercial electronic message" when it is within one of the listed purposes which include an "offer to supply or sell goods or services, advertise or promote goods and services, or to advertise or promote a supplier or prospective supplier of goods and services."

A commercial electronic message that has an Australian link, is prohibited unless the "relevant electronic account holder" to whom the message was sent consented, or there is a mistake by the sender, or the message is a "designated commercial electronic message."

The Act is much wider in application than either the UK Regulations or the CAN-SPAM Act. It covers all forms of electronic messaging such as mobile text messaging (SMS), multimedia messaging service (MMS) and instant messaging. Fax and voice calls are not covered. The Australian Consumers' Association consider that the Act should cover unsolicited marketing phone calls.

The practical guide for business put out by the Government lists three key steps to provide a clear explanation of the legislation's requirements:

"1 Consent Only send commercial electronic messages with the addressee's consent – either express or inferred consent."

2 Identity Include clear and accurate information about the person or business that is responsible for sending the commercial electronic message.

3 Unsubscribe Ensure that a functional facility is included in all your commercial electronic messages. Deal with unsubscribe requests promptly."

There are a number of exceptions for "designated commercial electronic messages" as defined in Sch.1. They must comply with s.17 and include information about the institution or organisation which authorised the sending of the message. Schedule 1, cl.2 and 3 outline the range of messages and list a number of bodies that are authorised such as government agencies, registered political parties, religious organisations, charities and educational institutions. Also excluded from the operation of the Act are purely factual messages but the sender must include accurate contact details of the message's originator (Sch.1, cl.2). Likewise if the relevant electronic account-holder consented to the sending of the message (Sch.2).

"Consent" means express consent; or consent that can reasonably be inferred from the conduct, and the business and other relationships, of the individual or organisation concerned.

The range of penalties is wide and it will depend on the history of the offender and whether or nor it is a body corporate or an individual as to the penalty imposed. ACA can issue infringement notices or penalties can be imposed by the courts. Under the former regime, the ACA may choose to issue a formal warning if a person contravenes a

civil penalty provision. Schedule 3 covers infringement notices, the object being to set up a system of infringement notices for contraventions of civil penalty provisions as an alternative to the institution of proceedings in the Federal Court.

Civil penalties are covered in Pt 4. The maximum penalties are substantial and are calculated on an increased scale for repeat offenders. If a business is found to be in breach of the Spam Act a penalty of up to \$220,000 for a single day's contraventions may be imposed. If, subsequently, the business contravenes the same provision, the possible penalty is up to \$1.1 million. For an individual first time offender the maximum is \$44,000 per day and for a repeat offender \$220,000 per day.

Injunctions may be granted in relation to contraventions of civil penalty provisions. The ACA is presently taking action against Clarity1 Pty Ltd of East Perth and its managing director, Mr Wayne Mansfield, and are seeking an interim injunction against the parties to be in force until the hearing because of the scale of the alleged breaches. It is alleged that the parties sent out at least 56 million commercial emails in twelve months after the Spam Act 2003 commenced in April 2004. Clarity1, which also uses the trading names Business Seminars Australia and the Maverick Partnership harvested some of the email addresses to which emails have been sent.

The ACA has been successful against a car company that advertised using text messages. Carsales.com .au was fined \$6600.

The ACA has been active in enforcing the Act by educating Australian businesses and consumers and it has been involved in joint action internationally in combating spam. Not only has it signed the M of U noted above with the USA and the UK to counter spam but it has also signed a joint statement with the Thai government on telecommunications and information technology.

On 1 December 2004, the Acting ACA Chairman, Allan Horsley, in a media release advised the anti-spam initiative with Pacific Internet and the software development company Spammatters. They are conducting a "world first" spam reporting system which enables Pacific Internet customers to report spam they receive via a number of methods including a plug-in to Microsoft Outlook and a web interface.

"When they receive spam, these customers will be able to use the software to forward it directly to the ACA's forensics database system for collection, research, analysis and action," Mr Horsley said. "The database system automatically extracts relevant information from the spam that may help the ACA to track down spammers. This information can be used as evidence in court because the database also saves the spam message with the header and body intact. This enhances its usefulness as legal proof."

"The database system reduces the need for manual spam investigations and is able to process and analyse very large amounts of spam."

Summary of the NZ Unsolicited Electronic Messages Bill compared to the Australian Spam Act 2003.

Clause 3 sets out that the purposes of the Act are to –

- (a) prohibit commercial electronic messages with a New Zealand link from being sent to people who have not given their prior consent to receiving those messages; and
- (b) prohibit promotional electronic messages with a New Zealand link from being sent to a person who has withdrawn consent to receiving those messages; and
- (c) require all commercial and promotional electronic messages to include accurate information about the person who authorised the sending of the message; and
- (d) require all commercial and promotional electronic messages to contain a functional unsubscribe facility; and
- (e) prohibit address-harvesting software and any electronic address list produced using that software from being supplied or acquired for use, or being used, in connection with sending unsolicited commercial electronic messages, or promotional electronic messages, in contravention of the Act.

The proposed Act will apply to marketing and promotional electronic messages whereas the Australian Act covers all commercial messages relating to an offer of goods or services, for example, quotes and invoices.

Clause 6 defines commercial electronic message. It means an electronic message that has, as its primary purpose,-

- (i) marketing or promoting-
 - (A) goods; or
 - (B) services; or
 - (C) land; or
 - (D) an interest in land; or
 - (E) a business or investment opportunity; or
- (ii) assisting or enabling a person to obtain dishonestly a financial advantage or gain from another person; but...the section then lists (i) – (viii) what an electronic message does not include – such as, a quote or estimate for the supply of goods or services. (viii) is a mopping up subsection. It does not include an electronic message that has any other purpose set out in the regulations.

A promotional electronic message means an electronic message-

- (a) that is not a commercial electronic message; and
- (b) that has, as its primary purpose, the promotion of marketing of an organisation, or its aims or ideals.

The Bill follows the Australian approach with regard to bulk spamming. It is not included in the definition but is relevant in terms of penalties.

Both the opt-in and opt-out approaches are utilised. The opt-in approach applies to unsolicited commercial electronic messages that have a New Zealand link. The opt-in approach involves a higher standard. The messages can only be sent if the recipient has consented to receiving them. This can be express or inferred from the conduct and the business and other relationships of the person concerned and any other circumstances that may be specified in regulations. Consent is deemed to have been given when an electronic address has been conspicuously published by a person in a business or official capacity and it is not accompanied by a statement to the effect that the relevant address-holder does not want to receive unsolicited electronic messages. The message sent must be relevant to the business, role, functions or duties of the person in a business or official capacity. Opt-out applies to promotional electronic messages that have a New Zealand link. They are prohibited from being sent to any person who has opted out of receiving messages. It defines how a person opts out of receiving promotional electronic messages. Commercial electronic messages and promotional electronic messages that have a New Zealand link must clearly and accurately identify the person who authorised the sending of the message; and include accurate information about how the recipient of the message can readily contact the person who authorised the message to be sent. The explanatory note to the Bill states that "Regulations made under the Bill, when it is enacted, may specify further conditions about the information that must be included in commercial electronic messages and promotional electronic messages." In addition a functional unsubscribe facility must be included unless the parties agree otherwise. In line with the Australian Act that facility must be reasonably likely to be functional and valid for at least 30 days after the message is sent.

Covered are all messages generated within New Zealand and all messages sent to a New Zealand email address. This is also in line with the Spam Act as are the provisions relating to prohibiting the supply, acquisition, and the use of address-harvesting software and harvested-address lists in connection with the unlawful sending of messages.

Again only civil remedies apply but for New Zealand the maximum is \$200,000 for individuals and \$500,000 for bodies corporate.

The Bill provides two defences. They are applicable where the person sent the message by a reasonable mistake of fact or the message was sent without the person's knowledge.

Consumers and users are required to resolve any spam problems with the sender and their Service Provider who in turn is required to refer matters to the government enforcement agency. Individuals cannot complain directly as according to the explanatory note to the Bill this places higher cost on Government and does not resolve issues by ISPs who are best placed to take technical measures in relation to spam originating from overseas. This could be unduly onerous for the ISP provides and it restricts the individual's remedies. The Department of Internal Affairs

is responsible for enforcing the new legislation, educating consumers, users and businesses and promoting compliance.

Has New Zealand emulated the Australian Spam Act?

The proposed New Zealand legislation is very similar to the Australian Spam Act. Is it better? The title differs as does the ordering of many sections. Likewise different words are used although essentially their purpose is the same, for example the Australian infringements are called contraventions. It is difficult to understand the reasoning behind some of the changes, particularly in view of the MoU and the frequent aspirations of a single economic market. A parallel development occurred with the New Zealand Commerce Act which was introduced after the Australian legislation but it is very similar. Some sections were reworded and the rewordings have proved to be detrimental. It is apparent that a lot of the changes in the Unsolicited Electronic Messages Bill are cosmetic only and seem to be of little benefit in the fight against spam.

The New Zealand Bill does include standard search and seizure provisions. Similar provisions were included in the Australian Telecommunications Act via the Spam (Consequential Amendments) Act 2003.

The New Zealand Government has had the benefit of a number of legislative models and their critics but has not taken advantage of the opportunity to make legislative innovations in the spam area.

Chetwin and Clarke suggest that a unique role for the law lies in requiring the deployment of technical defences against spam and in imposing heavy penalties not only for non-technical misdemeanours (such as buying and selling address lists) but also for operating email systems that lack these required technical defences. An example suggested is legislating that all mail-systems must implement technical barriers of a certain efficacy against spoofing.

Ryan Hamlin, the head of Microsoft's Technology Care and Safety Group has criticized the Bill as being "too broad" and feared for the future of email marketing. He advocates the American opt-out approach which New Zealand rejected as being too weak. In Hamlin's view, the Bill as it is could prevent businesses from sending out emails to people who had been customers. Labelling of advertising emails, for example by ADV in the subject line, would have the advantage that recipients could filter out the unwanted messages.

Conclusion

The Congressional Findings and policy in the CAN-SPAM Act summarised the problem with legislation which has been echoed in all other jurisdictions:

"(12) The problems associated with the rapid growth and abuse of unsolicited commercial electronic mail cannot be solved by Federal legislation alone. The development and adoption of technological approaches and the pursuit of

cooperative efforts with other countries will be necessary as well.”

Regardless of the jurisdiction discussed there are critics of the legislation in force or the proposed legislation. There is no easy answer. The Memorandum of Understanding on 2 July 2004 between the US Federal Trade Commission, the UK Department of Trade & Industry, the UK Information Commissioner and UK Office of Fair Trading and the Australian Competition & Consumer Commission (ACCC), the Australian Communications Authority (ACA) for mutual assistance in the enforcement of spam laws is a major step in the right direction. The ACA Acting Chairman acknowledged that on its own it will not solve the problem but it is an important start.

It is essential that New Zealand move quickly to pass legislation so that it can participate in any future international agreements and that spammers do not see it as a safe haven for transmitting spam. New Zealand has utilised the Australian Act as a model. The question remains why the minor unimportant changes which seem to be of little benefit? An international framework of legislation and law enforcement is required.

A SCADA System Application in Load Management

Ming-Yuan Cho Jung-chin Chen
Electrical Engineering Department
National Kaohsiung University of Applied Sciences, Taiwan
a092304104@cc.kuas.edu.tw

Abstract: The aim of this research is to study the operation and management cost reduction of the telecom industry through the supervisor control and data acquisition (SCADA) system application during globalization, privatization and liberalization competition. Yet this management system can be proposed functions: prevent faults, operating monitors, the analysis on load characteristics and to drop the cost of management.

Results indicated that the SCADA system has been highly willing to mobile and telecom industry in the development of power supply quality and to drop the operation and management cost. Also this research aims at measuring the benefit on SCADA system applications in telecom stations and to provide decision-makers and managers with useful operation and management strategies as reference.

I. Introduction

In Taiwan, the rapid growth of economy as well as the prosperity of industry and commerce, which result in the increase of power consumption year by year. Besides the construction of nuclear power station and power transmission and distribution was conflict with the doubts of their safety and environmental pollution from the general public. Therefore the projects for power development were hampered by these difficulties and the power supply of on-peak hours was gradually insufficient. Thus Taiwan Power Company (TPC) emphasize on the load management of those industries with large power consumption in this duration. There are therefore many papers and relevant reports related to load management of power energy ready for reference [1] [2] [3].

Recently, Taiwan government has been putting lots of effort on joining WTO and developing the operation center of Asia Pacific area. With these regards, how to open Taiwanese telecom market to be freely and internationally accessed by other communities is an important issue. However, the government owned companies deliberate our steps for performing on the international stage, since they have been criticized with low operating performance. Therefore, how to privatize the government owned telecom industry efficiently and efficiently is of major interest for the government and public. Taiwan telecom industry encounters the difficult of operation and management due to the dispersing of mobile stations and communication system. Therefore it is the important policy that how to draft an

effective management method and to drop the cost of management.

The purpose of this research is to apply SCADA system and a feasible load management options for the telecom industry to reduce the power cost from the view point of demand side management.

Now SCADA system applies in telecom stations and mobile stations in Taiwan, the characteristics of management and operation can be proposed such as monitor, control, load management and analysis [4].

II. A SCADA Management Framework Application in Telecom Industry

II.1 The Management Strategy of the SCADA System

In recent years telecom industry has experienced an unprecedented degree of change in management, process technology, customer expectations, supplier attitudes, competitive behavior and many more aspects. Indeed all the evidence suggests that change is now a permanent feature of business environment and that companies which can adapt to this new environment are likely to gain significant competitive advantage.

Thus, using the Porter (1980) generic strategies as a simple illustration, a firm operating an unfocused, differentiated strategy might also be capable of operating a focused differentiated strategy, but not for example an unfocused, least cost strategy [5]. Some transitions between strategies will be relatively easy, others will be more difficult. Abell (1979) suggests that strategy space can be represented as comprising a number of dimensions which might be market, product or technology groups. Within each dimension a number of levels will be open to the organization depending on its strategic competences [6].

Competitive advantage is commonly defined as a position attained by a business unit and perceived by its customers when it is compared with its competitors. They may be characterized as lower cost or differentiation [5]. Focus, which selects one or more segments of the company's advantage and tries to develop competitive advantages, such as A SCADA system.

A SCADA system management framework include: Terminal Processor (TP), Monitor and Controller (MAC), Sensors and Transducer, shown as figure 2.1.

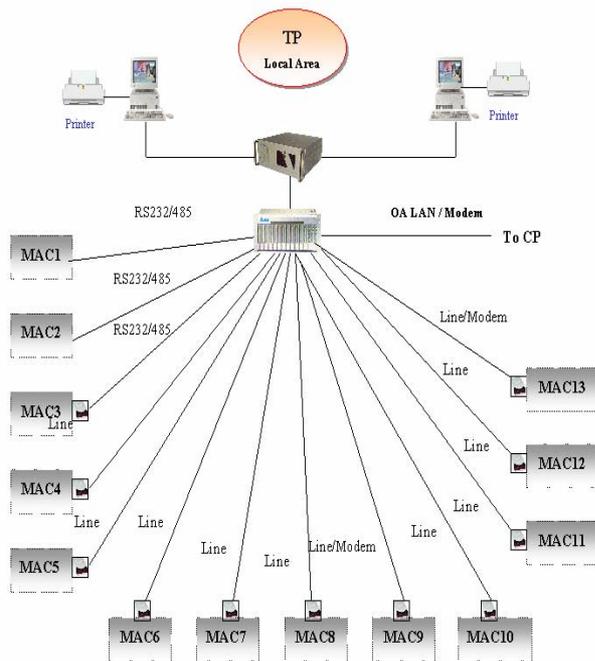

Figure 2.1 The TP Management Framework in SCADA System

II. 2 The Equipment of Monitor and Control in Telecom Station

Monitor And Controller (MAC) provides the interface of monitor and control in telecom station (see figure 2.2) [13] [14].

Alarm items include as follows:

- AC source -- AC current / AC voltage detect
- DC equipment -- DC equipment alarm / DC voltage output
- Air condition -- Air condition operating status and Temperature
- Control Entrance -- Control Entrance detect / Alarm detect

Control item include as follows:

- Air condition control -- Air condition operation / Fan / ON-OFF.
- DC equipment -- DC equipment alarm / DC voltage output.
- Load control and management
- Data collection and analysis

Data collection from SCADA system, the power consumption ratio of each process and power consumption of major equipment in the telecom industry can be analyzed to cope with load management procedure.

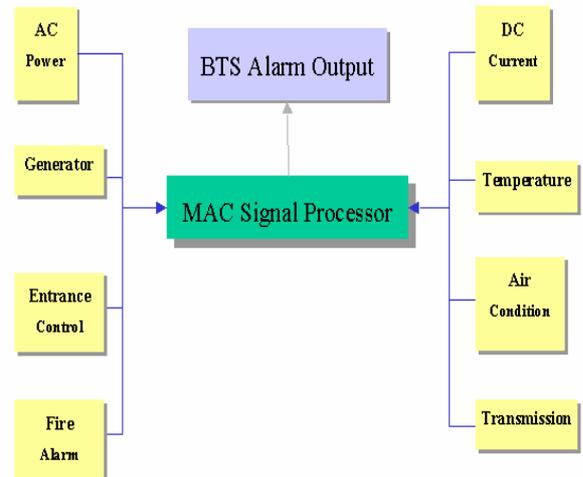

Figure 2.2 The MAC on Monitor and control equipment in SCADA System

III. The Load Characteristics and Rate Analysis

III. 1 Foreword

This chapter will study and analyze the rate policy of Taiwan Power Company. Afterwards the power consumption status of telecom station is observed through SCADA system gathering daily load curve characteristics. In the meantime the electricity rate of customer is served to evaluate its potentiality in the load management participation. This chapter will also discuss the customer's various load factors in order to sum up the power consumption characteristics of the telecom industry.

III. 2 The Load Characteristics Analysis

Generally the implementation of load management centers on price strategy. Assisted with the control of customer load and techniques in changing the power consumption ratio between on-peak and off-peak hours, the goal of price strategy can be achieved by applying various communication and control equipment. Yet the comprehensive and general rates in the price strategy such as demand charge, Time of use (TOU) rate are more complicated. Besides it can be applied to many customers and shall not be changed regularly and greatly. The power industries in the advanced countries adopt localization and selection policy. The target is set on those customers with large power consumption and high power cost. Along with price incentive, the results in the flexible use of power system & resource as well as load management can be attained. This is similar to the rate policy adopted by Taiwan Power Company.

The analysis on power consumption characteristics

Figure 3.1 depicts that the monthly power consumption of sampling customer. It indicates that on-peak power consumption is higher than off-peak power consumption.

For instance, on-peak power consumption in July is more than off-peak power consumption by 300,000 kilowatt-hour. The analysis of power consumption characteristics of sampling customer is as follows:

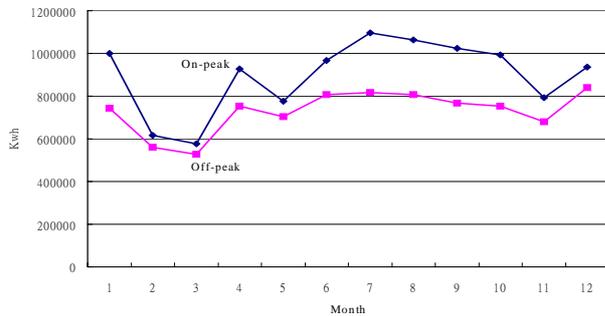

Figure 3.1 The Monthly Power Consumption Kilowatt-hour of On-peak and Off-peak Hours

The daily load curve of sampling customer is shown as figure 3.2, which indicates the power consumption in on-peak and off-peak hours is more than that in off-peak time. In this figure, the load factor in the scope of work day is within 70% ~ 85%, while that of non-work day is 80%.

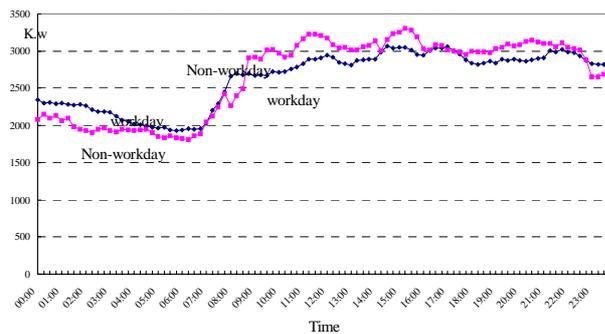

Figure 3.2 The Daily Load Curve

Figure 3.3 is the weekly demand factor of sampling customer. In this figure, the demand factor of work day is small and within 52% ~ 60%, while that of non-work day is about 57%.

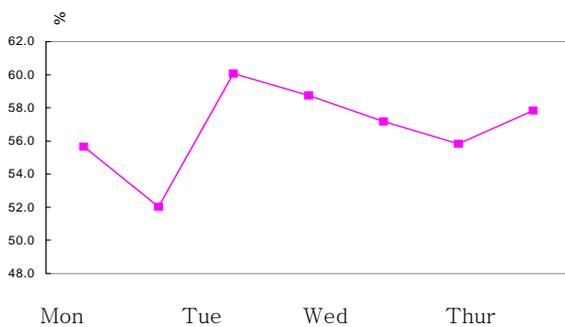

Figure 3.3 The weekly demand factor of customer

In figure 3.4, the demand factor of work day is small and within 52% ~ 60%, while that of non-work day is about 57%.

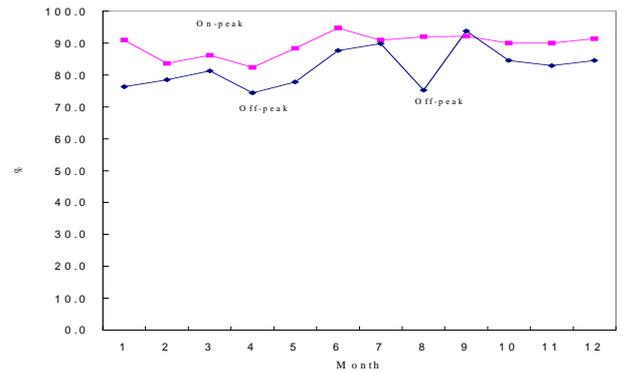

Figure 3.4 The Monthly Demand Factors in On-peak and Off-peak

IV. The Analysis of Load Management

IV.1 The Analysis of Interruptible Load

Taiwan Power Company is proactively engaged in the power development and implements the various load management measures such as the interruptible rate, TOU rate and seasonal rate in continuous effort with the hope that the reliability of system power supply and clipped peak load can be increased. Taking the interruptible rate for example, Taiwan Power Company started the implementation since 1987 and expanded as well as revised its contents year by year. Based on the power system, the six different scope of the interruptible rate is planned for different industrial customer's selection. Besides according to its interruptible capacity, Taiwan Power Company has its demand charge discount, if the customer inks the contract with Taiwan Power Company.

IV.2 The Load Demand Control Analysis

The control method of load consumption is another way to reduce electric cost. The load consumption in automatic control can prevent the customer from penalty of exceeding contract capacity. It means when the power consumption climbs up to the climax, this method can get rid of unimportant load or the interruptible electricity equipment [7] [8].

The rate, which Taiwan Power Company charges to the industrial customer, is the total power consumption in each months, i.e. how much is one kilowatt-hour? In addition, the added rate is defined as "how much is the power consumption climax in one month." The load control device of power consumption aims to prevent the occurrence of new climax with the hope of reducing the added rate.

Owing to the deviation factor, all electricity equipment doesn't operate at the same time. Besides the power consumption is in the status of dynamic variation due to the reasons of the boom-and-bust, season or production and sale plan. The customer has to carry out the control management of load consumption, if the purpose of the economical use on the electricity equipment is required. The monthly power consumption can be reviewed at any time to decrease the electricity cost.

IV. 3 The Analysis of the Optimal Demand Contract

With the rapid growth of air conditioner load, the peak loading of customer in summer daytime period increases dramatically and the condition of peak loading in 15-minute leading demand contract become more serious. According to the electric price system in TPC, customers are asked to pay extra cost with respect to the portion of basic fee in the case that the peak loading is higher than the demand contract. On the other hand the inappropriate higher demand contract setting can avoid the occurrence of previous stated problem but will results another problem of higher basic electric fee payment. The basic idea of optimal demand contract strategy is to derive a better demand contract such that the annual electric basic cost can be minimized.

V. Discussions and Conclusion

V. 1 Discussions

The Analysis of Implementation of TOU Rate (Strategy One)

During the plant visit, the customers expressed their interests in the daily load curve figure of the power consumption. In line with the power consumption and rate analytical figure of on-peak & off-peak hours provided by this research, the customer realizes that the TOU rate measures will save its electricity cost in very short time. Thus the customer participates in the load management options. Meanwhile, the telecom industry will consider how to change process to cope with various beneficial rate options provided by Taiwan Power Company.

Due to the characteristics of process and equipment running, the telecom industry can further implement the TOU rate options.

The Analysis of the willingness of participating the Interruptible Rate (Strategy Two)

The customer usually operates in the full load production. Yet under the recession impact, the actual peak load has already decreased to 75% of the original demand contract or it has been lower than that. It can be realized by introducing between the peak load and the demand contract of daily load curve. It is therefore suggested that the customer should review its actual load capacity to well coordinate with power consumption. The reduction of demand contract or participating the interruptible rate package can be the alternatives to drop down demand charge. Besides the customer can arrange the equipment of the original production equipment under the condition non-full loaded. Meantime the production procedure and time can be re-planned and arranged to avoid the concurrent operation of heavy load equipment which will result in the very high load demand can not be reduced.

Since the customer worries about damaging the semi-product; They will transfer the process to the night and thus increase the difficulties on management.

The Analysis on the Load Demand Control (Strategy Three)

The customer expressed willingness in the load demand control, but the installation of automatic load controller need extra operation cost which therefore reduce the participation willingness from the customer. From the long term viewpoint, this load management strategy will save electricity cost for the customer. After the explanation, the customer can accept the concept and will proceed to implement this alternative.

The Implementation of Optimal Demand Contract (Strategy Four)

In the plant visit, the optimal contract capacity is not well implemented for customer. As the customer roughly estimates the optimal demand contract based on the historical information and doesn't rigidly analysis by the mathematical method. Thus the expenditure of demand changed increase. After explanation and analysis, the customer willingly proceeds the implementation of optimal contract capacity.

V. 2 Suggestions

1. It is suggested that the telecom industry should review the ratio between current capacity and demand contract in order to decrease the demand contract or participate in the interruptible rate package for the reduction of demand charge.
2. It is recommended that the customer should adopt the load demand control to automatically adjust load as long as the load consumption varies so that the peak load won't exceed the demand contract.
3. The final suggestion is that the future research shall focus on the analysis of power consumption characteristics for the various industries with large power consumption.

The Segmentation Talisman - 'Consumption Pattern Strata'

Dhrupad Mathur

Lecturer, Center for Information Technology,
S P Jain Institute of Management & Research, Mumbai
dhrupad@spjimr.ernet.in

Abstract: Since the very inception of marketing discipline, there has been a quest to address the customer meaningfully. From the seller's market conditions to the buyer's market condition, this quest has become all the more prominent now, to the extent that the products and services are supposed to be intrinsically customer focused. Companies are fighting over the tough-to-get market shares.

All this has translated into another endeavor of catching the customers through different dimensions of the possible market implements. Information and Communication Technology has been very radical in transforming the traditional functional processes. Same applies here as well. This paper elaborates, how to develop customer segmentations with the help of IT tools. Therefore, shunning the traditional symptomatic attributes.

I. You Are What You Do

"It doesn't matter where you come from, who you are; what matters is what you do". This is the avowal that is going to change the paradigm of customers' segmentation in time to come. Traditionally, we all have been following the pattern of segmentation variables, which includes demographic, geographic, psychographic & behavioral. Or popularly the customer based, product based and competition based segmentation. However, in pragmatic sense what is more important is to understand the consumption pattern and preferences, because this clearly reflects the potential of a person to get into a segment more meaningfully (*we have the evidence of previous consumption*). To illustrate the concept- Hypothetically, from an international tour operator's customer profile, it is found out that 45% customers are middle aged graduate males residing in north Indian cities with population more than 10 lakhs. This is "what they are". Conversely, if we deduce a relation ship, which indicates that 45% of their customers already had a mobile phone, credit card and a four-wheeler. Therefore, there exists a stratum with a particular characteristic, which signifies that they seek a certain set of values. This is "what they do"

II. Old Is Not Always Gold

The value-based view of any business transaction should be considered. Segmentation is the process of identifying the value, while targeting is communicating the values and

values are delivered through positioning. The very concept of Segmentation is about identifying the values. The existing classification defines values sought in a vague manner. Consumption pattern is more relevant and is of epitome importance as it reflects the values sought and searched by the customer.

Astonishingly enough, the various traditional segmentation variables will automatically be taken care of in a more meaningful manner, chiseling of the unwanted when this stratum is carved out. For example, for person who is a user of both a cell phone and credit cards, there is a greater likelihood that he is at least aware about the various four wheelers available in the market, this chisels away and also gives proper shape to the important traditional segmentation variables like: behavioral – readiness stage, Demographic – age, Psychographic – social class etc.

Adapting the stratum approach will make the application of traditional variable redundant. As, out of the set intersection of traditional variables we search for the segments to be addressed, this refining will reflexively be done when we pick up a stratum dealing with similar set of product value. Therefore making it more comprehensive, addressable, meaningful and pinpointed.

Marketer endeavor to search for the customer preferences by various direct and indirect approaches, while the stratum identification itself speaks of the same. We can have reasons to assume that a high-school teenager, whose family income more than Rs. 1,000,000 p.a. is likely to go to a premium dress material showroom. But can be almost sure that this teenager will be a prospect for this dress material showroom if he is already having a premium segment car, goes to discotheque and is regular Hollywood movie watcher. "Consumption pattern" is the word.

III. Determination of Consumption Pattern and Identification of Strata

Correct identification of Reference groups & strata can be done using data mining and business intelligence. Therefore the businesses of tomorrow will be extending their arms to the customers predominantly relying on the technologies that are able to render very reliable and accurate information in diverse forms and this information shall have varied applications. The Integrated marketing communication will change and he direct marketing efforts will be better addressed.

This approach can effectively supplement the traditional segmentation variables, where the new markets are to be developed and not enough data regarding the existing pattern

is available. This will enable the marketers to address the various segments in a more meaningful and better way, empowering them to evolve the Unique Marketing Proposition rather than only Unique Selling Proposition. It has potential to stand through the dynamics of the business environment daunted by radical technological product innovations and business model obsolescence.

There would be a complete shift of focus from Product based view to the Customer based view of the marketing arm of the business. Not that how they are related to the firm but how they are related to others. Owing to the precision of data mining and exactitude of extraction of information, this stratum approach has tremendous potential to reduce IMC overheads and increase response rate. With ICT proliferation and e-Business adoption, soon its will become norm rather than exception.

Abstract: Inter-organizational systems are only used to some extent within the domain of transportation and logistics. Distributed agent technologies show a large potential to build a new generation of inter-organizational systems that overcome the hurdles earlier technologies were not able to take [2, 4]. In this paper we present an ongoing research project in which we try to establish a WebServices based agent platform to be used by a logistics service provider (LSP) in an inter-organizational context – which will connect the LSP’s internal processes, with processes that span organizational boundaries and therefore is likely to result in interesting process improvements; cost savings and improved competitive advantage are expected outcomes. This paper describes the process we followed, and gives a glimpse of our preliminary findings. We conclude the paper with a short discussion and our research agenda.

I. Introduction

Despite their ‘spider in the web’ character, the domain of transportation and logistics does still only show a limited application of inter-organizational systems [2]. Although sophisticated systems have been arrived and adopted for routeplanning, warehouse optimization and plant control, a widespread adoption of inter-organizational (planning) systems (IOS) is still lacking. Only some of the larger companies actively utilize EDI or XML technologies for integration with business partners, but most companies still use the phone and fax as their primary means for their inter-organizational coordination activities. Most of the solutions that do work, work in a point-to-point context: a direct integration between two companies. Centralized hubs or exchanges show only limited adoption [1].

We hypothesize that in order to get industry wide adoption of IOS several factors need to be satisfied: there is a need to utilize open non-proprietary standards, a need for (cheap) quick connect capabilities, and the system’s architecture should be of a decentralized control type: not giving away ones own business processes, only a basic exchange of data [6, 7, 9].

The Distributed Engine for Advanced Logistics (DEAL) project is a large Dutch government funded long-term research project focused on the creation of an agent based inter-organizational information system for road logistics. Seven partners participate within DEAL [10, 11]. Within the context of DEAL, a wide array of research takes place: ranging from work on performance indicators, to very technical agent technology research, and from mathematical optimization to work on LSP strategies.

This work-in-progress paper is the result of design research performed by the RSM Erasmus University at LSP Post-Kogeko, both partners within DEAL. We describe the approach we followed: from workflow visits to the planning and IT departments, to our redesign, and workshop-sessions that led us to new steps that improved our designs. Finally we give a first impression of the new designs we are developing and are about to prototype within the next months – i.e. we detail a customer linkage we are developing together with Post-Kogeko’s customer CoolControl.

II. Post-Kogeko

Post-Kogeko is a Maasland, The Netherlands, based Logistical Service Provider (LSP), active in distribution, forwarding and transport. This includes, among others the transport of: fresh goods, fruits and vegetables, bread, and sea-containers. Post-Kogeko employs currently around 300 employees, and is constantly seeking for growth opportunities and process improvements. It partners in DEAL, which it perceives as an important development to establish an information processing environment that might help them in better serving its customers needs.

Within the context of DEAL we started a process analysis project with Post-Kogeko, focused on their container transport unit. The choice to focus on the container unit was made together with Post-Kogeko management – its main reasons were the relatively low automation of this unit, its inter-organizational setting with many external stakeholders, and Post-Kogeko’s plans for further growth in this area.

The physical flow in the Post-Kogeko container business is almost always as following: a loaded container has to be picked up at a container terminal in the Port of Rotterdam,

transported to a customer's site, where it will be unloaded by the customer, after which the empty container is transported back again to the same or a different container terminal in the Port – this process is depicted in Figure 1. The (container) planning department takes care of all the work that needs to happen before actual execution can start: it receives the customer orders, handles the paper work with the customs and the terminal, checks whether containers are already available for transportation, and assigns specific

trucks to specific orders.

In principal a relatively straightforward and simple planning process, but complicated by the fact that from the containers that have to be transported during a certain day, only half of these is actually available at 6 O'clock in the morning when operations start. The rest will only leave the sea going vessel somewhere within the next twelve hours. As a result, planning truly has an event based character.

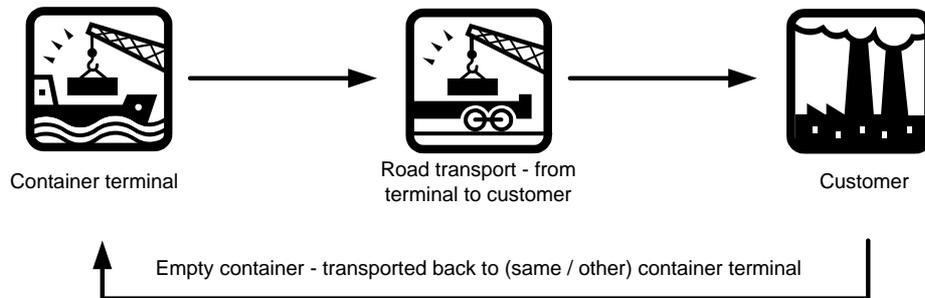

Figure 1 – Basic physical flow of containers in the Post-Kogeko container business

III. The Research Design

The research methodology we followed is a combination of design science as is a usual approach within the computer sciences [5], and action research [3] coming from the social sciences. The objective of our work was to first investigate whether there are actual possibilities and needs for an agent-based inter-organizational planning system within the Post-Kogeko container unit, and if so to move ahead and start designing and implementing such a system.

Two days on the planning floor were our starting point. We were sitting together with the planners, followed and observed their way of working. Meanwhile there was plenty of time to not only observe the way they worked, and the things they did, but also to ask for explanations and all kind of process details.

An in-depth session with the IT administrator responsible for the systems was our next step. He showed us the systems, the integrations, and gave us a login to CarrierWeb (one of the systems) and an Excel data dump of the planning system Qfreight.

Following this, we analyzed the data from the planning system, to further understand the environment, i.e. with respect to inter-organizational dependencies and linkages with respect to both customers and container terminals.

In parallel with the previous steps we worked on process descriptions of the container planning process – UML models, as well as textual descriptions. Our analysis of the business process revealed many small inter-dependent sub-processes, and therefore we choose to model the process in small sub-processes and not as one large integrated process. Having all those inter-dependent sub-processes, we started rethinking each and all of them which lead to some redesign suggestions – sometimes as simple as just automating the

process, sometimes creative solutions were we added new functionality.

IV. Data Analysis

The two days on floor, in-depth sessions at the planning department resulted in a series of UML-diagrams. We choose to model the process in smaller sub-processes, since that was what we observed in practice – furthermore this gives the advantage that it is easier to focus on specific parts. We will discuss the sub processes in order of appearance.

The first sub-process is the order-intake. See Figure 2, which shows the activity diagram for the order-intake. Here the customer sends an order to Post-Kogeko. If Post-Kogeko accepts the order (which they usually do), the order is entered in Qfreight – one of the two IT-systems Post-Kogeko uses. Customers usually sent their orders using fax (occurs the most), e-mail or telephone. In this phase errors can occur, due to manual re-entry of data, e.g. a planner can enter an order twice (which happened). This process can easily be automated using a database webfront or Webservice where customers can enter orders themselves. All what than would be left for the planner is to validate the order and accept it.

The remaining part of the process can roughly be divided into two separate sub-processes. The first sub-process concerns the planning of the first orders to be executed the coming day. This is done at the end of the previous day because of late-arriving orders. The second sub-process concerns the rest of the orders. This is performed in real-time during the day.

The first sub-process contains two steps. First, the planner marks all the orders that need to be executed first, see Figure 3. Customers define time windows for their orders, so this is fairly easy done. In the second step, the planner assigns a truck driver to each order he just marked.

Here the planner takes in mind personal preferences and other parameters of concern. See Figure 4. If there are not enough drivers available the planner asks the other department if they have drivers available. If they don't, they hire charters (which are external carriers/drivers that temporarily are employed for Post-Kogeko).

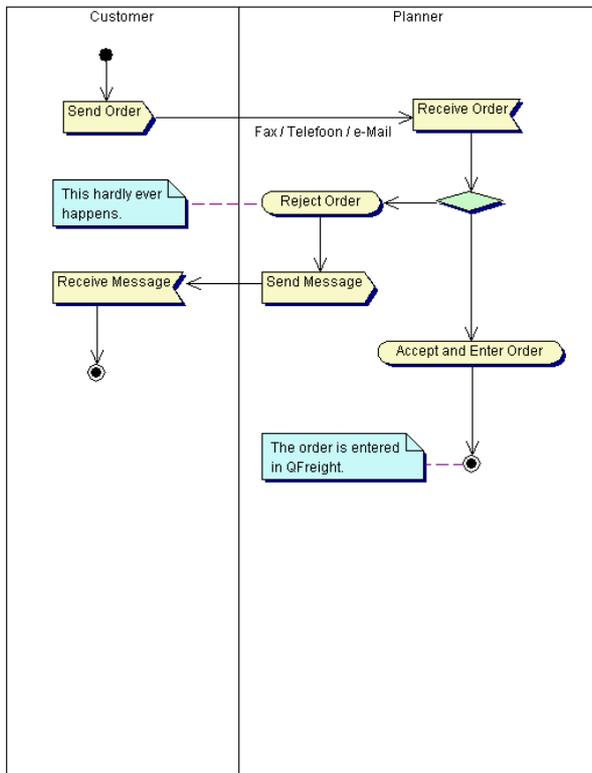

Figure 2 – Order-intake

This process can be automated using a decision-support system. The system could automatically build a list of orders to be executed first. It could also calculate how many truck-hours are needed and conclude that it would save a driver if for example an order is executed later. If you take this one step further, the system could also negotiate with the customer about the time-window the order had to be executed.

The second sub-process is the more complicated one. Here a planner assigns a new order to a driver when the driver is finished with a previous order, see Figure 5. On the one hand the planner continuously monitors the status of a driver (using CarrierWeb). On the other hand the planner monitors the status of a container and checks to see if the custom-papers are ready. Planners can check the status of a container on some of the websites of the terminals where the containers arrive. When both drivers are available and the container is unloaded from the ship, the driver can execute the order. This last part is complicated in a sense that the planner has to anticipate on the arrival of the containers. He already send the driver in the direction of the next order he/she is about to execute. This is also the part of the process where a lot of delays emerge, e.g. a driver is sent to a

terminal and when he/she arrives the container is still on the ship because it is delayed.

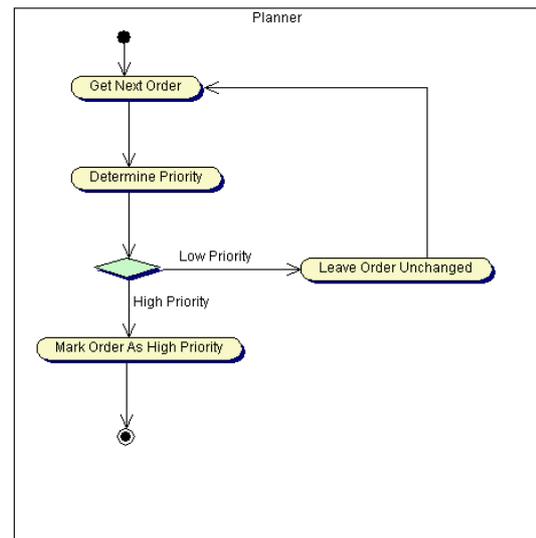

Figure 3 – Set priority orders

This process should be automated using a multi agent planning system (MAS). Within the DEAL-consortium, various parties are busy designing MAS' to overcome the planning problem.

The last part of the process is the order execution. The terminal loads the container and the driver drives to the destination-address. Here the customer unloads the container and afterwards the driver returns the empty container to the return-address (often the same terminal as the pick-up). Once empty the driver gets the next order assigned.

Another part of our process-analysis concerned about an analysis of a dataset of Post-Kogeko's orderhistory. Therefore we received all the orders executed in the first three weeks of 2005 – which accounts up to 1216 orders. Here we noticed some very interesting facts. For example, a small group of customers is responsible for the largest part of all orders. As can be seen in Figure 6, the nine biggest customers (1/3 of the total customer-base) equal 84% of all orders. One note has to be made, this data also contains 408 so called OffHire-orders, which are a special kind of order. If we leave these orders out of the dataset, CoolControl is the biggest customer. We estimate that if Post-Kogeko automates the order-intake process, it will roughly save them about half a day of work for one of its planners. This is the basis to make a prototype of an inter-organizational coupling to the customers.

Another interesting fact we noticed is that the four biggest terminals are responsible for 77% of the orders. See Figure 7. Planners now have to manually check a website of a terminal if they want to know the status of a container. We estimated that if we could realize an inter-organizational coupling to the four biggest terminals it will save Post-Kogeko about an hour a day.

V. Prototype Building

In a focused process workshop with the Post-Kogeko planners and management we went through our process analysis and redesign suggestions. The session was an interesting learning experience for both sides. A concrete choice was made to focus our efforts for the next period on three concrete sub-projects: namely the designing of an event-based internal planning engine, an inter-organizational coupling to the terminals, as well as one to the customers. Pragmatically, we decided to start with the latter, since the first will be worked on in parallel in a larger research effort within the DEAL consortium, and access to customers was easier to arrange than access to container terminals.

Together with Coolcontrol, which is one of Post-Kogeko's top customers, we sat together discussing their process and linkages with Post-Kogeko. We gained insight in their processes, and the way they communicate with Post-Kogeko. Coolcontrol, still largely working with the fax and phone, reacted very enthusiastic to our plans, and committed to work along with us in a redesign and prototyping effort to work on an electronic integration between them and Post-Kogeko.

After having ensured interest from Post-Kogeko in our redesign as well as from one of its customers we can start our design work. Concretely, we plan to utilize a WebServices based process orchestration environment [e.g. Oracle BPEL Process Manager – which is freely available for research purposes], to build a process oriented agent system [8, 9, 12, 13]. A BPEL process, or other specific WebService, can be seen as a light-weight agent, which is possible to trigger and interact with other services/agents. The advantages of such a platform above specific agent toolkits are the ease of integrating with existing systems, the proven technologies and use of open standards.

As we outlined in our research description, the next step was to have a detailed process workshop together with Post-Kogeko planners and management. In this session we validated our models and spoke about some suggestions for improvements and ideas how to build automated support functionality for these processes. In good conversation we decided to focus our design efforts on the design for an internal planning engine (which relates to the sub processes of planning the first and second order), an inter-organizational coupling to the terminals, as well as one to the customers – automating order intake, and giving a customer more visibility in Post-Kogeko's processes.

As the previous paragraph showed, a process redesign with inter-organizational couplings could be very profitable for Post-Kogeko. It not only makes the process more efficient, it also adds additional functionality. We choose to go for an agent-oriented design, and plan to utilize BPEL (Business Process Execution Language) – which is a WebServices based standard for the design and deployment of process driven WebServices. Those WebServices can invoke other WebServices, either inbound within the own organization, or externally to another organization's

information system. Using Oracle BPEL Process Manager we are able to build a service oriented architecture for Post-Kogeko. We utilize the open source application server JBoss as our application server platform, therewith making it of little risk for Post-Kogeko to start using it [since it does not need to invest in expensive server software before experimenting with our pilot system]. As a starting point we decided to look at the order intake process and set up the specifications together with the largest customer CoolControl – a firm active in the import and trade of tropical fruits.

CoolControl is very interested in automated order intake functionality for Post-Kogeko – a process that now still looks like fax-forwarding. Besides the ease of entering orders directly they also let us know that they are interested in a limited track&trace-functionality, e.g. they would like to know half an hour in advance when a container arrives at the destination-address. Concretely they stated: *“currently we call upto 20 times a day, to figure out where our containers are... we would be very much helped with such functionality automated on a website”*. Another functionality they are interested in, is a history of the orders they entered in the Post-Kogeko system. This way, they don't have to store it themselves – something they currently only do to a limited extend.

The next step is to built services that can be accessed via an external WebService or simply manually through a simple web-interface where the customer can log in and place orders, watch its order history, and view the status of orders in execution [container waiting to be picked up, container in transport, etc.].

The next inter-organizational coupling we plan to look at is a coupling with the container terminals. Together with them we plan to build a WebService which accepts container-numbers as parameter and returns the status of the containers – saving large amounts of time of planners manually tracking whether containers are available already. Additionally, a software agent can query the web services as long as a certain requirement isn't met, e.g. container not unloaded – this way avoiding process inefficiencies where containers are available already at the terminal, but not yet tracked/discovered by the LSP to be picked up. Additional inter-organizational couplings that are closely related to this terminal coupling is a coupling with the customs, to track whether paper-work is arranged already, and the container is declared to freely enter for hinterland transport.

Beside these inter-organizational couplings, which basically deal with information exchange, we also consider the actual planning itself. Currently various researchers working within the DEAL-consortium are designing MAS-planning systems. The agents from the planning system will use various WebServices for their requirements. Few are already implemented, and therefore we plan to build some prototype BPEL WebServices in order to get a fully functional system. The MAS systems designed by the different DEAL-researchers than could be relatively easily plugged in and evaluated within the Post-Kogeko context.

VI. Lessons Learned

The transportation industry is an industry with still surprisingly limited automation [10, 11]. And although some parties do use automated systems for their own planning purposes, most inter-organizational communication is still largely a manual process with many data re-entry steps.

Interesting enough, we notice a large availability of sophisticated technologies in the chain; like for example the CarrierWeb system that Post-Kogeko utilizes and that provides every minute an update on the location of all its trucks, the driving speed, the temperature of the cargo its transporting (if needed), and so on. What we however see is that all this information is largely led to human interpretation, and no (automated) intelligent services are build on top of these. It would for example be relatively easy to calculate knowing the location and speed of a particular truck when this truck is likely to reach its destination (i.e. when taking traffic jams into account, a service that can be obtained from elsewhere).

In this research we follow a very pragmatic approach, where we work along with the company stakeholders, observe their processes, and use these as a starting point for our redesigns. Reasoning from these we start small, with very obvious WebServices, but with some of the immediate needs. Perhaps not directly the most interesting parts that provide an intellectual challenge, but elements that are definitely needed in establishing a company wide information architecture, that is relatively easy to couple and link with other organizations – thus enabling a process driven inter-organizational system.

In this paper we show part of our data analysis and process redesign, our ideas for the prototype, and show some preliminary conclusions. Open research questions for the remainder of this research are, among others:

- Can we utilize WebServices environments to establish agent-based inter-organizational systems?

- How useful are such platforms in SME's?

Is this design approach, as described above, a good way to establish such systems in practice?

Abstract: Because of the booming of internet technology and the great promotion internet portal, on-line exchange is more popular in the recent years. This study attempts to integrate concepts of Information Integrate Theory; Anchoring and Adjustment Method to explore the buyer's trade behavior between two different cultures. After observing the historical data on Yahoo's Taiwan and Yahoo's America, the anchoring effect and order effect during the process of a C2C auction is proposed in this study. Chinese buyers seem willing to pay much their attention on pricing during the whole process of an auction than American people do. But, the same phenomenon does exist for American doing a bid on a higher-priced luxury commodity. It sounds for a luxury product, there is a common pricing strategy existed between people of two different cultures. The results provide a very promised direction for knowledge capture and decision analysis for trading, and more works for data mining on pricing for different commodities, cultures, or other kinds of variables related to products and members of market might be a possible future approach for building a knowledge management system for a pricing mechanism for the market.

Keywords: E-service Trading Mechanisms and Market Places; Anchoring and Adjustment Method; Order Effect.

I. Introduction

Questionnaire survey is mostly used to analyze for the studies of physical trading logistic, the on-line trading becomes more popular, which is very different from the physical trading logistic approach in the past and new analysis methods, such as market analyzing, are currently required. Because of the booming internet trade, every country is emphasizing on the development of international internet; however, the differences of cultures do affect the possibility of successful international business. According to the process of trading behavior on the internet, while buyers or sellers offer their negotiated prices, they have often had an initial price in their mind already. The initial price in their mind does refer to the past experience a trader setting up it, and continually presenting some complicated decisions in his brain. Anchoring and Adjustment process in the previous

study is used in this study to model the process of a C2C internet trade and to construct the relationship of a price function and a time sequence functions via a mapping of regressive fitness. So, this study attempts to integrate concepts of Information Integrate Theory; Anchoring and Adjustment Method to explore the buyer's trade behavior between two different cultures. And the historical data of trade on two websites of Yahoo's Taiwan and Yahoo's America is used and analyzed by numerical method.

II. Literature Review

Ackerman [1] reveals the different pricing behavior between Chinese culture and American culture in his physical Logistic study. Graham [6] analyzed the influence of the different cultures on the strategy of negotiation. Clark [5] denoted every country's culture has her unique characteristic. Even many researches have this theory proved, it has no doubt that some scholars also consider the cultural factor is no influence at pricing. Thus, Ackerman explained the reason of no influence at pricing as the culture factor includes too many factors that can't be measured during a complicated pricing negotiation. Comparing Chinese culture with American culture, Jacob [8] pointed out the cultural difference not only has a leading effect on product; but it is actually developed as more influence on the process of trading. Roo's study [10] shows Taiwanese are sensitive to price of personal shopping and tendency of Pragmatism does exist. According to the saving difference in the different countries, the pricing process of trade is very different among the countries they had studied.

Four kinds of pricing were proposed by Wyld [13], they are fixed price, sale price, promoted price, and dynamic price. The dynamic pricing is the one interested in this study. Online pricing is emphasized by incrementing the ability of information swap, electronic commerce is classified four types as auction, haggle, exchange and bidding process. A virtual market as an online auction must have the ability to integrate the demand between buyer and seller, protect the member's right for both side of market, decrease the trading cost and reach the asynchronous of trading target [3]. Based on the difference of degree of involvement for a consumer, the process of his buying decision are very different. A consumer with a higher involvement makes his decision is based on his cognition on a product he wants to buy at first, then changes his attitude gradually before he decides to by it.

But, a consumer with a lower involvement will have his cognition of product firstly, then sooner decides to buy the product, and then changes his attitude of product after buying it.

Payne's research [9] of the structure of human information process addressed that making decision is presented as a function. The effect of decision comes from the characteristic of task itself, such as number of cases, attribute, time pressure and reaction model. A human will refer his belief as an anchoring point, and then try to adjust it with some new information segment. It may be a positive or a negative adjustment. Every new information segment will be combined with an older one to become a new one. It might make the later occurred information having a more weight, thus order effect is happened. More strong points have more effect in the negative information. More weak points have more effect in the positive information [12]. There have two kinds of Anchoring points. The internal point does exist in a decision maker's belief or thought originally. The external point is expressed as common tasks, trade advertisement titles, numbers or texts. Chapman and Johnson [4] denoted a decision maker tends to search some evidences as his decision basis supporting his anchoring point. According to the selective accessibility model, when a human starts to ask and compare, he often is making his selective hypothesis. He assumes that the value of problem is equal to his anchoring point. For example, a bidding participant often applies the market value as his reference point for a target product he is searching for. The hypothesis in his mind is "the initial price is very possible closed to the market price" [2]. The stage of integration and adjustment includes the process from integrating the target and the anchoring point, and then adjusting the anchoring value up to his final decision is made. Information integration theory supporting the reaction of a decision maker can be presented as a function as follows [11]:

$$r_i = w_1 s_1 + w_2 s_2 + \dots + w_i s_i = (1 - w_i) r_{i-1} + w_i s_i$$

r : the decision maker's choice.

w : the weight

s : the estimation of information segment

i : the location of each information.

If a decision maker makes a different weight on each information segment, the order effect will be happened. According to his intuitional rule, a decision maker will start at the first point then adjust to a second information direction in order to precede serial information integration. The lack of adjusting anchoring point is found in the past study [7]. Because a human makes his decision via a psychological process and his behavior does interact with environment. Adjustment of human belief is a serial process of anchoring and adjustment. The original function can be fixed into this situation.

$$r_i = r_{i-1} + w_i (s_i - R)$$

r_i : the belief after receiving information segment i

r_{i-1} : the anchoring point

s_i : the value of information segment

w_i : the weight of information segment i

R : the reference point, it may zero or r_{i-1}

When $R = r_{i-1}$, the function is equal to the last one, but it is different in the symbol w .

III. Research Method

This study attempts to integrate concepts of Information Integrate Theory; Anchoring and Adjustment Method to explore the buyer's trade behavior between two different cultures. So, the historical data of trade on two websites of Yahoo's Taiwan and Yahoo's America is used and analyzed by numerical method. A method with the initial bidding price starting from one dollar is set up to for studying the bidding behavior in an auction for this study. After observing the historical data of trade on two websites of Yahoo's Taiwan and Yahoo's America, the anchoring effect and order effect during the process of a C2C auction is proposed in this study as shown on Figure 1. While a buyer entering the auction website with his own expect price for the bidding product called as a buyer's initial anchoring point. A buyer's initial anchoring point is a reference price point based on his past buying or bidding experience on a related product or process. It is the anchoring point defined in this study. After observing the phenomenon of frequency of offering price on two online trades, Order Effect model is applied to express the process of adjustment between buyers and sellers. In other words, while the bidding desire is increased by a positive effect, then they will try to show up online to offer a higher price frequently and to communicate more often in the bidding product information searching or pricing strategy suggestions on the discussion panel. On the other hand, while a negative effect does occur on a buyer, he might despair or post some negative on the broad. And each bidding price shown on the broad is a market price to a new entering buyer, and it will be an anchoring point to a new entering buyer. So, these bidding reference are dependent and related to each other, the order effect of positive or negative is continuously demonstrated during the whole bidding process for an online auction. It is more quickly and transparent than that for a traditional action. Due to the difference of degree of involvement on a bidding product, a process of anchoring for the pricing sensitivity would distinct into a buyer as a general buyer or an expert. A bidding product can be classified into general, specialty and luxury based on the degree of involvement. Using Information Integration Theory proposed by Anderson to integrate the on-line continuous segments of time series with the segment of entering the process of an auction. And the initial and current effects were shown on a graph and an equation using the statistic method to test its curve.

Therefore, the bidding decision of a series of buyers, as the order entering points of segment were corresponding to function of time with a different weight, can be equated into a pricing curve as the following model. The definition of parameters in the model is described as follows:

$$Y_x = C + W_i Z_x^i$$

$$Z_x = C + V_j X_k^j$$

$A\{X_1, \dots, X_k, X_n\}$: A set of sequence order for n persons in an auction process.

$B\{Y_1, \dots, Y_k, Y_n\}$: A set of bid price from persons in the process.

$T\{Z_1, \dots, Z_k, Z_n\}$: A set of the entering time point of a person for an auction process.

$W\{w_1, \dots, w_i, w_n\}$: the weight of variant in a pricing function, $i=1, 2, \dots, n$

$V\{v_1, \dots, v_j, \dots, v_o\}$: the weight of variant in a time sequence function, $j = 1, 2, \dots, o$.

X_k : the kth person in Set X, $k=1, 2, \dots, p$.

Y_k : the bid price offered from the kth person.

Y_0 : the initial price offered from the seller.

Z_k : the entering time pint of the kth order.

Z_0 : the ending time point set up by the seller.

W_i : the ith weight of a pricing function

V_j : the jth weight of a time sequence function

C : Constant

Pricing Function $Y=G(Z) =G[F(X)]$

Time Sequence Function $Z=F(X)$

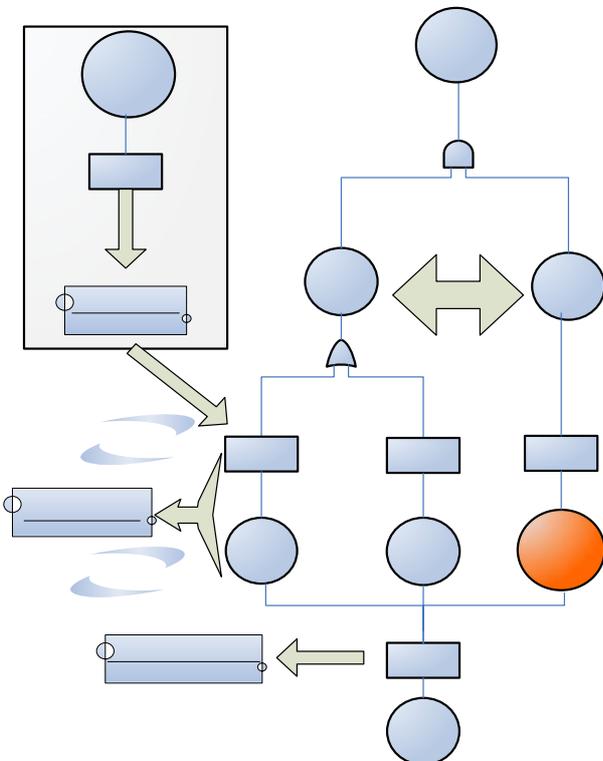

Figure 1 Anchoring Effect and Order Effect during a Process of a C2C Auction

IV. Research Result and Discussion

Using the equations defined in the model, six sets of historical data classified as general, specialty-pro, and luxury-higher price within two counties are applied for running the fitness test, and fitting into linear distribution, exponential distribution, square function with one unknown variable, cubic function with one unknown variable and logarithmic function. Functions with R-square > 0.9 explanatory power were chosen as the results are shown as Table 1, Figure 2 and Figure 3. Based on Bayer’s Rule and order effect, the reference point of an initial bidding was reflected on the pricing while a buyer entering into the process of trade as shown in Figure 3. Comparing on the difference of culture, the degree of pricing participation of a Chinese is higher. Chinese buyers seem willing to pay much their attention on pricing during the whole process of an auction than American people do. But, the same phenomenon does exist for American doing a bid on a higher-priced luxury commodity. It sounds for a luxury product, there is a common pricing strategy existed between people of two different cultures.

V. Conclusions

The findings of this study reveal the equations of a function of pricing related to anchoring and adjustment and a function of time sequence of bidding related to order effect can be constructed via the historical data from the data base of trading on the Internet. The phenomenon of trading online does demonstrate the human’s cognitive behavior. And the decision making on a bidding price online between Chinese and American are different, and there is a common decision behavior existed for some kinds of commodities too. The results provide a very promised direction for knowledge capture and decision analysis for trading, and more works for data mining on pricing for different commodities, cultures, or other kinds of variables related to products and members of market might be a possible future approach for building a knowledge management system for a pricing mechanism for the market.

A Mining-Based System Framework for Deploying Knowledge Maps of Composite E-Services

Jia-Yuan Lee, Chun-Feng Lee, Chih-Kun Ke, Duen-Ren Liu
Institute of Information Management
National Chiao Tung University
Hsinchu 300, Taiwan
E-mail: clay@iim.nctu.edu.tw

Abstract: Providing e-services and composite e-services on the Internet is an important trend of e-business. Composite e-services are complex processes which consist of various e-services provided by different e-service providers. In such complex environments, the flexibility and success of e-business depend on effective knowledge supports to access related information and resources of composite e-services. This work proposes a knowledge map platform to provide an effective knowledge support for utilizing composite e-services. A mining-based system framework is proposed to construct the knowledge map. Moreover, the proposed knowledge map is integrated with recommendation capability to provide users customized decision support in utilizing composite e-services.

Keywords: Dynamic E-service Discovery, Composition.

I. Introduction

With the explosive growth of Internet, more enterprises are providing various e-services for collaborative commerce online to achieve competitive advantages. Composite e-services are complex processes that require the cooperation among cross-organizational e-service providers. In such complex collaborative commerce environments, online user is facing the difficulty of how to select the appropriate composite e-services that suit their needs. Accordingly, an effective knowledge support system is essential to organize and access related information resources in e-service environments.

Many researches have focused on dynamic composition of e-services and system platforms to provide composite e-services [2][4][16][17]. Casti and Shan [4] proposed a model to compose e-services dynamically. Balakrishnan [2] proposed a Service Framework Specification to compose e-services. Several e-service platforms are proposed, for example, HP e-speak [10] and Microsoft .Net [15]. Basic features of these platforms are registering, advertising, monitoring, and managing e-services. However, conventional e-service platforms do not provide effective knowledge supports for managing information resources of composite e-services.

A knowledge map is a visual display of captured information and relationships, which enables efficient

communication and learning of knowledge [20]. Knowledge Maps have been used by enterprises to manage and navigate enterprises' explicit knowledge [5][7][12]. Accordingly, this work proposes a mining-based knowledge map platform to provide effective knowledge supports for utilizing information resources of composite e-services.

A data mining approach is employed to extract knowledge patterns from the usage records of composite e-services. The extracted knowledge patterns, which represent the important subjects and associations of composite e-services, form the kernel of the knowledge map. A topic map standard [11] was adopted to develop the proposed knowledge map, providing a bridge for managing and exchanging heterogeneous resources of composite e-services. Meanwhile, the proposed knowledge map is integrated with recommendation capability to generate recommendations of composite e-services via data mining and collaborative filtering techniques. The proposed knowledge map enhanced with recommendations can provide users customized decision support to effectively utilize composite e-services.

The rest of this paper is organized as follows; Section 2 introduces related work. Section 3 describes the proposed system framework. The architecture and functionality of the system are illustrated in Section 4. Section 5 presents the integration of recommendations. Section 6 demonstrates the prototype system. Conclusions and future works are finally made in section 7.

II. Related Work

Web services and composite e-services. Web services and e-services are similar but Web services place an emphasis on Web technologies. UDDI, WSDL, and SOAP, have been accepted as the de facto standards for Web services [20]. Composite e-services are composed by several e-services, and, intuitively, it can be seen as a workflow. Casati and Shan proposed a dynamic model for composing e-services [4]. Piccinelli and Williams [17] presented a DySCO infrastructure that uses a workflow model as a basis for composing Web services.

Knowledge maps. Successive knowledge map applications take advantages of the nature of visualization and navigation to locating and publishing knowledge [6]. Chung et al. [5] proposed a knowledge map framework for discovering business intelligence to alleviate information overload on the Web. Lin and Hsueh [14] applied information retrieval algorithms to generate and maintain a

knowledge map for virtual communities of practice. Kim et al. [12] proposed a road map to develop knowledge maps in the industrial community.

Topic Maps and XTM. The ISO standard ISO/IEC 13250 Topic Maps defines a model for the semantic structuring of link networks [11]. Topic Maps provide a bridge between the domains of knowledge representation and information management and link it to existing information resources. XML topic maps (XTM) [19] specified by TopicMaps.Org is an abstract model that uses XML grammar to express Web-based topic maps.

Recommendations. Collaborative filtering (CF) [3] has been successfully used in various applications [8][13][18]. The CF method utilizes preference ratings given by various users to determine recommendations to a target user based on the opinions of other similar users. Users' preference ratings are used to compute correlation coefficients among users. The correlation coefficient is a measure of the similarity between two different users' preferences.

Data mining. Data mining involves several tasks for different mining purposes, including association rule mining, clustering, classification, prediction, and time-series analysis [9]. K-means is a method commonly used to partition a set of data into K groups. Association rule mining aims to find an association between two sets of products in the transaction database [1]. The support of an association rule indicates how frequently that rule applies to the data. The apriori algorithm [1] is typically used to find association rules by discovering frequent itemsets.

III. System Framework of Kmap Platform

The proposed knowledge map (Kmap) platform includes two main sub-systems: knowledge map system and recommender system, as shown in Fig. 1.

III.1 Knowledge map system

The system includes four main modules.

Service collecting and planning. This module collects e-service information provided by various e-service providers. Predefined composite e-services are stored in the system. Moreover, the module generates service plan templates to assist users sketch a composite e-service.

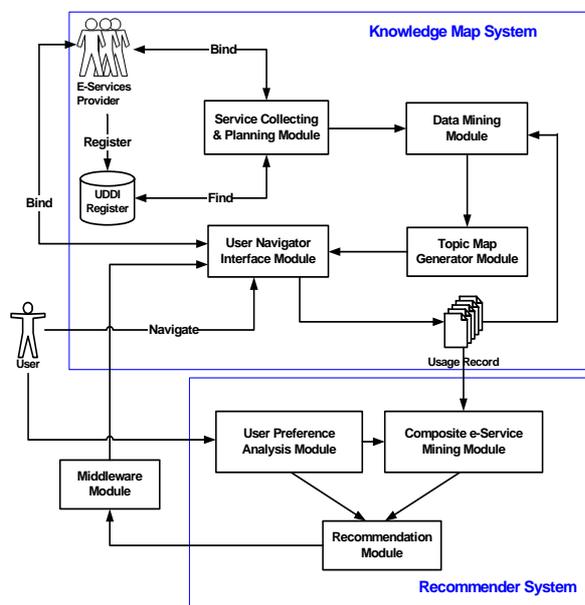

- **Data mining.** Data mining techniques are employed to discover valuable knowledge patterns from usage records and meta-information of composite e-services. The usage records log the historical executions of composite e-services conducted by various users. Important subjects (topics) and their associations of composite e-services are discovered via clustering and association rule mining techniques.

- **Topic Maps generator.** To facilitate knowledge exchange and sharing, XTM (XML topic maps) is employed to construct the knowledge map. The discovered knowledge patterns, including the valuable

subjects and their associations, are used to form the topics and topic associations of the knowledge map.

- **User navigator interface.** This module provides a navigator for user to browse composite e-services and related knowledge patterns by using the XTM-based interface.

FIG. 1. System framework of the Kmap platform

III.2 Recommender system

The proposed Kmap system can recommend the frequent attributes of each basic e-service, the ordering between e-services, and the composite e-services. Group-based recommendations are supported via analyzing the usage behaviors of interest-groups. Collaborative filtering is employed to recommending e-service providers for selected e-services.

- **User preference analysis.** This module uses *pearson* correlation coefficient to compute the similarity between users based on user's preference ratings on e-services served by various providers. The *k-NN* approach is used to derive a user's neighborhood (similar users). Moreover, a clustering approach is employed to cluster customers into interest-groups based on similarity measures.
- **Composite e-service mining.** This module uses association rule mining approach to discover *frequent attributes* of each basic e-service and *frequent ordering* between e-services from the instance execution logs. Moreover, the mining can also be conducted via considering the usage records of interest-groups to discover group-based frequent attributes and frequent orderings.
- **Composite e-service recommendation.** A scoring approach is used to recommend the top *N* composite e-

services according to the mining result. Group-based recommendations are achieved based on the mining result discovered from the usage records of interest-groups. Moreover, collaborative filtering (CF) approach is used to recommend e-service providers for the selected e-services. The CF approach makes recommendations via considering the preferences of neighborhood (similar users).

Middleware. The module is a bridge between the knowledge map system and recommender system. The module delivers recommendations generated by the recommender system to the navigator, while the user is browsing the knowledge map.

IV. Knowledge Map System

Fig. 2 shows the modules for deploying knowledge maps. This section introduces each module in the knowledge map system with details.

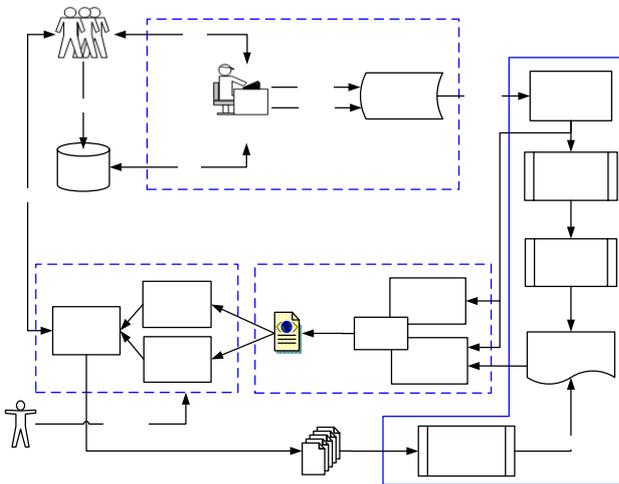

FIG. 2. Knowledge map system

IV. 1 Service collecting and planning

The module provides WSDL documents of Web services to illustrate the services and functions provided in each Web service. E-service and composite e-service information provided by the e-service provider are bind into the service database. Service plan designer can design a composite e-service by composing different e-services registered in the database. Attributes of these e-services and composite e-services are important information resources in data mining module for knowledge discovery.

IV. 2 Knowledge map template

Based on the information in the service database, attributes (meta information) of e-service and composite e-service are extracted for further discovery of knowledge patterns. Knowledge map templates are designed to record

the discovered knowledge patterns.

Meta information. Meta information is information about data which describes e-services and composite e-services. For the rest of this work, we use training programs, which contain series of training-courses (e-services), as the examples of composite e-services to illustrate the proposed work. A training-course generally consists of the following attributes: course name, provider, category, difficulty, location, time period, instructor, hours, and cost. MCS D (Microsoft Certified Solution Developers) is a certification of passing the exams for C programming, SQL server, and so on. The MCS D training program (composite e-service) includes a series of training courses (e-services) for taking MCS D exams.

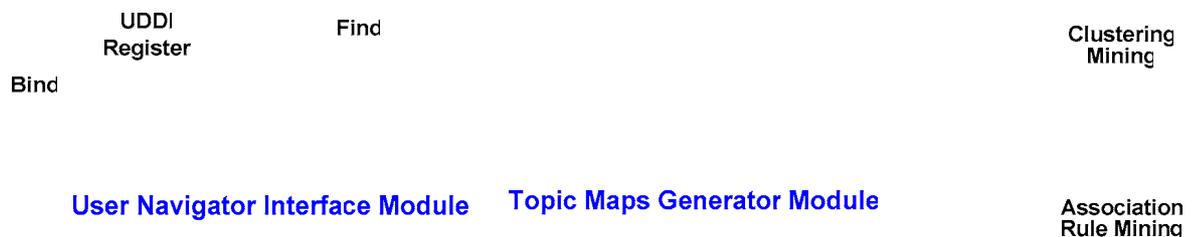

Topic Maps template. We use XML Topic Maps (XTM) [19] to construct the core structure of knowledge map templates. The general attributes for e-services are classified as follows – ServiceName, Provider, Category, Location, Cost and Rating. Moreover, extendable attributes of e-services corresponding to training courses consist of Difficulty, Instructor, TimePeriod, and Hours. Each class of the attributes is defined as a topic type in XTM. The relationships among topics are defined as associations. Several types of associations are defined as follows - Sequence: ordering relationship among e-services; Contain: structural relationship between a composite e-service and its e-services. The association type - RelateTo is defined to link e-services or composite e-services to an attribute. An association type - Relevance is defined to record the association patterns discovered from the mining results.

IV. 3 Discovering knowledge patterns

A two-phase data mining process is employed to discover valuable knowledge patters from usage records and meta-information. The usage records log the historical executions of composite e-services conducted by various users. Clustering technique is used to group composite e-services based on the similarity measure derived from meta information. Important topics (attributes) of each cluster (group) are extracted to represent the meta information of each cluster. Association rule mining is then employed to discover attribute associations (relevant relationship) in each cluster. The topics and associations form the kernel of the Kmap system. The “Relevance” associations between topics are used to recommend relevant topics during the navigations of the knowledge map.

IV. 3. 1 Clustering composite e-services

The clustering assigns similar composite e-services into the same group. The clustering assigns similar composite e-services into the same group. The clustering assigns similar composite e-services into the same group. The clustering assigns similar composite e-services into the same group.

represented in vector space model. A composite e-service's vector contains the meta information of a composite e-service and the union of all the vectors of basic e-services included in the composite e-service.

Calculate the dissimilarity. This work uses Euclidean distance measurement to compute the proximity distance between pair-wise vectors. The Euclidean distance measures the dissimilarity between two composite e-services.

Form clusters. The K-Means clustering technique is employed to perform clustering in which Euclidean distance is used to measure the dissimilarity between composite e-services.

Determine the important topics. A cluster centroid is extracted to represent the major attributes of a cluster of composite e-services. The frequently appearing attributes will form the cluster centroid. The extracted important attributes of a cluster centroid form the topics in the discovered knowledge map of composite e-services.

IV. 3. 2 Mining association patterns

This work employs *apriori* algorithm to find association patterns, namely frequent topic sets, from the usage records and meta information of composite e-services within a cluster.

Association patterns of basic e-services. Such association patterns are discovered via applying association rule mining to the usage records of e-services. The association patterns mainly consist of associations between attributes which are derived from the frequent attribute sets of the mining result. Each attribute corresponds to a topic with a defined topic type in XTM. The associations among several types of attributes can be discovered. The association: Instructor "Nancy" \leftrightarrow Difficulty "Basic" implies that the instructor "Nancy" often lectures courses with "Basic" difficulty.

Association patterns among composite e-services. Such association patterns are discovered via applying association rule mining to the usage records of composite e-services. The association patterns mainly consist of associations between attributes or e-services which are derived from the frequent attribute sets of the mining result.

IV. 3. 3 Recommendations by association patterns

The association patterns imply relevance relationships between topics, and can be used to recommend relevant topics during users' navigations of the knowledge map.

IV. 4 Topic Maps generator

This module generates the knowledge map of composite e-services in XTM documents based on the mining results. The important attributes of basic and composite e-services extracted from each cluster form the topics in XTM. Association patterns discovered from association rule mining form the topic associations. The association type "Relevance" is used to record the association patterns discovered from the mining results. The association type

represents the relevance relationship between e-services or service attributes. Several kinds of attribute associations can be discovered via association rule mining, as described in Section 4.3.2.

V. Recommender System

The recommender system implements two approaches to generate recommendations: collaborative filtering and association rule mining.

Group-based recommendations. The recommendation can be conducted by considering interest-groups to provide group-based recommendations. Customers with similar preferences are grouped into interest-groups. For a customer u , the group-based recommendation proceeds as follows. The instance execution logs of u 's interest-group are used to discover the frequent attribute sets of e-services and frequent ordering sets between e-services. Such discovered frequent attribute and ordering sets are then used to derive the scores of composite e-services and make recommendations.

E-service provider recommendations. Collaborative filtering (CF) approach is used to recommend e-service providers for the selected e-services. The CF approach finds the k -nearest neighbors (most similar users) of u , and then makes recommendations via considering the k -nearest neighbors' preferences on e-service providers and their similarity to u . Through the user's k -nearest neighbors, the system can predict user's preference on an e-service served by a particular provider.

VI. System Implementation and Demonstration

The implementation is conducted using several software tools, including ASP .NET(C#), JSP, Microsoft Visual Studio .NET and Borland J-Builder. Web server is setup on Microsoft IIS 6.0 and Apache Tomcat 5. Microsoft SQL server 2000 is used as the database system for storing related data of e-services and composite e-services. Microsoft UDDI Service is used as the UDDI engine for e-service search and registrations. Moreover, the data mining tool - Weka 3.4 is employed to discover the knowledge patterns as well as frequent attribute and ordering sets of composite e-services. The XTM files for storing the discovered knowledge patterns including topics and associations in each cluster is generated according to the XTM defined in section 4.2 and 4.4. ASP.NET is employed to develop the Web-based navigator which allows users to browse and navigate the XTM information of composite e-services. The Kmap system is integrated with the recommendation capability to provide more effective knowledge support for managing and browsing composite e-services.

System demonstration. The Kmap navigator shows the clusters of composite e-services with attributes of cluster

centroid attached. Once a user selects a cluster to browse, the attribute values of the selected cluster can be browsed further in the navigator. User can browse the topics in the navigator through topics of clusters, "RelateTo" and "Relevance" associations. Once a user selects an e-service "Programming a MS SQL Server 2000 Database", the χ map system displays the detailed information, as shown in Fig. 3. The relevant e-services are also suggested to provide further navigations of relevant e-services. When a user Mike logs in, the system identifies Mike's interest-group. Mike browses the cluster A of composite e-services to decide needed services. The navigator provides the recommended composite e-services which are derived from the usage records of composite e-services conducted by Mike's interest group. Mike can click on any e-service in selected composite e-service to obtain the details (frequent attribute values) of the clicked e-service. The system can also suggest providers to serve the e-service via the collaborative filtering approach.

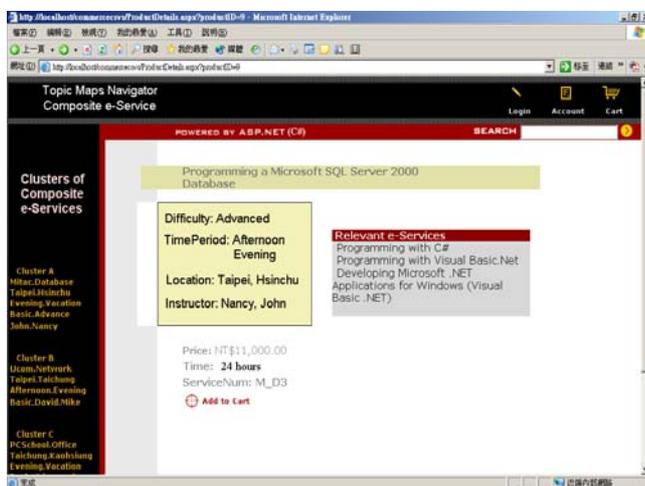

FIG. 3. Navigation with relevant e-services

VII. Conclusions

This work mainly develops a χ map system to provide knowledge supports for browsing and managing composite e-services. Data mining techniques are employed to discover valuable knowledge patterns of composite e-services. The discovered important subjects and association patterns are used as the kernel to generate the knowledge map. This work employs the XML topic maps to construct the knowledge maps of composite e-services. Consequently, the knowledge maps of composite e-services, expressed in XML Topic Maps, can be exchanged and interoperated more easily on the Internet. Effective collaborations of conducting composite e-services over the Internet can thus be facilitated. Moreover, the proposed system provides integrated browsing and recommendations of composite e-services. The proposed knowledge map enhanced with recommend-

ations can provide user customized decision support to effectively utilize composite e-services.

Instructing with Advanced Collaboration Technology: Lessons Learned and Unexpected Transformations

John T. Nosek
Temple University
609-605-9273 nosek@temple.edu

Abstract: This paper provides lessons learned and some unexpected transformations in the learning process when advanced collaboration technology was used to overcome limitations of a popular, existing collaboration technology. The activities pursued in these advanced undergraduate and graduate computer and information sciences courses replicate many of the activities in collaborative knowledge work in organizations. Therefore, the lessons learned should be applicable to transforming other kinds of joint knowledge work in general.

Keywords: Collaborative Learning; Collaborative Support Systems; Collaborative Technologies; Collaborative Work Systems; Collaborative Writing; Electronic Collaboration; Knowledge-Based Systems; Learning.

I. Introduction

This paper describes the use of advanced collaboration technology to improve instruction and how such technology can transform the learning process in unexpected ways. The activities pursued in these advanced undergraduate and graduate computer and information sciences courses replicate many of the activities in collaborative knowledge work in organizations. This paper discusses the limitations of a popular, existing collaboration technology which propelled us to try something new; discusses the co-development of joint artifacts; describes the new technology used; and explores lessons learned and some unexpected transformations in the learning process which should be applicable to transforming other kinds of joint knowledge-work in general.

II. Problems with Current Collaboration Technology

While there is overlap in functionality in collaboration technology, and these technologies can be used in a complementary fashion, it is useful to divide collaboration technology into three categories:

⇒ Technology that overcomes the limitation of people not being in the same time at the same place where they can meet face-to-face and can share common artifacts, such as documents. This includes real time technology such as Instant Messaging; web-, video- and tele-confer-

encing; and application sharing, such as Microsoft's Net Meeting. This also includes asynchronous technology such as email, email and attachments; shared folders on LANs and the WEB; and chat and threaded discussions.

- ⇒ Technology that assists in the co-development of artifacts. Specifically, technology that helps to overcome the social, cognitive, and procedural complexities in planning, creating, evaluating, negotiating, and consolidating joint artifacts.
- ⇒ Technology that assists in the coordination of tasks that can be completed independently but are interrelated to others. This includes workflow and project management technology.

Most collaboration technology seems to be stuck in trying to overcome the limitation of people not being in the same place at the same time [3, 6]. Blackboard™, an electronic version of a blackboard, is a popular collaboration tool used in education that fits within this category. Blackboard™ is the typical portal-based architecture that is mostly used to store various artifacts, such as syllabi, class documents, and presentations; and has little-used add-on tools, such as chats and threaded discussions. In Blackboard™, if one wants access to a document for displaying to and updating by a class, one must typically do the following: 1) navigate to the document through a series of Web pages; 2) download it; 3) navigate to the downloaded location; 4) open it up in the application; 5) modify it; 6) save it to the file system; 7) delete it in Blackboard™; and 8) re-add it to Blackboard™. While the document is available for viewing, the document cannot be jointly edited. This makes it all but useless in real-time and asynchronous interactions. In addition, Blackboard's functionality reinforces a prevailing notion that course documents are static. Is there something limiting in Blackboard's conceptual view of collaborative support as essentially providing a common depository for static artifacts that affects its design and usefulness [6]?

III. Co-development of Work Products within a Collaboration

There must be an intellectual break away from the notion of individual tools that incorporate collaboration functionality in a non-integrative fashion [6]. Joint work products that evolve as part of the sensemaking process include such things as plans, reports, budgets, specifications, architectures, contracts, designs, and software code. Technology must

support all phases [5, 8]:

- **Planning.** Collaborators establish the objectives, structure, and divide up parts of the shared work product to be created.
- **Creation.** Collaborators compose their portion of the joint work product. Although they may work alone, it is important that they are aware of what the other collaborators are doing.
- **Evaluation.** Collaborators review, propose changes, and add comments to each other's work.
- **Negotiation.** Collaborators discuss proposed changes with one another and decide on what changes should be made.
- **Consolidation.** The collaborators resolve conflicts and merge changes into the shared work product.

IV. Transformations to Instruction and Learning

One class is a senior-level, two-semester undergraduate course where groups of students create real information systems for real-world clients; the other class is a graduate course in human usability design. Much of the instruction focuses on experiential learning and deals with the co-development of information system artifacts for a given problem scenario over the course of the semester. Students are then tested in skill-based practical exams and teams apply these skills to design and develop real-world systems. This section describes the evolution of a better understanding of the process of co-development of joint artifacts and the unexpected transformations in the learning process that occurred as a result of using SenseMaker™.

Assessing Progress and Individual Contributions

Universally, instructors who employ demanding group projects find assessment of group progress and individual contributions within the projects difficult. SenseMaker™ can help mitigate these assessment issues by viewing work-in-progress and identifying individual contributions within overall group effort.

Transition Between Asynchronous and Synchronous Interactions Within Class

For the most part, the common notion of class is that an instructor interacts synchronously with his or her students. Usually the class breakout into project teams to work asynchronously. They then post solutions in SenseMaker™ to support transition back to synchronous interaction.

Peer Learning and Transition Between Asynchronous and Synchronous Interactions Between Class

This is similar to within a class, but more pronounced. A major problem in following a problem in-class throughout the semester is the problem of providing some way for the groups to continue to work on the problem between classes and then pick-up with some progression in the next class –

one can't easily save what each group has done on the board or project what one's solution is to the problem.

Several features of SenseMaker™ were invaluable to this process:

- ⇒ **Subdividing.** Artifacts could be subdivided and then assigned to teams to work on in parallel with other subdivisions by other team members. This permitted teams to work on their section and also see how other teams were progressing in their solutions. This also permitted progress on the solution as a whole.
- ⇒ **Suggesting Alternatives.** When class convened for the next section, some group's solution would be displayed to the class. As a class we could review the solution. However, instead of making changes directly to the solution, using SenseMaker™ an alternative can be suggested. This means a copy is made and linked to the original solution. Then, as a class, we could work on the alternative together and save it. Students have available the original result of their thought processes and the corrected version. In this manner, the differences of their understanding and the solution are always available for review.

This process meant almost the complete elimination of the use of the whiteboard in class and Blackboard™ in general. All work was created and available for use by the class. Since exams were practical exams to demonstrate learned skills; some students either downloaded the joint artifacts to their own notebooks for use during the exam, while others made hard copies. In the future, we intend to provide wireless access to SenseMaker™ artifacts during classes, including exams.

Co-development of Joint Artifacts

The enhanced features of SenseMaker™ provided "controlled" co-development of project submissions required of each team. Project teams could subdivide submission documents and work in parallel.

Joint Evaluation

SenseMaker™ permits parallel evaluation where instructor, teaching assistants, and students interact to understand each other to achieve satisfactory evaluation. In situations where the artifacts are created based on some interpretation, the feedback of the creator may be critical in understanding the thought processes. Instead of a black hole until the graded submission is returned, the student can see the evaluation in progress and even provide feedback to assist in the evaluation.

Virtual Nods (vnods)

An assumption behind most collaboration technologies is that face-to-face is the best medium and one must use technology to overcome the limitation of not being able to collaborate in person [1]. However, there is growing evidence that face-to-face interaction may not always be best

[2, 4, 7]. In an effort to incorporate motivational characteristics of face-to-face interactions within asynchronous interactions, SenseMaker™ records the date and time a participant “virtually nodded” by reviewing some content. In addition to the motivational benefit of virtual nods, Vnods within SenseMaker™ helps to controls interaction feedback in a number of ways: First, it eliminates countless numbers of emails that would be needed to incorporate virtual nods on ideas or comments; Second, the instructor “pulls” the information when needed by easily reviewing who in the project/class has visited some content; Third, there is functionality within SenseMaker™ for the instructor to easily “push (send email)” to request a vnod from the whole group or from the subset who has not yet vnodded on something.

Rethinking What is Static and Dynamic

With current web technology that provides the ability to post, there is an implicit assumption that the posted documents are static. For example, prior to using SenseMaker™, a syllabus seemed like a static document that was distributed or posted. However, the syllabus is far from static. The schedule can change. Students can have questions as to what is meant by some aspect of the syllabus. There could be errors in the original syllabus. Using SenseMaker™, the syllabus was subdivided into major subsections and these further subdivided as necessary. When a change was made to a section, only that section was updated. In the usual process, the complete syllabus would be deleted from the website, modified, and then reposted. In lengthy syllabi, it is unlikely that the student will take the effort to see the change; and without vnods, there would be no way to ensure whether the student is aware of the change. In another example, a student posted a question by attaching the question to a particular section. The response was made by the instructor and the section modified. Other students could see the question, the response, and the modification. Through the use of vnods, the instructor can see who saw the question, the response, and the modification. Finally, one can make questions that students have about the syllabus a positive experience. For example, students, who question the clarity of some wording in the syllabus, are encouraged to use SenseMaker™ to suggest alternative wording. This provides an opportunity to provide feedback to improve the syllabus and students gain practice in writing in a more clear style. Those students who provide such feedback can be awarded with extra credit.

V. Summary

Incorporating collaboration functionality in a piece-meal approach as add-ons within a portal-based architecture can limit the potential of collaboration technology to transform joint work processes. This paper discussed the limitations of a popular, existing collaboration technology which propelled the use to try more advanced collaboration technology. The co-development of joint artifacts was discussed and SenseMaker™ functionality was presented. The activities pursued in the advanced undergraduate and graduate computer information science courses replicate many of the activities in collaborative knowledge work in organizations. Therefore, the lessons learned should be applicable to transforming other kinds of joint knowledge work in general.

VI. Trademarks

SenseMaker™ is a trademark of SenseMaking Technologies Corporation. Blackboard™ is a trademark of Blackboard Corporation.

A Qualitative Analysis of Emerging E-Commerce Technologies and Their Effects on Changing Business Patterns

Nadir Ali Kolachi
Institute of Management & Computer Sciences
Bahria University, Karachi, Pakistan
nadir@bimcs.edu.pk
nadir.kolachi@gmail.com
Cell: No: 0320-2010004

Abstract: Technology of different shapes have got much race from 1960 to present. In 1970, the computer technology brought lots of faster modes of business when the faster calculations and saving data became possible. It further innovated the big information systems after 1985 when the manual work started to be converted into computerized means as computer based information systems. But one advent brought various solutions to the business and that is the miraculous advent of internet after 1992.

An internet is one of the biggest emerging Ecom technology which has facilitated the business platform in much faster and flexible standards. Due to the technology the business is advanced at an exponential rate of making life very easy and guiding to be equipped with other technological wonders of not only doing business but increasing education activities, knowledge and coordination through organization to organization and customers to customers.

The purpose of this paper is to identify emerging e-com technologies and get a sneak peak into internet and information literacy related technologies which will pull e-com any time to millions of people and push business to survive on modern business platforms. The study will focus on emerging e-com technologies that have emerged through the last decade or so. It will also focus on the current and possible applications and factors of important view which have brought significant role in business scenario.

The paper consists of five main sections: First is about the introduction, concept and definitions of the topic, Second is regarding the historical perspective of emerging technologies and identification of e-com emerging technologies and their changing phase in the faster pace of information technology and business aspects, Third focuses on the model of e-com and computer technology development. Fourth is about some examples on applications of emerging e-com technologies from available literature survey to support this research, Fifth is followed by the conclusions, recommendations, research methodology, references and bibliography.

Keywords: Emerging technologies; e-commerce an changing business patterns

I. Introduction

History of technology development is long story of electronic business affair but following are some of the important icons which initiated and proposed the emerging technologies development in an IT age.

EDI (Electronic Data Interchange)

EDI concept is the in the emergence since 1960 in US specially. A group of railroad companies concerned with the quality of inter-company exchanges of transportation data formed an organization to study the problems and to improve it. This organization was known as the Transportation Data Coordinating Committee (TDCC). EDI has always been in the help of better business but its high cost standards are complicated and its huge complexities in the application has hindered the EDI popularity in the business. But after the advent of an internet, it is a bit popular as internet EDI activities towards business processes.

Internet & Web.

The internet pushed many companies to be connected with their suppliers, customers and competitors in particular for the purpose of better business activities. This push compelled companies to have web existence to have an edge in miraculous innovations of information technology platforms.

XML and Web service.

XML provides a development tool for defining format of the data interchange in a wide variety of business communities where web service offer an effective architecture for the business and communication initiatives. An XML and Web service are shaping in a very effective manners to all e-com technologies.

DSL

DSL brought an exponential growth in the world of e-com due to its twenty four hours communication across the world. This provides digital communication on copper wire of the local telephone network. This was announced in California 1998 but it has also a unique history when an engineers at Bell research lab devised a way to carry a digital signal over the unused frequency spectrum in 1988 but it got much popularity after the faster pace of electronic business

scenario.

M-Commerce.

The development in mobile and portable gadgets created very easy and flexible platform for companies to provide all commercial activities at their time. Mobile commerce is an extension concepts of e-com which provides the all same facilities in mobile means. This concept was the result of the boom in dot com companies which brought lots of communication on the applications via broad band mobile telephony

II. Online Scenario

In this process, an online ticketing, online banking, online selling and all the results of advancement in networked devices and web services became common phenomena. This became much popular after the areas of internet and had become ubiquitous. The banking sector is much benefited by e-com concepts, the same is the case with trading, companies having an online trades etc. The ATMs facility of banking sector is one of the emerging technologies which is being adopted by almost every body.

Technology has always been a great influence on the business patterns because of its innovation and advancement in inventions. There are lots of technological icons which are responsible to modify the methodology of business trends but computer related technologies are the major controlling icons on the world's business desktop.

Following technologies are considered as important factors.

Computer Technology (Software Based)

- Information Technology
- Information Systems
- Information Superhighways
- Information Literacy
- Information Layers

Computer Technology (Hardware based)

Computer Systems

- IT Systems
- Machines
- Man-Machine Interface
- Network Gadgets
- Communication devices
- Mobile Phones

Business Related Technologies

- Electronic Commerce
- Electronic Business
- Electronic Marketing
- CRM
- ERPs
- SCMs

The changing business patterns are the results of customers' knowledge and preferences. The customers who are information literate and have an access to modern communication methods can check the competitor's

products and order them to get products with in no time. Such thing pushes the organization to change the outdated business styles but adopt the one which is most compatible with the needs of the country.

The major changes occurred because of the following business and technological flow which mainly started after 1970 with the introduction of microchip which brought lots of capacity of maintaining and preserving customers data, faster calculation and accurate methods. This other change submerged when the information systems go much popularity of changing manual information systems towards computer based information systems.

The third one which brought lots of other changes and turned the world into one village was the miraculous advent of internet. This technology facilitated the business organization to have web existence and ubiquitous scenario. This gave birth and flourished other wonderful emerging concepts of emerging technologies.

The technologies like electronic Business, electronic commerce, and mobile business and commerce. Such flexible and worldly available facility convinced many organizations to work for eruptive and disruptive concept of technologies and started to produce not only one product line but to come up with multiple product line offerings. For example, companies who were doing internet facilities came up with software, information system packages, providing compatible machines etc.

In this way the competitors started and all companies dived into the domain of designing strategic packages and acceptable product differentiations having an hawk's eye on the competitors strategies and predictive plans. Such competition brought a very good flow of choices for the customers and the power which was with the sellers shifted to buyers because of the countless choices in every domain of items.

Despite of tremendous accomplishments of internet and communication technologies, it has also been observed that world's major business activities depend on full integration of the globe.

Customers know the product but want to reach it with in no time. In this way, companies look for such kind of solution that can satiate the need of the customers immediately, that's why companies joined the party of major business trends which include greater pervasiveness of computers continuing convergence of computing and communication, greater automation of work, faster pace of business, accelerating global competitiveness and gradual acceptance of global standards.

Following is the model which explains the trend of technology from 1960 to present indicating the changing business patterns due to the advancement in computers, information technology and e-commerce which created a base for emerging definite technologies named as emerging e-com technologies.

Technology	Years	Emerging Technologies	Business Patterns
MRP MRP-II	1960s	EDI	Coordination, Simple processes In HRM and Engineering
Computers Microchip	1970s	EDI, Terminals and Computers	Faster processes, Faster calculation Methodology improved
Information Systems	1980s	Information Systems, MIS, CBIS, ESS, and DSS	Manual Information, Coordination and other business activities, communication flow from first line to middle and top level managers
Internet Electronic Commerce	1990s	Internet, TCP/IP, WEB services, DSL, Gateways SSL and SET	Modern information Systems (ERPs), Global village, World connectivity, World coordination, Online business, CRM and SCM.
Mobile Commerce	2000 to present	Wireless, WAP Mobile technologies Micro browsers	Mobile business All activities of e-com into the mobile means
Eye Blinking Business	Future	Eye rays Eye as an infrared	The time will come when a man will blink and the transaction will happen.

The model explains the historical background of technology identifying the pace by emerging technologies which pushes to flat the business patterns in different organizations and countries.

In 1960, when the MRP (Material Requirement Planning) was being used for the purpose of coordination at smaller level in the organization and the usage of EDI was possible at that time but at lesser scale. After a while it got much advancement in coordination patterns and expanded from coordination towards faster process and faster communication

The 1970s is the most memorable time because of the introduction of micro chip which exploded the world

computer technology and provided us with the faster pace, faster calculation devices and methodology of other fields was improved at satisfactory level. In this time, the EDI was also in use.

In 1980s, the time of information systems got much popularity when the manual information systems were converted into computer based information systems and many middle managers started using MIS, DSS and some ESS to know the complexities of maintaining data and communicating to top level hierarchy for structured and unstructured decision-making

The year 1992 is the most historical icon because of the miraculous and God gifted innovation of Internet which brought all human being together all over the world and people started sharing data, retrieving information and knowing what is being done in other countries of the world. This brought lots of concepts of information superhighway and technology which also facilitated the platform for electronic business using TCP/IP for simple communication and SSL & SET protocols for secure business transactions. This got world connectivity, communication, better relationship and reaching customers within seconds.

The era of 2000 and onward is the era of mobile connectivity, all which is possible by e-com and is converted into mobile means because of the advancement in universal mobile communication technologies.

Every time, whenever we get across with the technology innovation, we come across to know that another small form of computer has arrived in the market and all software can be merged in it and facilitate us with almost all things which are possible through desktop, laptop and palmtop computers.

The future is the talk of innovating smaller sizes and shapes of computers which may contain everything as communication, business transactions and sharing heavy data in particular. The futuristic amazing and interesting thing will be that small shape of technology or computers which may easily accommodate in our eye, so it will be as Eye Blinking Business when humans will look to do a transaction, they will just be required to blink and the moment they will blink, the transaction will take place. We can imagine anything and any thing can happen. Thanks to the inventors, developers, technologists, teachers and researchers for bringing every time some thing very amazing.

III. Applications of Some Emerging Technological Activities

Following are some examples where emerging and different computer and IT related activities which are taking faster paces to modify the business methods.

- The companies such as General Motors, Sears and K-Mart also addressing the inefficiencies of inter-organizational document movement by using their own electronic (but proprietary) systems with their major trading partners. By the mid 1980's, K-Mart's system-

EPOS was being used by over 500 companies. Where was the problem? The problem lay in the fact that each system was specific to the company that in a proprietary sense had no standard except. A hypothetical company in the late 1960s doing business with GM, Sears and K-Mart therefore needed three different system interfaces to cope up with such complexity and they got solution because of systems providing common interfaces.

- The story with the grocery industry was different. One EDI historical example is Super Value, a large American grocery chain. Because they had to first deal with larger "within-the-company" EDI issues, they recognized early on the need for industry specific standards. They felt that a universal standard was impractical and unnecessary for the technology levels that were available and the extent of their needs. In the 1970's, several industries sponsored a shared EDI system that they usually turned over to a third party network. In some cases, the shared system was developed by the third party for the group of common companies or industry trade group. Examples of this early sharing include IBM IVANS, which the U.S. property and casualty insurance industry sponsored. Another was ORDERNET, sponsored by the pharmaceutical industry.

These industry trade group systems had the same disadvantage as the company proprietary EDI system: they were standard, but limited in scope, and unable to communicate with other trade group EDI systems. (ORDERNET, for example, could not communicate with the transportation carrier's EDI system.) In 1973, the TDCC decided to develop a set of standards for EDI between companies and to invent a so-called "living standard"-i.e: a standard that included standards on how to change the standards! This resulted in the first inter-industry EDI standard in 1975 covering air, motor, ocean, rail and some banking applications. What evolved included generic formats for general business ANSI X12, first published in 1981.

- European development of TRADACOMS, ODETTE and JEDI started around 1984. In 1985, work started on EDIFACT (EDI for Administration, Commerce & Transport), an international standard through the auspices of the United Nations.
- Federal Express executives say that in some areas, the company increased productivity 30 percent in the early 1980s when it launched its Digital Assisted Dispatch System. FedEx was able to more efficiently route pick up and deliveries, keeping couriers on the road. Coupled with the Super Tracker, a handheld device that communicates location, shipping, and other information about deliveries to customers and FedEx, the company was able to pick up and deliver packages in real time after 1986. One of the immediate benefits was that the wireless system eliminated the need to write down numerous addresses per day, saving time and money.
- Office Depot teamed with Aether Systems to develop a way to track the retailer's vehicle fleet and to capture customer signatures via a Palm- or Pocket PC-based handheld from Symbol Technologies. Office Depot cannot charge a customer until a signed bill is logged in the system. With the mobile device, the signature and bill are shipped to the Web and delivered, in real time, back to the customer. The system has rapidly improved Office Depot's cash flow.
- Networkcar is taking advantage of legacy technology and warehoused information and transporting them to a wireless world. The newly launched company sells a plug-in device that connects to computer diagnostic ports that are standard-issue in cars made after 1996. The device beams vital signs to a dealer, who can remotely diagnose or spot trouble. The advantage is that dealerships can achieve competitive advantage by maintaining a closer bond with their customers.
- Kemet Electronics is the nation's largest manufacturer of tantalum capacitors (small heat- and corrosive-resistant components that regulate electricity in devices such as radios and DVD players). The firm made a deal with IBM's pervasive computing division to deploy a wireless network that allows its sales force to access Lotus-based e-mail, calendar, scheduling, and other corporate information through PDAs, pagers, and cell phones. The system has increased the effectiveness and efficiency of Kemet's salespeople.
- California utility firm, Sempra Energy, is equipping its engineers with wearable computers. The engineers currently return to an office to enter information about heating, ventilation, and air conditioning units run by big users such as hotels. The wearable computers allow engineers to transmit and receive data and to make necessary equipment adjustments without leaving customer sites. The company says the devices will save a "ton of money."
- iMetrikus is an online medical treatment provider that is planning on taking their monitoring services mobile during 2001. The company allows doctors and patients online access to medical records. Patients can report any medical problems and update their health-care provider on what type and quantity of drugs they are taking. This is information that physicians routinely monitor. One iMetrikus client, age 62, checks his blood-sugar level as many as eight times per day, regularly uploading results onto the Web so his health-care provider can monitor his status. When he is on the road, which is often, he ducks into cyber cafés when possible or stops at public libraries to obtain some free Internet time. He complains about the trouble he has maintaining a virtual link to his physician when he is on the road – a link that grows more tenuous the deeper he goes into back roads. But he sees hope in wireless. As a Verizon cellular subscriber, he says he had a decent connection throughout most of his travels, although reception was spotty in parts of Canada.

The above examples have been collected from the available literature survey to support the concept of this research and to identify some emerging e-com technologies aspects in this fast paced changing technological era.

IV. Research Methodology

The research is an exploratory in nature which is based on literature survey, observation and some unstructured interviews to explore the nature and development of emerging e-com technologies in the developed and networked e-arena. Since the literature on e-com emerging technologies is not much available, therefore electronic communication, electronic business. Computer technologies and its development and strategic methods are mostly studied to reach and find the proper data of the topic.

V. Conclusion

Emerging Ecom Technologies are always at the pace of development because of the compatible development in other computer and IT related technologies. But emerging e-com technologies will always be on the top because of the major pertinence of business activities.

Such technologies are always a very interesting topic for IT specialists to innovate and adopt for the betterment of business. In this way the technology adoption of prevailing

trends and needs have become an essential part of today's top notch gurus of the organizations.

VI. Recommendations for Prospective Companies

- Companies must be fluent with the flexible and worth adopting emerging technologies in order to achieve an edge in various issues.
- Companies must adopt the changing patterns of emerging technologies with the faster flow of technological advancements in the areas of networking devices and databases in particular.
- Companies must cope up with an IT strategy of updating some major information layered processes which are very much pertinent with modern business and strategic analysis of technology decisions.
- Companies are required to watch changing business patterns through the study of consumer preferences and their trend towards technology regarding e-com and m-com positions
- Organizations of today's age are also required to have IT experts having enough knowledge of current IT systems as to avoid from any delay to the adoption of emerging e-com technologies

Strategic Application of E-Commerce for Customer Satisfaction: A Study with Small Businesses in Korea

Choong Y. Lee

Department of Management and Marketing, 1701 S. Broadway, Pittsburg State University, Pittsburg, KS 66762
Phone: 620-235-4588, Fax: 620-235-4513, E-mail: lee@pittstate.edu

Abstract: Recent development of information technology has brought dramatic increase of strategic use of information system in businesses all over the world. This paper will examine e-business application for customer satisfaction especially in Korean small and medium businesses to illustrate the major impact of information technology on small and medium sized firms in Korea, find out the roles of e-commerce within their supply chain systems in those small and medium-sized enterprises, and then, identify major barriers that prevent Korean small businesses from entering into e-commerce. Finally, this paper will propose an analytical framework for e-commerce penetration into small firms as a guideline of future applications in similar cases.

I. Introduction

There are few articles published on the applicability of e-business and its practices in small and medium-sized businesses. Most of research studies focus on the U.S. or Japanese businesses, with little thought being given to their applicability to small businesses in other less developed countries, such as Korea.

Small businesses are very different from large ones in many areas, such as management style, production processes, available capital, purchasing practices, inventory systems, and negotiating power. However, the nature of E-business suggests that application of e-business to small businesses may work well as it does for large ones. Some of the e-business elements and programs appear to be more compatible with small businesses. Some benefits from e-business may be relatively more significant to small firms. In addition, most small firms may be suitable for applying e-business because of its basic features.

E-business elements can be classified into two groups: (1) those that are independent of the size of firm, and (2) those that relate to the size of firm and may be more difficult for small businesses to employ. Actually, many small firms all over the world have already implemented lots of e-business elements in their daily operations of business.

Most of earlier researches focused mainly on the potential of e-commerce and its general impact on business activities, but few studied effective models of e-commerce for companies different in size, nature, country specific location, and other characteristics. This study, in order to construct a reasonable business model of e-commerce for small and medium sized companies, will focus on clarify the

characteristics of small and medium sized firms in a dynamic economy of Korea.

Earlier researches talked much about the potential of e-commerce and its general impact on business activities, but they did not mention to an effective model for small businesses. Because small businesses face much more obstacles than large companies do, the model that is fit and effective for small businesses may quite different from ones for large enterprises. This study, in order to construct a reasonable business model of e-commerce for small businesses, will focus on clarify the characteristics of small businesses in new digitalized economy, referring to some cases in Korea.

II. Existing e-Commerce Distribution Channel Models

Literature review shows that there are a number of categories of e-marketplace. It refers to the firm that operates an e-marketplace as the "intermediary", which may be a market participant, an independent third party of a multiform consortium. It further differentiates the market participant into a friendly participant, a hostile participant, a single-buyer participant, or a single-seller participant. It also classifies e-marketplaces into three categories: the e-broker model, the manufacturer model, and the auction model. It also looks into the success factors of an e-marketplace as strategic factors, technical factors, and functional factors. Strategies include first-to-market, brand establishment, customer focus, targeted marketing, outsourcing, and development of a customer or user community.

E-commerce is now another channel to market or sell to customers and consumers. Websites and emails are the two main e-commerce applications that are used together to promote and advance the selling process to closure. Grasping the knowledge and know-how of applying these powerful tools will help small businesses benefit from e-commerce.

There are several ways that websites can be used as a new sales channel for a business. They are websites sales models, sales support websites, e-catalogue and e-marketplace. Beside website, another powerful application – emails can be used for generating traffics to websites and supporting the sales process such as using periodic email, mailing list, mail attachment, and so on.

Enterprises may change their business model into one of above mentioned models of e-commerce distribution channels, based on the following four factors: (1) characteristics of the firm; (2) competitiveness and management

strategies of the firm; (3) influences of internal or external parties on the adoption decision process; (4) characteristics of new model adopted. For small businesses, the adoption of e-commerce model may depend on the fifth one, considered as the most important factor, the innovative attitude and knowledge about IT of the CEO.

III. Korean Small Businesses and their Distribution Systems

Small businesses have contributed significantly to the economic growth in many countries all over the world. They have accounted for a large share of total employment in those countries. However, in Korea the success of large corporations, so called "Chaebols" or conglomerates, has been well acknowledged. During the last three decades Korea achieved prominence in every industry, especially in manufacturing, based mainly on large corporations. They played a vital role in promoting rapid growth during Korea's economic transition. However, since the financial crisis in Asia in 1997, Korean large corporations have been blamed as a major source of the economic crisis in Korea. The national strategy of economic development based on large corporations had seemed to be successful until just before the crisis, but actually created lots of social and economic problems behind the success stories.

The new economic environment after the economic crisis in Korea makes it increasingly difficult for Korea to continue economic development based on large corporations. With a high unemployment rate due to the recent economic crisis, small businesses have received more attention than ever in Korea to provide steady economic growth with employment opportunity as the Korean government adopts strong policies and programs for the promotion and development of small businesses. Fortunately, Korea now understands that small businesses can exert a strong influence on its economy, particularly in the fast-changing and increasingly competitive global markets. Korea believes that small businesses can be a major engine of economic growth and technological progress in the future. Small businesses are often more fertile than larger firms in terms of innovation. The features of small businesses, such as flexibility, innovativeness, and problem-solving action orientation, are now being considered as vital for success in the Korean economy.

With the new government policy for promoting and supporting small businesses' application of information technology in their operations of daily businesses in Korea, Korean small businesses may be more encouraged to adopt e-commerce than small businesses in other advanced technology countries. However, one of the initiative factors that impulse small businesses into engaging e-commerce is the way to reach customers' needs and wants, and serve them in high level of satisfaction. This factor is now familiar with small businesses, especially in such a competitive market. Next parts will discover the distinctive characteristics of Korean distribution systems in order to clarify the

way that small businesses use to adopt e-commerce in Korea.

Like in Japan, most Korean businesses have multi-layered distribution systems which are quite complex and costly. It results in a supply chain in which most products change hands at least two or three times before reaching the retail outlet, consumer prices rise up and the productivity of retail sector is quite low. Korea has far fewer department stores and general merchandise super stores per capita than most of developed countries. Actually, it has much more other retailing stores per capita.

'Chaebol' refers to a unique form of Korean conglomerate. A chaebol is a grouping or family of affiliated companies that form a tight-knit alliance to work toward each other's mutual success. This system is also based on an intimate partnership between government and businesses. It can best be understood as the intricate web of relationships that links banks, manufacturers, suppliers, and distributors with the Korean government. Korean Chaebols operate globally and are integrated both vertically and horizontally.

IV. E-Commerce as a Competitive Tool for Korean Small Businesses

Even though the history of e-commerce in Korea is not long, more Korean businesses have tried e-commerce in their operations recently. The characteristics of Korean e-commerce is that the major companies who enter e-commerce market are mostly huge or big companies which have large capital and enormous potential human resources to be mobilized for both delivery and information technology. There may thus be a particularly strong rationale for governments to address the problems that impede small businesses from adopting and using electronic commerce. And this is also the reason why the adoption and use of e-commerce raise special issues for small businesses.

Unlike small firms in the US, which tend to operate independently, Korean small firms usually work for large corporations or engage in special relationships with Chaebols, such as subcontracting. To adopt e-commerce as a new high-tech marketplace these business alliances still facilitate small businesses to acquire various knowledge of new technologies.

It is obvious that although the potential of e-commerce is quite persuasive, however, number of companies, especially small businesses, which have engaged in e-marketplaces, is rather limited in Korea. Lack of access to bank loans and venture capital, shortage of skilled workers, and low level of business and technology skills are cited as reasons for the difficulties in adopting e-commerce of small businesses. Reasons are including the trustworthiness of on-line activities, lack of financial resource, and so on.

The emergence of intermediaries has contributed to the fast development of the B2B e-marketplaces in Korea. An intermediary usually is a company that provides the technical expertise to develop and/or set up a multi-buyer, multi-seller electronic market. An intermediary can also be a firm, which shares its TPN with other companies, and

thereby facilitates and controls a B2B solution. Kannan, Chang, and Whinston (2000) describe five ways that an intermediary can add value to the market: (1) researching buyer information needs, (2) acquiring relevant information about products from suppliers, (3) managing intellectual properties and copyright, (4) authenticating information suppliers, and (5) complementing, processing, and adding value to information products. They indicate that electronic communities are increasingly called upon to play the role of intermediaries. These e-communities consist of a critical mass of members whose needs are mainly commercial and who use the communities mainly for networking and building business relationships.

IV. 1 Buyer-Driven Catalog and Bidding Solutions

Buyer-driven solutions are systems that manage procurement by posting Request for Quotes (RFQ) and inviting bidding, or by allowing access to approved suppliers' products and services on the buyer's internal computer networks. Requisitioners of the buying company can make purchases from preferred suppliers on their company intranet, within limits of automatically enforced buying rules set by purchasing management.

Besides the generic benefits of e-procurement that were discussed in the Introduction, automated order-entry eliminates errors and accelerates the approval process. The buyer-driven system also supports an on-line catalog that limits the range of suppliers in order to avoid "maverick purchases," the purchase of items that are not from authorized suppliers or items that are not offered at the negotiated price. The solutions also help capture purchasing data within the buying company for further analysis and review. For the vendor or intermediary who provides the B2B solutions, it is important to serve as a consultant to help the buying client develop RFQs, qualify suppliers, or set up and manage bidding events.

IV. 2 Third-Party Catalog and Trading Exchange Solutions

A third-party B2B solution can include a collection of electronic catalogs of multiple suppliers that can be accessed and searched through one site (portal) by multiple buyers. It can also host auctions and bid-quote exchanges. Third-party sites are also called electronic market places, vertical portals, and electronic commerce hubs. Most of these third-party solutions focus on industry-specific vertical markets. These solutions offer a variety of applications for negotiation, bidding, payment, and display. Selected sellers and buyers can also form private networks based upon membership with a third-party solution.

To a buyer, third-party solutions offer an economical way of accessing the most up-to-date catalogs while reducing web-site hopping search of suppliers. They are especially popular for commodity products and fragmented markets with well-defined buyers and sellers such as steel, chemical, plastic resins, and plastic and paper packaging products. To the sellers, third party solutions create market

liquidity with a critical mass of buyers.

IV. 3 Seller-Driven Portals or Extranets

A seller-driven solution is a sellers' web site or extranet that provides electronic catalogs and allows on-line ordering. It is another type of the multi-lateral IOIS, a Broadcast Sales System developed by a seller. The benefits are quite general, such as the ability to check order status, confirm pricing, confirm payment or delivery, access technical support, register for seminars, and so on. These benefits can also be found in the buyer-driven and third-party solutions. In this type of system the seller has the highest control over product offering information and the trading process. This type of solution can often be developed more easily and quickly than the first two types of solutions because it can build upon pre-existing trading relationships. Though many larger supplier companies are developing their own seller-driven solutions, small businesses can use purchased solutions to bypass complex and expensive EDI requirements to level the playing field.

IV. 4 Value Chain Management Solutions

The above three types of B2B solutions are primarily designed for making the trade happen, that is, matching the buyer(s) with the sellers(s). Some degree of "integration" is possible between the IT systems of the trading partners, and they vary across the three types of solutions. However, value chain management (VCM) solutions focus on the integration of business processes between trading partners after the purchase contract is signed. These business processes tend to involve the exchange of more frequent information over the life of the contract. They usually include order processing, manufacturing planning and scheduling, and logistical planning.

Some VCM solutions specialize in enhancing customer relationship management. These solutions integrate the sales, marketing, and service functions of the seller firm to unify their transactions to support a customer order. Such capabilities improve both customer satisfaction and efficiency and control for the supplier/seller. On the other hand, other VCM solutions strive to integrate a manufacturing (a "buyer") firm with its suppliers. These kind of solutions serve as decision support systems to help the manufacturing company optimize its production and logistics network configuration and synchronize day-to-day interactions with its suppliers.

V. Conclusion

E-commerce may represent a considerable share of economic activity and improve the quality of distribution system in Korea in the near future. Small businesses now cannot further ignore the potential prospects that e-commerce is not an easy work, especially for small businesses, because of the existing of numerous barriers. Considering carefully determinants of its strategic use such as communication requirements, intensity of competition,

support and incentives may help small businesses select the right business model to perform.

To intensify effectiveness of e-marketplace for small businesses, this paper suggests integration of some possible e-commerce models that use website and email as practical e-commerce tools in tandem with finding experiences of Korean small businesses. Forming new business alliances will take positive effect for small businesses. These considerations lead to a research framework for analyzing e-commerce business models by small businesses.

In this paper, however, we are bounded in pointing out a new model of e-business that may be an effective way to accelerate small businesses performance. From this knowledge of e-marketplace and the practical performance within Korean small businesses, the further research may explore potential productivity of e-commerce, and then design an effective e-commerce model for small businesses.

PO Box 42, Tweed Heads, NSW 2485, Australia
E-mail: jxu@scu.edu.au

Abstract: The research examines the required conditions and suitable model of Vertical Hub for Malaysian Electronics SMIs. The conditions required for a Vertical Hub were found in the Malaysian Electronics SMI sector and therefore, a Vertical Hub was supported. This research also reveals that the nature of transactions and business arrangements in the Malaysian Electronics SMI sector best suited the Exchange model of the Vertical Hub. The results of this study have both theoretical and practical implications.

Keywords: Competitive Strategy, Small and Medium Sized Industries Manufacturing, Electronic Commerce, Vertical Hub.

I. Introduction

The Malaysian Electronics Sector is the largest manufacturing sector and contributed 46.2% of Manufactured Exports in the period 1996 – 1997; amounting to RM 80,692.4 million [2]. The Small and Medium sized industries (SMIs) in this sector are facing stiff competition from lower cost countries, on top of the issue of restricted market access[12].

With the explosion of the Internet, Electronic Commerce has emerged as a mechanism that can offer a Competitive Strategy to organizations [1] [4] [14] [17]. Electronic Commerce is indelibly changing how businesses gain market access, present themselves and how they communicate with their buyers. Electronic Commerce, via a Vertical Hub, offers ubiquitous worldwide market access at a very low cost. It allows businesses to continue operating 24 hours a day, 7 days a week with remarkable ease [13]. Instantaneous access to information and acting on it immediately has now become a reality with the Vertical Hub, with new markets and channels being opened up that hold tremendous potential for all companies [14]. Electronic commerce provides Malaysian SMIs the opportunity to stay competitive at both locally and globally. The Malaysian government too has recognized the importance of Electronic Commerce and has setup the National Electronic Commerce Committee (NECC).

A Vertical Hub can provide Malaysian Electronics SMIs with numerous benefits, especially global market access at

an affordable cost, and enable them to compete effectively worldwide. In spite of the importance of the Electronics industry and the priority given to Electronic Commerce by the Malaysian Government, no research has been conducted to determine if a Vertical Hub could be setup for SMIs in this sector.

This Research therefore, is important, as it will help determine if a Vertical Hub can operate in the Malaysian Electronics SMI sector. If the conditions required for a Vertical Hub are present, this research will identify the market-making model of the Vertical Hub most suitable for the Malaysian Electronic SMI sector. Accordingly, the Research Questions are:

1. *Are the conditions that are necessary for a Vertical Hub present in the Malaysian Electronics SMI sector?*
2. *If these conditions are present, which market-making model of the Vertical Hub is best suited to Malaysian Electronics SMIs?*

This paper is organized as follows. The following section presents relevant background on vertical hub, the conditions and drivers required for a Vertical Hub, and different market-making models of Vertical Hub. The research method is then presented. Results of survey are presented and discussed in great depth. Finally, research limitations, future directions, and conclusions are presented.

II. Background

II.1 The Vertical Hub

Sometimes called a “Vortex”, “Butterfly Market” or “Net Market Maker” [14], the Vertical Hub is industry-focused and tends to foster a community for a particular industry. It attracts a more qualified, narrow and pre-selected audience, consisting of truly active buyers and vendors with high economic potential [16]. It uses the Virtual Community model as a strategy to bring buyers and vendors together; especially in markets where both have difficulty finding each other [18]. The Vertical Hub creates value by aggregating buyers and vendors, creating marketplace liquidity by mobilizing a critical mass of buyers and vendors, and thereby reducing transaction costs [9] [14]. In the mean time, Vertical Hub is cost-effective one-stop e-commerce solution and requires minimum upfront implementation costs [5] [11]. The Vertical Hub is a neutral community that offers independent and unbiased information [8]. Vertical

Hubs eliminate monopolies and force competitors to compete on the basis of value [7]. The anonymity, which is an important consideration for vendors, is also supported by Vertical Hubs.

There exist three different types of market-making models, namely Catalogue, Auction and Exchange, in Vertical Hubs. A Vertical Hub can operate in three different models – a Catalogue model, Exchange model or Auction model. The Catalogue model provides buyers with electronic catalogues of vendors participating in the hub and allows direct online comparisons. Some examples are: Echemicals (<http://www.e-chemicals.com>), Spplly Search (<http://www.supplysearch.com>), Hong Kong Trade Development Council (<http://www.tdc.org.hk>), E-steel (<http://www.esteel.com>), Fast-Net (<http://www.worldparts.com>), among many others. The Exchange Model offers a forum for both buyers and vendors to make bids and offers on a product or commodity. This format facilitates multi-lateral bids, offers and negotiations - allowing many buyers and vendors to simultaneously make bids and offers. Industry conditions and other characteristics determine which model is best suited to a particular industry. Some examples are ChemConnect (<http://www.chemconnect.com>), Altra Energy (<http://www.altrinet.com>), Bond Network (<http://www.bondnetwork.com>), IMX Exchange (<http://www.houstonstreet.com>), Paper Exchange (<http://www.paperexchange.com>), among many others. The Auction Model automates the process of allowing multiple parties to bid on an offer to sell or a request to buy. It improves efficiency, maximizes returns and is becoming increasingly popular due to the scale, reach and real-time attributes of the Internet [16]. It matches buyers and vendors in a secure trading environment and provides dynamic, real-time pricing [16]. A good example is freemarket.com.

A Vertical Hub is particularly desirable for SMIs, as it does not impose a heavy financial burden upon them. An SMI can enjoy all the benefits of Electronic Commerce and extensive market access, with either minimal upfront costs or only a commission payable for every successful transaction. No technical expertise is required as the Vertical Hub operator undertakes all implementation tasks. Discussions with industry experts and government officials have also revealed that virtually no research has been conducted in the area of Vertical Hubs for the Malaysian Electronics SMI sector. The researcher aims to extend the body of knowledge by filling this gap and determining if the conditions required for a Vertical Hub are present in the Malaysian Electronics SMI sector. If these conditions are present, this research will attempt to identify the market-making model most appropriate for this important sector.

II. 2 Industry and Market Conditions

For a Vertical Hub to be successful, certain conditions and drivers have to exist. These are a large and competitive industry consisting of technology savvy players, high pre-transaction costs resulting from market inefficiencies and difficult and costly market access. The Investment Analyst

company Bear Stearns, listed several market or industry characteristics that help define which industries will better support a Vertical Hub [3]. The more of these characteristics that exist, the more likely a Vertical Hub will be able to provide enough value to attract a community of buyers and vendors. These characteristics include:

- ❑ Large and Competitive Industry.
- ❑ Fragmented Supply Chain (High Company Search Costs).
- ❑ High Information Search Costs.
- ❑ High Product Comparison Costs.
- ❑ Difficult Market Access.
- ❑ Knowledgeable and Sophisticated Buyers.

An extensive literature review undertaken shows that the literature is silent on the Vertical Hubs for Electronics SMIs. Discussions with industry experts and government officials have also revealed that virtually no research has been conducted in the area of Vertical Hubs for the Malaysian Electronics SMI sector. The researcher aims to extend the body of knowledge by filling this gap by examining the following two research questions:

R1: Are the market conditions that are necessary for Vertical Hub present in the Malaysian Electronics SMI sector? Has the competition in the industry increased in the recent years?

R2: If the conditions required for a Vertical Hub are present, which market-making Model of the Vertical Hub is best suited to Malaysian Electronic SMIs?

III. Research Method/Design

Questionnaires were sent to the one hundred five Electronics SMIs, who are members of Small and Medium Industries Development Corporation (SEIDEC). The Ministry of International Trade and Industry has defined an SMI as (a) less the RM25 million turnover per year and (b) less than 150 full-time employees. No distinction was made between Malaysian and foreign-owned companies and discussions with senior ministry officials revealed that to the best of their knowledge, there were no foreign owned Electronics SMIs in Malaysia. The data was entered into the computer program “Statistical Package for Social Sciences” or “SPSS”.

IV. Results of Survey

Demographic Information

A total of 31 responses were received back from the population of 105. The bulk of Electronics SMIs in Malaysia were located in Selangor/KL, Penang and Johor. These three regions accounted for 82% of the Electronics SMIs in Malaysia. Discussions with MITI and SMIDEC officials had indicated that SMIs in these regions were more likely to respond to the questionnaire. Hence, it was anticipated that SMIs in the other regions would typically not respond to a

survey questionnaire. MITI and SMIDEC officials had confirmed that the Selangor / KL, Penang and Johor regions formed the hub of the Electronics industry in Malaysia.

Conditions Required for A Vertical Hub for Malaysian Electronics SMIs

Table-1 presents summary of analysis if conditions for a Vertical Hub. It can be seen from Table-1 that all the conditions required for a Vertical Hub for Malaysian Electronics SMIs were met, and Malaysian Electronics SMIs required the benefits that could be provided by the Vertical Hub.

Table-1 Results for Research Question 1

	Research Question 1 & Sub-Questions	Answer
1.	Are the market conditions that are necessary for the existence of a Vertical Hub present in the Malaysian Electronics SMI sector?	YES
a)	Has the competition in the industry increased in the recent years?	Yes
b)	Is competition expected to increase further with globalization?	Yes
c)	Is the Malaysian Electronic Industry large enough to support a Vertical Hub?	Yes
d)	Is the industry fragmented with no dominant seller or buyer?	Yes
e)	Are Vendor-search costs high?	Yes
f)	Do buyers and sellers have trouble finding each other?	Yes
g)	Do the SMIs have difficulty gaining market access?	Yes
h)	Are market gaining activities expensive?	Yes
i)	Are market gaining activities within the means of the SMIs?	No
j)	Is there unrecognised vendor or product differentiation along non-price dimensions such as product availability, delivery, support, etc?	Yes
k)	Are the products manufactured by the SMIs commodity-like and generic in nature?	Yes
l)	Are there rapid product introductions; i.e. products have short life cycles?	Yes
m)	Are there rapid inventory changes?	Yes
n)	Do these changes result in excess supply and inventory situations?	Yes
o)	Does excess inventory have to be disposed of anonymously?	No
p)	Are there rapid price changes?	Yes
q)	Do products have many features and characteristics, some of which are difficult to define or find?	Yes
r)	Do the products come in complex configurations?	Yes
t)	Is the transaction cost of the procurement process high?	Yes
w)	Are the buyers knowledgeable, sophisticated and aware of the power of the Internet and Electronic Commerce?	Yes

Suitable Market-making Models

The results in Table-2-5 suggest that the Exchange model was fully supported for Malaysian Electronics SMIs.

Table-2 Results for Research Question 2

	Research Question 2 and its Sub-Questions	Results
	Which market-making Model of the Vertical Hub is best suited to Malaysian Electronic SMIs?	Exchange Model
a)	Is the market fragmented with many buyers and sellers, with no one company having the lion's share?	Yes
b)	Are the demand and supply conditions predictable or volatile?	Volatile
c)	Are the products well defined?	Yes
d)	Are the products commodity-like?	No
e)	Are the products custom-designed?	Yes
f)	Are the products hard-to-find products?	No
g)	Is price volatility frequent?	Yes
h)	Are the prices fixed?	No
i)	Are prices negotiable based on supply and demand conditions?	Yes
j)	Is there often a need to dispose excess stock or inventory?	Yes
k)	Is there a need to regularly sell used or obsolete equipment?	Yes
l)	Do buyers only purchase from pre-qualified suppliers?	Yes
m)	Are pre-defined business arrangements with buyers necessary or can products be sold in a "spot market"?	Necessary
n)	Is the frequency of transaction with a buyer high, medium or low?	High
o)	Is there an anonymity requirement when surplus inventory is to be sold?	No
p)	Are the SMIs willing to pay set up costs or annual costs to implement Electronic Commerce?	Yes

Table-3 Exchange Model Conclusion

	Exchange Model
Fragmented Market	Yes
Volatile Industry Conditions	Yes
Business Arrangements	Pre-qualified
Standardized Products	Yes

Table-4 Catalogue Model Conclusion

	Catalogue Model
Fragmented Market	Yes
Differentiation Requirements	Yes
Run of Mill Purchases	No
Standardized Products	Yes

Table-5 Auction Model Conclusion

	Auction Model
Excess Supply Conditions	Yes
Absence of Pre-qualified Business Arrangements	No
Varied Product Types	Pre-qualified

V. Results Interpretation and Discussions

From the results in Table-1, it can be clearly seen that all the conditions necessary for a Vertical Hub are indeed present. While there exist required conditions for Vertical Hub for Malaysian Electronics Industry, the task of setting up a Vertical Hub for the Malaysian Electronics SMIs will be greatly assisted by the fact that there is awareness of the benefits that Electronics Commerce can bring and just as importantly, there is a willingness to use Electronic Commerce. Government organizations such as SMIDEC and others should be used as catalysts to involve SMIs in Electronic Commerce activities to improve their domestic, regional and international competitiveness. They should also be used to educate SMI on major Electronic Commerce trends such as Supply Chain Management and other differentiation models that are being deployed by organizations in the western world. There is a clear need for the Government to have a specific policy on Electronic Commerce with respect with SMIs and to incorporate Vertical Hubs in this policy. The results of the study (Table-2, 3, 4,,5) clearly show that the only market-making model supported by the conditions in the Malaysian Electronics SMI sector is the Exchange model.

A Vertical Hub and in particular the Exchange Model, provides easier and lower-cost access to buyers that otherwise, may have been difficult or expensive for vendors to reach. Government organizations such as SMIDEC and others should be used as catalysts to involve SMIs in Electronic Commerce activities to improve their domestic, regional and international competitiveness. They should also be used to educate SMI on major Electronic Commerce trends such as Supply Chain Management and other differentiation models that are being deployed by organizations in the western world. There is a clear need for the Government to have a specific policy on Electronic Commerce with respect with SMIs and to incorporate Vertical Hubs in this policy. The task of setting up a Vertical Hub for the Malaysian Electronics SMIs will be greatly assisted by the fact that there is awareness of the benefits that Electronics Commerce can bring and just as importantly, there is a willingness to use Electronic Commerce.

VI. Conclusion and Future Research Directions

This research has shown that the conditions necessary for the establishment of a Vertical Hub exist in the Malaysian Electronics SMIs. The findings of this research have shown

that shown that the Exchange model is the most appropriate model of Vertical Hub for Malaysian Electronics SMI sector. A Vertical Hub will greatly enhance domestic market access. Globally, there are already several Vertical Hubs for the Electronics industry. For the Malaysian Electronics Vertical Hub to be successful, buyers that participate in the other Vertical Hubs have to be attracted to participate. Unless there is participation from global buyers, a Vertical Hub set up for the Malaysian Electronics SMIs will provide only improved domestic access.

Further research is required to ascertain how these global buyers can be attracted to participate in the Malaysian Electronics Vertical Hub. Further research is also required to determine how linkages can be formed with the existing Vertical Hubs to improve international market access using the Malaysian Electronics Vertical Hub. Further research is also required to determine whether a low-touch or high-touch hub is more appropriate for Malaysian Electronics SMIs.

Value-at-Risk for e-business Project and Portfolio Appraisal and Risk Management

Stefan Koch

Institute for Information Business
Department of IS and Operations
Vienna University of Economics and BA
Augasse 2-6, A-1090 Vienna, AUSTRIA
EMAIL: stefan.koch@wu-wien.ac.at

Abstract: This paper makes the case for adopting a risk measure from the finance sector for the evaluation of e-Business projects and portfolios. The proposed value-at-risk method constitutes a well-tested approach in high-risk environments, especially banking, and reports the expected maximum loss (or worst loss) over a target horizon within a given confidence interval. Value-at-risk is computed using either an analytical, parametric approach, or resorting to simulation, either based on historical samples or Monte Carlo methods. In this paper, both the use for evaluating single e-Business projects and also associated portfolios is discussed. Small examples are given and assessed to illustrate both applications. The main advantages of using value-at-risk measures are that they are methodologically consistent with modern IS evaluation approaches like real options, that they offer possibilities for management and assessment of project portfolios, and that the results are easy to interpret.

Keywords: Technology Management, Investment Analysis, Value-at-Risk, Risk Management.

I. Introduction

In the last years, the evaluation of IS/IT and especially e-Business projects has been the center of much debate. One of the reasons for this debate has been the e-commerce and Internet bubble which exploded a few years ago. Naturally, investments into new technology, especially e-Business, and respective start-ups need to be carefully analysed, especially in this new environment. Associated with this trend, risk management has become a center of attention, both within an organisation performing one or multiple projects or for an investment in a portfolio of start-ups [19] [5] [10].

Regarding valuation of IS/IT projects, the real options approach [27] gained prominence in the extant literature in the last years [21] [6] [25]. This approach is based on option theory from finance, and tries to incorporate the management's flexibility into decision making. Especially several possible options like abandonment, or expansion (growth) options offered by pilot projects are of interest in IS/IT projects. In the literature, several applications for real options have been described, including software growth options used in evaluating software platform decisions [25] [26], or investment timing in the development of point-of-

sale (POS) debit services [6] [7]. In the last years, the focus has shifted from evaluating one (or more) known options embedded in a project towards active management and planning of options in IS/IT investments for managing and controlling risks [5].

Extending the approach of using analogies with finance, this paper argues for adopting a value-at-risk approach in evaluating e-Business projects and for improving risk management. The main advantages of using value-at-risk measures are that they are methodologically consistent with modern IS/IT evaluation approaches like real options, constitute a tested and used approach in high-risk environments, especially banking, that they offer possibilities for management and assessment of project portfolios including existing dependencies and diversification effects, and that the results are easy to interpret.

The structure of this paper is as follows: First, an introduction to value-at-risk will be given, highlighting both shortly its history in the finance sector and the main points of the computation itself. Then, the application for evaluating a single e-Business project will be discussed, afterwards detailing the use for project portfolio risk management. In both cases, small illustrative examples are given and discussed.

II. Introduction to Value-at-Risk

II.1 History and Applications

The history of value-at-risk is deeply interwoven with the finance sector and especially banking. In the strive for financial stability, a first landmark decision was the 1988 Basle accord by the central banks from the G-10 countries, which defined a minimum standard of capital requirements for commercial banks, using a percentage of risk-weighted assets [2]. As this first approach has faced criticism, including that neither portfolio risk, nor netting, nor market risk have been accounted for, modifications have become necessary. In 1993, one of the most important documents, the Group of Thirty's report on derivatives was published, explicitly endorsing value-at-risk for measuring market risk [11]. This concept was then popularized by the RiskMetrics system originally developed by J.P. Morgan [16]. The Basle accord, after an amendment for market risk in 1996 [3], in its latest version from 2001 now also 'strongly recommends' that banks disclose their value-at-risk [4]. The U.S. Securities and Exchange Commission (SEC) also now requires all large U.S. publicly traded corporations to report

quantitative data on market risk exposure in their report to the SEC, listing value-at-risk as one of three possible methods for doing so [22] [12] [13]. Recently, it has been empirically shown that value-at-risk disclosures of banks are significantly related to future market risk [13].

In the last years, applications of value-at-risk measures have started to begin in areas other than finance, including inventory management [15], the purchasing process [20] or even real estate investment [14].

II. 2 Computing Value-at-Risk

While several definitions for value-at-risk can be formulated, it basically indicates the greatest potential loss of a position or a portfolio, which can be verified with a certain probability, within a defined time horizon [24] [8]. Or, as Jorion puts it, value-at-risk summarizes the expected maximum loss (or worst loss) over a target horizon within a given confidence interval [12].

These definitions already hint at several important characteristics of value-at-risk: It can be computed both for a single position or for a diversified portfolio, and it has some discretionary power, in that both the holding period (time horizon, target horizon) and the confidence interval need to be defined by the user. The holding period should be set with the type of portfolio considered taken into account, setting a horizon corresponding to the period necessary for orderly liquidation [12]. For example, a bank computing their value-at-risk for a portfolio of highly liquid currencies might even resort to using one day as holding period. The confidence interval chosen should necessarily either reflect regulatory imperatives, risk attitude, or depend on characteristics of the underlying distribution.

Having set both holding period and confidence interval, value-at-risk is computed by estimating the probability distribution of gains and losses of the considered position or portfolio over the time horizon, and then finding the point at which the probability of incurring greater losses corresponds to the set confidence interval (in fact to one minus the confidence interval). Therefore, value-at-risk reports a single, easy to interpret figure: The loss of money that is not exceeded at the probability of the confidence interval over the defined time horizon. In the most general form, value-at-risk can therefore be derived from the distribution of the future portfolio value $f(w)$, finding for a given confidence interval c the worst possible realization W^* such that:

$$c = \int_{W^*}^{\infty} f_{\tau}(w) dw. \quad (1)$$

The value-at-risk can be either reported relative to the mean (the expected portfolio value) or as absolute loss relative to zero.

For computing value-at-risk in practice, three approaches are proposed, each with specific strengths and weaknesses. These are the parametric, or analytical or variance-covariance approach, historical and Monte Carlo simulation [18] [23]. Sometimes the latter two are grouped together under the name of simulation or full valuation methods [8]

[12] [24]. While historical simulation necessitates large historical samples (and attendant assumption of stable volatilities), Monte Carlo simulation naturally can become complex and costly in computer resources for large real-world portfolios (although in the last years several ways were proposed to increase the speed of Monte Carlo simulations [18]). Most often used, due to being the first version having been developed, ease of implementation and conceptual fit with modern portfolio theory, is the parametric approach.

The main hypothesis behind the parametric approach is that the future portfolio values (and hence returns) follow a parametric distribution, the most common assumption is that they follow a normal distribution. Therefore, value-at-risk can be derived directly from portfolio standard deviation σ (using a multiplicative factor α dependent on the chosen confidence level). For a single position with initial investment W_0 , the value-at-risk below the mean then is given by:

$$VAR(mean) = W_0 \alpha \sigma \sqrt{\Delta t}. \quad (2)$$

For a portfolio of assets, as the return of each single asset is assumed to be normally distributed, the portfolio return as a linear combination of normal variables is necessarily normally distributed as well. Due to the diversifying effects of a portfolio, the value-at-risk of a portfolio is not the sum of the value-at-risks of all single positions, but needs to incorporate the respective covariance matrix. The delta-normal method defines relations between financial positions and underlying, primitive risk factors which again are normally distributed. For an instrument whose value depends on a single underlying risk factor S , first the portfolio value at the initial point is computed, together with the first partial derivative Δ_0 with respect to the underlying risk factor S , the sensitivity of value to changes in the risk factor at the current position, termed delta for derivatives. The potential loss in value dV is then computed as

$$dV = \Delta_0 \times dS, \quad (3)$$

using the potential change ds in the underlying risk factor. If the distribution is normal, the value-at-risk can be derived from the product of the exposure and the value-at-risk of the underlying variable:

$$VAR = |\Delta_0| \times VAR_S = |\Delta_0| \times (\alpha \sigma S_0). \quad (4)$$

For a portfolio, the delta-normal method uses a set of primitive risk factors, onto which the positions are mapped using the respective delta-positions denoted by vector \mathcal{Z} , and the covariance matrix Σ between risk factors over the target horizon together with the specified confidence level to

compute the portfolio value-at-risk:

$$VAR = \alpha \sqrt{\chi' \Sigma \chi}. \quad (5)$$

Especially with derivatives like options, due to their non-linear nature, including the second derivative using delta-gamma approximation is recommended to increase the fit. For a more thorough treatment of value-at-risk than is possible here, the works of Jorion [12], Best [8], Pearson [17] and Allen, Boudoukh and Saunders [1] are useful starting points.

III. Value-at-Risk for e-Business Project Evaluation

III.1 Introduction

The first and most important question is whether the value-at-risk can in general be determined for an e-Business project. Following the most generic terms and definition of value-at-risk, it can naturally be derived. Every e-Business project entails a certain amount of uncertainty, therefore a probability distribution of gains and losses over a set time horizon naturally exists. Necessarily, any arbitrary confidence level can thus be set, and the cutoff point in the probability distribution specifying the loss not exceeded with corresponding probability can be determined, thus giving the value-at-risk.

Before specific problems of computation, uses and advantages and disadvantages are addressed, specification of both confidence level and time horizon in the context of e-Business projects need to be discussed. While the confidence level can be determined quite analogous with classic value-at-risk, e.g. using 95% or 99%, but keeping in mind possible characteristics of the underlying distribution, the time horizon needs to be more carefully evaluated. Depending on the reason for project evaluation, the holding period should be set accordingly. In finance, the holding period normally corresponds to the time period necessary for orderly liquidation of the asset considered. For e-Business projects, liquidation is most often available by stopping a project, which is normally possible at short notice or immediately. Due to the fact that e-Business projects (normally) are not traded assets, this would mean exercising an abandonment real option, forfeiting any further benefits but also costs. While this analogy would lead to assume very short holding periods, the volatility of an e-Business project's gains and losses over short periods of time will be small. Therefore longer holding periods should be considered in the context of e-Business projects. If a single project is considered, the holding period could even be set to the assumed project length. For application within a larger organization performing several concurrent projects, evaluation of a start-up portfolio or similar as will be detailed in the next section, the holding period should necessarily be reduced to be in the area of one or several months, maybe a quarter.

In the evaluation of single projects, value-at-risk measures can be computed both at the beginning (normally using project length as holding period), and also during the project for continuous monitoring. At the point of an investment decision at project start, value-at-risk measures allow for easy to understand, monetary quantification of associated risks, and therefore offer a good complement for other measures like net present value. On the downside, computing value-at-risk is either trivial and therefore offers little additional information, necessitates strong assumptions like normal distributions or gets complex if Monte Carlo simulation is employed. Using historical simulation will be mostly problematic due to missing large historical samples.

III.2 Examples

For illustrative purposes, a first simple e-Business project will be considered. This project will, over its projected length of one year, necessitate costs of about 100 monetary units (MU), and is projected to generate positive cash flows of 140 MU with probability $p_1 = 0.4$, of 120 MU with probability $p_2 = 0.2$, of 100 MU with probability $p_3 = 0.2$, of 80 MU with probability $p_4 = 0.1$ and of 0 MU with probability $p_5 = 0.1$. No embedded options are considered at this stage, and temporal aspects, i.e. discount rates, are neglected.

The resulting probability distribution for project value after one year therefore is discrete and is easily constructed. Setting a confidence level of 95% allows to easily determine the cutoff point in this distribution, leading to an absolute value-at-risk below zero of 100 MU, or a relative value-at-risk to the mean $E(P) = 8$ of 108 MU. While this seems straightforward and trivial in this simple case, stating these figures already offers additional information regarding risk for the project, and might serve as an important complement to reporting only mean project value, or a measure like discounted cash flows.

Next, we will consider the case of a software growth option, implementing a web-based e-commerce system, embedded into a platform change from SAP R/2 to SAP R/3. This option and its data are taken from a paper by Taudes, Feurstein and Mild [26]. They give the spot price S_0 with 880,000 MU and a volatility $\sigma = 0.8$. The valuation of this american call option using the Black-Scholes formula [9] gives a value of 514,000 MU, with a delta (exposure) of 0.7756. Using delta-normal valuation and 95% confidence level (which corresponds to $\alpha = 1.645$) in equation (4) results in a value-at-risk of 898,207 MU.

IV. Value-at-Risk for e-Business Project Portfolios and Risk Management

IV.1 Introduction

There are numerous examples for when an e-Business project

portfolio needs to be evaluated regarding the contained risks. These include the classic case of a large software developing organisation that performs several concurrent projects. In that case, overall risk assessment is of high interest, especially if a diversification effect is possibly in place or is strived for. The next application is to evaluate a portfolio of e-Business startups, as held or being built by an investor. While this is more akin to the use of classical instruments from finance, start-ups in this area can also be seen as e-Business projects, as they usually have a very focused area of business.

The last, and maybe the most often occurring possibility is a portfolio of an e-Business project with several embedded options. In that case, an assessment of the underlying risk factors is necessary. If only a portfolio of a project and an embedded option for example to defer the investment, priced as an American call on the gross present value of the completed project [27] is considered, there is only one underlying risk factor, project value, which eliminates any diversification effects. This would reduce the associated covariance matrix Σ in the delta-normal method to a scalar, the risk factor's variance σ , with a vector χ of two delta-positions describing the exposure of both positions, project and option, to this risk factor (see also equation 5). On the other hand, options on a different underlying asset embedded in a project could maybe depend on one or more other primitive risk factors. Therefore, a portfolio composed of one project and one or more options is to be considered, the risk of which should necessarily be assessed. In this case, diversification might be present, and needs to be included in the computation of the portfolio value-at-risk. In the second example given in the last section, a growth option for implementing a web-based e-commerce system was evaluated according to its value-at-risk on its own. As this option was embedded into a platform change from SAP R/2 to SAP R/3 together with four others, with these option values leading to a positive expanded (strategic) net present value of the platform change [26], the whole portfolio of platform project and real options needs to be evaluated together. Simply evaluating each component separately and summing the resulting value-at-risks would negate any benefits from diversification, and give a result which accordingly is too high. While two of the options implement EDI-based solutions, the others including the e-commerce system and the main platform project would be exposed and mapped to different risk factors.

IV. 2 Example

For illustration, we will now expand on our treatment of the option as presented in the last section, complemented with the main platform project. Again, data are taken from the paper by Taudes, Feurstein and Mild [26], although a volatility for the main project of $\sigma_{project} = 0.2$ is newly introduced. Data for the web-based e-commerce system remain unchanged from last section. Furthermore, we presume the presence of two risk factors, with each position

exposed to one of them, the option according to delta-normal method with delta 0.7756 as in the last section, the platform project with its full value at -416,500 MU. Lastly, a correlation of 0.3 is assumed between the risk factors. Using equation (5) at confidence level 95% corresponding to $\alpha = 1.645$ gives

$$\begin{aligned} VAR_{div} &= \\ &= 1.645 \sqrt{\begin{bmatrix} -416,500 & 0.7756 \times 880,000 \end{bmatrix} \begin{bmatrix} 0.2^2 & 0.3^2 \\ 0.3^2 & 0.8^2 \end{bmatrix} \begin{bmatrix} -416,500 \\ 0.7756 \times 880,000 \end{bmatrix}} \quad (6) \\ &= 828,907. \end{aligned}$$

The portfolio value-at-risk therefore is 828,907 MU, which due to diversification effects is smaller than the sum of individual value-at-risks (the undiversified value-at-risk). This sum can easily be computed for a comparison by applying equation (4) for the project and adding the result for the option from the last section (also derived from using equation 4) as

$$\begin{aligned} VAR_{undiv} &= VAR_{project} + VAR_{option} \\ &= (1.645 \times 0.2 \times |-416,500|) + 898,207 \\ &= 137,028 + 898,207 = 1,035,235. \quad (7) \end{aligned}$$

The resulting difference of 206,328 MU therefore represents the effects of diversification present in the portfolio due to the fact that both positions are mapped to different primitive risk factors, which are not highly correlated.

IV. 3 Risk Management

Especially the aspects of value-at-risk described in this section, i.e. the possibility to compute and value any effects from diversification on the risk of portfolios, is an important asset of this method. In analysing portfolio value-at-risk, the change in value-at-risk due to addition of a new position can be computed, termed the incremental value-at-risk, as well as the component value-at-risk, giving the reduction of the portfolio value-at-risk resulting from removal of a position. Due to diversification, both measures would in most cases be different than the individual value-at-risk of the position. This can also easily be seen from the above results. These possibilities allow for an in-depth analysis of different components in a portfolio, or could even be used as a constraint for portfolio optimization [28] [29].

An important point to consider when using value-at-risk to evaluate an e-Business project and/or portfolio with or without options is which primitive risk factors to choose, and especially how to map the different positions to them, if the delta-normal method is to be applied. A survey of the extant literature yields a list of several risk factors commonly associated with IS/IT projects, including the main

groups of technological and organizational risk [26]. The most complete taxonomy currently to be found is by Benaroch [5], who distinguishes between the group of firm-specific risks, including monetary, project, functionality and organizational risk, of competitive risks and of market risks including environmental, systemic and technological risk. He further argues for real option analysis to assist in risk management by deliberately embedding suitable options to address the various risks and thus optimally configure the investment during the different stages in the investment lifecycle [5]. This line of research therefore shows distinctive relationship with the value-at-risk approach argued for in this paper, with value-at-risk offering a way of quantifying any risk reduction afforded by embedding certain options into the investment portfolio.

V. Conclusion

This paper has argued for adopting the value-at-risk approach in the evaluation of single e-Business projects and also of portfolios constructed from these projects and/or related real options. As has been detailed, value-at-risk is a common and accepted measure in the finance sector, especially in banking, and offers several advantages also for the area of e-Business projects and portfolios. While there are several approaches for computing value-at-risk, not all of these might be suitable for e-Business projects and portfolios, as large historical samples will in nearly all cases be absent. On the other hand, both Monte Carlo simulation and an parametric or analytical approach seem feasible, with the former being computationally more taxing.

Using small, illustrative examples, we have shown that value-at-risk can indeed offer additional information in evaluating single e-Business projects or real options on such projects, offering an easy to interpret way of quantifying and comparing associated risks, and especially in evaluating e-Business project and/or option portfolios, as this method explicitly accounts for diversification effects. In addition, the changes in risk exposure due to changes in the portfolio, both from eliminating and adding new positions, can easily be determined, making value-at-risk a useful tool for risk management and assesment, therefore ideally complementing and extending the real options approach.

If value-at-risk is indeed adopted, many further enhancements are possible, including the introduction of a risk adjusted performance evaluation of business units or project managers. Their performance is in this case adjusted for the risk taken, by using for example profit over value-at-risk for assessment [12] [8]. Naturally, many further issues still need to be investigated in the context of value-at-risk for e-Business projects and portfolios, especially the definition of primitive risk factors, the mapping of different positions to these and some others. Nevertheless, adopting value-at-risk might provide important additional information for decision makers in the area of e-Business, and might constitute a necessary step towards implementing e-Business risk management.

Abstract: Application frameworks is a technology concerning with building and implementing reusable software artefacts. Most current application frameworks are object-oriented and often domain specific. Advocates of application frameworks claim that the technology is one of the most promising technologies supporting large-scale reuse, increasing the productivity and quality, and reducing the cost of software development. Many of them project that the next decade would be the major challenge for the development and deployment of the technology. The objective of this study is to investigate the theory and practice of application frameworks and to determine if it has made a difference in systems development. The study indicates that the technology is still immature and not yet to be another silver bullet but potential is imminent.

I. Introduction

Software development markets expect the developers or development companies to deliver quality products at an affordable price within a required time frame. The developers and management alike are looking for technologies that can be used to increase the productivity and quality of the software products. Matured engineering disciplines, such as automobile design, have proven that reuse is the best way to increase the quality and productivity of products. However, despite the effort of last decades-long research the result of software reuse is still limited in code or class reuse (also known as small-scale), and developers are still 'reinventing the wheels'. Application frameworks are a technology anchored in this situation to promote reuse in terms of not only the code or class but also the module and architecture (also known as large-scale) of the reusable software artefacts to increase software productivity and quality.

II. Application Framework Technology

The Microsoft Encarta English Dictionary 2001 defines framework as "a structure of connected horizontal and vertical bars with spaces between them, especially one that forms the skeleton of another structure; a set of ideas, principles, agreements, or rules that provides the basis or the

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 769 - 776.

outline for something that is more fully developed at a later stage." The common sense of the word of framework appears to be "the skeleton of another structure", which has been well adopted into the context of modern information systems development. Booch, Rumbaugh and Jacobson [4] define a framework as "an architectural pattern that provides an extensible template for an application within a domain". In this context a framework is essentially a design skeleton that allows systems developers to create part of a system in the first place, and add design details when necessary. Johnson [23] states that the definitions of frameworks vary, but the one used most is that "a framework is a reusable design of all or part of a system that is represented by a set of abstract classes and the way their instances interact". Another common definition is "a framework is the skeleton of an application that can be customized by an application developer". The former concerns the structure of a framework while the latter describes the purpose of the framework. Lewis et al. [24] argues that a framework is more than a class hierarchy. Fayad [14] claims that a framework is a reusable, 'semi-complete' application that can be specialised to produce custom applications. Zamir [34] defines "an object-oriented framework is the reusable design of a system or subsystem implemented through a collection of concrete and abstract class and their collaborations. The concrete classes provide the reusable components, while the design provides the context in which they are used. " The concepts of frameworks and application frameworks are often used interchangeably in the context of systems development. The definitions by different researchers or authors vary, some of them are more abstract and concerning more on the analysis and design phase, and others are more interested in design and development phase. The different emphases does not conflict each other but rather enrich and enlighten the further research issues related to the field of application frameworks technology.

Application frameworks can be domain independent such as graphical user interface (GUI) framework or domain dependent/specific such as CIM framework. They can also be classified according to the scope, reuse perspective, the control aspect and the development process of application frameworks. According to the scope of application frameworks, Fayad [17] proposes to classify it into three categories namely as system infrastructure frameworks i.e.

graphical user interface (GUI) and Microsoft Foundation Class (MFC); Middleware integration frameworks i.e. BEST and JAWS; Enterprise application frameworks i.e. SEMATECH CIM, OSEEFA and PRM. He claims [15] that application frameworks are generally domain specific applications such as computer-integrated manufacturing frameworks, distributed systems, networking and telecommunications, or multimedia collaborative work environment. From the perspective of the reuse application frameworks can be classified into whitebox and blackbox frameworks [33] [17]. Fayad [17] also proposes a greybox approach, which is a mix between the whitebox and blackbox frameworks. A whitebox application framework is a framework customised by subclassing existing framework classes and providing concrete implementations. To implement whitebox frameworks application developers use more inheritance and polymorphism. Application specific functionality is expressed by inheritance and new implementations. Implementation inheritance tends to require knowledge of the superclasses' implementations. In the last few years application frameworks researchers are more interested to develop blackbox application frameworks, which rely more on composition rather than inheritance. In blackbox frameworks approach, the extendability of the framework is achieved by defining interface for components that can be plugged into the framework using composition. Object composition is based on forwarding rather than delegation, merely relies on the interfaces of the involved objects. In a blackbox framework [17], an application developer selects from the set of subclasses provided by the framework as blackbox components and binds it to the hot spot (plug in point). Thus, the developer may create an application without programming, merely by selecting, configuring, and parameterizing framework components. From the perspective of taking control application frameworks can also be classified as callable framework and calling framework [17]. A callable framework allows the application to retain the thread of control and provides services when the application calls the frameworks. A calling framework provides a control loop that calls application-provided code at appropriate times. From a development process perspective application frameworks can be divided into analysis frameworks, design frameworks, and implementation frameworks. Analysis frameworks typically focus on analysis level constructs, without making any commitment. They are typically the product of domain analysis. Most of the current application frameworks are either a design framework or an implementation framework.

Most of the application frameworks are domain specific such as a financial application framework or a manufacturing framework. An application framework domain is a set of rules and roles and their semantic models codified in the framework itself. It provides a generic incomplete solution to a set of similar problems within an application domain. Fayad [17] states that an application framework embodies generalised expertise in the domain based on analysis and synthesis of a wide range of specific

solutions. He argues that analysis and synthesis of a wide range of specific solutions will help to understand a design of the proposed application framework. It is proven that the research community has more understanding in some domains such as financial, manufacturing, communication and networks and social welfare than others [13][17].

The development of application frameworks research is related to the development of objects technology although there is no evidence of that the technology is exclusive to objects technology. However, the majority of the researchers in that area of application frameworks and most of the current application frameworks are object-oriented. Iterative and incremental development approaches have been the main development methodology supporting the development of application frameworks [15]. Application frameworks design can be bottom-up and pattern driven or top-down and target driven [17][31][33]. The bottom-up design works well where an application framework domain is already well understood. Starting from proven patterns and working one's way up has the advantage of avoiding idiosyncratic solutions in the small, problematic solutions that should be replaced by application of an established pattern. Top-down and target driven approach is preferable where an application framework domain has not yet been sufficiently explored but where the target domain to be served by the framework is well understood.

Research [15][17][24][29] has indicated that building application frameworks is hard and implementing application frameworks is as hard as building application frameworks. According to a survey [17] the minimum time spent in developing an application framework was half of person month and the maximum time to develop an application framework was 1000 person months. The average time to develop an application framework was about 21 person months. An application framework conventionally consists of the core classes of an application, and one has to understand the basic architecture of a particular application type to be able to specialise the framework [29]. Using an application framework may simplify application developers' life since a framework provides generic solutions for a particular application domain. However, the average learning time is a big factor in establishing the cost of final application. The application developers have to understand what solutions the framework provides, and to comply with the rules imposed by the framework.

Chen [8] promotes that reusable components and frameworks must be accumulated in a standardised format. Most of the researchers agree that the classification structure of an application framework must be appropriate and manageable. Application developers will have difficulties with understanding the framework if the structure of the framework is not clear and standardised. Currently literatures indicate that application frameworks still lack of standards. Fayad [15] [16] [17] states that building and implementing application frameworks still need more methodological support.

There are a few domain specific application

frameworks have been used in the industry, for example, San Francisco framework, SEFA framework and SEMATECH CIM framework. The San Francisco framework is an application framework based on Java technology to develop business applications. It provides both a software solution for implementing business applications and a collection of concepts or strategies to develop business applications. According to the white paper from IBM [22] that the San Francisco framework is motivated from over 130 software vendors. The project was started when several software vendors asked IBM to help modernising their application products but there were several barriers preventing them from being able to update their applications. IBM claims that the San Francisco framework can solve 70% of the business related problems and leave 30% to the applications developers. IBM also claims that the framework makes it easier to move to object-oriented technology because developers use well-tested services instead of building their own. The project helps to solve these problems by offering developers Business Process Components. It is designed as a framework that provides an object oriented infrastructure, and a consistent application programming model and some default business logic. The San Francisco Framework is designed to make many types of extensions easy for application developers, allows overriding the default business logic in supplied methods, and adds additional attributes to existing classes. The San Francisco Framework offers three layers of functionality such as business processes, business objects, and foundation classes, each of which may be used and extended by developers to build their applications. OSEFA (German: Objektorientierter Softwarebaukasten für Fertigungsanlagen) is a blackbox application framework. It contains models of technical components as well as models of conceptual task-related components, and of application logic components. The prototype of the project was built in 1993 and the full version of the framework became operational in early 1996. The architecture of OSEFA has five layers, a machine and communication specific layer, a standardised machine layer, a task specific layer, a part processing layer, and a machine order layer [31]. He claims that through the project of OSEFA they have demonstrated how to use design patterns to create a sophisticated class structure from a simple result of object-oriented analysis. OSEFA [32] discloses the cost issues and states that developing a blackbox application framework takes around two to three times as much effort as developing a fixed application from the domain. This number may vary with the domain and includes the costs of analysing the domain and sufficiently generalising the class structure, but not the cost to acquire knowledge of framework structure and design. OSEFA claims that developing an application framework is worth the effort. The investment will pay off after the creation of about the third application from the framework. OSEFA experience indicates that another advantage of using application frameworks approach is the short time span required for the creation of a customer-specific or product-

specific application from a framework. SEMATECH is the semiconductor manufacturing technology consortium, whose member companies are AMD, Digital, Hewlett-Packard, IBM, Intel, Lucent, Motorola, National Semiconductor, Rockwell, and Texas Instruments. CIM is an instance of callable framework and component is the smallest unit of functionality that can be added, deleted, enabled or disabled in a CIM framework-compliant application. The goals of CIM include flexibility, interoperability, substitutability, integration and reuse [17]. Standardisation of CIM framework was started by the Semiconductor Materials and Equipment International (SEMI) organisation in early 1997. In 1998 the SEEMI Global CIM Framework Task Force initiated two successful letter ballots, resulting in adoption of the first two parts of the CIM framework standard. The first part, the Provisional Specification for CIM framework Domain Architecture establishes the architecture foundation for the component structure and partitioning, and identifies the responsibilities of each major component of the framework. The second part is a document- Guide for CIM Framework Technical Architecture, defines required infrastructure technologies needed to support framework and their customers must be prepared to make [17]. The experience from CIM [17] indicates that implementation experience is essential; frameworks increases initial cost; infrastructure coupling is hard to avoid; frameworks overlap; technology is immature and standardisation is an important issue for industry wide application frameworks such as ICM.

III. Foundations of The Application Frameworks

Though application frameworks is not exclusive to object-oriented community the majority application frameworks are developed and implemented using object oriented technology. Object-oriented technology is one of the fastest growing technologies of the last two decades promising better quality, productivity and interoperability through software reuse. Coad and Yourdon [9] define "an object is an abstraction of something in a problem domain, reflecting the capabilities of the system to keep information about it, interact with it or both". In that sense objects are used to model an understanding of the application domain, which concerns the system and abstraction. Deitel [11] defines "Object technology is a packaging scheme that facilitates the creation of meaningful software units". He explains that these units are usually large and focused on particular application areas and most of them can be reused. For example, there are data objects, time objects, audio objects, video objects, file objects, record objects and so on.

The central idea of the object-oriented technology subsumes abstraction, modularity, encapsulation, inheritance and polymorphism - concepts that, on the face of it, lend themselves to reuse. The notable development of the technology consists of a comprehensive set of object-

oriented modelling methods for analysis, design, and implementation, designed to realise the concepts mentioned above. Consequently, object-oriented technology has led to the development of patterns, components and application frameworks. The object-oriented concepts have been applied in the process of developing and implementing application frameworks. Fayad [15][16][17] stresses that frameworks build upon object-oriented concepts, which provides a conceptual base for more complex programming constructs and reusable implementation structures for large systems application. Eliens [13] states that object oriented approach will pay off when we have arrived at stable abstractions from which we have good implementations, that may be reused for a variety of other applications. Application frameworks is a technology aimed to achieve large-scale reuse by applying object-oriented concepts. In the following sections some of the object-oriented concepts and principles will be explored in relation to application frameworks and systems development.

IV. Application Frameworks and Other Reuse Techniques

Application frameworks is a reuse technology aimed at large-scale reuse and it has a close relationship with other reuse techniques used in software engineering. An application framework is a collection of components, a generic solution for a class of problems, a frame of mind for solving problems and a set of architectural constraints. An application framework integrates and concretises a number of patterns to a degree required to ensure proper interleaving and interaction of participants involved. An application framework is a kind of library, which provides reusable objects for applications but in contrast to ordinary software class libraries, frameworks may at times take over control when the application runs. From reuse perspective the application frameworks technology is closely related to other reuse techniques such as patterns, class libraries and components. Application frameworks use those reuse techniques mentioned above to achieve the goal of large-scale reuse.

IV. 1 Architecture

Software architecture is the foundation of system construction. Graham [21] defines “Software architecture deals with abstraction, with composition and decomposition, and also with style and aesthetics. Bass et al. [3] describe, “The software architecture of a program or computing system is the structure or structures of the systems, which comprise software components, the externally visible properties of those components and the relationships among them”. While, Szyperski [33] depicts “System architecture is a means to capture an overall generic approach that makes it more likely that concrete systems following the architecture will be understandable, maintainable, evolvable, and economic. It is this integrating principle, covering

technology and market that links software architecture to its great role model and justifies its name”. Despite the different concentration of the definitions above a software architecture is about an over view of a system. Generally speaking software architecture can be seen as a set of rules, guidelines, interfaces, and conventions used to define how components and applications communicate and interoperate with each other. Recent software development experience has proven that sound software architecture for the software systems is necessary as software systems are more complex than before. Szyperski [33] stresses that architecture prescribes proper frameworks for all involved mechanisms, limiting the degree of freedom to curb variations and enable cooperation. Architecture needs to be based on the principal considerations of overall functionality, performance, reliability, and security. Software engineers have learnt from practice such that architecture is needed in any systems if they seek for guiding rules for design and implementation.

Architecture needs to create simultaneously the basis for independence and cooperation of systems. Independence of systems aspect is required to enable multiple sources of solution parts. Cooperation between these otherwise independent aspects is essential in any non-trivial architecture. System architecture is the structure of a software system, which provides a platform for application developers to build the system. It may be as concrete as providing detailed implementation requirements to as abstract as given a generic idea of how the system should be implemented. Application frameworks technology promises reuse of not only the frameworks source code, but also more importantly architecture [15]. A standardisation structure allows a signification reduction of the size and complexity of code that application developers have to write.

IV. 2 Class libraries

Class libraries is as set of reusable classes, often defined as part of the implementation or design environment [34]. Many programming languages have some ready usable classes embedded available to application developers especially visual development such as VB Studio.Net and J2EE. Class library in general offers static inheritance facilities but framework is more likely to support dynamic, run time binding facilities. Application frameworks defines ‘semicomplete’ applications that embody domain specific object structures and functionality. It can be viewed as extensions to object oriented class libraries. In contrast, class libraries provide a smaller granularity of reuse. For example, class library components like classes for strings, complex numbers and arrays are typically low-level and more domains independent. Fayad [18] states that class libraries are typically passive and frameworks are active and exhibit ‘inversion of control’ at runtime.

IV. 3 Patterns

Classes and interaction structure of object-oriented designs may become fairly complex, and consequently difficult to

develop and understand, which have led the study and development of patterns. Design patterns are standard solutions to recurring problems, named to help people discuss them easily and think about design. Design patterns can be used as a micro-architecture that applies to a cross-domain design problem such as linked list and other classical data structure design. A design pattern describes a concrete solution to an architectural problem that might arise in a specific context. The solution proposed by the patterns is typically a way of structuring a cluster of objects and their interaction [7]. Schmid [31] states that the repetitive use of design patterns created an overall architecture though each design pattern represents a micro architecture. He argues that design patterns give a better, since more concrete guidance for how to realise a framework. Patterns are abstract, therefore, are not ready-made pluggable solutions. They are most often represented in object-oriented development by commonly recurring arrangements of classes and the structural and dynamic connections between them. Graham [21] argues that patterns are most useful because they provide a language for designers to communicate in. In particular, design patterns have proven their value in structuring the variable parts, called hot spots (allow plug in software artefacts) of a framework [28]. Fayad [17] defines patterns as a conceptual solution to a recurring problem. Schmid [31] argues that design patterns are an excellent means to describe the details of object and class interactions but they are not suited to give an overall picture. Design patterns are reusable architecture, object template, or design rule that has been shown to address a particular issue in an application domain [34]. Most of design patterns come either as a static description of a recurring pattern of architectural elements or as a rule to apply dynamically for when and how to apply the pattern. The majority of software patterns produced to date have been design patterns at various levels of abstraction but Fowler and Graham [20][21] introduce the idea of analysis patterns as opposed to design patterns. Fowler's patterns are reusable fragments of object-oriented specification model generic enough to be applicable across a number of specific application domains.

Patterns and frameworks both facilitate reuse by capturing successful software development strategies. The primary difference is that frameworks focus on reuse of concrete designs, algorithms, and implementations in a particular programming languages. In contrast, patterns focus on reuse of abstract designs and software architectures. Frameworks can be viewed as a reification of families of design patterns. Likewise, design patterns can be viewed as the micro architectural elements of frameworks that document and motivate the semantics of frameworks in an effective way [18]. Design patterns have been used extensively in developing application frameworks. Many researchers [15][17][31] have suggested using as many patterns as possible for developing application frameworks because the abstractness and design expertise are embedded in patterns.

IV. 4 Components

Szyperski [33] points out that component technology is standalone, which has gone beyond object orientation. He defines "software components are binary units of independent production, acquisition, and deployment that interact to form a functioning system". In that definition a software component is best thought as a unit with well-defined interfaces and has explicit context dependencies. He explains that insisting on independence and binary form is essential to allow multiple independent vendors and robust integration. Components are not just a big object. Eliens [13] describes that components usually consist of a collection of objects that provide additional functionality that allows components to interact together. Szyperski [33] states that component is a unit of independent deployment, a unit of third party composition, and it has no persistent state. By contrast, an object is a unit of instantiation, which has a unique identity, it has state, which can be a persistent state, and an object encapsulates its state and behaviour. A component is likely to come to life through objects and therefore would normally consist of one or more classes or immutable prototype objects. Component oriented programming requires the support of polymorphism and modular encapsulation [33].

A component has well-specified functionality with standard interface and behaviours, and a concrete implementation of an area of the system. Components in a framework provide a generic architectural skeleton for a family of related applications and complete applications could be composed by inheriting from and /or instantiating framework components. Atkinson [1] states that there are two types of relationship between component instances that are important at runtime. The first is composition, which captures the idea that one component is a part of another. The key aspects of the composition relationship are: 1. Composite objects are responsible for the creation and destruction of their parts. 2. The parts of a composite object take their identity from their composite object. 3. Composition is transitive. The other one is the client/server relationship. A client/server relationship between two components instances defines a contract between them. For components to be independently deployable, their granularity and mutual dependencies have to be carefully controlled from the outset.

Component and application frameworks have close relationship. Many application frameworks use Common Object Request Broker Architecture (CORBA) to increase the interoperability among each part of the framework. CORBA, a big component essentially has three parts: a set of invocation interfaces, the Object Request Broker (ORB), and a set of object adapters. For invocation interfaces and object adapters to work, two essential requirements need to be met. First, all object interfaces need to be described in a common language. Second, all languages used must have bindings to the common language [33]. Fayad [18] states

that frameworks can be used to develop components. Equally, components can be used in blackbox frameworks.

V. The Analysis of Current Application Frameworks Practices

There are a number of application frameworks projects developed during the 90's including some notable domain specific application frameworks such as San Francisco, OSEFA, and SEMATECH CIM. The application frameworks research community has accumulated considerable experiences in some domains such as finance, manufactory and telecommunications about building and implementing application frameworks in the last decade. The followings are core experiences identified during the study:

V. 1 Object-oriented concepts applied

Object-oriented application frameworks approach takes advantage of object-oriented concepts such as abstraction, inheritance, encapsulation and polymorphism as well as the use of object-oriented programming language. Though application frameworks is not exclusive to object oriented technology, the object-oriented concepts have a great impact on the development of application frameworks as a foundation of building and implementing application frameworks.

V. 2 Large-scale reuse

Application frameworks is different from other reuse techniques such as code reuse, design pattern reuse, class library and component reuse. It is aimed at achieving large-scale reuse in which the application developers are not only reuse the code but also the module and architecture of the application frameworks.

V. 3 Domain specific

Application frameworks is likely domain specific such as a financial framework or manufacturing framework. A domain specific framework extracts domain expertise and current solutions of the domain. Domain knowledge is crucial for developing application frameworks, which can be extracted from the domain experts and the current solutions of the domain. The development of application frameworks in some domains has accumulated more experience than others.

V. 4 Existence in any development stage

Concerning the scope of reuse and development process, an application framework can be as abstract as analysis framework or more concrete as implementation framework. Majority of the researchers tend to agree that application frameworks is a kind of semi-completed applications and the reuse can potentially exist in any development stage such as analysis, design and implementation.

V. 5 Development approaches

Though it is not proven that the object-oriented technology is the only way to develop application frameworks, most of the applications frameworks are developed by using the object-oriented technology. Iterative and incremental development approaches have been the main development methodology supporting the development of application frameworks. Framework design can be bottom-up and pattern driven or top-down and target driven.

V. 6 Issues identified to date

Application frameworks research has shown considerable achievement in the context of systems development. However, some obstacles have been identified during the study involving in the theory and practice of application frameworks using object-oriented technology. The issues are organised into the sections of 3.2.1 to 3.2.9.

V. 7 Developing and implementing effort

Developing application frameworks is hard. Due to the complexity, size of application frameworks, and the lack of understanding of framework design process, application frameworks is usually designed iteratively requiring substantial restructuring of numerous classes and long development cycles. Implementing application frameworks is as hard as developing application frameworks. A framework conventionally consists of the core classes of an application, and one has to understand the basic architecture of a particular application type to be able to specialise the framework.

V. 8 Infrastructure coupling

The application developers will have to rely on the architecture structure defined by the application framework while implementing the framework. Infrastructure coupling is very difficult to avoid for a whitebox framework since inheritance is the main mechanisms of implementing the framework that cause widespread coupling (the result of extensive use of inheritance), and consequently restrict the extendability of the application developed by the framework. In contrast, the traditional object-oriented development approach can eliminate the problem by reducing the unnecessary use of inheritance.

V. 9 Combining frameworks

Combining frameworks is not a straightforward task. One of the perceived advantages of using application frameworks is to increase extendability [17]. However, combining two or more frameworks without breaking their integrity is difficult because a framework assumes that it has the main control of an application [29]. Also, the difference of architectural style is another problem, which may potentially prevent two frameworks from combining together [4]. It is also difficult to combine applications developed from a framework with legacy systems because the new application generally contains behaviour for internal framework functionality in addition to the domain specific behaviour, but the legacy system in general only has the functionality of the domain.

V. 10 Overlap and potential gap

Application frameworks is often developed to capture specified domain knowledge. A domain specific application framework is a skeleton of architecture for a domain. It is possible in practice that the real world entity can be classified into different domains and consequently stored in different application frameworks. In application, it is desired to have only one object to represent the real world entity (single inheritance). The entity overlapping in different frameworks may confuse the applications building based on two or more frameworks. Also, potential gap may exist among two or more frameworks because it is possible that two frameworks cannot still be able to meet an application's requirement. In that situation substantial effort is needed to modify the design of the application or using mediating software [4]. In either case the implementation becomes very complex and difficult to handle.

V. 11 Testing

There is little research relating to frameworks testing. According to the nature of application frameworks, a framework is 'a skeleton of structure' with the notion of abstraction. It would, therefore, be very difficult to conduct testing. Currently, most of the researchers are testing the applications developed from the framework and iteratively evolve the framework. A well-designed framework component typically abstracts away from application specific details, however, it increases the complexity of module testing since the components cannot be validated in isolation from their specific instantiations [14]. It would be difficult to test the application developed using calling frameworks in which the frameworks calls the application when the application runs. It could be complicated to follow a thread of execution, which was mostly buried under framework code.

V. 12 Documentation

Documentation is used by both the framework developers and application developers who implement the framework. Fayad [17] classifies it into two categories such as for framework developers, which is used to modify and enhance the structure as well as the performance of the framework, and for application developers, which is employed to understand and use the framework. The current research indicates the documentation is still inadequate for application developers, which has potentially increased the difficulty of the learning curve [17]. The current documentation approach (text plus model diagram plus code example) is often difficult to acquire understanding of frameworks.

V. 13 Maintenance

Current research has no indications of that the requirement for maintenance would be reduced by adopting application frameworks approach. As a long-term investment, frameworks evolve over time and need to be maintained.

Most of the application framework developments adopt iterative and incremental development strategy. Thus, when a change made to a framework the applications developed using the framework will be affected as well because the application use the structure and partial code of the framework. In this case the application development must be delayed if the major new version of the frameworks is about to be available in the near future. The company may have even to maintain more than one version of the framework since there may exist applications based on the old version of the framework.

V. 14 Feasibility

There is little feasibility study conducted in the area of application frameworks. However, OSEFA discloses the cost issue and states that developing a blackbox framework takes around two to three times as much effort as developing a fixed application from the domain. Reusable framework like other reusable technologies is only as good as the people who build and use them. Developing robust, efficient, and reusable application frameworks require the project team to have a wide range of skills. It needs expert analysts and designers who have mastered design patterns, and software architectures and expert programmers who can implement these patterns and architectures in the application framework. Even though it may be feasible to develop a framework for a particular domain from a technological perspective it is not necessarily advantageous from a business perspective. The return on investment from a framework developed may come from selling to other companies, but to a large extent, relies on future savings in development effort within the company itself. However, future earning is not obvious to be justified as the technology itself and business environment is changing. It is difficult to estimate the amounts of work required for a specific application. It is also difficult to foresee if a specified business requirement is supported by the framework.

VI. Conclusions

The application frameworks technology supports large-scale reuse and increase the quality of the software products. An application framework can be described as a skeleton of software systems upon which application developers are able to build applications. Though application frameworks is not exclusive to object oriented technology, most of the current work is coming from object-oriented community. Application frameworks have a close relationship with object-oriented technology in which object-oriented principles are adopted. The results of the study indicate that application frameworks technology is still immature and not yet to be another silver bullet but potential is imminent. The experiences accumulated by the research community indicate that application frameworks apply object-oriented concepts, aimed at large-scale reuse, likely domain specific and can exist in any development stage. Also, some issues relating to application frameworks have been identified in terms of development and implementing effort,

infrastructure coupling, combining frameworks, overlap and potential gap, testing, documentation, maintenance and feasibility. Applications developed by implementing application frameworks may increase quality in terms of correctness and reusability with some penalty factors. The extendability and interoperability may be reduced due to the high inheritance coupling nature of the application developed from application frameworks. The results of the study suggest that the use of application frameworks technology has made a difference in systems development in terms of: (1) a number of application frameworks such as GUI, San Francisco and CIM frameworks have been developed and used by industry; (2) application frameworks technology supports large-scale reuse by incorporating with other existing reuse techniques such as design patterns, class libraries and components. The results of the study discover that the methodological support concerning building and implementing application frameworks is inadequate. The results of the study also point out that one of the claims, made by the advocates of application frameworks technology regarding the technology can increase the extendability of the software systems developed by application frameworks, are debatable.

VII. Future Work

Application frameworks technology may become one of the promising technologies in systems development if the following two research areas achieve significant breakthrough in the future. (1) Methodological study especially, the process of building and implementing application frameworks. (2) Solving technical issues related to building and implementing application frameworks such as how to increase the interoperability and extendability in frameworks approach.

Abstract: The purposes of this research were to evaluate Information and Communication Technology (ICT) management of public universities in Thailand using balance scorecard (BSC) and to develop key performance indicators (KPIs) of ICT in order to develop new ICT strategic model. This proposed model provide some guidelines to improve Investment and worthwhile ICT management and to conform with strategies of universities. The research methodology were both qualitative and quantitative research. The findings of this research showed how universities have been developed ICT as strategic management and the efficiency of ICT management. Further more, the specific KPIs have been created to measure and follow up the use of ICT. Then, the proposed ICT strategic model could apply to other public organization.

Keywords: ICT strategic model; KPIs; BSC.

I. Introduction

Since, all 41 campuses of Rajabhat University have been used ICT to service students and employee and to support administration. The amount of spent on investment of ICT is quite high and keep on increasing with time[1]. The usability of ICT equipment is not suitable, break even and used not extremely benefit[2]. Because of management is not suitable, policies and strategies of ICT can not be executed in reality. Moreover, Evaluation and monitoring of ICT management were proceed. The balanced scorecard (BSC) soon be came a tool for managing strategy[3]. Strategic Implementations were using measurement to align their business units, shared service units, team and individuals around overall organizational goal[4]. The BSC emphasize that financial and non-financial measures[5]. It has been implemented in companies to both measure as well as manage the IT effort[3], [4], [5], [6]. BSC has many dimension for execution decision and to mangle all level of

strategies. It combines objective, planning, initiatives an measures with organization strategies[7]. Measure results would be data for evaluation of ICT management[8]. Because of problems to use ICT is not suitable and to execute strategic ICT effort. Researchers have studied to find suitable methods for ICT management. It also use BSC principles to create strategy by emphasis Implementation. The ICT strategy align with strategic themes of university. It set the role of ICT suitable business base on IT Maxim[9]. The result of this evaluation of ICT management developed key performance indicators (KPIs) and ICT strategic model for Rajabhat Universities.

II. Related Research

The researchers have conduct a study on information technology management, information technology evaluation and relevant researches, used for the concepts and theories related to this research, as follows:

II.1 An Information and Communication Technology Management

In order to obtain strategies for information and communication administration strategic administration is an administration on systematic planning and plan implementation and the actual operation as to the set plan, the strategic planning for information and communication technology is also a mechanism of strategic administration for information and communication technology so that such plan would be actually beneficial to the organization. Therefore, the strategies of the university together with the demand for information and communication technology to be sued to create or to support the main university strategies must be mainly considered.

II.2 IT Maxim

Creating business driven IT infrastructure involves a series of decision points based on a sound understanding of the firm's strategic context. This understanding of the firm's strategic context. This understanding is articulated and communicated through a series of business maxims. Business maxims lead to

the Identification of IT maxims which express how information technology resources should be deployed and the way in which information and data needs to be accessed and used [9].

II. 3 The evaluation of Information and Communication Technology management.

The benefits gained from the measurement would cause the evaluation on the IT administration [10]. The evaluation on ICT is considered the first step of strategic planning and the result from the evaluation would generate strategy creation[13]. In the past, many people tried to search for various evaluations on ICT administration, especially the economic-conceptualized evaluation [12], which did not give an importance only to the financial aspect but the evaluation on the utmost benefits gained from the resources [13]. The worthiness of ICT investment as a part of ICT administration can be mainly concluded as follows:

1. Benefit

The evaluation of ICT reward divides tangible benefits and intangible benefits by considering the role of ICT [9], ICT capacity [5], ICT by-product and actual benefit affecting the organization operation[15],[16].

2. Cost

In the past ICT use in organization increased. The important point for considering ICT investment is the cost reduction which extremely saves the cost [2] in terms of suitable ICT investment for organization operation, service providing and good management. The cost would correspond to the benefits for the society or the organization.

3. Risk

The risk in the evaluation comprises the evaluation of ICT investment risk before the investment [14] by analyzing the possible risk [12]. A good evaluation must give an importance to the risk management [12].

4. Customer satisfaction

IT is used to create customer satisfaction to attract customer group [12], [15].

II. 4 Balance Scorecard Principle

Balance Scorecard (BSC) is a concept developed from "The Corporate Scorecard" or the Balanced Scorecard" of Kaplan & Norton[5],[6].It is a tool leading to the strategic Implementation by measurement which would create unity to the organization and lead to organization achievement[3],[4],[5],[6]. Researchers use BCS base on 4 perspectives which are financial, customer internal business process and learning and growth to evaluate ICT management. Moreover develop a suitable model for ICT management for Rajabhat Universities by emphasis on reality .

III. Research Methodology

The research methodology were both qualitative and quantitative research. The population are 41 campuses of Rajabhat University. The sampling group into 4 groups follow 1) Board of University who have duty and responsibility of ICT management, 2) Middle manager who control and manage ICT policies to proceed, 3) Group of person who concern with ICT

and 4)Students. The data collecting use interview and observation for the sampling group 1 and questionnaire for the sampling group 2,3 and 4. The data analysis use content analysis and interview for qualitative data and analyze questionnaire for quantitative data. The researchers use Delphi technique analysis from professionals to analyze accordance of opinion about developmental strategic model.

IV. Preliminary Results

From the interview with the chief Information Officer(CIO) in Rajabhat Universities and from the analysis on the document contents, the preliminary data of the research under the BSC is as follows:

IV. 1 Financial Perspective: It Was Found That:

1. For the budget allocated for ICT, 66.67% was not appropriate and only 33.33% was appropriate.
2. The budget for ICT was not clearly defined but up to demand and emergency.
3. Most CIO see that ICT investment is worthy.
4. The ICT administration for earning income to the university was very low.

IV. 2 Customer Perspective : It Was Found That:

1. Demand on ICT usage increased.
2. Demand on advanced technology existed.
3. Demand on network with hi-speed data transfer existed.

IV. 3 Internal Business Processes Perspective : It Was Found That:

1. Only 66.67% of ICT administration with ICT master plan was found
2. The university could actually implement only 52.5% of the master ICT plan.
3. ICT development as to the master plan was very low 16.67%.
4. 83.33% of the executives agreed with the development of e-university.
5. Problems and difficulties found: Lack of technical specialists, lack of consistent budget support, the actual performance did not correspond to ICT policy and Teacher/Staff did not adjust themselves Improper use.

IV. 4 Learning and Growth Perspective : It Was Found That:

1. Lack of monitoring and evaluation to review ICT policy.
2. ICT users were not certain that they would gain any benefits or sustainable knowledge.
3. The university had not enough programs or projects to develop the quality of ICT human resource.

The next part of questionnaire survey asked respondents to detail what ICT management from middle managers, employee and students all 41 campus at Rajabhat University.

V. Proposed ICT strategic model

Kaplan & Norton,[4][5][6] suggest BSC that aims to balance the traditional perspective of accounting for intangibles by adding four perspectives related to: innovation and learning business process improvement, customer relationship, and , value creation in financial and intangible terms. In contrast to other tools, this proposed model provides an integrated focus on both management and measurement systems for management with focus on financial and non-financial indicators relevant to organizational performance. Broadbent & Weill[9],proposes the ICT used to align with business. The ICT strategy align with strategic themes of universities[3]. It set the role of ICT suitable business IT Maxim[9]. The proposed conceptual model is detailed in this paper for consideration when ICT investments is worthwhile and suitable. It is divided into six hierarchical levels of ICT management ; strategic themes, ICT for Rajabhat University, an evaluation of ICT management , KPIs, ICT strategic map and Implementation.

V. 1 Strategic Themes :

The framework begins with consideration of the Rajabhat university wide strategic context, synergies Amongst business units and the extant to which the firm wishes to exploit those synergies. Strategic themes are derived from the strategic context and identify the future concern of the Rajabhat Universities as whole.

V. 2 Identifying ICT RU :

The ICT RU (Information and Communication Technology for Rajabhat University) are statements which how ICT needs to support main missions of university. The ICT RU express the way in which information and data to be accessed and used. In addition, what technology resources need to be deployed to ensure adequate technical capabilities, integration and standards. The expectations for ICT investment are classified in terms of the balance between short term cost with minimum investment level and future options and flexibility which might require an over investment based on current need.

V.3 An Evaluation of ICT Management Using BSC:

An evaluation methods that are very popular and used widely at the present. This method does not consider only results of goal achievement but also considers linking about vision, mission, and content strategies. The BSC provides executives with a comprehensive framework that translates the university's vision and strategy into a coherent determination of performance measures.

V. 4 KPIs.

Key Performance Indicators are evaluation result of ICT Management base on four perspective of BSC.

V. 5 ICT Strategic Map

BSC can be used within the ICT department to assess its own performance as well as to integrate itself to organization as a whole[3]. There are a variety of approaches to implementing on ICT scorecard.

V. 6 Implementation

This is the implement part of proposed ICT strategic model. Since, it can proof that if this model is suitable in practices.

VI. Conclusion

From the CIO' opinions, it was found that ICT investment was fairly worthy. From the management's opinions, it was found that the policy of the master plan did not correspond to the actual operation. The master plan could create knowledge learning process to the operations at a level and the operations could obtain knowledge on ICT use. Moreover, it was found that related parties as staff and student were satisfied, at a level, to gain or use ICT service. From the staffs' and students' opinions, it was found that ICT was beneficial to them. They were satisfied at a level and learned how to use ICT. They also need the operation which could make the service or the use to be extremely corresponding to the demand. An evaluate result of ICT management could be develop key performance indicators KPIs). The alignment between technology and the organizational processes using the balance scorecard methodology requires a redefinition of ICT management and can provide some guideline to improve Investment. This paper has sought to emphasize the importance of a structured evaluation framework to evaluate ICT management. The BSC approach was chosen as the template for this model due to its success in wide spectrum of organizations. The model is in this paper with ICT performance perspectives and indicators developed specifically for ICT management.

The Impacts of National Cultures on Customer Relational Benefit – Loyalty Link: A Study of the Chinese Community

HsiuJu Yen¹, Eldon Y. Li², Yiping Song³

1 National Central University, Chung Li, Taiwan

2 National Chengchi University, Taipei, Taiwan

3 Fudan University, Shanghai, China

I. Introduction

Developing and maintaining enduring relationships with customers have been becoming a major business emphasis over the past few years. Most of previous studies focused on the benefits of establishing long-term customer relationship for the firms, but the maintenance of successful relationships would be affected by the benefits received by the customers too. Marketing literature suggested that various types of customer relational benefits (CRB) exist, and the fulfillment of these benefits predicts the future development of the existing relationships (Bendapudi and Berry, 1997; Gwinner, Gremler, and Bitner, 1998; Reynolds and Beatty, 1999). The research by Gwinner et al. (1998) represents the most extensive study of CRB, which suggested that CRB should encompass three factors: confidence, social and special treatment benefits. Recently, Hennig-Thurau et al. (2000) proposed that consumers would stay in a relationship with a service provider that is capable of adding meaning to their self-concept, and the relational benefits is named as identity-related benefits.

Until now, academic research on CRB has been conducted almost exclusively with North American consumers with few exceptions. Pattern and Smith (2000; 2001) replicated the study of Gwinner et al. (1998) in Asia and found that people from Thai considered special treatment benefits as a benefit more important than their American counterparts. Because the nature and development of relationships is highly culturally dependent, the reliance on U.S.-based research has left a large gap in our understanding of CRB in different cultures. Abundant of studies have evidenced the influence of cross-culture difference on service quality perceptions. For example, several studies discovered that service quality dimensions are affected by cultural factors (Winsted, 1997; Mattila, 1999; Liu et al., 2001; Furrer et al., 2000). Also, consumers' expectation of service quality varied as a function of four Hofstede's (1991) cultural dimensions (Donthu and Yoo, 1998). Although these studies did not address the cross-cultural issues of relational benefits, the close bonding between service quality and relationship marketing would imply the possible influence of cultural factors on the link between CRB and customer loyalty.

While most studies tend to treat consumers within countries as homogeneous and to segment the market based on clustering countries, literature also calls for the needs to consider the difference within countries and similarities across countries for international segmentation (Kale and Sudharshan, 1987). In accordance with this argument, Furrer et al. (2000) found significant correlations between SERVQUAL dimensions and Hofstede's (1991) cultural dimensions while cultural inclination was measured at the individual level. The approach to consider the cultural heterogeneity with nations or clustering countries should become more prominent as Internet and other communication medium have expedited the exchange of cultures globally. This might be particularly true for the Chinese community (i.e., Hong Kong, China, Taiwan) that has experienced a lot of economic transformation and a great deal of influences from Western cultures. However, it is also noticeable that some people in the community are more receptive to the influence of western culture while others are affected to a lesser degree.

II. Research Purpose

The current study aims to investigate the influences of cross-cultural influences on CRB-loyalty link in the Chinese community. Specifically, this study explores whether the importance of CRB on loyalty is a function of the individual's inclination on Hofstede's cultural dimensions in two different regions of the community. As service providers increasingly expand their operations into Asia countries, developing a thorough understanding of the relational benefits that consumers desire in Asia cultures will be of growing importance.

III. Research Method

College and graduate students are the primary data collectors for the current study. They were recruited from two universities in Shanghai, China and Taiwan, and they have distributed the survey to their friends, families, and colleagues. This has been a successful technique for data collection in previous studies (e.g., Gwinner et al., 1998; Hennig-Thurau et al., 2002). The final sample consists of 942 (471 from eastern China and 471 from Taiwan) usable cases. The subjects were asked to answer questions assessing customer relational benefits based on their prior experiences with a service provider. The questionnaire also measured the respondent's inclination on the four Hofstede's cultural

dimensions.

IV. Analyses and Results

Exploratory factor analyses on the data revealed four factors for Hofstede cultural measures and four CRB factors (confidence, social, special treatment, and identity), which is consistent with the proposed constructs of two sets of variables. Independent sample t-tests were first performed on the major variables. Compared with eastern China, respondents from Taiwan reported a higher level of social, confidence, and identify benefits. Taiwan respondents also scored significantly higher on "uncertainty avoidance", and significantly lower on individualism and masculinity. Multiple regression analysis was then conducted to test the influence of the four CRB factors on customer loyalty to the service provider in the two regions. In both regions, confidence and identify benefits are the strongest predictors of loyalty (Beta's $\geq .354$, $p < .001$). However, the regression analysis revealed a different third predictor of customer loyalty for each region. For respondent in eastern China, special treatment benefit is the third predictor of their loyalty to the service provider, while social benefits is the other significant predictor of loyalty in Taiwan. In order to compare the results with the findings from Gwinner et al. (1998), another regression analysis was performed without including the new CRB, identity-related benefits. The findings are similar to the study with American subjects, with confidence benefits as the most important predictor of customer loyalty.

In order to explore the relationship between cultural influence and CRB, the current study applied two step clustering analysis to group the respondents from the two regions. The hierarchical clustering analysis suggested that the three-cluster solution has the best fit with the data. K-means clustering analysis was then performed to group the respondents into three clusters. Cluster 1 is characterized as highly collective, high uncertainty avoidance, high power distance and high masculine, which match the stereotype of traditional Chinese. Cluster 2 is consisted of respondents score relatively lower on the four Hofstede's cultural dimensions, and can be conceptualized as modern Chinese. The third cluster is made of respondent similar to cluster 2 but with higher emphasis on achievement and individualism.

A series of regression analyses was performed for each cluster to test the effects of CRB on customer loyalty. The analyses showed that "confidence" and "identity-related" benefits are significant predictors of customer loyalty in all three clusters (all Beta's $\geq .265$, $P < .001$). For cluster 1 that is comprised of traditional Chinese, social benefits is another significant predictor of loyalty (Beta=.106, $p < .05$). Special treatment benefit is the other significant predictor of loyalty for cluster 2 (Beta=.120, $p < .05$), while no additional significant predictor was found for cluster 3.

V. Conclusion

The findings from the current study provide further support to the presence of heterogeneous culture in Chinese community. Quanxi has been a dominant concept in Chinese society, and the significance of social benefits in cluster 1 suggests that "relationship" itself is still a key determinant of loyalty for traditional Chinese. On the other hand, for Chinese consumers that have been affected by the modernization in recent decades may also look for economic and additional services as the benefits of staying in a relationship with a service provider. And that's why special treatment benefits emerged in cluster 2. The results offer important implications for marketing services and implementing CRM programs in the Chinese market and confirm the argument that consumers in the same cultural context may exhibit heterogeneous cultural patterns.

Abstract: The emergences of the Internet and World Wide Web have changed the way businesses ply their trades. Many organizations now have established an online presence, particularly businesses that provide products or services directly to consumers, the so-called business-to-consumer (B2C) e-business. Trust is an important component for the continued viability and success of online businesses, as unlike traditional businesses, consumers do not have physical contact with the products to evaluate their suitability and quality. In this paper, we adopt the trust model constructed by Lee and Turban [7] to study how the drivers of trust in B2C e-commerce would affect the level of trust consumers have in online shopping in Singapore. We will also investigate if there are any moderating effects due to consumer' trust propensity on the relationship between each trust driver and consumer trust in online shopping. Our results show that most of the trust drivers identified by Lee and Turban have a positive effect on the level of trust on online shopping and trust propensity also has a moderating effect on the relationship between the trust drivers and consumers' trust in online shopping.

I. Introduction

The emergences of the Internet and World Wide Web and the rapid growth of the number of Internet users have changed the way businesses ply their trades. Due to higher scalability, wider market reach and lower costs, many organizations have established an online presence, particularly business that provide products and services directly to the consumers, the so called business-to-consumer (B2C) e-business.

According to Internet World Stats, the number of Internet users in Singapore has grown from 1.2 million in year 2000 to 2.135 million in 2005 [11]. But according to a survey of Singapore Internet Project in 2001, it was still quite rare for a Singaporean Internet user to make purchases online for personal purposes, only 8.1% did so in the past 12 months [12]. The risks involved in online purchases could be a possible reason for the low number of Internet users to make online purchases. Consumers generally perceive risks associated with online shopping to be higher than traditional shopping in physical stores as the products and services provided by online vendors are virtual, intangible and

heterogeneous and assessment of their suitability and quality is inherently difficult and uncertain ([2], [4], [9]). Furthermore, the 'invisible' nature of e-business may give rise to opportunistic negative behaviors such as overcharging to increase sales volume ([3], [10]). Thus, trust in online buyer-seller relationship plays a crucial role in the success of online business and it has gradually become an essential competitive tool in B2C e-commerce and is deemed critical for the success of e-commerce ([1], [5]). Furthermore, "lack of trust is one of the most frequently cited reasons for consumers not purchasing from online shops" [7]. Thus, it is important to know the factors that influence consumers' trust in online shopping so that trusting relationships can be developed between sellers and buyers. This would very likely lead to higher profits as consumers "with a higher level of trust in e-commerce are more likely to participate in e-commerce" [2] and purchase more items online more frequently.

Past researches have extensively examined, in both conceptual and empirical frameworks, the various drivers of consumer trust in online shopping. In this study, we would adopt the trust model proposed by Lee and Turban [7] (with some slight modifications) to determine the effects of the various trust drivers on consumers' trust in online shopping and also to determine the moderating effects of trust propensity of consumers could have on the relationship between each trust driver and consumer trust in online shopping in the Singapore context.

II. Literature Review

Past researchers have used both the conceptual and empirical approaches to study the drivers of trust in online shopping. Studies on trust using the conceptual approach can be found in [1], [5], [8] and [10], while those using the empirical approach can be found in [2], [3], [4], [6], [7] and [9].

The general notion of trust has been examined and discussed extensively in the past in different disciplines such as sociology, psychology and marketing [4], [7]. However, trust in e-commerce has only been explored recently. Lee and Turban define trust in e-commerce as "the willingness of a consumer to be vulnerable to the actions of an Internet merchant in an Internet shopping transaction, based on the expectation that the Internet merchant will behave in certain agreeable ways, irrespective of the ability of the consumer to monitor or control the Internet merchant" [7], while

Kolsaker and Payne define trust as “the dimension of a business relationship that determines the level to which each party feels they can rely on the integrity of the promise offered by the other” [6]. In general, it is recognized that trust in e-commerce is a complex process and multi-dimensional as it involves not only trust between humans but also trust between humans, machines and the ‘invisible’ entity Internet. As stated in [7], online shopping “involves trust not simply between the Internet merchant and consumer, but also between the consumer and the computer system through which transactions are executed”.

The trust model proposed and tested by Lee and Turban [7] is adopted in this study. The components that influence consumers’ trust in online shopping in the model include trustworthiness of the Internet merchant, trustworthiness of the online shopping medium, online shopping contextual factors, other factors and trust propensity.

‘Trustworthiness of the Internet Merchant’ involves assessing the ability, benevolence and integrity of the online seller, which collectively represent its reputation [7]. Ability refers to the online vendors’ competence in achieving the results desired by the consumers and benevolence involves the online vendors’ motivation to act in the interest of their online customers. Integrity reflects the vendors’ honesty and dependability in fulfilling their promises and obligations ([1], [3], [8]). An online vendor that is consistently willing and able to serve consumers’ interest is likely to be rewarded with a high level of consumer trust. Thus, ability, benevolence and integrity of online merchants are expected to positively affect the level of consumer trust in online shopping. In this study, we will examine the effects of perceived ability, benevolence and integrity of online vendors could have on Singaporean consumers’ trust in online shopping.

‘Trustworthiness of the online shopping medium’ refers to the level of confidence consumers have with respect to the technical competence and performance level of the IT infrastructure, for example, computer system through which online purchases are transacted [2], [7]. The technical competence of a computer system involves its ability to correctly perform the required and intended tasks, and its performance level is measured by its speed, reliability and availability [7]. With the use of technically competent and high performance computing system, it is expected that the level of consumers’ trust in online shopping will increase and this expectation is supported by findings in [2].

‘Online shopping contextual factors’ deal with issues about Internet security and privacy in building trust between online sellers and consumers. In particular, several studies have looked at the effects of security and privacy assurances by third-party certifications have on the level of online consumers’ perceived risk and trust. Assurances provided by third-party certifications could appear as tangible cues or quality symbols on websites that exemplify the various legal or regulatory impositions put in place to ensure favorable conditions for successful e-commerce ([1], [8]) and may reinforce the trust relationship that has already been

established between the online vendors and their customers [6]. Hence, third-party security and privacy certification is expected to increase consumers’ level of trust in online shopping. However, this expectation is not supported by the findings in [7].

‘Other factors’ that may influence consumers’ trust in online shopping that are not included in the above three components include website design/infrastructure, size and reputation of online vendors. In B2C e-commerce, the vendor’s website is the main interaction channel through which the vendor maintains contact with its customers, hence the website quality, the layout, appeal and ease-of-use are possible factors that may play a role in influencing consumers’ trust ([1], [2], [5]). Quality websites help alleviate the perceived risks in online shopping and consequently it is expected that website quality will positively affect consumer trust in online shopping and this expectation is supported in [2]. Chen and Dillion indicate that “characteristics such as firm size, number of years that a firm has been in business, reputation, and brand recognition are considered important in influencing a customer’s trust towards an online vendor” [1], hence online vendors that are huge in size are perceived to have attained their size by having high level of commitments to safeguard its reputation and provide services to their customers and this will positively affect consumer trust in online shopping.

Another component of the trust model is ‘trust propensity’. Trust propensity is a personality trait [7] that represents a person’s consistent natural tendency to depend or rely on others on how much to trust in various situations. Consumers with high trust propensity generally regard others as good-natured and reliable, and believe that better outcomes could be achieved by treating others as though they had meant well. Hence, it is expected that trust propensity would have a moderating effect on the four components of the trust model and it is likely that the effect is a positive one.

III. Methodology

A survey with self-administered survey questionnaires was conducted to gather the necessary information for the study. The survey questionnaires were adapted mainly from [7] and [2] to suit the purposes of this study. The various constructs in the proposed trust model are measured using the 5-point Likert-type scale items.

A pilot study with 15 National University of Singapore students was first conducted to assess the clarity and accuracy of the survey questions. The questions were generally seen to be clear and unambiguous by the respondents and only minor modifications were done to the questionnaires. Subsequently, a street survey was conducted outside a major public transportation station. Every fifth person that passed by the station was approached and asked whether he or she has ever accessed the Internet before and only those who answered positively were requested to complete the questionnaires. A total of 208 responses were

obtained.

Based on the model we have adopted, the possible hypotheses are that the attributes of the four components of the trust model are expected to have positive effect on consumer trust (CT) in online shopping. That is, perceived ability (PA), perceived benevolence (PB), perceived integrity (PI) of the online merchant, technical competence (TC), performance level (PL) of the online shopping medium, third-party certification (TPC), website quality (WQ), size of online vendor (SZ) and reputation of online vendor (RP) would affect positively on consumers' trust in online shopping. Also, trust propensity (TP) is hypothesized to have a positive moderating effect on the relationship between all the abovementioned attributes and consumer trust in online shopping.

A regression model is used to assess the relationships between consumer trust in online shopping and the various attributes of the trust drivers:

$$CT = \beta_0 + \beta_1(PA) + \beta_2(PB) + \beta_3(PI) + \beta_4(TC) + \beta_5(PL) + \beta_6(TPC) + \beta_7(WQ) + \beta_8(SZ) + \beta_9(RP) + \varepsilon \tag{1}$$

where β_i is the regression coefficient that measures the effect of the i -th attribute on consumer trust and ε is the random error term.

A regression model is also used to assess the moderating effects of trust propensity of consumers could have on the relationship between each trust driver and consumer trust in online shopping. The average score of the two items used to assess trust propensity is used as a measure of the respondent's trust propensity. The moderating effect of trust propensity on each attribute of the trust drivers towards consumer trust is measured by the interaction between the attribute and trust propensity. The model used is as follows:

$$CT = \alpha_0 + \alpha_1(TPxPA) + \alpha_2(TPxPB) + \alpha_3(TPxPI) + \alpha_4(TPxTC) + \alpha_5(TPxPL) + \alpha_6(TPxTPC) + \alpha_7(TPxWQ) + \alpha_8(TPxSZ) + \alpha_9(TPxRP) + \varepsilon \tag{2}$$

where α_i measures the effect of trust propensity on the relationship between consumer's trust and the attributes of the trust drivers.

IV. Results

Altogether 208 responses were obtained, out of which 53% are males and 47% females. About two thirds of the respondents are above 21 years of age and about half of them have monthly allowance/income of \$1000 or less.

IV. 1 Relationship between Consumer Trust in Online Shopping and Trust Drivers

To assess the direct effects of the attributes of the trust drivers on consumer trust in online shopping, model (1) is used with the following results:

Table 1: Estimates of Effects of Attributes

Attribute	β_i	p-value
Ability	0.063	0.205
Benevolence	0.117	0.008*
Integrity	0.290	0.000*
Technical Competence	0.028	0.276
Performance Level	0.119	0.022*
Third-Party Certification	0.222	0.000*
Website Quality	0.475	0.000*
Online Vendor Size	0.049	0.091
Online Vendor Reputation	0.112	0.000*

* significant at 0.05 level

The overall model is significant ($p < 0.05$) and about 88% of the variation in the levels of consumer trust can be explained by the model. Inspection of the residual plots and the normal probability plot for the residuals does not reveal any serious violations of the usual assumptions of regression model.

As seen from table 1, two attributes of the trustworthiness of Internet merchant, perceived benevolence and integrity, have significant effects on consumer trust, while perceived ability does not have significant impact on consumer trust. These results are consistent with the findings of Lee and Turban [7].

As for the trustworthiness of online medium, the attribute performance level is found to have a positive effect on consumer trust and this is similar to the finding in Corbitt et al [2]. But, the effect of technical competence is found to be insignificant and this result is contrary to that found in [2]. This could be because of the different methodology employed as the sample used in [2] is a voluntary sample through invitation by emails.

Third-party certification is found to have a significant positive effect on consumer trust in online shopping and this result is not consistent with the findings of Lee and Turban [7]. Again, this could be because of the different methodology used as a convenience sample is used in [7]. The quality of website and the reputation of the online vendor are also found to have significant positive impact on consumer trust in online shopping while the size of online vendor does not have a significant impact.

IV. 2 Moderating Effects of Trust Propensity

Model (2) is used to assess the moderating effects of trust propensity on the relationship between the trust drivers and consumer trust. The results obtained are as follows:

Table 2: Moderating Effects of Trust Propensity

Interaction between Trust Propensity and Attribute	α_i	p-value
Ability	0.011	0.561
Benevolence	0.003	0.814
Integrity	0.008	0.000*
Technical Competence	-	0.295
Performance Level	0.009	0.616
Third-Party Certification	0.067	0.000*
Website Quality	0.073	0.000*
Online Vendor Size	0.003	0.760
Online Vendor Reputation	0.027	0.007*

* significant at 0.05 level

The model is again significant and about 84% of the variation in the level of consumer trust in online shopping can be explained by the interactions between trust propensity and the attributes of the trust drivers. There are also no serious violations of the usual assumptions on the model.

The trust propensity of consumers is found to have a significant positive moderating effect on the relationship between perceived integrity of online vendors and consumer trust and this is in line with the finding in [7]. While for the other two attributes of trustworthiness of online merchant, trust propensity does not seem to have any moderating effects on them.

The trust propensity of consumers is found to have no significant moderating effects on the relationship between consumer trust and both attributes of the trustworthiness of online medium. Contrary to Lee and Turban [7], we find that trust propensity does have a significant moderating effect on the relationship between third-party certification and consumer trust. For the other factors, trust propensity has significant moderating effect only on the relationship between website quality and reputation of online vendor and consumer trust.

V. Limitations

The random sample obtained for this study included those who have accessed the Internet before, but no distinction was made whether they have made any online purchases before. The perceptions of trust between these two groups are likely to be different and the effects of the trust drivers on consumer trust could also be different. Perhaps, the differences between these two groups could be investigated further when the base of actual online consumers becomes larger.

The limited scale items used in this study to represent some of the constructs of the trust model may not fully reflect the complexities of the constructs. For example, consumer trust and reputation of online vendors are each

measured with a 1-item instrument and this may not accurately reflect the true level of trust and reputation.

The proposed trust model does not include the consequences of trust. Since the consequences of trust are related to consequences of risk taking, as pointed out in Lee and Turban [7], an understanding of trust that does not examine its relationship with risk is incomplete.

VI. Conclusions

This paper uses the trust model of Lee and Turban [7] to study the relationship between consumer trust and the four trust drivers, namely, trustworthiness of Internet merchant, trustworthiness of online shopping medium, contextual factors and other factors in the Singapore context. Though some of our findings are different from that in [7] and also that of Corbitt et al [2], there are also a lot of similarities between our results. The differences could be because of the different methodologies used in drawing samples and it could also be due to the differences between the societies in terms of willingness to accept new technologies, technical knowhow and the sophistication of Internet infrastructures.

Some of the results obtained here can be used as guidelines to build trusting relationships between online merchants and consumers. For example, in marketing and advertising activities, size of online vendor and its technical competence need not be emphasized since they do not seem to have any effect on consumer trust, whereas the performance of the vendor, its commitment to customers and perception of security by third-party certification should be emphasized. Also, trust propensity seems to have some moderating effects on some the trust drivers, hence it might be beneficial for online merchants to provide spaces on their websites for consumers to post comments and ratings on their products and services.

² Department of Health Administration, Tzu Chi College of Technology

³ Department of Business Administration, Takming College

Abstract: Online shopping behaviors, different from traditional shopping behaviors, are related to information system and characterized with uncertainty, anonymity and potential opportunism. This paper is to conceptualize and analyze customer online behaviors, trust, customer satisfaction and customer loyalty based on Technology Acceptance Model (TAM). 1258 valid questionnaires are gathered from online customers having e-shopping experiences in Taiwan. Using structural equation modeling, the empirical results indicated that perceived use of use, perceived usefulness, and trust has the significant effects to facilitate customer satisfaction and customer loyalty, and further, effects customer's intentions and behaviors toward online purchasing.

Keywords: Technology Acceptance Model, Trust, Customer Behaviors, Customer Satisfaction, Customer Loyalty.

I. Introduction

Internet/WWW usage changes ways of doing business as well as the way we live. The number of people who use the Internet has increased dramatically and has exceeded the 1.4 billion in the 2003 [1]. The electronic commerce and Internet business market has grown rapidly, at an exponential rate, accompanying the increase in the number of Internet users. According to a recent study by the Pew Internet and American Life Project, the Internet has gone from novelty to utility for many users, and an increasing number of customers are spending more time shopping electronically for books, music, and airline tickets and so on [2]. This is supported by a U.S. Census Bureau report, by U.S. Department of Commerce, that B2C EC reached \$69 billion in 2004, as compared to \$15 billion in 1999 [3]. These online-shopping trends indicate a remarkable potential and an alternative to the traditional brick-and-mortar shopping.

However, research indicates that 80%-85% of those that browse Web sites for goods and services do not engage in online purchases [4] [5]. Additionally, while many web users are motivated to start an online purchase transaction, 75% of them discontinue the transaction or are termed abandoning their shopping cart [6]. This implies that web users are

identifying attractive shopping opportunities on the web, but there are barriers and other concerns preventing the purchase from being completed. Besides, despite the recent rapid growth in Internet user numbers, the penetration rate of online-shopping is still low. One of the most plausible reasons is a lack of consumers' trust [7].

Moreover, in the online environments, it is more difficult for company to build customer loyalty when consumers can leave with just a mouse click away [8]. Although customer increasing their interactions with company through websites, there are plenty online shops offering the same product or service, customer can easily switch their purchasing decision than they do in physical environment. For the companies, attracting new online customers will be more difficult and costly to retain existing ones [9], therefore, customer satisfaction and customer loyalty are another important issues in online retailing.

Technology Acceptance Model (TAM) is developed to explore a user behavior model when an individual is using an information system [10]. TAM is a mature model because it has been validated in widely information contexts. This study, based on TAM model, expands the application on online environment to analyze customer online behaviors.

Recently, there have been a number of researches investigating online customer satisfaction or the role of trust in the specific context of e-commerce. However, it still lack of the understanding about the relationships between trust, customer satisfaction, customer loyalty, and online consumer behaviors with theoretical base. The objective of this paper is to explore the factors affecting online purchase intentions in consumer markets. Elucidation of online consumer behaviors will benefit e-venders in their efforts to sell products or services online in the future.

II. Literature Review

II.1 Electronic Commerce

Electronic Commerce (E-Commerce, EC) is described as "*the capability of buying and selling products on the Internet and other online services*"[10]. Generally, the business transactions that conducted in Internet technology such as computer, information networks, electronic data exchange (EDI) and so on are called EC.

The definitions of EC vary with different perspective [11]. In communication perspective, EC is the delivery of information, products/services, or payments over telephone line, computer networks or any other electronic means. In business process perspective, EC is the application of

technology toward the automation of business transactions and workflow. In service perspective, EC is a tool that addresses the desire of firms, consumers and management to cut service costs while improving the quality of goods and increasing the speed of service delivery. In On-line perspective, EC provides the capability of buying and selling products and information on the Internet and other online services. Communication process service on-line definition

EC are divided into three broadly recognized categories: intra-organizational, Business-to-Business (B2B), and Business-to-Consumer (B2C) [11]. Intra-organizational EC includes facilitating the organizational internal function and increasing the satisfaction of target customer. B2B EC is referred to facilitate and integrate the network form between organizations. B2C EC, is referred to improve the transaction between business and customer with electronic technique. Offering products/services in Internet is a kind of B2C EC and it is named as B2C. Making profit from the advertisement by establishing website attracted stream of people is another kind of B2C EC and it is named as C2B. The key of B2B EC is to establish good relationship with the co-operational partner. C2C EC is stressed on the credit of buyer and seller. Otherwise, B2C EC put more importance on security and identification. The key of C2B EC is to attract a great number of visitors to browse the website. The Internet biasness we discuss in letter is focused on the B2C EC.

II. 2 Theory of Technology Acceptance Model

Technology Acceptance Model (TAM), developed by Davis in 1989, is one of the most influential research models in studies of the determinants of information systems/information technology (IS/IT) acceptance to predict the intention of use and acceptance of IS/IT by individuals. Based on TRA Model, TAM points out two particular beliefs — perceived ease of use (PEOU) and perceived usefulness (PU), to represent the antecedents of system usage in TAM. PEOU is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance" and PU is defined as "the degree to which a person believes that using a particular system would be free of effort" [10]. In the TAM model, PEOU positively affects the PU. Moreover, PEOU and PU positively affect the attitude toward an information system, and further, positively affect individuals' intentions to use and accept of the information system.

Numerous empirical tests have indicated that TAM is a robust model of technology acceptance behaviors in wide variety of information systems and countries [12, 13, 14]. A website is, in essence, an information technology. As such, TAM is suitable to be applied in explaining online behavior. Accordingly, the following hypotheses were cast and tested:

- H1: A consumer's PEOU toward using online store positively affects his /her PU toward using the online store.
- H2: A consumer's PEOU toward using online store

positively affects his /her attitude toward using the online store.

- H3: A consumer's PU toward using online store positively affects his /her attitude toward using the online store.
- H4: A consumer's PU toward using online store positively affects his /her intention toward using the online store.
- H5: A consumer's attitude toward using online store positively affects his /her intention toward using the online store.
- H6: A consumer's intention toward using online store positively affects his /her behavior toward using the online store.

II. 3 Trust and Technology Acceptance Model

Trust has different definition in the various social science literatures such as sociology, social psychology, and organizational behavior. Trust, in a social psychological sense, is the belief that other people will react in predictable ways. In brief, trust is a belief that one can rely upon a promise made by another [16]. In the context of e-commerce, trust beliefs include the online consumers' beliefs and expectancies about trust-related characteristics of the online seller [17]. The online consumers desire the online sellers to be willing and able to act of the consumers' interests, to be honest in transactions (not divulging personal information to other vendors), and to be capable of delivering the ordered goods as promised.

Many trust studies in psychology and organizational behaviors focus on interpersonal relationships; other trust studies in economic and strategy field, on the other hand, focus on the inter-organization relationships. However, the analysis of trust in the context of electronic commerce should be considered as the relationship between firm and individual aspects. The technology itself—mainly the Internet—has to be considered as an object of trust [18]. As a result, online shop also could be considered as an object of trust.

TAM has been considered a robust framework to investigate how users develop attitudes towards technology and when they decide to utilize it [10, 19, 20, 21]. Several studies have applied TAM and trust in their models. Based on the previous literatures, trust is a mixed belief-intention variable in trust studies. However, when trust is integrated into TAM, the trusting intention is replaced by the intention variable of TAM. In other words, trust in TAM is trusting belief, reflecting the online consumer wants the online sellers to be willing and able to act matching the consumers' interests, to be honest in transactions (and not divulge personal information to other vendors), and to be capable of delivering the offered goods as promised.

There are several studies have investigated trust based on TAM [13, 16, 24, 25]. After the literature review on customers' online trust and TAM model, we decided to integrate "trust" into our expanded TAM model. In order to focus on the relationships among trust and TAM concepts, we examine these studies again within the TAM framework.

Koufaris and Hampton-Sosa [23] and Pavlou [16]

suggested that customers' PEOU and PU of the website have positive effects on trust of e-vendor. These authors believe trust could reduce the need for consumers to understand, monitor, and control the situation and facilitate transaction and make it effortless. In the e-commerce context, trust would reduce the consumer's need to monitor the vendor's actions and check every detail, which make on-line transactions easier. Accordingly, the following hypotheses were tested in this study:

- H7: A consumer's PEOU toward using online store positively affects his /her trust U toward using the online store.
- H8: A consumer's PU toward using online store positively affects his /her trust U toward using the online store.

Most studies indicated that trust plays a significant role in determining a customer's actions regarding that company. Empirical research has shown that trust increases customer intention to purchase a product from a company [22] as well as intention to return to that company [26]. Some research indicated that customer trust (a belief) influences customer attitude. Based on the TAM, we believed trust affects attitude directly and trust also affects intention indirectly through attitude.

- H9: A consumer's trust toward using online store positively affects his /her attitude toward using the online store.
- H10: A consumer's trust toward using online store positively affects his /her intention toward using the online store.

II. 4 Customer Satisfaction and Customer Loyalty in Virtual Environment

There are many studies investigated customer satisfaction in physical environment. With the rapid growth of e-commerce, researchers and managers are now interested at customer satisfaction in online settings. There are two theoretical perspectives related to satisfaction when customer online shopping. One is customer satisfaction from marketing perspectives, and the other one is user satisfaction about information system from information technology studies

In the marketing perspective, customer satisfaction is an individual's subjectively derived favorable evaluation about his or her consuming experiences. Customer's experiences of purchasing involves with several processes: need arousal, information search, alternatives evaluation, purchase decision, and post-purchase behavior [27]. Although consumer behavior in e-commerce contexts is essentially the same as any other consumer behavior, there are certain technology related features that play a part in consumer decision making [28]. For example, in the online environment, Internet offers online user several benefits about information-search stage by reducing the search cost and increasing shopping convenience and the richness of information. However, in the evaluating and ordering stages,

customers lack for physical checking and they have the security problem when they purchase online. It implied the customer experience of online shopping is much different to traditional way. Because online shopping is an interaction between marketing and technological characteristics, customer satisfaction in e-commerce context is more complicated than physical environment.

Otherwise, technology information studies focused on the end-user satisfaction from information system (IS) using perspective. User satisfaction is considered a significant factor in measuring IS success and IS use [29, 30, 31, 32]. Empirical studies indicated the more satisfied users are, the more successful the IS facilitate is. Moller and Licker [33] applied IS success model to investigate the e-commerce system success and they indicated that the user satisfaction toward e-commerce system is one of the determinants to e-commerce system successes.

In the e-commerce contexts, customer satisfaction toward online shopping is composed of customer satisfaction in purchasing process and user satisfaction in using information system (in this case, information system means website). We merge marketing perspective and IS perspective about satisfaction as "E-satisfaction" to explore the customer satisfaction when they shopping online. In this research, E-satisfaction is defined as the customer's pleasurable fulfillment about his or her prior online experience (including browsing experience and purchasing experience) with a given electronic commerce website.

Satisfaction is usually defined as to customer favorable or unfavorable feeling about the prior experience in marketing literature. Operationally, satisfaction is an attitudinal variable, because satisfaction represents favorable or unfavorable feeling which is related to judgments. Clarke [34] also indicated that satisfaction is an attitude to determine future behavior based on the analysis of the service-buying process. She stated that there is an evidence of a robot result that customer satisfaction is an attitudinal variable. In TRA and TAM's belief-attitude-intention-behavior model, attitude is measured by the person's favorable or unfavorable feeling about performing the behavior. Adamson and Shine [35] also indicated that TAM could be used to explore use satisfaction. Therefore, we believe customer E-satisfaction is a facet of attitude to predict customer's intention and behavior toward using website and we integrate customer E-satisfaction as an attitudinal variable into customer online behavior model based on TAM framework.

- H11 : PEOU toward using at online store positively affects E-satisfaction.
- H12: PU toward using at online store positively affects E-satisfaction.
- H13 : Trust toward website will positively affect E-satisfaction in the using behavior model.
- H14: E-satisfaction will positively affect intention toward using the online store.
- H15: E-satisfaction will positively affect behavior

toward using the online store.

While the importance of customer has been mentioned in the marketing literature, the conceptualization and empirical validation of customer loyalty in e-commerce context has seldom been addressed [36]. In the online environments, it is more difficult for company to build customer loyalty when consumers can leave with just a mouse click away [8]. There are plenty online shops offering the same product or service, customer can easily switch their purchasing decision than they do in physical environment. On the other hand, e-vendor can create more profit than before, because customer increasing their interactions with company through websites. According to Griffin [37], "one of the most exciting and successful uses of this revolutionary technology may be the Internet's role in building customer loyalty and maximizing sales to your existing customers." In increasingly competitive markets, being able to build consumers loyalty become the key factor in winning market share and developing sustainable competitive advantage [36]. In this study, "E-loyalty" is used in order to highlight the role of loyalty in e-commerce contexts when customer shopping online.

For lacks of consistent psychological meanings of loyalty, Oliver [38] purposed four stages of loyal formulation: cognitive sense first, then later in an affective sense, still latter in a conative manner, and finally in a behavioral manner.

We found that Oliver's model represents the similar concepts of TAM. Both of Oliver's model and TAM believe cognitive (belief) first, then later in affective (attitude), still latter in a conative manner (intention), and finally in action (behavior). However, in Oliver's model, the definition in cognitive dimension is far away from the definition of loyalty in marketing literature. Besides, behavior dimension of loyalty in Oliver's model is basically reflective behavior concept in TAM. Therefore, the behavior dimension of loyalty could be replaced by the "actual behavior" in TAM. In Oliver's models, only the affective dimension and conative dimension match the definition of loyalty in marketing studies. Therefore, we purpose that loyalty is an attitudinal-intentional variable, involving in feeling and linking to purchase intention.

H16: E-satisfaction will positively affect E-loyalty in the using behavior model.

H17 : Attitude toward using at online store positively affects E-loyalty.

H18: E-loyalty will have a positively effect on intention toward using the online store.

H19: E-loyalty will positively affect behavior toward using the online store.

III. Research Methods

III.1 Research Model

The relationships among trust, E-satisfaction, and E-loyalty towards other TAM constructs in this study are drawn as

Figure 1. In the Figure 1, there are three belief variables (PEOU, PU, and Trust), two attitudinal variables (attitude towards using the online shop and E-satisfaction), an attitudinal-intentional variable (E-loyalty). All of these constructs have directly or indirectly effects on customer intention and actual behavior toward using the online shop. Based on the literature review, E-satisfaction has three determinants: PEOU, PU and Trust. E-satisfaction also has three consequences: E-loyalty, intention toward using the online shops, and the actual usage. Additionally, E-loyalty plays as a mediator variable between two attitudinal variables, intention variable and behavior variables.

III.2 Measurement

These scales were established based on the reliability and validity of the TAM measures. Items of attitude toward purchasing online were modified from Suh and Han [24], Chau and Hu [20], in studies of consumer acceptance of electronic commerce. Items of purchase intention were adopted from Geffen and Straub [13,14] on their study of consumer behavior in B2C e-services. The scale of actual purchase behavior was captured with a standard item measuring on-line shopping frequency by Pavlou [16]. In addition, rather than devising a new scale for the dependent variable, this convention makes it possible to measure the dependent variable with extant scales that have been proven in measurement properties. Measures for trust are adapted primarily from Bhattacharjee [39], Suh and Han [24], and Pavlou [40]. The measurement items from the studies were collected and items with the same meaning were merged. Items of E-satisfaction and E-loyalty are adopted from Anderson and Srinivasan (2003) on exploring the relationship between E-satisfaction and E-loyalty. The items of E-satisfaction and E-loyalty, adopted from Anderson and Srinivasan [41], were based on the scale of customer satisfaction by Oliver [38] or Gremler [42]. All the items were measured on a seven-point scale ranging from strongly disagree (1) through neutral (4) to strongly agree (7). The higher values indicate higher degree of attitude, intention or actual purchasing online.

III.3 Sample

With purposive sampling method, a total of 3360 questionnaires were distributed through the 120 Executive MBA students and 4 lecturers of National Dong Hwa University in Taiwan. 2035 questionnaires were returned. We set a critical standard to define the "valid questionnaire". A questionnaire having more than 10 items clicked continually in the same score was considered to be invalid. Although the critical standard reduced the number of questioners, it could improve the quality of valid questionnaires. As a result, 88 were eliminated for conflicting and incompleteness and 689 respondents claimed they have never bought online. Eventually, 1258 valid questionnaires were collected. The net response rate is 37.8%. With descriptive statistic analysis, there was a relatively even split between males (46%) and females

(54%) respondents. The majority of respondents age from 21-35 years old representing 69% of the whole responses. In terms of occupation, the respondents reveal a quite even distribution: student (19%), service trades (20%), finance (15%), government/military (14%), business (12 %) and industries (9%).

Table 1 presented the results of factor analysis and alpha coefficients for each construct with reliability analysis. The

result of reliability analysis is shown as Table 1. Conbach's alpha values of each construct are from 0.71 to 0.90, indicating a level above the 0.70, the threshold recommended by Nunnally [44]. Most of them are even above the 0.8. Additionally, the variance extracted values are from 53% to 69%, exceeding 50%. It reveals that the scale of trust exhibits strong internal reliability.

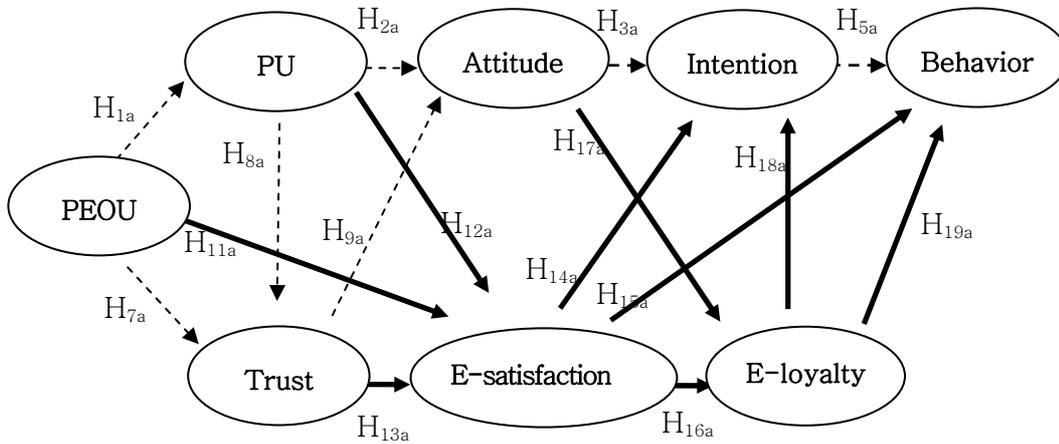

Figure 1 The Relationships among Trust, E-satisfaction, E-loyalty, and Customer Online Behaviors

Table 1 The Result of Reliability Analysis

	Number of Items	Variance Extracted	Scale Reliability (alpha)
Perceived ease of use (PEOU)	6	61.20%	0.87
Perceived usefulness (PU)	6	63.29%	0.88
Attitude	6	65.68%	0.89
Behavior Intention	5	65.91%	0.87
Usage(Actual Using Behavior)	4	53.19%	0.71
Trust	6	69.28%	0.90
E-Satisfaction	7	63.15%	0.90
E-Loyalty	6	61.31%	0.84

IV. Results and Discussion

After assessing the reliability and validity of measurement model, we tested the hypothesis and overall fit of the path model by using the maximum likelihood (ML) technique to estimate the parameters. The scale for each factor was set by fixing the factor loading to one of the indicators (items). The path coefficients and overall model fit indices of research model are drawn as Table 2 and Figure 2.

Table 2 Structural Equation Model Analysis

Hypothesis	Constructs	Coefficients
		s

	From	To	
H ₁	PEOU	→ PU	0.94***
H ₂	PEOU	→ Attitude	0.19**
H ₃	PU	→ Attitude	0.37**
H ₄	PU	→ Intention	0.58**

V. Conclusions and Limitation

V.1 Conclusions

With the empirical results, the path coefficients of PEOU to PU (H1), PU to attitude (H3), attitude to behavioral Intention (H5), behavior intention to behavior (H6) are significant at the 0.001 significance. In other words, H1, H3, H5, and H6 are supportive. However, the effects from PEOU to attitude (H2) and PU to intention (H4) are not significant. It implies that there is a linear causal relationship among PEOU-PU-attitude-behavioral intention-behavior.

The purpose of this study was to explore the role of trust in the mechanism of online shopping. We hypothesized that trust is the consequence of PEOU and PU, and trust is also the antecedent of attitude and intention. The empirical results indicate that trust played similar roles as PU because it is the consequence of PEOU and the antecedent of attitude. As in previous researches, consumer trust, as PU, led to increase the using intention [13,14]. However, trust does not influence intention directly. Trust affects intention through the attitude mediator variable. Besides, trust might affect PU, but this is not supported in all online behavior models.

It is note worthy that consumer trust has a stronger effect on attitude than PU does. It corresponds to the result of Gefen and Straub [13, 14]. It implies that online shopping service depends not only on the operational characteristics of websites, its PU and PEOU, but also, and possible to a greater degree on consumer trust toward the websites. Therefore, managers need to take this into account in their website planning efforts. Furthermore, with the empirical results, it indicated that E-satisfaction was only affected by PU and Trust and E-satisfaction only affected E-loyalty. Although E-satisfaction not affects Behavior directly, it might affect Behavior through E-loyalty and Intention.

In the TAM model integrated Trust, E-satisfaction and E-Loyalty; there are three belief variables (PEOU, PU and Trust), three attitude variables (Attitude, E-satisfaction and E-loyalty), one intention variable, and one behavior variable. Belief variables positively affect Attitude toward website, and further, positively affect the individual's intention to use (including browse and purchase), finally affect the individual's actual using behavior. In addition, in three belief variables, PEOU was the antecedent of PU and Trust, and PU also had influence on Trust. Although PEOU was belief variable, it not affect other attitude variables directly, but

affect other attitude variables through PU and Trust. In three attitude variables, both Attitude and E-satisfaction were affected by PU and Trust, and affected E-loyalty. The Intention affected by Attitude and E-loyalty. The Behavior was affected chiefly by Intention and secondarily by E-loyalty. In briefly, Trust played the similar role as PU; E-satisfaction played the similar role as Attitude; and E-loyalty was the consequence of E-satisfaction/Attitude and the antecedent of Intention.

In the original TAM, Attitude was merely affect by PEOU and PU. However, we found Trust has had a stronger effect on Attitude than PEOU and PU did. The effect from PEOU to Attitude was even not significant in our models. It indicated trust was the most major belief factor to influence customer online behavior. Trust also the chief factor to affect E-satisfaction.

V.2 Following Research and Suggestion

The sample in this study consisted of 1258 online customer having e-shopping experienced from various occupation (Student=19%, Service trades=20%, Financial =15%, Government/ Military=14%, Business=12% , Industry=9%), various age group (under 20 =11%, 21-25 group=23%, 26-30 group= 26.1%, 31-35 groups= 20%, 36-40 groups=11%, above 41= 8%, various websites, split of male (46%)and female (54%). It demonstrated the generalizability in our study and our results can generalizable to various types of customers and websites.

TAM is a mature model and has been validated in different contexts. Because Internet is a kind of technology, it is proper to applied TAM to explore the user (customer) behavior online. However, this is not without limitation. Because this is the first study to divide using behavior to browsing behavior and purchasing behavior, the validity of scales to measure each construct might be need to be confirmed for further studies. For examples, the reliability and validity of behavior construct didn't not perform as well as other constructs. It was resulted from the items measuring behavior were not measured on a seven-point scale. Not like the other perceived constructs could be measured with seven-point scale, the frequency and amount of browsing and purchasing were not proper to adopted seven-point scale and resulted in lower reliability and validity and it might further affect the results of research models. We hoped that further studied provide more guideline about this for web-based companies who are looking to improve their customer based and sales.

Roy.Wybrow@jcu.edu.au

Abstract: The structure and layout of various websites across a wide spectrum of service industries was analysed using the WebQuality Analyser (WQA). The WQA incorporated forty five critical success elements delivered by quality on-line websites. These success elements covered information technology (IT) and marketing-services related sectors, and were further divided into five key drivers encapsulating each sector. Each sector driver was then divided into four or five customer-enabler features (covering structure and function), each with several feature components. A present / absent approach determined each component. A seven-point, Likert scale encapsulated the relative presence of the features of each driver.

Although it houses both measurable and subjective components, the WQA offers a useful means to compare relevant websites, and to understand the differences with respect to one's competitors.

Further investigation of the specific on-line driver ratings demonstrated where key competitive advantage may reside. This benchmarking tool defined website strengths and weaknesses thereby allowing for corrections to the website structure of the specific business. This paper introduces the WQA, and reports on the marketing-services sector of this new benchmarking tool.

Keywords: Service Operations on the Web; benchmarking; website; analysis; service value networks; analysis; compare.

I. Introduction

Benchmarking delivers a "comparison of a company's performance in certain areas with that of other firms in its industry and / or with those firms that are identified as world class competition in specific functions and operations" [1]. It can also cut across traditional lines, providing opportunities for new and innovative ways to increase performance, and be a "search for industry best practices that lead to superior performance" [2][3]. Modern benchmarking was initiated by Xerox. They modelled their spare parts distribution on the warehousing and distribution practices of L.L. Bean. Since then Xerox has continued to promote best practices. In 2000 the American Productivity & Quality Center recognised Xerox's development of 'proactive strategies to identify, retain, and re-use knowledge so that individual expertise is

transformed into real working knowledge.'

Benchmarking, best practice, and reengineering are key pathways to achieving dramatic improvement in critical contemporary areas such as cost, quality, service and speed [4]. Reengineering often involves the disruptive [5] reinventing of processes and / or the substantial redesign of existing procedures, and is not merely the delivery of continuous incremental changes. Reengineering without benchmarking will generally deliver smaller improvements than reengineering with benchmarking [6]. By studying other best practice operations, companies may identify, and import new technologies, skills, structures, training and capabilities [7]. Hence, including these identified best practices may then deliver new competitive advantages [8][9].

Today firms routinely share best practice and benchmarking information, and often seek help from one another to achieve higher quality and better performance. At times they may even jointly market their services to customers or even work closely with their competitors. The Cairns Super-Yacht Cluster [10] now houses over forty local businesses who previously competed with each in the fishing, large marine taxi, and tourist related marine activity sectors. These former competitors collaboratively use their world-class facilities, competitive technologies, and specialist best practice skills to repair, maintain and refit foreign registered super-yachts. They have created a world-class, dynamically benchmarked, business block that in 2004 generated an economic impact of over \$40M. This industry has technologically reengineered into a best-in-world super-yacht re-builder.

II. Benchmarking and the Web

Benchmarking, best practice and reengineering also apply to virtual businesses or Internet- based website businesses, and also to those physical businesses incorporating internet-based websites into their business models. Evans [5] suggests that if the entire value chain (including devices, networks, standards, and applications) is handled correctly on the supply side and combined as an e-business, new opportunities for both business agility and competitive value may be extracted. In addition, Evans [5] considers the business's customer-driven demand side with its cost reductions, revenue generation, customer satisfaction, increased productivity, reduced cycle times, speed and flexibility and suggests these functions may be reconfigured to drive innovative use of technologies. He suggests these

attributes, once benchmarked, and assessed, may allow mechanisms that allow the business to differentiate itself from its competitors.

Benchmarking and competitive intelligence gathering activities are necessary website marketing activities. [11] Competitive intelligence delivers a collage of information about selected competitors. This gathered information is then applied to short and long term strategic planning to facilitate better and smarter business decisions [12]. Competitive intelligence involves data collection and storage, data analysis and interpretation, and the dissemination of intelligence. The process is information-based, systematic, and delivers 'actionable information' [13]. Thus a tool to analyse relative website competitiveness will likely be an important aspect of a business's competitive intelligence.

In addition to marketing considerations, latest advances in website-related technologies such as Microsoft Research's 3D TaskGalley [14] offer new ways to present information, and to maximise the quality of information conveyed whilst minimizing the effort applied by the end user. This technology enhancement also impacts on website marketing functions [16]. Microsoft's 3D smart visual website interfaces present more information. This 3D space or room, with information objects arranged on the floor, ceiling and walls, moves the most important information to the front, and the least important information to the back. Hence, the productivity of the website may be enhanced.

Considering web-based business-customer encounters, the bundling of products and services has become another important trend to add value and drive sales. These encounter areas are best delivered via a three pronged approach that incorporates the areas of: marketing, services, and technological application [15][16]. Website visitations, unlike physical business contact times are generally of very short duration, and so require a quick focussing of customer intent. However other advantages remain, these include – open for business 24/7/365 with continuous revenue generation possibilities and ease of modification to on-line 'shopfront', products and services. Lists of website features have been compiled [17], with over 460 features being displayed in one list. Some of these features constitute customer-related 'benchmarkable' areas [18].

Many researchers have investigated various aspects of website benchmarking. Van der Wiele & Brown, [19] focused on information content analysis based on the traditional 4P's (product, price, place, promotion and other website information not fitting the above four categories. Scoring used Whiteley's [20][21] method assigning '0' to indicate absence of a feature's components, or '1' to indicate presence of a component of a feature. This method lends neatly to development of a computerised solution. On rare occasions a subjective decision concerning a component may be required. In this situation a conglomeration of items may blur the decision as to whether a component is rated present or absent.

Today websites are evaluated using a variety of methods including 'web assessment models' [20][21][22]; QFD,

'feature assessment analysis' [23]; 'strategic positioning' [24][25]; 'customer interface marketing design elements' [26]; 'industry-wide comparisons' [16]; 'objective feature presence' [23][28, and various benchmarking systems'. Barton [29] use 0-10 point scales to scale their identified features and analyse these via Ho's [30] customer perception of value added benefits, and via their own Five Quadrants Evaluation Model. Still others use benchmarking teams and Baldrige criteria to evaluate websites [31], but even these measures have not accurately reflected comparisons between websites, especially from an IT services and marketing approach [16].

This paper compiles the combinations of the above research with that of website details [32](w3C.com); hexagonal comparison grid [33]; service value networks [16]; and a 100 point measurement tool (worldsbest website.com) to develop a new model for benchmarking and rating websites. This Web Quality Analyser (WQA) was initially tested on the on-line (or e-business) real estate industry. Subsequently, additional testing indicated it had more general application and the WQA may be applied across the gambit of on-line business ventures. It was also tested against small sole-operator businesses, medium sized operations and through to large portal-sized ventures.

III. Website Marketing Drivers and Component Features

The key structure and function feature components used in assessing the weighting of the five features for each driver within the website information technology sector of services industry are presented under the driver blocks of: functionality, design, content, originality and effectiveness. The drivers for the website marketing-services sector are: company product presence, value adding services, target market, searchability and creative expression. These components and features of the five marketing-services WQA drivers are each discussed next.

III. 1 Company – Product Presence

Product Representation: here products / services are faithfully described; 'sold' to the user as quality items; quality-badged; accurately costed [18] [35][78][79][80].

Product Information: is accurate and concise; linked to databases; linked to additional user information; capable of showing alternative products / services [25][63].

Company Representation: shows the company as modern and professional business [18][80][81].

Company Information: presents relevant company information; accreditations; contacts; 'About Us' [40] [80] [81].

III. 2 Value Adding Services

Value Added Links: cover links to internal or external added-value sites e.g. lending facilities, financial institutions, removalists, etc; are responsive to user demands; cover internal SC members and external peripheral partners)

relate to the product and / or service, and how the website should be moulded. This paper assesses the marketing-services related drivers of the WQA.

A standard data-collection criterion was used [89]. A multidimensional scaling technique drawing on the combination of subjective (or perception), objective (or measurable), and respondent feature preference (idea patterns) rating scales allowed the comparison of individual business websites [90]. A present ('1') or absent ('0') rating scale similar to those used by Whiteley and Everett [21][23] was used at the feature component level, and was then converted to a feature Likert measure. The traditional seven point 'more' or 'less' Likert scale was adopted as the prime scaling measure for each feature. This summated rating scale actually measured multiple questions in one, with the numeric score reflecting the degree of attitudinal or measurable 'favourableness'.

The ten website drivers – five IT, and five marketing-services related drivers (or factors), presented forty five Likert scale features (indicator variables). Each four or five features influence each driver.

The forty five dataset features (indicator variables representing their respective components) measured, easily met all reliability criteria. These features were then used to compile comparison datasets. The business's ability to deliver desired effects (when compared to its competitors) was thus measurable. Feature presence (or absence) was either measured, or estimated. Individual differences were controlled using a sufficiently large dataset, and a relative effectiveness scale could be produced from the dataset.

Trials with tertiary student groups (across first, third and MBA levels) were conducted over 2003 and 2004. Typically, final year undergraduate student groups, averaged 30 persons per class per location, Students from Sydney, Melbourne, Townsville and Cairns, Singapore and Malaysia participated. These trials delivered a successful website ratings model called the Web Quality Analyser (WQA). This paper reports on the 2005 study, and only considers the marketing-services components of the WQA.

In 2005 the WQA was tested in the business community across Australia. Twenty eight, IT-skilled, data-collectors each rated websites similarly. In addition sixty five marketing persons across Australia tested the marketability drivers. Again feature classifications were rated similarly.

IV.1 Sample

The sample size consisted of 126 service industry websites. In order to avoid possible bias firms selected were drawn from across the services industry. These included: financial services (3%), hospitality (14%), logistical transportation - including airlines (30%), Real Estate (24%), recruitment and careers (10%), legal services (10%), and tourism (10%). Within these sectors a spectrum of large, medium and small firms were selected. In addition multiple testing of certain areas was conducted to ensure consistency of results.

Predominant businesses were of micro and small to medium size, with approximately 18% fitting the major or

global corporation's category. This approximates with the Australian Bureau of Statistics 2004 data where 79% of businesses are small to medium sized industries, and is in accordance with the Australian services industry mix, and implies that the sampling error is low at around +/- 5% for the overall sample.

IV.2 Dimensionality

Here a large range of components, features and drivers have been identified. Figure 1 summarises the factorial models for each of the five marketing-service sector drivers. As can be seen from this diagram all features (competencies) are considered first order factors.

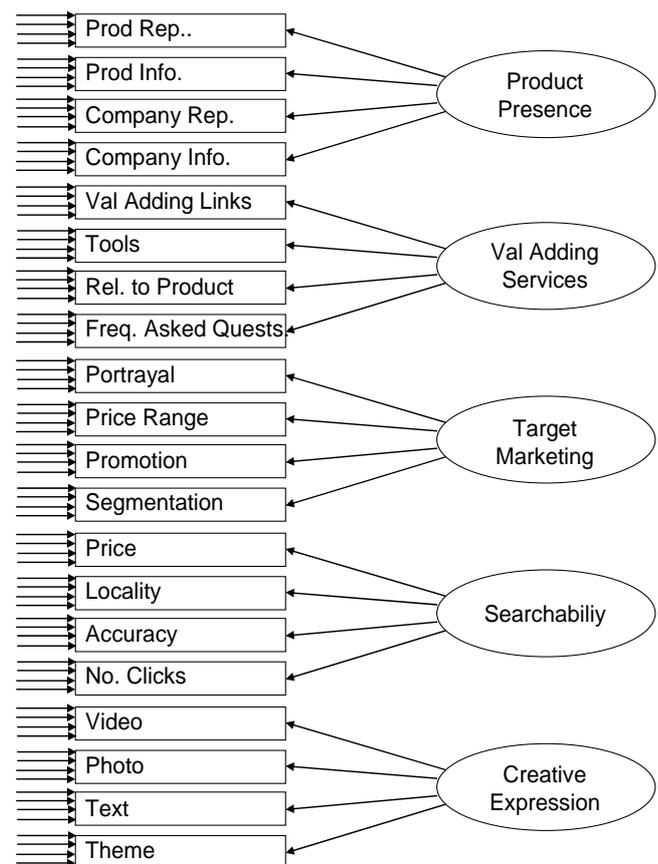

Figure 1: Factorial Model: WQA Marketing-Services Sector

Considering this model and the uniqueness of each service sector driver, a confirmatory factor analysis (CFA) was conducted and an estimation of the model was theoretically deduced from each scale.

Dimensionality of the tool was tested utilising factor analysis using Varimax rotation across all twenty indicators (termed features, and listed in section 3.6. to 3.10 above) to reduce these indicator variables into the predicted model five factor areas. Factor analysis tested appropriateness of the indicators divisions into the selected driver groups as used in the WQA. The Kaiser-Meyer-Olkin measure of sampling adequacy yielded a value of greater than 0.6, being 0.894,

with Bartlett’s tests for sphericity at 0.000, being highly significant, (with 190 degrees of freedom). Thus indicating factor analysis was deemed appropriate. Using the Varimax rotation method with Kaiser normalisation factors a convergence to the five marketing-services sector driver factors of the WQA were reached after only six iterations of rotation.

Table 1: Varimax Factor Loadings: WQA Marketing-Services Sector

Driver (Factor)	Initial Eigen-values			Extraction Sums of Squared Values			Rotation Sums of Squared Values		
	Total	% of Var.	Cum.%	Total	% of Var.	Cum. %	Total	% of Var.	Cum. %
Presence	10.413	41.653	41.653	10.413	41.653	41.653	6.220	24.879	24.879
Val	2.680	10.722	52.374	2.680	10.722	52.374	3.676	14.704	39.582
Searchability	2.110	8.440	60.815	2.110	8.440	60.815	3.570	14.281	53.863
Market	1.743	6.970	67.785	1.743	6.970	67.785	2.702	10.870	64.670
Creativity	1.400	5.603	73.386	1.400	5.602	73.386	2.176	8.716	73.386

Principal factor analysis conducted on the five drivers, yielded all drivers with eigenvalues above 1.0. After Varimax rotation, the first driver (factor) - ‘Product Company Presence’, reflected that all four features (indicator variables) loaded highly. Similar trends applied to the other marketing-services drivers, albeit at slightly lower levels. The five Varimax drivers (factors) ranged from 24.9% to 8.7% of total variance, and accounted for 73.4% of the total variance. The five factors were subjected to a comparison analysis with eigenvalues calculated using the Montocarlo PCA – Parallel Analysis. All five drivers (factors) chosen had eigenvalues greater than their comparable Montocarlo compatriates, and were therefore retained.

Table 2: Montocarlo PCA Parallel Analysis: WQA Marketing-Services Sector

Number of variables		20
Number of subjects		200
Number of replications		50
Eigenvalue	Random Eigenvalue	Standard Deviation
1	1.6046	0.0744
2	1.4861	0.0432
3	1.3997	0.0407
4	1.3241	0.0258
5	1.2659	0.0278
6	1.2035	0.0286
7	1.1532	0.0256

Montocarlo PCA – Parallel Analysis

Table 3: Varimax Factor Loadings: WQA Marketing-Services Sector

Driver (Factor)	Initial Eigen-values			Extraction Sums of Squared Values			Rotation Sums of Squared Values		
	Total	% of Var.	Cum.%	Total	% of Var.	Cum. %	Total	% of Var.	Cum. %
Presence	10.413	41.653	41.653	10.413	41.653	41.653	6.220	24.879	24.879
Val	2.680	10.722	52.374	2.680	10.722	52.374	3.676	14.704	39.582
Searchability	2.110	8.440	60.815	2.110	8.440	60.815	3.570	14.281	53.863
Market	1.743	6.970	67.785	1.743	6.970	67.785	2.702	10.870	64.670
Creativity	1.400	5.603	73.386	1.400	5.602	73.386	2.176	8.716	73.386

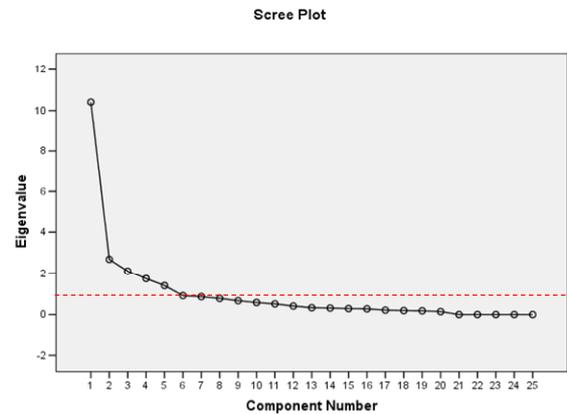

Figure 2: Factor Analysis Varimax Rotation: WQA Marketing-Services Sector

Table 3 and Figure 2 summarise the Rotated Component (Factor) Matrix five driver (factor) outcomes which map the WebQuality Analyser tool.

Table 4 and Figure 3 display a further factor analysis to ensure a more concrete factored model. This Oblique rotation, accounts for any non-orthogonal mapping of factors. Again a high degree of variance is explained by the first five factor components eigenvalues, which explain 68.1% of the total variance.

Table 4: Oblique Factor Loadings: WQA Marketing-Services Sector

Component	Initial Eigen-values			Extraction Sums of Squared Values			Rotation Total
	Total	% of Var.	Cum.%	Total	% of Var.	Cum. %	
Presence	7.421	37.107	37.107	10.413	41.653	37.107	6.094
Searchability	2.100	10.502	47.609	2.680	10.722	47.609	3.806
Value Adding	1.674	8.369	55.978	2.110	8.440	55.978	3.486
Market	1.304	6.519	62.498	1.743	6.970	62.498	1.900
Creativity	1.121	5.603	68.100	1.400	5.602	68.100	2.631

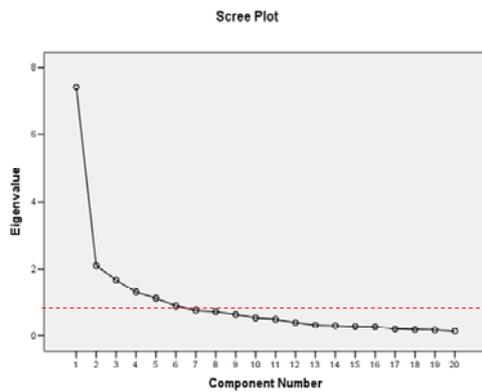

Figure 3: Factor Analysis Oblique Rotation

IV. 3 WQA Marketing-Services Sector

The resulting Pattern and Structure matrices, are displayed in Tables 5 and 6. These matrices were constructed after rotational convergence of nine iterations which strengthened the factors originally computed via the Varimax rotations, the Oblique methods thereby displaying a strong inter-correlation between the factors.

The ‘goodness-of-fit’ over each of the twenty features (indicator variables), as well as across each indicator variable comprising the five factors. Goodness-of-fit was calculated using Pearson’s and Deviance Chi-Square under multi-regression analysis. This resulted in a solid significance of 1.000 for each driver (factor) model. Thus, each marketing-services driver was deemed unidimensional, and driver measurement supports its distinctiveness against the other marketing-services drivers.

Principal Component Analysis; Oblique Rotation with Kaiser Normalisation; Rotation Convergence: 9 iterations.

IV. 4 Reliability Analysis

Individual reliability testing using Chronbach’s alpha indicated equal to or greater than 0.5, while composite testing indicated equal to or greater than 0.7. Further testing was achieved utilising Friedman’s ANOVA Test (between groups). Here, a large significance of greater than 0.2 showed no difference between the indicators of the services sector driver group. In addition a significance of equal to or greater than 0.05 signified a difference between the indicators of differing services sector driver groups. The entire twenty indicator set provided a composite Chronbach’s Alpha of 0.905, and a Friedman’s In-Between ANOVA of 0.000, thus indicating significant differences between all groups.

IV. 5 Content Validity & Convergent Validity

Content validity was grounded in the literature, with all indicators (features) of the measurement considered covered across all important aspects of the latent variable (driver) to be measured. In addition extensive pre-testing enabled scales suitable for this research.

Convergent validity correlated the various indicator measurements (features) required to evaluate the latent variables (driver) to each other. Each indicator variable was tested for convergence using a variety of tools. Considering appropriate chi squared values, and the statistical significance of factorial loadings, a high level of convergent validity was shown – with all Bentler-Bonnett coefficient values close to one (0.975→1.0), and the individual factorial loadings of each driver having t values above 1.96.

Principal Component Analysis; Oblique Rotation with Kaiser Normalisation. (All estimated parameters are statistically significant at 95% (>1.96))

IV. 6 Discriminant Validity

Discriminate Validity was tested using Bagozzi & Phillips ‘pairwise test’ to determine whether paired factors fitted the data better than a single factor. A series of chi squared difference tests were conducted. Here, at p values of 0.000, each showed statistically significant differences. Thus from their correlation values, the drivers were interrelated, and each concept differed from the other. Hence, the existence of discriminant validity was affirmed.

V. Discussion

The analysis of marketing-services aspect of this tool has been discussed above. It is a reliable, viable, useful tool.

The WQA offers a simple, yet highly useful, means to compare relevant competitive (or benchmarked) websites. It

offers a mechanism to better understand differences between competitors. A comparative benchmarking standard may be established, allowing a business like an on-line real estate firm to enhance its relative competitive position using value-added features such as - distance to local schools, average time to drive to city, local council contacts, help services, and the like. It may then develop a more 'customerised' [24][25] services-product suite – offering increased 'one-on-one' customer satisfaction [26], and possibly, increased return on investment (and profit) [16].

VI. On-Going Research

A valid tool for comparing and benchmarking websites is now under development, with a computerised version of the WQA currently being prepared for commercial release.

One limitation within the marketing-services sector of the WQA remains to be solved. Within a couple of features inside the total IT marketing-services sector, occasional difficulties were encountered by users when rating certain complex feature components. This technical weakness in measurement capture is currently under investigation for both the marketing services, and the IT sectors of the WQA. New additional measurable component datasets are under test, and are likely to be incorporated into the final computerised WQA model.

Another area possibly warranting additional investigation is the issue of 'search', or 'trawling the web to locate a website'. The ability to find a website is vital for both the

user and the vendor. Other 'search for airline' studies [20][21], further highlight such problems. Research into 'search' requires additional structured experimentation, and was considered beyond the initial scope of this research.

VII. Conclusions

The marketing-services sector of the WebQuality Analyser (WQA) is an empirically validated, useful tool for the analysis of e-business enabled web sites. When married with its IT sector, two previously disparate approaches to benchmarking websites deliver a new, empirically developed benchmarking and comparison tool. The WQA is more accurate than existing alternatives. It unites: (1) a process oriented analysis involving the stages within the trade cycle, with (2) a HCI approach (focusing on technology, R&D outsourcing, application development, client focus, and core business delivery) treating user or client visits as personalised website e-business-client encounters. Overall, the WQA contains the key elements necessary for valid, detailed, assessment of websites.

The use of the WQA as a benchmarking and comparison tool, also contrasts with the website 'gut reaction' often provided by web users. Schaffer and Sorflatten [91], report that many web users assess a web site as: too slow; disorganised or confusing; or not offering the required service; and then move-on - to other websites! The 'gut reaction' does not deliver an objective basis for benchmarking or comparing websites (other than on a two point scale), nor for planning website improvements. In comparison, the WQA delivers a thorough, empirically supported and well tested benchmarking tool. In addition the WQA delivers an instrument that may be used as a strategic management tool.

Thus, this research supports the use of the WebQuality Analyser's the five marketing-services sector drivers and their inherent features as indicators of marketing-services website quality.

Author Profiles:

John Hamilton is the Director of E-Business at James Cook University. His extensive domestic business ownership and management experience includes: importing, exporting, mining, rural, wholesale, manufacturing, and several small-medium businesses (supermarket, video wholesale, fashion stores, florist/gifts, restaurants,) His international business experience includes: Sapphire mining, processing and gemstone sales; plastics manufacturing; importing/export-

ing; and international finance.

John Hamilton is a driver of innovation, market leadership, and creative thinking. He developed: the world's first abalone aquaculture farm - and perfected live export techniques (1980-4); rock lobster aquaculture procedures (1981-4); a plastics manufacturing plant in China (1987-8); computerised sapphire gem cutting machine technologies (1991), offshore financing procedures (1991), Ed .Qld.'s Centre of IT Excellence - programming, database implementation, e-commerce, multimedia, robotics and communications technologies (1994-2001); and JCU's MBA/MIT E-Business strategic initiative (2002-2005).

John Hamilton has extensive business, management, consulting and research experience. He is an active researcher. His current specialisations include: development of strategic web-based instruments; QFD; strategic positioning; strategic e-marketing; logistics, killer strategies for business; service value networks, industry-wide future technologies and solutions; and the performance, value and alignment of customer-business interfaces.

Roy Wybrow has worked in IT/IS business related fields including aircraft R&D, engineering, e-commerce and ERP for various MNE's in Vietnam, China, Malaysia, Fiji, Papua New Guinea, and Australia.

He lectures in statistics, e-business, communications technologies and venture management at James Cook University.

He is a skilled researcher, especially in the statistics and information technologies arena. He is currently researching across a wide range of industrial sectors to determine the factors driving successful industrial clusters.

His consulting firm has identified, developed, and commercialised, many unique business solutions including: computerised fruit picking, energy efficient housing, sophisticated IT/IS solutions for business, and value adding, peripheral, sugar-based industries and associated industrial clusters. He has also consulted, developed and implemented Balance Scorecards for SME's.

Managing Wireless Communications in Taxi Services

Ziqi Liao

Department of Finance and Decision Sciences

Hong Kong Baptist University

Kowloon, Hong Kong

Telephone: (852) 34115227 e-mail: victor@hkbu.edu.hk

Abstract: This paper describes the wireless communications in the context of taxi service operations. Human-system interaction is necessary to taxi vehicle dispatching. However, the process is influenced by various variables in relation to dispatch data conveyed to drivers, display panel, mechanical noise and vibration. The in-vehicle wireless dispatch interface must be ergonomically designed to cope with environmental influences. The findings have practical implications for managing services operations.

Keywords: Technology management, service operations, wireless communications

I. Introduction

The Automatic Vehicle Location and Dispatch System (AVLDS) has been implemented by several taxi companies such as Comfort, CityCab and Trans-Island Bus Services in Singapore. It effectively supports the operations management of taxi fleet and considerably enhances the taxi services. The AVLDS comprises differential Global Positioning System (GPS), wireless data communications, computerized dispatch systems and interactive voice responses. A number of stations have been established for the transmission of data between the control center and individual taxi vehicles equipped with GPS antenna, receiver and transmitter. The system can immediately detect the nearest taxis to a particular customer, and identify each vehicle's route and location. Therefore, it enables the taxi company to immediately respond to a customer request for taxi service. It also enables collaborative operations between call operators and individual taxi drivers. This paper presents the wireless dispatch process and discusses the environmental variables in relation to in-vehicle human-system interactions.

II. Dispatch Operations

The GPS has been extensively used for vehicle navigation and transportation management [1] [2] [3] [9]. In the present case, the GPS-based dispatch system can automatically locate taxi vehicles running within ten kilometers to a customer when a request for service is received from a dedicated terminal or an automated call handling system. It is a significant improvement over the radio-paging system

used previously. The computer-assisted dispatch process involves the transmission of a request for service via wireless data communications to a number of taxi vehicles. When a job is circulated, a taxi driver can easily respond to the control center by pressing a button on an in-vehicle dispatch device if he would accept the job. However, if the drivers of those taxis within ten kilometers do not respond to the request for service within a preset period of time, the system will automatically search for the next nearest taxi vehicles and the job will be dispatched again. Upon successful matching, the taxi number and expected time of arrival will be immediately relayed to the customer. As a matter of fact, the expected time of arrival is relatively accurate, because the system has the capability to continuously calculate the time needed for the taxi to arrive at a particular destination. Although the system tends to circulate a job to those taxis within a relatively short distance to a customer, it is able to relay different zones to track other taxi vehicles.

III. Interface

The wireless dispatch device installed in the taxi vehicle enables a driver to read message, send message and review job record. The driver can easily read the dispatch data on the display including name of a customer, pick-up address and time. He can also communicate with the control center using a few keys on the device. For instance, if he presses "Auto" on the device, he will be given a job when his vehicle is identified closest to a customer. In this case, he must accept the job and proceed to the pick-up point, when there is a service request appearing on the panel. On the other hand, if the driver presets "Can Bit" on the device, a request for service together with the pickup address and time of a customer will be received from time to time. If he would like to take up the job, he must bit for it by pressing a "Bit" bottom. Because a number of taxi vehicles may receive the same request for service concurrently, he should respond to the request quickly in order to get the job.

The in-vehicle wireless dispatch device can automatically record and memorize the job completed by a driver. Table 1 shows a record of the sixteen jobs done by a driver on a particular day. In this case, he has completed five jobs (i.e. requests for service) allocated by the control center. In addition, he has served nine different customers hailing taxi service on the street and a customer specially arranged (i.e. special job done). Moreover, there is an "advance register" because the driver has a regular service of sending

someone to office at 8:30 am every morning. Lastly, he has accepted an advance booking to the airport at 6:30 am next morning.

Several functions associated with the in-vehicle device are summarized in Table 2. If a driver is not sure of the venue and is not able to locate a customer to a particular designation, he can easily ask the control center by pressing "Address not clear." He can also communicate with the control center through wireless mobile phone. The system can provide a taxi driver with road information, route guidance and assistance, since the geographical information system associated with the AVLDS contains a database with electronic maps and road directory.

The driver can inform the control center "Late for pick up," in case he recognizes the difficulty to reach a particular customer on time due to heavy traffic. He can also tell the control center "Far from pick up," if he believes that there is a relatively long distance between his current location and the pick-up point of the customer. Moreover, the driver can report to the control center and request for towing service if his vehicle is breakdown or has any malfunctions. He can also report to the control center if there is a traffic accident. Accordingly, the control center can ask ambulance and traffic police for assistance. Finally, the driver can inform the control center in case of any emergency through a hidden alarm activator, while the control center can immediately identify the location of the taxi and provide prompt aid to the driver.

Table 1 An Example of Job Record

Job specification	Number of job
Call job done	5
Street job done	9
Special job done	1
Advance register	1
Total job done	16
Job rejected	0
Advance job accepted	1

Table 2 Report to Control Center

Function key	Request for assistance
1	Car breakdown
2	Address not clear
3	Far from pick-up
4	Late for pick-up
5	Car accident
6	Towing service
7	Radio me every five minutes

The AVLDS improves the communications between control center and taxi drivers, because it not only enables the transmission of dispatch information in a precise manner, but also cultivates a collaborative operational platform for call operators and taxi drivers. The previous radiophone often caused misunderstanding between a call operator and

taxi driver, because both sides had to withstand the drone of sound emitted by phone. Hence, the customer reservation information conveyed by the call operator to drivers might be distorted. In comparison with the previous radio paging system, the working environment of call operators has been greatly improved since the noise level has been considerably reduced.

The system eliminates ineffective communications, because the reservation is digitally transmitted to different in-vehicle devices. In particular, the standardization of data entry and data processing enables an operator to easily handle several calls within a specific time frame. As a result, it permits more reservations to be processed with the similar level of manpower. The efficiency of call operators has been enhanced, because the system effectively enables the call operators to match the call for taxi service from individual customer. With the implementation of the system, the operator is able to quickly retrieve the pick-up location when receiving a call for service.

Many public telephones are equipped with automatic-dial services in Singapore. For example, one can reserve a taxi by pressing the CabLink Hot Button, which is a label indicating one of the taxi companies at a public telephone. Such a request for service will directly go to the dispatch system of that company, in which the reservation is instantly processed because the pick-up location can be automatically identified. Finally, individual customers are encouraged to register the use of the GPS-based dispatch system. Hence, the taxi company can provide them with more customized services. For instance, a regular pick-up at a particular point of time can be arranged for a customer.

IV. Discussion

The implementation of the AVLDS effectively facilitates the management of large number of taxi vehicles and enables the achievement of operational efficiency. The taxi drivers have benefited from the system, because it helps reduce operating costs, obtain on-line route guidance and ensure security and safety. Prior to the use of GPS-based dispatch system, it was not uncommon that an average cruises empty was about 40% of the time. The drivers not only wasted his time, but also used additional fuels. Today, the taxi company is able to accept more reservations, thus creating more jobs for taxi drivers. The drivers have experienced an increase in productivity, because they can serve more customers, while decreasing daily operating costs and empty cruising. Some even prefer to wait until the system matches them with the nearest pick-up point of a customer.

The wireless communications and human-system interactions are influenced by a number of environmental variables [4] [5] [6] [7] [8]. It is therefore necessary to develop an ergonomic in-vehicle interface. The wireless in-vehicle device plays an important role in facilitating communications and dispatch operations. It also enables individual taxi drivers to effectively communicate with the control center and respond to a request for service. The

concerns in relation to the human-system interactions include the installation of in-vehicle dispatch device, data presentation on the display, manual operations of the device and the impact of external environment.

The wireless in-vehicle device should be installed close to the driver without interfering automotive instrumentations. When receiving a dispatch message appearing on the display panel, the driver may pay less attention to the road condition, and his attention might shift away from the primary task of driving. In particular, he has to read the message on the display in bright condition such as direct sunlight. Although the brightness of the display can be manually adjusted, the device must be properly installed to avoid extremely bright lighting. It should also enable the driver to read the dispatch data in the dark environment. The dispatch data conveyed to drivers should be short and precise.

The control functions of the wireless dispatch device have an impact on drivers' interactions with the system. Some drivers might not be able to adapt the system within a short period of time. Therefore, manual operations for responding to a request for service should be simple and easy to use, while unnecessary data transmitted to the panel should be eliminated. It might be difficult to customize an in-vehicle display to different drivers. The template of distributing dispatch data should be standardized. Some simple symbols should also help drivers appreciate a dispatch message and react to a request for service.

Finally, the noise mechanically generated by the vehicle considerably influences a driver's response to a request for service. A steady noise from the engine might compete with audio alarms and voice messages. In order to draw the driver's attention towards the dispatch data, the audio output of impulse noises emitted in short burst from the dispatch device should be adjusted appropriately. Finally, the driver has to pay more attention to the road condition when there is a significant vibration. The dispatch data conveyed in such a circumstance might affect the driver's performance and impair his ability to drive safely. The impact of vibration should be taken into account when installing the dispatch device. In sum, there are a number of variables in relation to dispatch data conveyed, display panel, mechanical noise and vibration. Because these variables considerably influence the communications and dispatch operations, they must be

ergonomically handled when designing the dispatch devices.

V. Conclusion

The effective wireless communications interface facilitates the improvement of taxi services in terms of time required for processing reservations and dispatching vehicles. With the AVLDS, customers are able to conveniently reserve taxi service at a particular pick-up point such as office and home. They can also easily get a taxi at different locations. In addition to vehicle tracking and dispatching, the system provides useful data for the management of taxi operations and helps the taxi company to optimize the use of limited resources. It also enables the taxi companies to achieve higher productivity and better service quality. However, the interface of wireless communications must be ergonomically designed in order to achieve the expected capacity of the dispatch systems. Environmental variables associated with in-vehicle operations must also be effectively tackled. The present observations not only provide information for improving taxi services, but also have practical implications for managing service vehicles in different environments.

Abstract: Assessing use is very important for organizations selling and using customer services system in Internet environments. Based on a conceptual model, this paper is to empirically study individuals' assessments of a new customer services system in Internet environment. The model has three phases; pre-use, test and use. In relation to the three phases, the concepts of value and quality are discussed. The main contribution of this paper is the understanding of the difference between the concepts of value and quality being illustrated in the conceptual model. Customers' assessment of value and quality could have implications for companies developing new customer services system in Internet environments.

Keywords: Assessment, Customer services system, Quality, Value.

I. Introduction

Assessing use is of vital importance for organizations selling and using services in Internet environment (Davis et al., 1989; Philip and Hazlett, 2001). In the areas of information technology and management the introduction by Davis (1989) of the technology acceptance model (TAM), was in many ways pioneering in understanding the psychological factors influencing information system use. Davis emphasizes the role of the individual in the organization. Furthermore, Orlikowski (2000) puts forward that since most technologies can be used in a number of ways, users shape the meaning of technologies as they integrate them into everyday practice. Emphasized in this paper is the users' interaction with technology solutions in everyday practice in an organizational context.

Bobbitt and Dabholkar (2001) share a similar understanding as Davis (1989) when they put emphasis on attitudinal beliefs to predict and understand use of technology-based self-services. Not entirely emphasized in the models by Davis (1989) and Bobbitt and Dabholkar (2001) is a broader understanding of usage than attitudes and intentions of usage, because intentions predict use, but not usage over time (Chau, 1996). Karahanna et al. (1999), on the other hand, put forward the importance of studying technology adoption across time. Karahanna et al. highlight the importance of organizational issues and the affect on the individual, particularly for potential adopters of information technology. A framework is presented where they

combine innovation diffusion and attitude theories to study differences in pre-adoption and post-adoption beliefs and attitudes. The consciousness of the difference between adoption and usage is a critical factor when understanding adoption. The importance of different phases in time, by Karahanna et al. (1999) labelled pre- and post-adoption, is of equal importance in this paper.

In addition to the distinction, made by Karahanna et al. (1999), in pre-adoption and post-adoption, a middle phase is implemented in the conceptual model presented in this paper. The middle phase is labeled the test phase. The reason why assessment of usage of a new customer services system in Internet environment should contain an additional phase is users involvement in development processes and its affect on users' assessment of the service in Internet environment in the test phase. Therefore, when users are involved in the development process of a new service in Internet environment, the assessment of usage should be based on three phases (Figure 1). The purpose of this paper is to use a conceptual model (Figure 1) to empirically study individuals' assessments of a new customer services system in Internet environment over time.

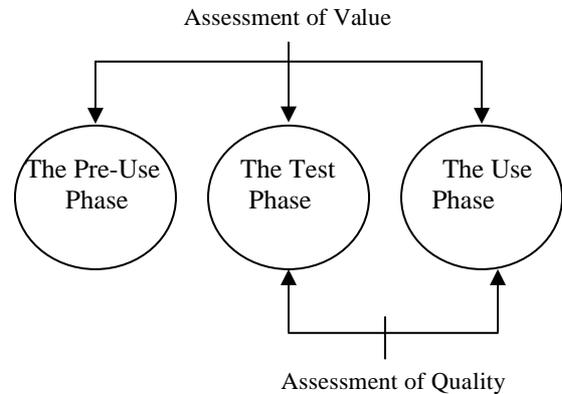

Fig. 1 User Assessment of Value and Quality of a New Service in Internet Environment.

In connection with these three phases, two concepts of great importance for user assessment will be discussed. The concepts are value and quality. McDougall and Levesque (2000) put forward that the concepts of quality and value are closely linked; "quality is just one side of the satisfaction equation." (p. 403). However, the difference between the concepts of value and quality is the main contribution of the conceptual model (Figure 1). The underlying principle of our model and the reason why the concepts of value and quality are important is that users' ability to assess the value of a service in Internet environment is possible without usage.

As for quality assessment, usage of the service in Internet environment is a requirement.

The structure of this paper is as follows; first, a brief introduction of the concepts of value and quality will be carried out. Thereafter, a discussion of the three phases will be presented with regards to the concepts of value and quality. In conjunction, early results from an ongoing study will be presented. Data collection in this study has been generated by the means of qualitative in-depth interviews over a period of two years. Interviews have been conducted with four pilot-customers of a new service in Internet environment in three different time phases, i.e. the pre-use, the test and the use phase.

II. Value

Perceived value is a difficult concept in that it is hard to define and measure (Zeithaml, 1988; McDougall and Levesque, 2000). Broadly defined, perceived value is the results or benefits customers receive in relation to the total costs. In other words, it is the difference between perceived benefits and costs (McDougall and Levesque, 2000).

According to Zeithaml (1988), customer-perceived value is the consumer's overall assessment of the utility of a product based on a perception of what is received and what is given. This can vary between people but also from occasion to occasion for the same person (Zeithaml, 1988). Caruana et al. (2000) state; "value is seen to be more individualistic and personal than quality and involves both a give and get component" (p. 1339). Raval and Grönroos (1996) suggest that customer-perceived value has to be related to different personal values, needs and preferences. In addition, they state, that the financial resources of the consumer must be taken into account.

III. Quality

Quality originates from Latin and means the attribute or the constitution of something. The ground of the competition is made up by the customers' experience of quality in relation to the costs (Edvardsson, 1996). Grönroos (2000) presents the concept of total perceived quality building upon the gap between expected and experienced quality.

Palvia et al. (2001) present a socio-technical framework for quality assessment of computer information systems. When assessing a system, the authors state; "the quality of an information system should be concerned with both the technical and the social subsystems. The technical subsystem covers the nature of the tasks to be accomplished and the technology that enables their accomplishment. The social subsystem involves the individuals who are responsible for accomplishing the tasks and the means whereby their work can be coordinated. In short, the assessment of system quality reflects the task, the supporting technology, the people involved and the organization" (p. 238).

For individuals and organizations, value and quality are two important aspects. As a consequence, questions about how value and quality are perceived by individuals are essential when services in Internet environment are developed and assessed. Below, the concepts of value and quality will be discussed in conjunction to the three phases of the conceptual model (Figure 1). Based on a chronological order, the first phase, the pre-use phase will be presented, followed by the test phase and finally the use phase. The presentation will focus on theoretical as well as empirical findings.

IV. Empirical results

For individuals and organizations, value and quality are two important aspects. As a consequence, questions about how value and quality are perceived by individuals are essential when services in Internet environment are developed and assessed. Below, the concepts of value and quality will be discussed in conjunction to the three phases of the conceptual model (Figure 1). Based on a chronological order, the first phase, the pre-use phase will be presented, followed by the test phase and finally the use phase. The presentation will focus on theoretical as well as empirical findings.

IV. 1 The Pre-use Phase

The first phase in the conceptual model is the pre-use phase. At this point the potential user has a service present-at-hand, which means that information about the service and/or visual experience are the only sources available for the potential user to assess the service in Internet environment (Winograd and Flores, 1996). The importance of the pre-use phase is highlighted by Barki and Hartwick (1994), where they argue that it may be more easy to change users' "thoughts and feelings" before implementation. Early results from the study show an overall positive attitude towards the future service in Internet environment. Possible explanations could be that users perceive the service in Internet environment to be valuable or that users involvement in the development process has influenced users thoughts and feelings in a positive manner.

Davis et al. (1989) state that the most vital problem, when assessing user acceptance of IS in the early stages of development, is the difficulty to give users a clear picture of features and functions of the new system. Likewise, our study shows that although pilot-customers were given a short introduction in the early stages of the development of the upcoming service in Internet environment, they had difficulties in expressing opinions about the quality of the service.

Davis et al. (1989) discuss the importance of finding new methods for evaluation of acceptability of a system as early as possible in the development of information systems. This could better help to decide if the system needs to be changed and decrease the risks of developing a system that is not going to be used. The overall picture in our study is that

pilot-customers feel that they have had good opportunities to share opinions and concerns regarding the upcoming service in Internet environment. Pilot- customers concerns of missing features and functions in early presentations of the upcoming service in Internet environment were taken into consideration and later developed and implemented into the service. In line with the conceptual model (Figure 1), pilot-customers in the pre-use phase were able to express general opinions about quality issues, but not to make assessment of quality issues. However, assessment concerning values of features and functions of the upcoming service in Internet environment were possible to express opinions about.

IV. 2 The Test Phase

Emphasized by Davis et al. (1989) is the interest in the possibility to forecast and explain user behavior after a very short time of interaction with a system. In order for computer systems to improve organizational performance they must be used (Davis et al., 1989). As the users interact with the service in Internet environment in the test phase, it is possible to form a judgment about the quality, or excellence of the service (Zeithaml, 1988). After the pilot-customers had used the in Internet environment service for approximately a month, value and quality assessment were easier to express opinions about.

Orlikowski (2000) points out that technology users shape the meaning of technology as they integrate them into everyday practice. In other words, technology structures are not external from the user. In the test phase, the user repeatedly interacts with the service in Internet environment, which shapes their view about it and accordingly their use. Davis (1989) suggests that two determinants, "perceived usefulness" and "perceived ease of use", are especially important when people accept or reject information technology. Both variables influence users' attitude, intention and finally behaviour. In the test phase, as in the pre-use phase, the role of the individual is critical. It is of utter importance for the success of the application that the user finds it useful and easy to use. In our study, pilot-customers expressed difficulties in using the service in Internet environment for the first time. It was not obvious how to make an error-report in the service in Internet environment, although error-report is an essential function of the service. Pilot-customers assessments are important to take into consideration in the test phase since the determinant "perceived ease of use" (Davis, 1989) will have an influence on users behaviour in the use phase.

IV. 3 The use phase

In the test phase, but even more apparent in the use phase, the user gradually becomes more aware of the service in Internet environment not only in the own working tasks but also in the organizational context. As Palvia et al. (2001) point out, when assessing a computer information system, a wider socio-technical view is important. Therefore, the

quality of a computer information system should be concerned with both the technical and the social subsystems. A longer use of a service in Internet environment in an organizational context, "technology-in-practice" (Orlikowski, 2000), will have implications for users' judgment when assessing the service in Internet environment in the use phase.

Hu et al. (1999) state that the organizational context is new to IT acceptance and adoption research. Taylor and Todd (1995) argue for the importance in understanding determinants of information technology usage in organizations. Barki and Hartwick (1994:77) state that when new systems have been implemented and used, feelings and thoughts among the users were "likely to have greater impact on the use of new systems". In accordance with Taylor and Todd (1995), the importance of organizational issues and its affect on users' assessing services in Internet environment will be stressed throughout the use phase.

V. Conclusion

Our findings in the pre-use and the test phase indicate support for the conceptual foundation of the model (Figure 1) that is, the difference between the concepts of value and quality in relation to user assessment in three time phases.

Ulrich.Remus@wiso.uni-erlangen.de

Abstract: Organizational changes are becoming more and more important due to increasing competition and rapid technological evolution. However, the intended benefits of organizational changes depend strongly on how effectively process innovations are implemented within an organization. Hereby, the management of the employee's acceptance is considered as one of the most critical tasks in change management projects.

Normally, employee acceptance is evaluated using theory-based acceptance models. We start by reviewing the existing process innovation-related acceptance models. In a next step, we describe a new model, called DART, which is based on the idea of the balanced scorecard, using a meta-structure in order to identify a balanced set of individually measurable acceptance criteria. Guided by an action research approach, we further describe a case example showing the application of DART in a process reengineering project.

We close our paper by reviewing the consequences of our research, as well as the suitability of DART in the research context. The results presented in this paper are expected to have important implications for both, researchers who should benefit from a very flexible acceptance model as well as managers and process designers who should gain valuable insights for their change implementation efforts.

Keywords: Process Reengineering and Redesign, Employee Acceptance, Process Innovation, DART, Action Research.

I. Introduction

Organizational changes are becoming more and more important due to increasing competition and rapid technological evolution. In order to successfully implement these changes, concepts of business process redesign have been introduced to improve performance and raise customer satisfaction.

However, the benefits of process redesign projects strongly depend on how effectively these process innovations are

implemented within an organization. Researchers as well as practitioners agree on employee's acceptance being a key success factor in change implementation projects ([23], [13], [18]). Neglecting employee's acceptance can cause resistance among employees, often leading to project failures.

Thus, the management of employee's acceptance is a crucial task in change management projects. According to DeMarcos "you can neither predict nor control what you cannot measure" ([15]), the detailed measurement of employee's acceptance is considered as a fundamental part in achieving this goal. Based on the acceptance evaluation, context-specific measures and actions can be taken, improving the overall acceptance of process innovations.

Usually, acceptance is evaluated with the help of theory-based acceptance models. Much research has been done at the organizational level, exploring the diffusion and the adoption of process innovations within an organization (i. e. [14], [16], [34], [33]). In contrast, on the individual level, only little research is done exploring individual reasons why employees accept or reject process innovations ([19], [22]).

Consequently, our research questions to guide this paper are: "What factors influence an employee's acceptance of a redesigned business process?" and "How can these factors be used to generate appropriate measures and actions to improve employee's acceptance?"

In order to answer these questions, we start by reviewing the existing acceptance models, which are focusing on the individual level. We then describe a new model, called DART which is based on the idea of the balanced scorecard using a meta-structure in order to identify a balanced set of individually measurable acceptance criteria. After the specification of the model, we describe a case example showing the application of DART in a process reengineering project guided by an action research approach. We close this paper with reviewing the consequences of our research as well as the suitability of the DART approach with regard to the research context.

II. Review of Existing Acceptance Models on the Individual Level

Process innovations are defined as "any innovation that changes the way a job is performed" ([20]). In general,

acceptance is defined as an antagonism to the term refusal and means the positive decision to use a (process) innovation ([5]). Acceptance research has its origin in both, industrial and business science. While industrial science focuses on the conditions of user friendly technologies and techniques, the business science discusses acceptance in various disciplines, e. g. marketing, organization, production theory and information systems research ([2]).

Here, employee's acceptance is discussed mainly from the perspective of organization theory and information systems research. Two classes of models can be distinguished ([20]): intentional models focusing on social and psychological issues and technology-related models focusing on process supporting technologies.

Intentional models highlight the intention of individual employees, in most cases unspecific to process innovation characteristics. Consequently, psychological models like the Theory of Reasoned Action (TRA, [17]), the Theory of Planned Behavior (TBP, 0), and the Goal-Setting Theory (GST, [21]) are applied.

The second class considers organizational changes by combining process and technological innovations. They usually rely on marginal extensions of technology acceptance models like the Technology Acceptance Model (TAM, TAM2 [12], [37]) or the Task-Technology Fit model (TTF, [19]). Table 1 provides an overview of common models together with their core constructs and a brief summary.

Table 1: Overview of common models utilized for the acceptance analysis of process innovations

Acceptance model	Core constructs	Short summary
TRA	Attitude toward behavior and subjective norm	TRA is one of the most fundamental and widely-used theories of human behaviors drawn from social psychology.
TBP	Attitude toward behavior, subjective norm, and perceived behavioral control	TBP extends TRA by adding the construct of perceived behavioral control.
GST	Situational and personal factors influencing the valence and the expectancy of goal attainment	Individuals use their personal and situational beliefs and attitudes to formulate goal commitments before taking action.
TAM (TAM2)	Perceived usefulness, perceived ease of use, (subjective norm)	TAM/TAM2 is designed to predict information technology acceptance and usage on the job.
TTF	Technology, task, individual	Task-oriented approach to address the acceptance of IT systems in a specific job context.

Previous studies, which compared the explanatory power of the difference classes of models revealed, that none of the classes is superior (cf. [30]). As consequence, integrated models, using elements from both, intentional as well as

technological-related models are developed and discussed in literature (cf. [36], [38]).

Although both classes of acceptance models are based on mature research areas providing valuable insights, the unspecific foundation of the models leads to an important problem: Specific acceptance criteria related to process innovations are widely ignored due to the limited perspective of the adapted models.

To address this shortcoming, a generic but adaptable framework considering process innovations is needed. A framework, which helps to identify individually important, measurable and independent acceptance criteria, is presented in the following section.

III. Specification of the DART Acceptance Model

DART is a highly flexible acceptance model, designed for the analysis and evaluation of user and employee acceptance in a variety of different application areas, e. g. situation-dependent mobile services, web based aptitude tests and enterprise portals (cf. [2], [3], [4], [5]).

According to Amberg et al., the fundamental design criteria of DART are:

- The use as a permanent controlling instrument,
- A balanced consideration of relevant influencing factors,
- The applicability during the whole development and implementation process, and finally
- The adaptability to individual requirements of the research item ([2]).

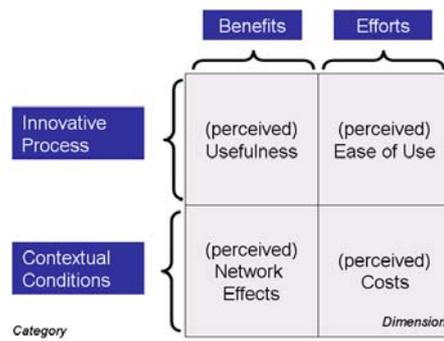

These design criteria are useful to integrate acceptance analysis into the development, evaluation, and implementation of process innovations. In the following, we describe the architecture of DART.

III. 1 Architecture of DART

DART is based on the idea of the balanced scorecard using a meta-structure in order to identify a balanced set of individually measurable acceptance criteria ([25]). As a key characteristic, DART's meta-structure emphasizes the employee's individual point of view by an explicit consideration of the employee's perception ([39]).

DART uses the following complementary and orthogonal categories:

- Benefits and Efforts comprising all positive and negative facets of process innovations (cf. TAM, TTF).
- Process Innovation and Contextual Conditions including basic socio-cultural and economic conditions, which also have an important impact on employee's acceptance (cf. TRA, TBP, and GST).

Fig. 1: Meta-structure of the DART acceptance model

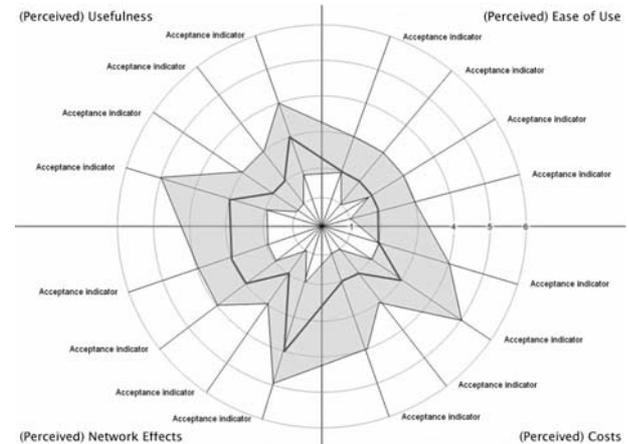

These categories lead to four acceptance dimensions that are relevant for an in-depth analysis of the employee's acceptance (Fig. 1):

- (Perceived) Usefulness, build by the categories benefits and process innovation, describes the individually perceived usefulness of a process innovation (cf. [12], [37]). Acceptance criteria of this dimension might be employee motivation or change demand.
- (Perceived) Ease of Use, characterized by the categories of process innovation and efforts explain the degree to which a person believes that using a particular process innovation would be free of effort (cf. [37]). Criteria measuring this dimension are for example the adaptation effort or the process complexity.
- (Perceived) Network Effects: The categories benefits and contextual conditions lead to the dimension of perceived network effects. The dimension considers the contextual aspects of a process innovation depending on economical, social and organizational factors (cf. [17]). Stakeholder Support and External Motivation are typical criteria to measure this dimension.
- (Perceived) Costs finally formed by the dimension contextual conditions and efforts describe the monetary and non-monetary efforts not directly associated with the process innovation itself (cf. [19], [21], [11]). Suitable acceptance criteria might be Individual Uncertainty or Risks.

The resulting structure supports a systematical identification of acceptance criteria. According to the BSC approach, the intention is to find a set of precise criteria with high significance, meeting the requirements of sustainability, measurability, achievability, reasonability and timeliness. No complete set of acceptance criteria is defined in advance; rather they have to be defined according to the concrete research item.

In addition to the meta-structure, DART provides a visualization approach for an appropriate visualization of the employee's acceptance. DART's visualization approach is based on spider charts, being composed of several radial spokes, one representing each acceptance criteria. The acceptance criteria themselves are structured by the means of the DART meta-structure, which means, they are classified in

the DART categories and dimensions (cf. Fig 2).

Fig. 2: Visualization approach of DART (DART chart)

The results of the acceptance evaluation should be quantified and normalized, e. g. by using a scale from one to six as shown on the horizontal axis in the figure above. The minimal value is located near the center of the chart (e. g. the value of one) illustrating a high acceptance level, while the maximum value near the border of the chart (e. g. the value of six) indicates a low acceptance level.

Using this scale together with the meta-structure of DART, an individual acceptance curve can be drawn (bold black line in the figure). This acceptance curve represents the average acceptance level for each acceptance criteria (the statistical median). The statistical spread resulting from the spread of opinions in the survey could be used to draw a surface (utilizing the upper and the lower quartile, cf. [39]). According to the visualization, acceptance criteria receiving a median located in the upper range of the scale (e. g. in the range four up to six), are considered as acceptance challenges. With regard to the statistical spread, acceptance challenges are considered as critical if the lower quartile (the outward bound of the gray area) reaches the highest possible acceptance level (e. g. the value of six). This indicates that a significant number of employees strongly disagree with the process innovation.

The used presentation is similar to the popular dart game where a dart hitting the centre of the disc denotes the highest possible score. By means of this visualization approach, potential acceptance challenges and resistances can easily be identified, addressed and eventually be reduced. In the next section, we describe a case example that shows the application of DART within a process reengineering project.

IV. Case Example: Application of the Acceptance Model

According to the research questions identified in the first section, the case example has two main goals: First, to analyze the general applicability and explanatory power of DART by generating suitable acceptance criteria, and second

to analyze DART's ability to generate appropriate measures and actions together with a review of the impact of those interventions.

IV. 1 Research Method

Because of the character of the acceptance evaluation, i.e. to provide insights and modifications to the research item, a research design supporting these interventions was necessary. According to Iverson et al., action research was chosen to be suitable ([23]).

Action research is defined as a widely-used class of iterative research methods aiming at solving practical problems ([35]). The use of action research is expected to produce "highly relevant research results, because it is grounded in practical action, aimed at solving an immediate problem situation while carefully informing theory" ([6]).

The central idea of action research is that complex processes can be studied best by introducing changes into the real world and observing the impact of those changes ([7]). Thus, intervention is the main instrument for knowledge generation in action research. Mingers consequently categorizes action research as an interventional, post-positivist research approach ([31]).

Action research was originally developed for the use in social sciences by Lewin ([26], [28]) and therefore has a long tradition in studying individual behavior. In the past, action research has led to a huge variety of specialized action research methods, detailed by Baskerville & Wood-Harper in [8].

In this research, we apply Checkland's action research cycle as one of the most widely used approaches ([9]). Checkland uses the following elements in his specification: an intellectual framework of linked ideas or a theory, a methodology of using this framework, and finally an area of application with specific research questions.

Checkland's action research cycle is composed by the following activities: Initiating, Iterating, and Closing. First, the concrete problem situation is entered by the researcher (Initiating). This includes the appreciation of the problem situation as well as a literature study of the concepts and existing models.

The second step (Iterating) comprises several activities, starting with the establishment of the roles of the researcher and practitioner in the corresponding area of research. Moreover, the research framework and the research methodology are based on literature study and practical experiences. Based on this framework, changes to the area of application are planned and scheduled. After that, researchers and practitioners take part in the change process. The second step closes with rethinking about the implemented changes and their effects. This in turn can produce two results: On the one hand, the effects of the implemented change may produce the expected outcome, thus, the cycle can be considered as successful and the loop can be exited. On the other hand, the reflection may show that an additional iteration is needed to rethink the framework and/or the implemented change. In this

case, the iterating phase starts again with the establishment of the roles.

In a last step, all experiences of the research are carefully reflected (Closing). This includes the refined framework, the changes on the problem situation itself as well as their impact, and eventually the suitability of the methodology itself.

In our case, the intellectual framework to be researched would be the DART approach. The methodology for using this framework would be the action research cycle by Checkland.

The selected area of application is a German company offering products and process-orientated services to the healthcare industry worldwide. At present, the company is dealing with the improvement and standardization of its IT processes aiming at a more effective, efficient and service-oriented structure. In order to achieve this goal the management chose to implement the IT Infrastructure Library (ITIL) standard in the IT Infrastructure division.

Our research was scheduled for eight months and included two complete action research cycles. The key activities of this study took place from December 2004 to July 2005. In the following section we start by describing the problem situation of our research in detail.

IV. 2 Initiating

The project presented in this paper focuses on the ITIL-based redesign and implementation of the technical change management process, which rules software and hardware changes to the production system. The project was chosen to be an interesting research item because of the following reasons: The project is of high strategic relevance, it affects a high number of employees (81) and the project could be accompanied through all important stages. At the beginning of our research, the process design team had already completed the as-is analysis and currently works on the redesign of relevant processes.

The impact of the changes varied across the seven teams of the IT infrastructure division. While the teams IT-Network and IT-Systems Management were considered to be affected in a major way, the other five teams were influenced in a less direct way.

Prior to the acceptance analysis itself, four brainstorming sessions were held to identify the key acceptance criteria. These workshops were attended by researchers and practitioners.

In further meetings, a total of 20 key acceptance criteria were identified and taken as basis for the subsequent analysis:

- (Perceived) Usefulness: Anticipated average life, change demand, employee motivation, transparent competences, and potential usefulness
- (Perceived) Ease of Use: Efficiency & effectiveness, integrity, employee integration, adaptation effort, and process complexity

- (Perceived) Network Effects: Communication, change agent qualification, organizational flexibility, stakeholder support, and external incentives
- (Perceived) Costs: Individual uncertainty, implementation costs, ongoing costs, opportunity costs, and risks

IV. 3 First Iteration

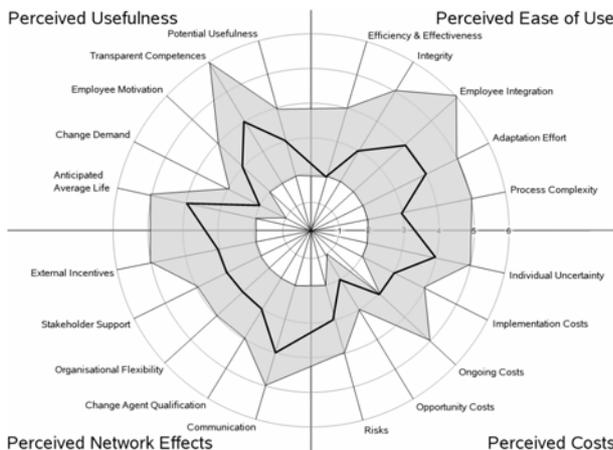

The first iteration was performed in the late design phase based on a draft of the new process. This draft provides an appropriate foundation for the acceptance evaluation because modifications on the process draft could easily be integrated.

The acceptance criteria identified in the previous section were used to develop a standardized questionnaire used for the acceptance survey. Each criterion led to a number of suitable questions. Based on experiences in other acceptance analysis, a six-point Likert scale was selected (cf. [29], [5]), ranging from strongly agree (indicated by number one) up to strongly disagree (indicated by number six).

Subsequent to the preparation of the questionnaire, a conceptional presentation of the process draft was prepared.

We performed three different evaluations. Next to the acceptance of the whole division, the two mainly affected teams IT Network and IT Systems Management were visualized separately (Fig. 3 to 5).

Fig. 3: Acceptance in the IT Infrastructure division (Total)

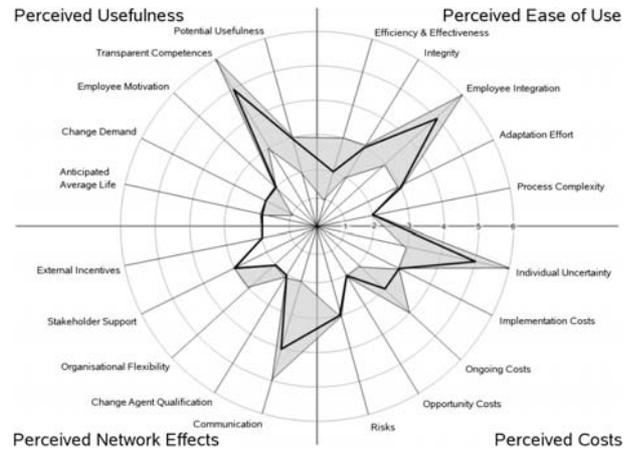

First, the evaluation of the IT Infrastructure division in general shows acceptance challenges especially located in the criteria anticipated average life, transparent competencies, employee integration, adaptation effort, individual uncertainty, and communication (each obtaining an average acceptance level of four).

The spread among the employees (the gray area) indicates a high diversity of opinions among employees. Furthermore, the acceptance levels of transparent competencies and employee integration are seen as critical, indicating that a high number of employees strongly disagree with these aspects.

The visualization of the IT Network Team (Fig. 4) shows that acceptance challenges are located within the same

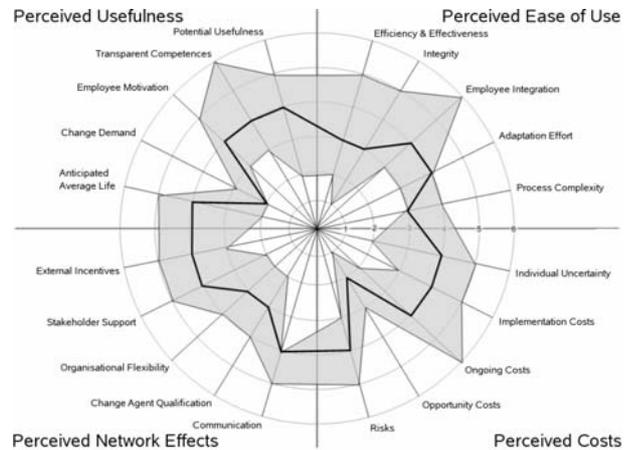

criteria as the whole division. The criteria transparent competencies, employee integration, and individual uncertainty (each obtaining acceptance levels of five) as well as the criterion communication (obtaining a level of four) are considered as acceptance challenges.

Fig. 4: Acceptance in the IT Network team

Comparing to the spread among the employees to the IT Infrastructure division as a whole, employees from the IT Network team largely agree on most acceptance criteria, resulting in a smaller gray area shown in the figure. As identified in the IT division as a whole, the criteria transparent competencies and employee integration are considered as critical, but this evaluation shows an additional critical criterion, the individual uncertainty.

Fig. 5: Acceptance in the IT Systems Management team

The DART chart of the IT Service Management team shows the most negative evaluation (Fig. 5). Acceptance challenges can be identified in 13 criteria, each receiving an average level of four: Anticipated average life, employee motivation, transparent competencies, potential usefulness, employee integration, adaptation effort, individual uncertainty, implementation costs, ongoing costs, risks, communication, stakeholder support, and external incentives.

Again, the statistical spread is considered as high. This time, the criteria transparent competencies, employee

integration, and ongoing costs are considered as critical.

To sum up, acceptance challenges can be located in several acceptance criteria, varying from team to team. In order to produce a positive effect for the whole division, and, at the same time, considering the importance of the mainly affected teams, we concentrated our further actions on acceptance criteria which appear in all of the three evaluations.

This led to the following four acceptance criteria: Transparent competencies, employee integration, individual uncertainty, and communication.

For each acceptance problem dedicated measures and actions were derived to improve the individual acceptance level:

- **Communication:** At first, communication was addressed by setting up a project-related intranet site which provides relevant documents, presentations and even the result of the acceptance analysis itself.
- **Transparent competencies:** To improve this acceptance criterion, it was necessary to clarify the redesigned process and to enlarge the supplied documents. Role based essays containing requirements, competencies, and responsibilities were generated to specify the future competencies in the teams more precisely and provided on the project's intranet site.
- **Employee integration:** Furthermore, regular discussion meetings about process-related issues were scheduled to increase employee integration. Moreover, a moderated discussion forum was established on the project's intranet site to enable employee's feedback in an independent and anonymous way.
- **Individual uncertainty:** To improve this criterion, the project goals, namely to improve and standardize IT processes, have to be communicated and clarified. Additionally, the management commitment to keep all jobs in the IT Infrastructure division was emphasized. It was expected that this could reduce the fear of job losses or the ambiguities about future requirements.

IV. 4 Second Iteration

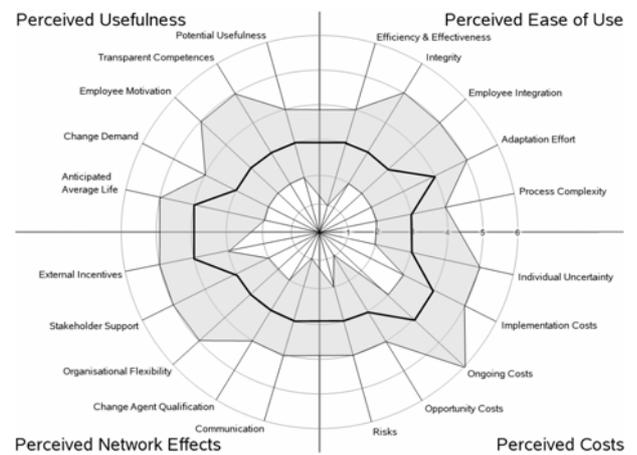

The second iteration was performed three months later, just before the implementation of the redesigned process itself. The analysis performed in this cycle was similar to the analysis of the first cycle, however with some minor modifications to the process with regard to the increase of transparency of competencies and affected roles, respectively.

The new process draft was presented to the employees in several workshops concluding with a discussion of the pros and cons of the new process. Subsequent to the discussion, all employees were asked to fill out the questionnaire again. Figure 6 shows the visualization of the evaluation results in the whole IT Infrastructure division.

The analysis could identify acceptance challenges especially in the criteria anticipated average life, adaptation

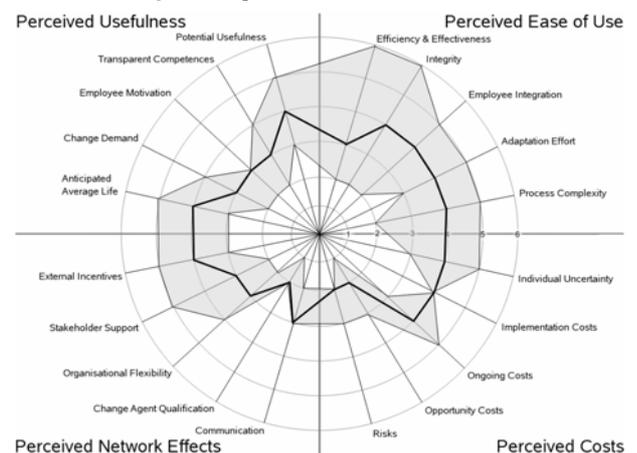

effort, implementation costs, ongoing costs and external incentives (each obtaining an average acceptance level of four). As already observed in the first iteration, the spread among employees is relatively high. However, only one acceptance criterion is seen as critical in this iteration (the criterion ongoing costs).

Fig. 6: Acceptance in the IT Infrastructure division (Total)

Comparing the results with the first iteration, the analysis shows that all addressed acceptance challenges could be improved significantly. Now, each of the four criteria shows an improvement of one acceptance level. Furthermore, all critical criteria could also be improved significantly. On the other hand, the analysis reveals a number of new acceptance challenges, located in four criteria whose acceptance level decreased in comparison to the first analysis, each by the value of one. The fifth acceptance challenge, the criterion anticipated average life, kept its level of the first iteration.

Fig. 7: Acceptance in the IT Network team

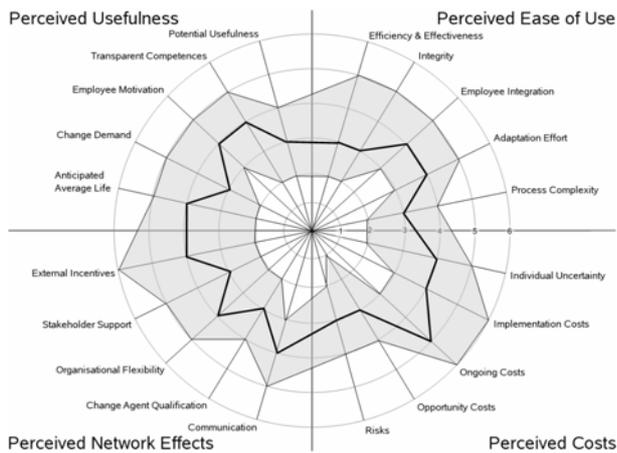

The analysis of the IT Network team (Fig. 7) also shows both, acceptance improvement as well as acceptance challenges. The following criteria are considered as challenges: Anticipated average life, positive usefulness, integrity, employee integration, adaptation effort, process complexity, individual uncertainty, implementation costs, ongoing costs, and external incentives. With regard to the

spread among employee's opinions, only the criterion integrity must be considered as critical.

Comparing the results with the first iteration, again, all addressed criteria could be improved by an average level of one up to two. Only one could be improved to level three and is therefore no longer considered as acceptance challenge (transparent competencies). All other criteria remain on acceptance level four and need to be addressed further on. Similar to the evaluation of the whole division, several new acceptance challenges emerge (in total seven), each decreased by an average acceptance level of one up to two.

Fig. 8: Acceptance in the IT Systems Management team

The analysis of the acceptance in the IT Systems Management team (Fig. 8) led to acceptance challenges in ten acceptance criteria: employee motivation, transparent competencies, employee integration, adaptation effort, individual uncertainty, implementation costs, ongoing costs, communication, organizational flexibility, and external incentives. The spread among employees was almost on a constant level. Critical criteria are implementation costs, ongoing costs and external incentives.

The comparison with the results of the first evaluation shows, that none of the four addressed criteria could be improved significantly. Nevertheless, the spread of opinions could be improved in two of the four criteria, namely transparent competencies and employee integration. Two additional acceptance criteria were identified as acceptance challenges.

Again, measures and actions were derived from the evaluation results. Here, four of the five acceptance challenges appearing in all of the three evaluations have been taken into account: Anticipated average life, adaptation effort, implementation costs, and ongoing costs. The external incentives challenge was left unattained, because of a lack of budget for dedicated incentives as well as unhelpful experiences of the management with external incentive systems in other change implementation projects.

- **Anticipated Average Life:** The acceptance challenge, which corresponds to the anticipated average life of the new process, indicates frequent business process changes

in the past. In order to support a stronger commitment towards the new process design, top management support is demanded.

- **Adaptation Effort:** In order to improve the acceptance challenge adaptation effort, the process design team decided to provide tools for reducing the individual change effort, e. g. document and e-mail templates. Selected employees were integrated into the development of these tools to ensure applicability and to reduce the individual change effort.
- **Implementation Costs:** This acceptance challenge seemed to be difficult to reduce because the corresponding budget was already spent on consulting by external ITIL experts and other process consultants. However, the discussion meetings revealed that the negative assessment of this criterion is correlated directly with the perceived lack of employee integration. For future change projects this will be kept in mind and more employees will be integrated into the change team and less consulting will be called externally.
- **Ongoing Costs:** Finally, the challenge at the criterion ongoing costs will lead to major changes in the process draft. The discussions revealed that the employees found their processes to be cumbersome and bureaucratic. As consequence, the whole process has to be simulated by the process designers and selected employees of all teams. In addition, process automation and workflow aspects will be discussed. It is expected, that this method will lead to more light-weight processes which reduces the negative ongoing costs perception.

At this point, it was decided to exit the iterations because of the time constraint of our project. Furthermore, our experiences from the two iterations already suggested that the DART approach was in a stable and useful form.

IV. 5 Closing

Finally, the two iterations were discussed and assessed at a closing meeting including senior management. The importance of the results concerning our research was emphasized by all participants leading the management to carry out additional acceptance evaluations in future change projects. As a result, the company's change management guidelines were extended by the necessary steps for the DART acceptance analysis. Templates for the questionnaire and the evaluation were generated and integrated.

Our final activity was to generate lessons learned, in particular with regard to our action research approach.

V. Discussion

Many authors provide universal tools for developing change commitment and acceptance (cf. [10]). However, in our research, we followed Dent and Goldberg expecting that only specific and targeted actions can contribute to the efficient

implementation of changes ([16]).

In this context, a multidimensional view on employee's intentions with respect to the proposed change was expected to enhance the accuracy in predicting employee behavior and acceptance ([32]). Therefore, we utilized the highly flexible and adaptable DART approach to identify a number of 20 acceptance criteria providing a differentiated, multi-facet view on employee's acceptance.

Further on, we didn't follow another common perception in literature, as Lawrence put it, the expectation that all the people involved in organizational change projects will resist the change in the same manner ([26]). Rather, employees, who are affected significantly by a change, provide a lower likelihood of commitment and acceptance ([11]). In order to analyze these possible different perceptions of change, we performed three evaluations of the employee's acceptance, one for the IT division in general and one for each mainly affected team, IT Network and IT Systems Management.

In a subsequent selection process, we defined acceptance criteria with a median of four or more as acceptance challenges. This selection is consistent with the corresponding literature, e. g. referring to Judson arguing that acceptance and resistance represent two poles of a continuum ([24]).

The selection of acceptance challenges in these three clusters led to a total of 13 (first iteration) respectively 14 (second iteration) distinct acceptance challenges. In order to reduce this amount of challenges to a manageable number, also with respect to the derivation of measures and actions, we focused on acceptance challenges that occur in all of our three evaluation groups. This led to 4 respectively 5 acceptance challenges (first/second iteration) which were addressed by further measures and actions.

If we look at the success of the measures and actions that have been carried out, we can see significant improvements of the corresponding acceptance criteria for the IT division in general and the IT Network team. The last team, IT Systems Management, doesn't show a significant reaction to our inventions.

Having Patterson and Conner in mind who claim, that building commitment to organizational change is a complex development process ([11]), our research clearly outlines both, the evolution of employee's acceptance as well as the maturing of our process draft over time. The importance of this development process is emphasized by Piderit in underlining the necessity of discussion and improvisation for revising the initial change proposal in an adaptive manner ([32]).

VI. Summary and Outlook

The purpose of our research was to develop a model that explains the employee's acceptance of process innovations in order to derive measures and actions to improve the acceptance.

After reviewing existing process innovation-related

acceptance models, we proposed a new model, called DART, which is based on the idea of the balanced scorecard, using a meta-structure in order to identify a balanced set of individually measurable acceptance criteria. Beyond the specification of the model, our paper also described the evaluation of the DART approach in a process redesign project.

In summary, our research findings confirm usefulness of the present model for generating suitable acceptance criteria as well as for defining corresponding measures and actions. Therefore, researchers are expected to benefit from an increased understanding of the employee acceptance as key influencing factor in change implementation projects. Managers and process designers should also gain valuable insights in their efforts to promote the acceptance of process innovations among employees.

Although we provide a balanced set of acceptance criteria, suitable for our individual research setup, researchers and practitioners must be aware of other factors that affect the employee's acceptance of process innovations.

The model proposed in this study represents a first step in developing a model of process innovations acceptance of individual employees. Further research will be required to test and extend the boundaries of the current model. For instance, the validity and reliability of our results need to be analyzed in one or more longitudinal field studies.

Abstract: Business process reengineering (BPR) is an outstanding management theory but with a high failure rates of 70%. One of the major problems in many BPR efforts is lacking of a disciplined method to model business process. In addition, the implementation methodologies in past literature and famous consulting firms were incomplete, and lack of practical experience or academic foundation. After analyzing and comparing the pros and cons of several representative BPR implementation methodologies, this study proposes a new methodology which combines previous academic outcomes and practical experience in consulting firms. Based on a hands on project, the detailed approaches, targets, needful materials, and expected results of each stage are elaborated as well as the commonly used BPR techniques and tools. Furthermore, the innovative methods and steps in this methodology which ensure the success of the project are discussed.

Keywords: Process reengineering & redesign, BPR implementation, methodology

I. Introduction

Business Process Reengineering (BPR) was a new management tool introduced by Michael Hammer and James Champ in early 1990s, and was defined as “radical thinking and redesign of business process in order to gain breakthrough improvement in the business performance, such as cost, quality, speed, and service”. Hence it quickly caught the imagination of western corporate leaders and became a major subject of attention in academia and industry. Since its first launch in China in mid 1990s, BPR was soon familiar to the internal corporations along with the popularity of ERP in less than ten years.

BPR is a very controversial topic in management literature. Despite isolated success stories at several firms, many organizations have encountered serious problems during their BPR implementations [1]. While BPR supporters claim that BPR is the only way to gain competitiveness and will lead to the reconstructed revolution instead of the industrial revolution, the discommenders bring forward the disappointed results of BPR efforts that the failure rates are as high as 70% [2]. Various reasons for this have been given in the past research. As William J. Kettinger

said “like most new managerial innovations, reengineering experienced an initial period of chaotic “trial and error,” with a lack of accepted methods”, one of the major problems in many BPR efforts is lacking of a disciplined method to model business process [3] and the BPR implementation always without a proper method supporting systematic redesign [4] [5].

So, is there a BPR implementation method that can enhance the success rate? Many experts and scholars have explored on this way for many years and have summarized some useful models, but the process of implementing BPR is still incomplete and fragmented in past literature [6]. Some worlds leading reengineering consulting firms, such as ISS, DMR Group, Andersen Consulting, Mckinsey C., all make use of their own proprietary BPR methods and experience to fulfill their clients’ unique needs. But they have not further summarized their useful treasures. Besides, they lack enough theoretical proofs to support the correctness of their methods. Thus, even given the plethora of BPR consulting services now available, there has not been a study placing these methodologies, techniques and tools into a classification framework permitting project planners to assess the “fit” between their unique organizational problem situations and available tools [7].

So, in this paper we will propose a new BPR implementation method which is feasible both in theory and practice by combining previous academic outcomes and practical experience in consulting companies. Also, commonly used BPR techniques and tools are mapped to each implementing stage. Especially, the efficiency and correctness of the implementation methodology has been validated and checked by a practical BPR project of KK Company.

II. Literature Review

To put BPR into action, methodological choices play a key role for the success of BPR [6]. In BPR literature, Many BPR implementation methods have put forward to fill the void of the critical mass of BPR projects, e.g. Wastell et. Al, G. White , 1996 [8]; Hammer, champy, 1993 [9]; Kettinger et al., 1997 [7], etc.. Table 1 summarized several typical implementing methods [7] [9] [10] in BPR literature in terms of the stages and activities included. As usual, BPR project can be implemented in three stages according to the domestic and international BPR project experience [11]. It is the simplest reengineering method among them while the

six-stage mode is the most complicated one. The composite stage-activity methodology based on the descriptions of 25 BPR methodologies derived by Kettinger et al. (2001) helps

the leading BPR project planners come out of the confusion of various reengineering methods choice [6].

Table 1 Representative methodologies, stages and activities

Methodology	Stages and activities					
Simple three-step mode	Categorize process <ul style="list-style-type: none"> • Categorize the process into three main sorts using value chain analysis: core process, boost up process, and sustaining process 	Analyze process <ul style="list-style-type: none"> • Identify improvement space of the candidate process • four indicators: cost, elapsed time, service quality, and performance influence 	Reorganize <ul style="list-style-type: none"> • Form implementing team • Reorganize • Dynamic evaluation and improvement 			
Four-step mode (Michael Hammer, Champy, 1993)	Make an agreement <ul style="list-style-type: none"> • Gaining top managers' support • Develop vision • Form BPR team • discover redesigning opportunities 	Analyze the business process <ul style="list-style-type: none"> • Analyze current process • Identify external demands • Define improvement objectives 	Redesign the process <ul style="list-style-type: none"> • Identify alternative solutions • Develop prototype • Create detailed design of system functions 	Implement business process <ul style="list-style-type: none"> • Implement infrastructure changes • Train employees • Perform process and system intergradations • evaluation 		
Five-step mode (Peppgaard J.Rowland P.,1998)	Build business condition <ul style="list-style-type: none"> • Develop business vision • Win top managers' support • Form a plan • Develop train • Identify core processes • Form BPR team • Develop vision 	Process diagnosis and redesign <ul style="list-style-type: none"> • Train BPR team • Diagnose current process • Diagnose current conditions • Benchmark • Design new process • identify redesign solution 	Redesign organizational structure <ul style="list-style-type: none"> • Examine the human resource • Examine the technical structure and abilities of employees • Redesign human resource structure • Redefine posts and train employees • Transpose labor into new process • Establish new IT infrastructure and application 	Implement pilot <ul style="list-style-type: none"> • Choose pilot • Form pilot team • Confirm the customers and suppliers involved • Run, monitor and support the pilot • Examine and collect feedback • Identify transform order and implement step by step 	Realize business vision <ul style="list-style-type: none"> • Evaluate performance • Make the benefits and efficiency apperceived by clients • Dig for more efficiency • Improve continuously 	
Six-step mode (Kettinger et al., 2001)	Envision <ul style="list-style-type: none"> • Establishing management commitment & vision • Discover reengineering opportunities • Identify IT level • Select process 	Initiate <ul style="list-style-type: none"> • Inform stakeholders • Organizing reengineering teams • Conduct project plan • Determine external process of customer requirements • Set performance goal 	Diagnose <ul style="list-style-type: none"> • Documentation of current process • Analyze existing process 	Redesign <ul style="list-style-type: none"> • Define and analyze new process concepts • Prototype and detailed design of a new process • Design human resource structure • Analyze and design IS 	Reconstruct <ul style="list-style-type: none"> • Reorganize • Implement IS • Train users • Process cut-over 	Evaluation <ul style="list-style-type: none"> • Evaluate process performance • Link to continuous improvement programs

The BPR implementation methodologies outlined in table 1 have their own specialties and properties. The three-step methodology is very consistent with its tools, and its evaluation standard is quite effective for its simpleness. So it quite suits the situation that the project has clear objectives and time limited. The four-step methodology is applicable to the common situations, i.e. if the project is some urgent, it can flexibly choose implementation approach and tools to reduce the time needed, or if the time is enough but the objectives are not very clear, it can choose corresponding implementation approach to identify the final aim in a longish period. The five and six steps methodologies are relatively mature and they are both suitable for the project which has undefined aim but with enough project time since they have a very detailed approach and its result is always perfect. However, all the methodologies have some its fatal weaknesses. For example, the three-step methodology is

only for the project which has definite demands and specific evaluation index, and if the demand of the company is not systemic, the whole results will run in the opposite direction. Though the four-step methodology is mature, it emphasizes particularly on theory and its implementation approach. It ignores the real demands and the people in the company. Lacking the support of people and without agreement on the project results will lead to failure in practice. The five-step and six-step methodologies have the similar problem with the four-step methodology. They totally ignore the people in BPR implementation. Even though they have noticed gaining the support of top leaders, they overlook the demand of the staffers. Besides, they don't have a definite approach to solve the compatibility between the new process and the existing process which is also a factor results in failure. Finally, the five and six steps methodologies have long period of project schedule which will increase the

investment and aggravate company's burden.

In conclusion, we summarize the following evaluation sheet of the above BPR implementation methodologies by considering several basic BPR principles (see table 2).

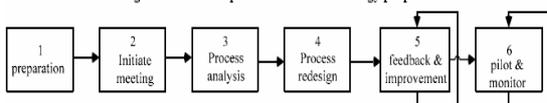

Table 2 BPR implementation methodology evaluation model

Basic Principles of BPR	Three-step mode	Four-step mode	Five-step mode	Six-step mode
Clear targets	Bad	Good	Excellent	Excellent
Extent focused on IT	Bad	bad	Excellent	Excellent
Reliability of project team	Bad	Good	Good	Good
Evaluation standard of project results	Good	Bad	Excellent	Excellent
Top managers' support	Bad	Good	Excellent	Good
Reduce the resistance from the people involved	Bad	Bad	High	Bad
Resistance from internal company	High	General	General	General
Choice of candidate processes	Excellent	Excellent	Good	Excellent
Solve the problem of compatibility	Bad	Bad	Bad	Bad
Pilot process	Bad	Bad	Excellent	Bad
Time needed	Short	Moderate	Long	Long
Feasibility	Bad	Bad	Good	Good
Continuous improvement	Bad	Bad	Good	Excellent

III. A Project-Based BPR Implementation Methodology

Is there a BPR implementation methodology which can not only gain the support of the whole company, but also can ensure the implementation quality as well as be time flexibility? With these questions in mind, we try to propose a BPR implementation methodology that can satisfy these requirements. By synthetically considering the pros and cons of the previous methodologies and referencing to the practical experience of several famous consulting firms, we put forward a new six-stage BPR implementation methodology which had been taken into action in the BPR project of KK Company (See Fig.1).

Fig. 1 New BPR implementation methodology proposed

Preparation

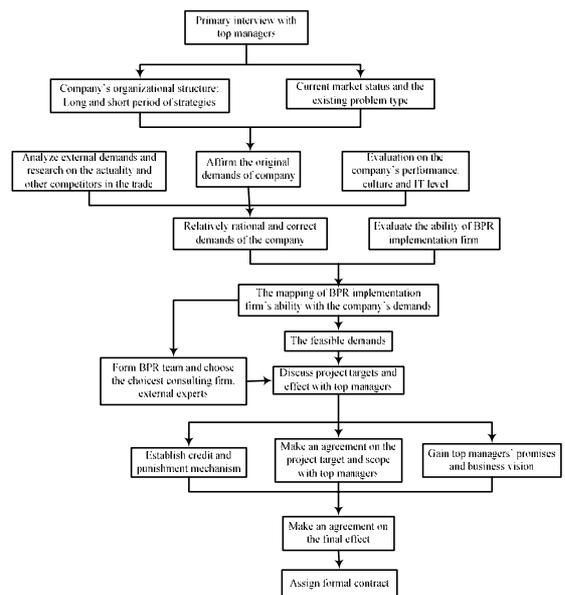

Before the start of BPR project, some prophase preparation should be done, such as collecting the basic information and demands of its client. Only if the client has the belief that the BPR consulting firm has truly understood its problems and requirements, it will be interested in further communication. Otherwise, it will not engage the firm to do the project. Accordingly, the implementation firm can also evaluate if its resource may meet the client's requirements correctly. Only with plenary capability can the BPR consulting firm ensure the quality of the project.

Another task in the preparation stage is winning top managers' support. As BPR is a long strategic innovation which has a far-reaching influence on the company, the top

managers' understanding seems so critical to the successful of the project. In this stage, BPR team should make the top manager fully understand the importance and necessary of BPR, and be on to BPR is an inevitable direction that the success has direct relationship with his own career development. On this precondition, we can remove their uneasy caused by the change of management process and their resistance to the reformation of human resource. If the top managers are eager to the success of BPR instead of embarrassing it, they will delegate power to the BPR team and support their work. The agreement on the aim, business vision, and final effect of the BPR project is also necessary other than winning the trust of top managers. BPR is not a heal-all and its effect can't appear immediately. Therefore, the agreement on the effect and vision of BPR project is propitious to the fair evaluation of the BPR effect made by top managers latter. Certainly, the top managers we have mentioned here must be the one has absolute authority in the company who own the final Power to make decision of the BPR project.

Table 3 summarized the main targets, needful information, expected results, and the tools and techniques available in this stage. The detailed implementation approach is also displayed in Fig. 2.

Fig. 2 detailed approaches in preparation stage

Initiate Meeting

Initiate meeting is very important in BPR implementation. It's the first meet between project members and the company members involved. There are several important tasks in this meeting including interpreting the cause and targets of the project, propagandizing the foreground of BPR, representing the detailed implementing methodology and approach, lessening the resistance of related people and winning support, and establishing the reliability of the BPR team.

During BPR implementation, the most pivotal factor is

people. Whether the employees in the company support BPR and are willing to provide relevant information is of great

importance. It is dangerous to implement BPR without

Table 3 summarization of the preparation stage

Main targets	Input information	Expected results	Tools and techniques
<ul style="list-style-type: none"> ◇ Win the support of top managers 	<ul style="list-style-type: none"> ● Organizational structure ● Long and short periods of strategic target ● Type of currently encountered problem, e.g. the change of government's policies or competitors' strategies. 	<ul style="list-style-type: none"> ● Make an agreement on final project effect ● Assign reengineering team ● Choicest consultants and external experts 	<ul style="list-style-type: none"> ● Fast Cycle Full Participation Change Methods ● Search Conference ● Visioning
<ul style="list-style-type: none"> ◇ make agreement on the final effect of BPR 	<ul style="list-style-type: none"> ● Current demands, e.g. for survive, develop or expand? ● Company's market status ● External demands of the Co. ● Evaluation of the company's performance, culture, and IT level 	<ul style="list-style-type: none"> ● Gain the promises and business vision of top managers ● Make an agreement on the scope and targets with top managers 	<ul style="list-style-type: none"> ● Persuasion Technique ● Team-Building Techniques ● Project Scheduling Techniques
<ul style="list-style-type: none"> ◇ Form BPR team and subscribe contract 	<ul style="list-style-type: none"> ● Researches on trade actuality, e.g. surveys on competitors, suppliers, partners and customers ● The mapping of the ability of BPR implementation firms with the demands of company ● Basic research on other companies 	<ul style="list-style-type: none"> ● Win support of top managers ● Establish credit and punishment mechanism ● Assign the formal contract 	

Table 4 summarization of the initial meeting stage

Main targets	Main participants	Prepared materials	Tools and Techniques
<ul style="list-style-type: none"> ◇ Inform the project planning 	<ul style="list-style-type: none"> ● Top leaders who supervise the project directly ● Middle-level or top managers who participate in the project directly 	<ul style="list-style-type: none"> ● Company's background analysis ● Company's strategic aim ● Company's capability analysis 	<ul style="list-style-type: none"> ● Fast Cycle Full Participation Change Methods
<ul style="list-style-type: none"> ◇ Reduce the resistance of project 	<ul style="list-style-type: none"> ● The indirectly participant managers or employee deputies who can provide information or suggestions 	<ul style="list-style-type: none"> ● Trade's actuality analysis ● Competitor analysis ● Description of main problems ● Importance and urgency of main problem 	<ul style="list-style-type: none"> ● Search Conference ● Persuasion Technique
<ul style="list-style-type: none"> Establish reliability of the implementation team 	<ul style="list-style-type: none"> ● Employee representations who have influence on and can communicate with other employees 	<ul style="list-style-type: none"> ● Project targets and expectant result analysis ● Implementation approach of project ● Schedule of project ● Introduction of team members 	

sufficient support of employees. Therefore, the importance of initiate meeting in BPR project can't be ignored.

The BPR consulting firm should inspire the related people of the company with proper exciting methods, such as putting forward the fascinating foreground of BPR and reasonable reengineering approach. By this way, employees can understand that BPR can bring continuous development to the company and also benefits to himself indirectly. Thereby, the inimical psychology of the employees who are afraid of the short-term loss caused by reengineering can be lessened. Besides, top managers' support and delegation can also remove the BPR objectors' gaingiving and can make for the following work greatly.

Finally, the self-introductions of the team members in this initial meeting can set up the team's prestige and trust by making all the employees know each team member's ability and specialty, which is of great benefit to solve problems during the reengineering implementation.

In table 4 we have summarized the main participants in the initial meeting, as well as the materials prepared beforehand and usable tools and techniques in this stage. Also, the detailed approaches are presented in Fig. 3.

Process Analysis

The next stage is describing and analyzing current process after the initial meeting. Company always has its own written process and the posts for running the process.

Therefore, BPR implementation team should understand and summarize the written process and its corresponding posts. After that, team members need to arrange a meeting with the charges in the company for further communication and try to find out the difference between the process in action and the process in documentation, and the reason for it. The profound understanding about current process will provide the team members with feasible and innovative ideas for the process redesign.

On the basis of understanding current process, team members have to find out which process should be improved. The feasibility of improvement must be analyzed carefully and the impossible ones should be eliminated. Afterwards, the importance of the candidate processes need to be sorted for solving the most important problem with the limited resources and promoting the competitiveness of the company furthest.

The main targets, needful information, expected results, useful tools and techniques are indicated in table 5 as well as the detailed approaches presented in Fig.4

Process Redesign

In this stage, a new process which should meet strategic objectives and operable is developed as well as corresponding organizational structure, IS and social system. Firstly, the principles and benchmark of BPR should be reaffirmed with the top leaders in the company, because BPR

principle and benchmark varies with different companies and different targets. For example, if A Company pursues quick response ability and B Company pursues high precision of the process not response ability of process, then even the same project team will adopt different methods. Certainly, the new processes designed are different. Afterwards, BPR team has to further analyze the improve space of process and carry through the process redesign by using innovative ideation and advanced reengineering techniques.

Hereon, the fundamental of business reengineering -- ESCRI can be utilized. Namely, Eliminate: eliminate needless functions and no value-adding activities; Simplify: simplify the complicated process; Combine: consider combining the irrevocable tasks; Rearrange: whether the order of tasks can be rearranged; Increase: increase the functions needed but have not been in existence.

The main targets, needful information, expected results, and useful tools and techniques are also summarized in table 6 as well as the detailed approaches of this stage presented in Fig. 5.

Fig. 3 detailed approaches in initial meeting stage

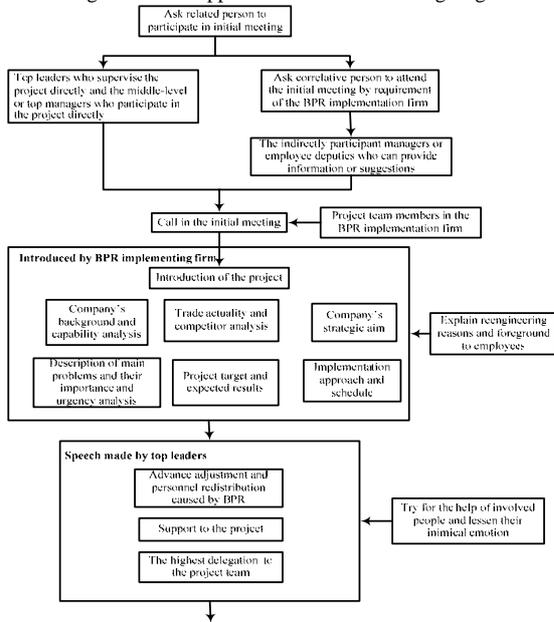

Fig.4 detailed approaches in process analysis stage

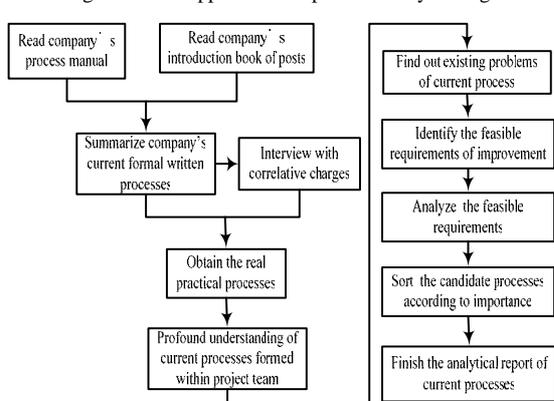

Fig. 5 detailed approaches in process redesign stage

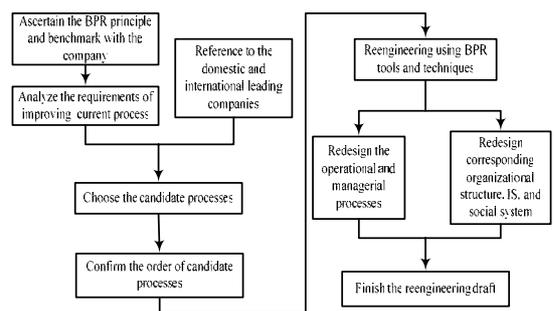

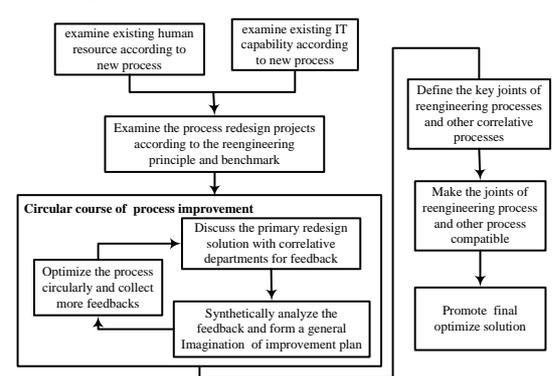

Fig. 6 detailed approaches in the evaluation stage

Feedback & Improvement

The elementary checkout and melioration of the new designed process should be done in this stage. BPR team will estimate whether the new process fits well with the company's manpower and technical level, and achieves expectant targets. Then, according to the real condition, the preliminary revise solution should be developed and be checked in terms of BPR principles and benchmark. Whereafter, the following steps should be repeated by 3 or 4 times.

- 1) document the revised process and distribute the documentation to the related people in the company
- 2) the project team members make an interview with related directors and all the managers in the company to collect feedbacks
- 3) Collection and analyze of feedback and identify valuable ideas which will be used to optimize the new process once again.

After tree or four times' repeat, project team should find out and check the compatibility of the pivotal joints of the new processes and the existing processes. The final process optimization is finished after solving the problem of compatibility.

Table 7 summarizes the main targets, needful information, expected results as well as the available tools and techniques, and Fig. 6 presents the detailed approaches of this stage.

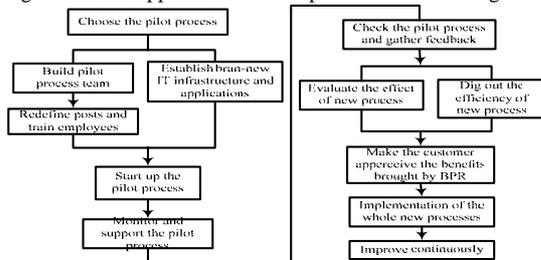

Pilot & Monitor

How to put the new process into action is an important question after advancing the final BPR solution. Usually, the

project team has to choose a pilot process from the reengineered processes. Given the urgency, the pilot process should be the one that has the least changes of posts and the employee training can be finished in short periods. Besides, the IT structure and applications needed for running the pilot can be set up quickly. Once the pilot process has been chosen, the project team starts to go about forming a pilot team, defining posts, training employees, and designing new technical platform. During the pilot experiment, the pilot team should monitor its status as well as its backup process, and collect feedbacks. Making use of the pilot, the effect of the new process can be evaluated and its efficiency can be further spotted. Furthermore, the client also can appreciate the benefits brought by BPR and be confident of the implementation of all the new processes. Thus, the whole new processes can put into action and be further ameliorated if the pilot process rolls one's hoop.

The main targets, expect results, and tools and techniques available in this stage are summarized in table 8 and detailed approaches are presented in Fig. 7.

Fig.7 detailed approaches in the pilot & monitor stage

IV. Discussions Based On a Hands on Project

Project Background

KK Co. is one of the leading companies in domestic household appliances trades. Its products such as DVD, telephone, language repeater and so on have been dominant in market. In order to making the most of its previous customer base, brand priority and channel management, KK Company launches new product ranges continuously for further development. Recently, KK Co. has launched a series of middle-level products, and prepares to promote the sales of them in next phase. It wants to become a leading company in domestic mini-music center market by further consummate its product structure. In order to be better customer orientated, the company engaged a consulting firm to reorganize the process of new product development and marketization for solving the current profit bottleneck ASAP. In sum, KK Co. wants to improve the following aspects.

- 1) identify the demands of the target customers
- 2) develop vision of new products and annual plan
- 3) the basic way for improve new product design
- 4) examine and approve the new products development

- 5) design and develop according to the concept of new product
- 6) identify the marketing and selling solutions
- 7) market popularize and track record analysis.

Discussion of the Project Results

This suit of new processes has been used by one of KK Company's new products—mini- acoustics. Employees in the company generally consider that the orientation of products is more accurate now. It has gotten rid of embarrassments caused by eyeless development and produce, and has been truly customer oriented.

The practice of the BPR project in KK Company has proved the feasibility of this innovative BPR implementation methodology which integrates both the distillate of previous BPR theories and the experience of the consulting companies. It assures the feasibility of implementation and the correctness of the BPR results by following innovative methods and steps:

- 1) understand the actuality and demands of the company clearly before the start of the project
- 2) definitely determine the targets of the project and its evaluation standards with the top managers of the company before the start of the project
- 3) win the support of the top managers of the company before the project starts
- 4) gain the support of the whole employees in the company at the initiate meeting
- 5) delegate power to the project team at the initiate meeting
- 6) choose appropriate analysis tools and methods according to the current condition of the company
- 7) choose proper reengineering solution on the basis of practical condition of the company
- 8) obtain continuous improved redesign solution by a closed loop of circular feedback
- 9) settle the contradictions and problems of new process by using the pilot

Though the time needed in this BPR methodology, it is quite feasible for some steps can be abridged or adjusted in different situations. For example, if the company has strong self-awareness and knows the direction of BPR and evaluation method clearly but with an urgent time requirement, then the first, second and the fifth step can be eliminated, besides, the step of running the pilot in the sixth step can also be eliminated if time limited. Thus, the BPR implementation methodology is similar with the simple three-step mode recommended before. The implementation is quick as the convenient and simple steps. Using the model introduced before (see table 2) to evaluate this new BPR implementation methodology. We will have the following table (table 9).

V. Conclusion

Nowadays, there are numerous theories and methodologies in management science, but have few revolutionary ones, while BPR is an outstanding one among them. Many enterprises win great success by business process reengineering. However, the high rate of failure indicates the huge risks in BPR implementation. The failure of BPR usually leads to quite turbulence of the company, some time even collapse. But it is a crag-fast situation that if doesn't carry out BPR the rigescent company will also be devoured by rivals in the competitive market. Various BPR implementation methodologies have been put forward by scholars which aim at enhance the success rate of BPR. But many of them are incomplete and lake of practical experience. However, the implementation methodologies in the consulting firms which have plenty practical experience are always lack of systematization and theorization. The new model for implementing BPR advanced in this paper combines both previous valuable BPR theories and practical experience in the consulting firms. It has a strong theoretical and practical proof. Especially, it is quite forceful for its good production in the practical BPR project of KK Company. It is believed that if implementing the BPR according to this methodology and choosing proper implementation team, it will greatly enhance the success rate of BPR project. We hope that this new BPR implementation methodology will be supported and further perfect by researchers, who are interested in this domain, and have made a certain contributions for the revolution of modern enterprises.

Table 9 Evaluation model of the new proposed

BPR implementation methodology

Basic Principles	New BPR implementation methodology proposed
Clear reengineering targets	Excellent
Extent focused on IT	Excellent
Reliability of project team	Excellent
Proper evaluation standards	Excellent
Top managers' support	Excellent
Reduce the resistance of related person	Excellent
Resistance in internal company	low
Choice of the candidate processes	Excellent
Solve the problem of compatibility pilot process	Excellent
Time needed	elastic
Feasibility of the implementation	Excellent

Modeling Business Process: Analysis of Goal-Oriented Approaches

Abstract: A crucial management issue for most corporations is the effective design and implementation of their business process. However, existing approaches describe an enterprise in terms of activities and tasks view without offering sufficient guidance towards a process-centric description of the organization.

Goals have long been recognized to be essential components involved in the business process. Business process engineering research has increasingly recognized the leading role played by goals in the business process. Such recognition has led to a whole stream of research on goal-oriented approaches. The study of goal-oriented methodologies indicates that modeling of organizational goals constitutes a central activity of the business process.

In this paper we advocate the use of goal-oriented approaches to business process modeling. Some systematic approaches to developing and documenting business processes on the basis of the explicit or implicit business objectives are discussed. From the representation view of model, the way that models are expressed is demonstrated.

Keywords: Business process modeling, Goal-oriented approaches, Representation

I. Introduction

The traditional practice of managing an enterprise adopts a functional view in which the business is organized along individual types of work performed, resulting in organizational structures which reflect the particular functional view adopted by the business. The main reason for adopting a functional organization is the achievement of maximum performance of individuals or business functions. Nevertheless, this inward focus 'internal' performance rather than 'global' efficiency suffers from a number of drawbacks, especially when business improvement is sought. In particular, improvements occur piecemeal and independently of one another, while concentration on the symptoms of one function ignores causes in important cross-functional interdependency.

Current business challenges such as deregulation, mergers, globalization and increased competition, have given rise to a new philosophy of business management that organizes an enterprise in terms of processes rather than functional and tasks. The basic characteristic of this approach is the re-orientation of business from performing

as a cluster of functions or divisions to integrating activities within a limited number of core processes. Each core process captures cross-functional interdependencies and concentrates on few strategic objectives that determine competitive success. Therefore, a process-centric approach links improvement efforts in different functions to a shared set of strategic objectives.

Adopting a process view however, requires suitable tools for identifying, modeling and measuring business processes. Existing business modeling approaches describe enterprise in term of activities and tasks offering little or no guidance towards a process-centric description of the organization. In this paper we advocate the use of the goal-oriented approach whereby a business is seen as a purposeful system aiming to achieve defined objectives which add value to its customers.

The paper is organized as follows. Section2 introduces the notion of business process in term of its defining characteristics and presents a critique of existing process modeling techniques. Section3 briefly introduces some goal-oriented approach to business process modeling. Section4 discusses the relation between the existing goal-oriented approaches. In addition, from the representation view, the way that models are expressed is demonstrated. Finally, section 5 concludes goal-oriented approaches can be used by an enterprise that wishes to develop a new business process, or alternatively model, document and analyze an existing process.

II. Business Process Modeling

The concept of business process is a key issue in the process-centric paradigm. However, there is a considerable controversy around the numbers and types of process appropriate to a given organization [33]. The difficulty derives from the fact that there exists no explicit way for determining business processes. There is a lack of a coherent and universally accepted definition of business process definition of what a business process actually is. Nevertheless, there are some common features of business processes should be defined in the literature [33] [28] [24] [27] that provide guidance as to how business process should be defined. In summary a business process in the process-centric organization demonstrate the following characteristics.

- A business process has well identified products and customers, such that business objectives are matched through the (product offering) business process and delivered in form of the product; customers may be external or internal to the organization; products may

include finished goods or services

- A business process has goals, i.e., it is intended to achieve defined business objectives aiming to create value to customers
- A business process involves several activities which collectively achieve defined business process goals and create value to customers
- A business process crosses functional and organizational boundaries; it concerns the collaboration between organizational actors that are contributing to (or constraining) the satisfying of business objectives

In these terms a business process constitutes the manifestation of what organizational actors do in order to achieve business objectives. Organizational actors include individuals or groups which may be internal or external to the organization (e.g., company employees, organizational departments, customers, suppliers etc.) and influence the realization of business objectives. Business objectives aim at creating value to customers in other words they concern customer value goals.

Business process modeling is a generic name that refers to a collection of techniques which are used to model the behavior of business systems. Existing process modeling approaches mainly originate from the software engineering field and fall in one of three categories:

- Activity-oriented approaches describe a process as a set of ordered activities (SADT[7], IDEF0[18], DFD[34], Workflows[22], the F3 process[19]). The emphasis is on what activities take place. Each of these activities is decomposed in smaller tasks corresponding to smaller steps in the process. In addition to a collection of tasks activity-oriented models define the order of task invocation or condition(s) under which tasks must be invoked, task synchronization, and information flow.
- Agent-oriented (or role-oriented) approaches specify and analyze the role of the agents that participate in the process (e.g., Role Activity Diagrams[27]), Role Interaction Nets[4], the ORDIT approach[21]). The focus is on the entity that performs a process element. Roles represent the sequences activities carried out by agent engaged in a co-operative behavior.
- Product-oriented approaches represent a process through the evolution of its product (e.g., [31], [23]). Product-oriented models do not put forward the activities involved in a process but rather the result of these activities. The focus is on products and transformations made on them. Each product entity has a defined a sequence of states and triggers that cause state transformations.

All the above approaches promote a view of a process that is based on the notion of activity. Activity-oriented approaches focus solely on description of activities. In addition to product-oriented approaches couple activities to their output (the product), while agent-oriented approaches establish an explicit link between the activities and the agent

responsible for these activities.

Existing approaches offer little guidance for identifying business processes. In activity-oriented approaches the main mechanism for grouping activities into processes is that of composition/decomposition. This mechanism however, does not offer a unique way to identify a process. The difficulty derives from the fact that processes are almost indefinitely divisible; the activities involved in fulfilling a customer order, for example, can be viewed as one process or hundreds. Agent-oriented approaches on the other hand, group activities into processes according to the organizational agent that performs these activities. Yet a process may cut across the organization involving several organizational agents. Finally, product-oriented approaches group activities based on the product that they manipulate and this notion of a process is in accordance with the suggested business process definition as the delivering of products to customers. However this focus on product rather than organizational behavior fails to describe other important components of a business process such as the business goals the process intends to achieve and the collaboration of the agents that contribute to realization of process goals[9].

III. Goal-Oriented Approaches to Business Process Modeling

Business processes, unlike processes that are executed by machines, exist in social organizational settings. Organizations are made up of social actors who have goals and interests, which they pursue through a network of relationships with other actors. A richer model of a business process should therefore include not only how work products (entities) progress from process step to process step (activities), but also how the actors performing these steps relate to each other intentionally, i.e., in terms of concepts such as goal, belief, ability, and commitment. When an organization seeks new ways for organizing work, actors who have goals and interests are likely to evaluate these proposals strategically, e.g., in terms of potential opportunities and threats [11].

Therefore, it becomes obvious that taking a single modeling perspective (product, activity or role) is no sufficient for expressing business processes. A business process model is a description of the main constituents, purpose, processes, etc. of an organization and how they relate to each other. It is essentially a representation (on paper or on a computer) of the organization's knowledge about itself or what it would like to become. Here 'organization' can mean anything from a large corporation or government department to a small team or a one-man company. Similarly, the level of detail represented in the model can vary depending on its purpose[25]. As a result, a business enterprise is described as a network of related business processes which collaboratively realize business goals.

From the above analysis, goal plays an important role. This area has received increasing attention over the past few

years.

During the goal-oriented business process modeling approaches, EKD[9][30] is a systematic approach to developing and documenting enterprise knowledge, helping enterprise to consciously develop schemes for implementing changes. The approach is part of a larger enterprise knowledge modeling framework, known as the Enterprise Knowledge Development (EKD) approach. EKD advocates a goal-oriented view to business process modeling. Instead of imposing a single modeling criterion EKD offers a more general modeling framework that follows several modeling views (or rather modeling components), using the notion of business goals to structure business components in coherent business process. The above are summarized in Fig 1 which presents an concepts.

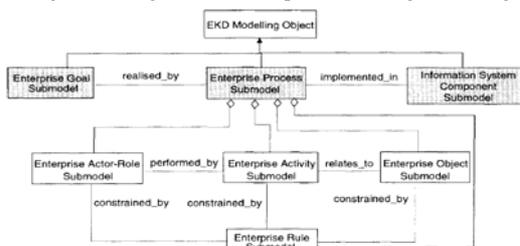

The EKD framework integrates three complementary views (submodels), namely: the enterprise goal view, the enterprise process view and the information systems components view.

The enterprise goal submodel uses a ‘network’ of goals that are used to express the casual structure of an enterprise, in terms of the goals-means relations from the ‘intentional’ objectives that control and govern the system operation to the actual ‘physical’ enterprise processes and activities available for achieving these objectives. The enterprises process submodel represents the organizational and behavioral aspects of an enterprise. An ‘enterprise process’ is a composite of four key enterprise components:(a)the roles that are played by enterprise actors in order to meet the process goals;(b)the activities involved in each role;(c)the objects that are involved together with their evolution from creation to extinction(within the context of the enterprise process);and(d) the rules that determine the process components. Finally, the information system component submodel focuses on the information systems components that support enterprise processes.

In using EKD modeling concepts one may start at any enterprise knowledge submodel (enterprise goals, processes or systems) and move to other levels, depending on the situation.

The totality of the EKD concepts form the enterprise knowledge ontology, i.e., the enterprise knowledge metamodel(EKM). This defines the logical form of the enterprise knowledge. The metamodel includes information about the semantics of the enterprise knowledge; it identifies the enterprise entities their attributes and explicit relationships between them.

Fig1 Modeling views in enterprise knowledge modeling

In addition to the above approach the i* framework (Distributed Intention, pronounced i-star) for modeling intentional, strategic actor relationships is another goal-oriented approach. The framework consists of two main components. The Strategic Dependency (SD) model describes a business organization in terms of the dependencies that actors have on each other in accomplishing their work. It is used to represent a particular design for a business process. The Strategic Rationale (SR) model provides a more detailed level of modeling by looking “inside” actors to model internal intentional relationships. Intentional elements (goals, tasks, resources, and softgoals) appear in SR models not only as external dependencies, but also as internal elements arranged into (mostly hierarchical) structures of means-ends, task-decompositions and contribution relationships.

Earlier versions of the framework has been presented in the context of requirements engineering [12], business process reengineering[13][14], software process modeling[15], and analysis of the organizational impact of computing[16]. Yu extends his earlier work by defining the features of the SR model and giving the highlights of its formalization. It also further clarifies how the framework assists in the understanding of business processes, and the generation and evaluation of alternatives.

The i* approach provides a description of work organization in terms of dependency relationships among actors. This approach acknowledges the fact that actors have freedom of action, within the social (inter-actor) constraints, called strategic dependencies. An actor is an active entity that carries out actions to achieve goals. Intentional components i.e., goals to be achieved, tasks to be accomplished, resources to be produced and softgoals (non-functional requirements) to be satisfied, are made specific embedded in the dependencies between actors [10].

In the goal-based workflow approach proposed in [5] an organization is seen as a tuple [G, A, R] where G is a set of goals, A is a set of actors, and R is a set of resources. Actors act collaboratively using resources in order to attain their goals.

Similarly, Lee's Goal-based Process Analysis (GPA) is also goal-oriented approach[20]. GPA can be used to analyze existing processes in order to identify missing goals, ensure implementation of all goals, identify non-functional parts of a process, and explore alternatives to a given process.

The GEM model and methodology[3] is another goal-oriented approach of business process modeling. According to GEM business processes are collections of suitably ordered activities, enacted by individual persons, depending on their role within an organization. Every process has a purpose which is to achieve a goal or react to an event. GEM offers a number of models that can be used for specifying processes: the role interaction model, the purpose model, the procedure model, the internal data model and the corporate data model. The GEM methodology consists of three steps: defining the scope of the business process, doing process analysis and doing system design. The process analysis step

consists of the following stages: goal hierarchy analysis, basic procedure analysis, detailed procedure analysis, input/output data analysis and performance metrics specification.

IV. Discussion

The need for developing an overall view of goal concepts and goal-oriented approaches has also been argued in [17] and [2]. The former investigates the use of goal analysis in terms of different activities. On the other hand, the latter compares different goal-oriented methodologies on the basis of their goal modeling and specification approaches. In addition it provides an overview of different goal modeling strategies (goal refinement, goal decomposition, analogical reuse, goal operationalization, goal conflict management, and selection between alternatives). Rather than providing a comprehensive framework for analyzing the contribution of alternative approaches, the objective of these works has been mainly to stress the significance of goal concepts in business process and to draw the attention of the research community to goal-oriented business process. It also assists us to understand and accordingly select the best fit for goal-oriented modeling method.

For example, let us consider a BPR project concerning the reorganization of an electricity distribution company due to market deregulation. In order to meet the conditions in the competitive market the company needs to re-examine and improve the way of servicing its existing customers as well as to adopt new ways of working for servicing eligible customers. The implications of these forces on this organization is that any reform, requires, prior to (re-) designing business processes and support information systems, a clear understanding (and a sharing of this understanding between many stakeholders) of the current enterprise situation. Thus, a goal modeling approach such as the *i** strategic dependency modeling method or EKD, that focus on understanding the current organizational situation should be used [10].

We should also pay attention to other situational factors that affect the applicability of a method may include the use of appropriate tools that facilitate method execution and the familiarity of engineers with the applied strategies and supporting technologies. The selection of a particular method cannot be fully prescribed. Furthermore, even when one follows a certain goal-oriented modeling method the situational factors dominating the project may cause a number of adaptations to it.

Another observation is that additional benefits can be gained by integrating different methods. The combination of the two approaches can lead to a more complete methodology. An example of this type of integration is found in [8].

It should be noted that any type of integration should also take into consideration the system and representation views in order to ensure compatibility between different methods and consistency between the different goal representation formalisms. Initial analysis of the goal

concepts used in different approaches [1][29] shows that integration of goal models resulted from different methods is feasible, additional work is required however, in order to efficiently manage different formalisms and notations used in different approaches for expressing goal concepts.

From the representation view concern the way models are expressed. Models can be expressed in a variety of formats, using more or less formally defined notations. We differentiate between informal, semi-formal and formal approaches. Informal approaches generally use natural language text to express models; semi-formal use mostly box and arrow diagrams; finally, in formal approaches goals are expressed as logical assertions in some formal specification language [10].

In general, formal approaches use specification language to formally define model: Telos, Temporal Logic, Structured, Situation Calculus and ConGolog language, etc.

The vast majority of business process modeling efforts lack formal methods for modeling business processes. EKD uses entity-relationship models to represent structural information and Role-Activity Diagrams [26] to represent roles and their activities. EKD is a semi-formal approach.

*i** use the Telos language to formally define their models. The popularity of Telos is due to its ontological extensibility. This allows the capture of the semantics of one level at upper meta-levels inside Telos itself, thus allowing the definition of a customized conceptual language [32].

Rao [3] gives only a short informal description of the models and methodology. A methodology for developing multi-agent systems based on concepts similar to the ones in GEM appears in [6].

Semi-formal is the most widely used technique for model representation. Semi-formal models are imprecise in the sense that: (a) the meaning of modeling entities is described solely by the name given to it in the diagram and (b) the relationships between entities are loosely defined. Nevertheless, these models do provide an adequate basis for discussion between stakeholders and they also establish a framework for further analysis. Using these models stakeholders can confirm their shared view of the situation and agree the boundary within which a more detailed analysis will be performed.

Formal approaches offer more expressive languages and are therefore more amenable to formal reasoning. The main advantage of formal methods is that they can be used by sophisticated business analysts to capture business knowledge in an intuitive and unambiguous way. They can also be used to analyze processes in a formal way; this would have been impossible if the business analyst used an informal approach. However, they lack the freedom necessary to adequately support goal elicitation (e.g., to allow conflicts and inconsistencies among goals), and they lack the simplicity, flexibility and ease of use of semi-formal representations. Thus, semi-formal and formal representations are best seen as complementary contributing to an evolving framework for expressing models.

V. Conclusion

In this paper we have presented some typical goal-oriented approaches for modeling business process. In contrast to traditional business process modeling approaches which focus on business activities, the paper advocates the concept of business goal in order to describe the collaboration between business actors.

The paper has discussed some methodologies that enable business analysts to go from high-level enterprise objectives, to detailed and specifications of business processes for reasoning these objectives. The methodologies can be used by an enterprise that wishes to develop a new business process, or alternatively model, document and analyze an existing process.

Abstract: The sampling groups in this research are customer who use the banking service via Internet system and the customer of D-Computer Co., Ltd. who usually use Internet Banking services such as inquiry about outstanding balance, fund transfer between accounts, and transfer payment for public utility. The sampling group specification of this research are must use Internet Banking services at least once a month. The research tools are questionnaires in the Web page form. Questionnaires are adapted from the tools that are used to evaluate the service quality called "The dimension of quality by David A. Garvin" by evaluating the quality of eight dimensional services: Performance, Features, Reliability, Conformance, Durability, Aesthetics, Serviceability and Perceived quality. During the sampling survey, we received 300 questionnaires that being answered completely. For information analysis, we use the fundamental statistics to analyze the characteristics of sampling group and test the relative variable factor by means of Chi-square and obtain the result to build a variance factor linear prototype.

The results were as follows:

1. The quality level of internet banking service of commercial banks in Thailand in the perspective of performance was different in each bank.
2. By weighting the important of criteria that used to evaluate the Internet Banking service quality in Thailand, the most important was the dimension of reliability, serviceability and durability. The less important was in dimension of perceived quality.

Keywords: Internet banking, e-Banking, service quality, dimension of quality.

I. Introduction

In the present days, internet consistently increases its importance as an effective communication channel providing unlimited, speedy and effective facilitation because of

its geographic advantage and low cost. Internet becomes well known and used in household, business, bank and government sectors. Leading commercial banks in our nation have developed their working system by introducing computer system into their operation for speedy operation, and elimination of documentation and document expenses.

In the early period, banks used computer to keep and gather the information on credit, savings and other office works. Later, Thai commercial banks have developed computer system to be modern and correspond to the changing circumstances. In the age of communication and information development, the speed of data access and more effective advantages enhance the step to e-banking.

From 12 commercial banks in Thailand now [1], only eight banks, namely, 1. Bangkok Bank Public Company Limited, 2. Krung Thai Bank Public Company Limited, 3. Bank of Ayudhya Public Company Limited, 4. Kasikorn Bank Public Company Limited, 5. TMB Bank Public Company Limited, 6. Bank Thai Public Company Limited, 7. The Siam Commercial Bank Public Company Limited and 8. Bank of Asia Public Company Limited, provide alike internet banking services. In fact, the internet banking system has been available for not less than 4 years by Bank of Asia Public Company Limited and The Siam Commercial Bank Public Company Limited as the pioneers [2].

Internet banking service is available 24 hours. Customers do not have to pay traveling charge to do any transaction because it is accessible via internet system from the user's house or office. However, internet banking service is less popular than counter service or call-center service but it shows the sign of continuous progress.

From the study conducted by Winnie Chung and John Paynter [3], the following 3 points of internet banking service should be considered as important, namely, security system, data update and responding period. What is found not important for the service is the animation. Worasri Tantichattanon [4] said that the main issues of the unpopularity of internet banking were the security system, unreliability and insecurity of the service whereas the factors creating the confidence of the users of internet banking service were the accurate data and good security system.

II. Conceptual Framework

The conceptual framework in this research is the study on the satisfaction of the customer of internet banking service. The quality of service is measured by the use The Eight Dimension of Quality by Garvin [5], namely, performance, features, reliability, conformance, durability, serviceability, aesthetics and perceived quality. These perspectives were transformed to be a questionnaire on a web page to measure the quality of service of internet banking in Thailand.

III. Research Methodology

The first part of the research is to evaluate eight Thailand banks regarding their Internet Banking services quality. This is an objective evaluation that aims to examine whether there is any difference among the eight Thailand banks. The Eight Dimension Quality was used as a basis for the evaluation in this part of the study.

Components that appear in the Eight Dimension Quality are performance, features, reliability, conformance, urability, serviceability, aesthetics and perceived quality. These components are the starting criteria that were used to evaluate the eight Thailand banks.

This dimension quality model (Table 1) was used to measure the services quality of each bank by presence of each element.

Table 1: The Eight Dimension Quality Model

Components	Elements
Performance	Up to date Information Response time Download time Complete Product Information Tutorial / Demonstration Help Function
Features	Online Registration Transfer funds between bank Other Language in addition to English Keep data safe Require encryption (SSL) 24 hours – 7 days Innovation features Ease of use
Reliability	Require Authentication Limit to change data Complete data Correct Link Manage font display

	Clear Instructions
Conformance	Product Information Locating Information How Informative Explains Symbol Internal Connection System Responsiveness
Durability	Announce change something Complete Display System Performance Continue to Use Connection failed Able to fix problem
Serviceability	Search Function Navigation menu / buttons Online Help Communication with Security Rapidly Services
Components	Elements
Aesthetics	Font Format Display Color Font Picture/Graphic/Animation Picture Size Layouts Color Theme
Perceived Quality	Company Information Competitions or rewards Development Basis of Honest Basis of Reliability Basis of acceptably

The second part of the research is a survey that aims to compare the overall services quality of Internet Banking and factor of Internet Banking service between each bank in Thailand and each dimension of quality by David A. Garvin.

The data in this research was gathered from the samplings of customers of internet banking of the eight banks of which the 2 main groups were users from D Computer Co., Ltd and general users of internet banking service in Thailand. In order to obtain comprehensive data as to the research objectives and the data accuracy, reliability, the qualifications of the samplings were set at the use regularity - or at least once a month.

During the sampling survey, we received 300 questionnaires that being answered completely. Quota sampling was used to select the samplings. Chi-square test and coefficient of correlation test were used to analyze the data. The result was brought to create Multiple Regression model to test the hypothesis.

IV. Preliminary Results

1. General information of samplings

Most of the samplings who were the users of internet banking service of the eight banks were female with the educational level of bachelor degree. The frequency of service use was 2-3 times a month. The ages of the samplings were between 21-30 years and their salary was less than 15,000 Baht a month.

2. Research hypothesis

2.1 The quality level of internet banking service of commercial banks in Thailand in the perspective of performance was different at the statistical significance of 0.5. For other perspectives, the quality level of each bank was not different at the statistical significance of 0.5.

2.2 The users of internet banking service gave importance to the eight perspectives of quality. The most importance one was the reliability, serviceability and durability respectively.

The least important perspective was perceived quality of the commercial bank.

V. Conclusion

From the study on the quality level of the internet banking service in Thailand, it was found that reliability, namely the security system and information accuracy, was the most important perspective for the user.

Comprehensively, reliability – the perspective which creates the reliability for the user - should be developed and improved for better performance. This would positively affect the commercial banks and lead to higher customer satisfaction.

The result of this research could be able to use as a guideline to setup a form of service in order to satisfy the needs of target group accurately and appropriately. Using as a database to set the market strategies in order to penetrate the target group efficiently, and also being use as a guideline to create a new form of service so that the users get more variety choices.

A Last-Minute E-Auction for Hotel Rooms

Vatcharaporn Esichaikul Clemens Bechter Le Thi Nhan
Asian Institute of Technology, Thailand

Email: vatchara@ait.ac.th, bechter@ait.ac.th, lethi.nhan@ait.ac.th

Abstract: Electronic auctions have rapidly become one of the most widespread applications in electronic commerce. Within e-auctions, the online products are almost anything imaginable such as electronic parts, artwork, vacation packages, airline tickets, etc. In this paper, the reverse auction was implemented by proposing a suitable bidding mechanism for perishable products like hotel rooms. These vacant rooms should be sold as soon as possible before their value zeroes. Therefore, the Last-Minute Auction not only helps the buyers get their desired rooms, but also helps the hotels to selling their rooms in time. The research combined the Hungarian algorithm and Branch-and-Bound search to match the buyers' demand and the sellers' supply and optimizing the auction site's revenue.

Keywords: Hospitality Business and the Internet, Reverse auction, Last-minute auction, Hotel room.

I. Introduction

An electronic auction (e-Auction) plays an important role in online business world today. With e-Auction, suppliers can sell their products at a price that meets buyers' expectations, saving time, reducing costs, increasing revenues and acquiring more benefits as well. On the other hand, consumers have chances to bargain, buying goods and services at affordable price anytime and anywhere.

Travel products such as air tickets, hotel rooms, and car rentals are last minute commodities with a limited lifetime. That is why the supplier should sell or rent them as early as possible to induce more revenues. How does a supplier make a dynamic decision to sell products early enough to maximize revenues? Even more important, how do consumers get hold of their desired product at the low price?

A reverse auction is beneficial for both parties. From the customer's perspective, it offers lower prices combined with a broader supplier base and a more efficient procurement process. Online buyers can save money when purchasing goods through the online auction because the very nature of an auction tends to force suppliers to reduce asking price progressively, in sync with demand.

However, reverse auctions are better suited to only particular kinds of product such as high-volume bulk commodities, while they tend to become less advantageous for goods that are more specialized. An auction can hardly handle such issues as complex product specifications, because the more complicated is the item description, the higher turns to be the risk.

This paper aims to apply the mechanism of a reverse auction for sales of a last-minute product, such as hotel rooms. In addition, the paper proposes an appropriate mechanism needed for the last-minute auction in accordance with the increasing role that reverse auction plays in an electronic business nowadays.

II. Background on E-Auction in Travel Industry

In travel industry, all major airlines, vacation services, travel agencies, car rental agencies, hotels, and tour companies provide online services. Auctions and bids are also conducted online permitting customers to bid for a ticket, a hotel room, or a rental car. There are many online auction sites in travel industry. Among the two major sites are following:

II.1 Lastminute.com

Brent Hoberman and Martha Lane Fox (<http://www.lastminute.com>) founded lastminute.com in 1998. It has become Europe's leading online travel retailer offering lifestyle products as well as travel-related services. Based on the idea of matching supply and demand, it offers consumers last minute opportunities to acquire airline tickets, hotel rooms, package holidays, entertainment tickets, restaurant reservations, home delivery, services, gifts and auctions. At lastminute.com, buyers bid for goods or services of a certain vendor who may be lastminute.com or a third party using three auction formats: English Auction, Reserve-Price Auction and Dutch Auction.

II.2 Priceline.com

Founded in 1998, Priceline.com is a reverse auction site where buyers select products they want to buy and the price they are willing to pay. The goods and services for sale or rent include airline tickets, hotel rooms, cars, packaged vacations and cruises. Priceline.com provides one auction format - sealed-bid first-price format. First, the potential buyer selects the city and the date that he or she wants to stay. Next, the buyer selects the specific areas and the quality level of a hotel. Then the buyer names the maximum price that he or she is willing to pay. When the system reviews the request, the buyer enters their credit card information. After that, Priceline.com searches its database for available hotel rooms and when a matching room with the price lower than the asking bid price is found, the bid is accepted, buyer's credit card is charged for their asking price with applicable taxes, and the buyer gets the room.

III. Proposed Last-Minute E-Auction

In the proposed Last-Minute auction, there are four major components: 1) Registration; 2) Room Request Posting; 3) Hotel Bidding; and 4) Demand and Supply Matching.

III.1 Registration Component

This component permits a customer to register as a member of the system. After the registration process, a customer obtains a login name and a password to log in the system.

III.2 Room Request Posting

This component permits a customer to post a hotel room request. A customer can request hotel rooms by specifying the city name, an area in the city, desired hotel star rating, number of rooms, and the maximum rate per night. To complete a request, a customer must provide credit card information.

III.3 Hotel Bidding

This component forwards room requests to participating hotels and invites them to place a bid. For bidding, each hotel must supply the number of vacant rooms and room rate per night. When there is a lower bid, the system will notify

hotels asking whether they want to reduce their bids.

III.4 Demand and Supply Matching

This component will match customers' need providing the supply of the hotels. The matching process starts with summarizing all requests, according to criteria - city name, area, hotel star rating and specified room rates. After that, system sends all requests to relevant hotels inviting them to place their bids. All received bids from the hotels are summarized according to above criteria. Then customers' demands are matched with the supply of the hotels, which allows maximizing the revenue of the auction site. In case when a customer requests more than one room, a match ensures that all rooms requested by a customer are in the same hotel.

In the matching process, the system uses the Hungarian algorithm (see Figure 1) developed by Kuhn and Munkres (also known as Kuhn-Munkres algorithm). The problem is represented by a bipartite graph, $G(X, Y, X * Y)$, with weights $w(e_i)$ assigned to every edge. The set X represents buyer's room, and the set Y represents seller's room. The weight of an edge represents the mark-up money for a (buyer's room, seller's room) pair. The algorithm finds the matching with the greatest total weight.

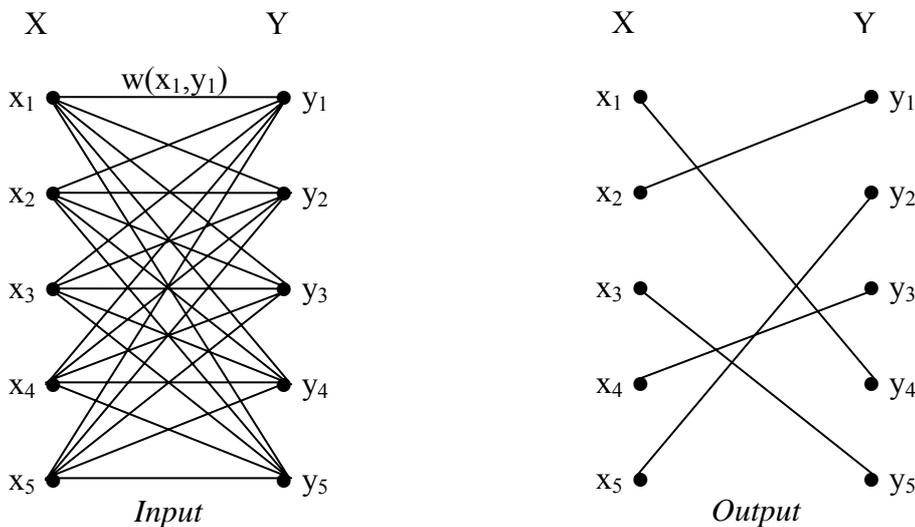

Figure 1: Hungarian Algorithm

An example of assignment problem and Hungarian method is outlined in the following matrix. The weight w_{ij} are the entries of an $n \times n$ matrix, and the elements of X and Y are

identified with the rows and columns of the matrix respectively. Let's assume that there are three requests named 1, 2, 3 and two hotels named 1, 2.

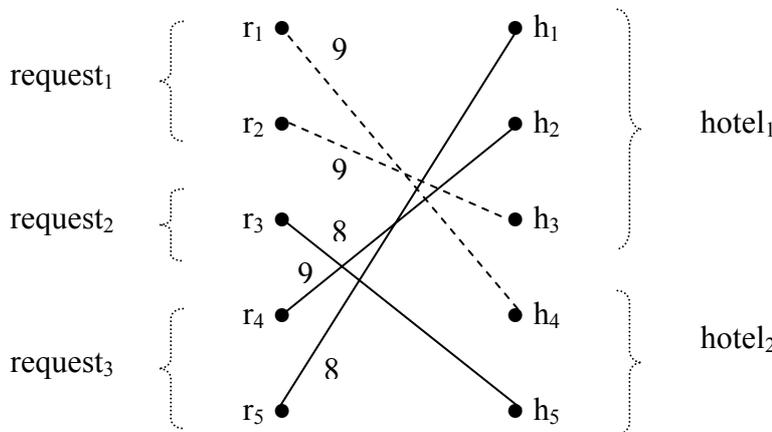

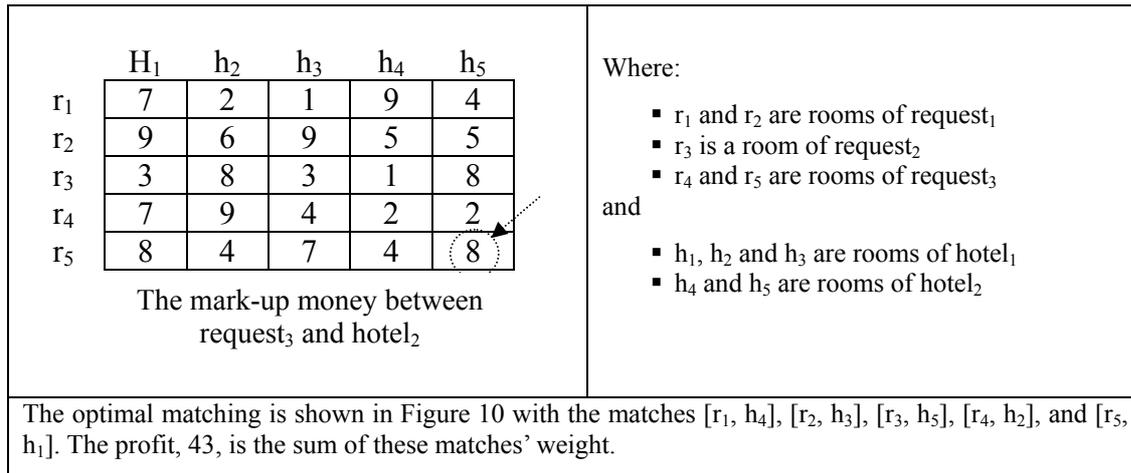

Figure 2: The Example of Hungarian Algorithm.

However, the requirement of current matching problem is more complex than the requirement of basic weighted matching. In the above example, the request₁ does not satisfy the requirements of the problem, because the request₁ is assigned to different hotels. Therefore, the result from Hungarian algorithm is not optimal but is acceptable as a temporary solution if all bad matches are being filtered. In the next step, we will use exhaustive search algorithm, particularly a Branch-and-Bound search, to get optimal solution. Using exhaustive search algorithm takes some time, so it will be formulated with the following conditions in order to quickly yield a solution.

- In the process of searching, the case that cannot yield the solution will be early eliminated.
- To get solution early, the exhaustive search algorithm has to choose the case having a better solution than the Hungarian algorithm's solution. Thus, the heuristic method will be used to implement the estimated profit function. In this function, the total

profit of all remained requests and supplies are calculated in advance. After that, the result of estimated profit function will be added to the current profit and compared with temporal solution, the lower bound from Hungarian method's solution.

Using exhaustive search, a customer's request may or may not be satisfied by hotels. Therefore, the type of exhaustive search where each node will be considered as a feasible solution.

IV. Prototype Implementation

The Last-Minute auction prototype is implemented based on the following technologies:

- Platform: Windows XP Professional is used as operating system at client side and Windows 2000 Advanced Server is used as operating system at server side.

- Web Server: Microsoft IIS 5.1 (Internet Information Service) is used to manage the website.
- Database Server: Microsoft SQL Server 8.0 is used to manage all the data of the auction.
- Software Development Tool: Microsoft Development Environment 7.1 and Microsoft .NET Framework 1.1 are used to develop the application. ASP.NET (Active Server Pages) is used as a technology to build the application.
- Aid Tool: Rose Enterprise Edition 2002.05.00 is utilized to analyze and design the application.

The interface of proposed Last-Minute auction is divided into three parts: customer interface, hotel interface and auction site administration interface.

V. Conclusion

The Last-Minute auction was designed and implemented for auctioning vacant hotel rooms. From the customers' perspective, its bidding mechanism permits them to specify their requirements and join the Last-Minute auction. From the sellers' perspective, the Last-Minute Auction helps them sell quickly vacant rooms with reasonable rates. Sellers or hotels can decrease their bids to compete successively with others and win the bids. For the auction site, the proposed mechanism helped them earn maximum revenue through the proper matching of customers' demand and hotels' supply.

The matching algorithm was designed to solve the complex problem of having many matching criteria, such as the same city, area, hotel star rating, number of room and rate. The combination of Hungarian algorithm and Branch-and-Bound search has yielded the accurate answer, which satisfied the requirements of the problem. Another solution for the weighted matching problem and the profit optimization, which has not been examined yet, is Genetic Algorithm. The solution generated by Genetic Algorithm can be a direction of the future work.

Abstract: Integration technologies like Enterprise Application Integration (EAI) and Web Services allow organisations to collaborate with their partners, increase flexibility and gain competitive advantages. Despite the benefits that the integration of Information Systems (IS) can offer to enterprises, little attention has paid on the adoption of integration software by Small to Medium Sized Enterprises (SMEs). The body of literature suggests that the findings that derive from the study of large enterprises can not be generalised and applied in SMEs due to the nature and characteristics of SMEs. In an attempt to study this area, research questions were raised. These research questions are investigated in this paper and supported the authors to propose a research model. The proposed model might be used to explain why SMEs and large organisations take decisions for the adoption of integration technologies focusing on different factors. The results of an empirical study carried out on a sample of 102 companies of any size in Taiwan are presented, aiming at highlighting any significant difference in the way SMEs and large companies approach integration technologies.

Keywords: SMEs, Integration technologies, EAI, Web Services, Integration technologies adoption.

I. Introduction

Despite the advantages that IS integration can offer to organisations as mentioned in the literature, little attention has been paid to the adoption of integration technologies by SMEs [22][43]. Iacovou *et al.* [23] reported that SMEs differ from large companies in many ways that affect the adoption of integration technologies. These differences include: the lower levels of resources available for this [23] [28], the substantially less sophisticated IS management [25][43], the needs for integration and their characteristics, and the quantity and quality of the available environmental information [33]. For these reasons, Kuan and Chau [28], among others suggested that the general applicability of the studies in large organisations may be questionable if applied to small businesses. Thong [46] also argued that because of the unique characteristics of small businesses, there is a need

to examine whether those models for IS adoption developed for the large business context can be equally applied to small businesses.

Although the adoption of integration technologies is recognised in the normative literature as being different between large and small companies, the literature on the adoption of integration technologies by SMEs remains limited [28]. Nevertheless, among the existing works, their focus mostly emphasises on either the adoption decision or the successful implementation factors [9][28][38]. To the best of the authors' knowledge, there are no studies on the reasons why SMEs and large companies take the decision to adopt integration technologies, which focus specifically on the different factors. Thus, this presents a research issue which needs further investigation. This paper attempts to address this issue by studying the factors affecting the adoption of integration technologies by comparatively analysing the adoption factors between SMEs and large companies. The proposed research model is tested through a survey study in Taiwan IT industry (with 68 usable responses and 87% of the responding firms' integration technology users).

Therefore, this paper aims to identify the significant differences in the way that SMEs and large companies approach integration technologies. In doing so, the parameters are identified that can be used to explain the adoption of integration technologies between SMEs and large firms, which are the nature, company size, integration needs, adoption factors for SMEs and large organisations and time. It is argued that this paper is of value in highlighting the specific parameters in SMEs and large organisations in relation to integration technologies adoption.

II. Research Issues Analysis

II.1 Nature of Organisations

Globalisation forces many enterprises to change the way they do business. To compete in global markets, SMEs need to develop new business strategies and deploy new technologies. For example, Web Services and EAI are relatively new technologies. However, Storey [41] argued that the size of small businesses creates a special condition, which can be referred to as resource poverty, that distinguishes them from their larger counterparts and requires some different management approaches. Thus, it is

vital to identify the nature of SMEs to assess what makes them distinct from other types of organisation (e.g. large organisations), as the nature of SMEs might be a real obstacle to their adoption of integration technologies.

SMEs consist of a significant part of the economy and are characterised by high firm failure rates [42]. Storey and Cressy [41] reported that about 11% of small businesses fail to survive in any given year. This failure rate is six times higher for smaller than it is for larger businesses. This is due to SMEs usually:

- Having little ability to influence market price by altering their output [27].
- Having small market shares, so are unable to erect barriers to enter their industry [15].
- Can not easily raise prices and tend to be heavily dependent on a small number of customers [42].

Small businesses can not usually afford to pay for the kind of accounting and book keeping services they need, nor can their new employees be adequately tested and trained in advance [49]. Small businesses are also under increasing pressure to employ IS to maintain their competitive positions. At the same time, there are more barriers to IS implementation in small businesses than there are for large businesses, due to the high capital investment and skilled manpower involved in implementing and operating IS [47]. Welsh and White [49] also pointed out that resource constraints (time, finance and expertise) in small businesses are based on the concept of the resource-based theory. The resource-based theory is often used to explain the adoption and use of information systems and technology in SMEs. According to it, firms are characterised as being collectors of resources or capabilities. A firm's resources may include both tangible and intangible assets, including capabilities, organisational processes, information, and knowledge, that are all controlled by a firm to enable them to conceive and implement strategies that improve its efficiency and effectiveness [2]. The resource-based theory emphasises an understanding of the internal capabilities that enable organisations to secure competitive positions and the importance of internal resources in a company [2] [4]. In this research, the resource-based theory is applied to explain the importance of the natural resources of a company, in terms of the integration of their technologies adoption decision (e.g. time, finance and expertise constraints).

Time constraints refer to the limited amount of time available for activities beyond the normal job responsibilities of individuals in small businesses. Financial constraints refer to the limited amount of finance available for activities beyond the normal operations of the small businesses. Expertise constraints refer to the limited amount of expertise within the small businesses to carry out activities beyond their designated job responsibilities. Based on these, Welsh and White [49] reported that: (a) SMEs have to control their cash flows carefully, as they do not have unlimited funds for their IS project; (b) SMEs tend to choose the cheapest system, which may be inadequate for

their purposes; (c) SMEs usually underestimate the amount of time and effort required for adopting integration technologies; and (d) SMEs normally engage consultants and IT vendors to develop and support their information systems [47]. For example, SMEs might prefer to outsource most of their activities, whereas large companies might only prefer to outsource those activities which are not directly related to their business strategies, or even to manage these activities totally on their own.

Resources such as time, finance, and expertise that are all necessary for planning, represent the most critical difficulties for small businesses [10]. Due to this reason, Kagan *et al.*, [25] and Tagliavini *et al.*, [43] claimed that SMEs usually have substantially less management over their sophisticated information systems and that this might affect the way that they approach integration technologies. In addition, according to Attewell's [1] technology diffusion theory, it emphasises the role of external entities (e.g. consultants and IT vendors) as knowledge providers in lowering the knowledge barrier or knowledge deficiency on the parts of potential IS adopters. Small businesses tend to delay in-house IS implementation because they have insufficient knowledge to implement IS successfully [47].

Thus, based on the discussion in this section, it appears that the nature of SMEs, in terms of external and internal resources (e.g. time, finance and expertise), impacts on the way that they approach integration technologies. To this end, the following research question is raised for further investigation.

RQ1: *Is the nature of SMEs a real obstacle to integration technologies adoption.*

II. 2 Company Sizes

Apart from organisational or strategic remarks, various literature emphasises size as one of the issues that is increasing the need for the co-ordination and control of organisational activities [21][32][50]. Tagliavini *et al.* [43] proposed that company size is an important factor affecting ERP adoption. DeLone [16] also suggested that computer usage characteristics are different in organisations of different sizes. Other research works, like IDC's [24], suggest a direct relationship between the size of organisations and the percentage of those organisations in which ERP has been implemented. All these studies indicated that the size of the organisations have many different impacts on the ways that the organisations do things.

As reported in the literature, SMEs can be categorised as micro sized companies if they have up to 20 employees. SMEs can also be defined as small sized companies if they have up to 100 employees, whereas SMEs can be classified as being medium sized companies if they have up to 500 employees. Companies that have more than 500 employees can be seen as large organisations [11]. Company size is important, as a company with 20 employees and a company with 500 employees have different ways of managing their

IS. For example, the same system might be managed by 200 employees from the IT department in large companies, but only managed by 20 or less employees in small companies. In accordance with the views discussed here, the authors suggest that there is a possibility that companies of different sizes follow different approaches towards the adoption of integration technologies. Thus, company size is included here as a factor that affects the adoption of integration technologies.

In accordance with the views discussed in this section, the researcher suggests that it is possible that companies of different sizes may follow different approaches for their adoption of integration technologies. Thus, a research question is proposed for further investigation:

RQ2: *What is the relationship between integration technologies and their adoption in companies of different sizes?*

II. 3 Need for Integration

It was found that organisations adopt a new technology only if it provides significantly better benefits than their existing ones [39]. A new technology has to provide solutions for existing problems or open up new opportunities to motivate an organisation to take a proactive decision to adopt it with a trading partner. Although the organisational structure of larger organisations could be very different from SMEs, companies of any size show a critical need for the coordination and control of business activities [43]. Thus, it is important to understand organisations' motivations/needs for adopting a new technology.

According to the literature, the reasons that push large companies to turn to enterprise application integration, include among other things: (a) their Enterprise Resources Planning (ERP) systems cannot fully automate and integrate organisations since ERP coexists alongside other applications, (b) technical reasons, (c) financial reasons, (d) managerial reasons and (e) strategic reasons [45]. However, the authors found that the motivations mentioned by Themistocleous [45] are not appropriate to explain SMEs' need for integration. For example, some small firms might not even have ERP systems. Therefore, by reviewing the existing literature on the adoption of integration technologies by SMEs, a number of reasons that push SMEs to turn to integration technologies to support their IS have been identified. These reasons are explained as follows:

- **External Pressures:** External forces tend to have more impact on small businesses than they do on large businesses [23] [49]. In many cases, a company may adopt a technology due to the influences exerted by its business partners and/or its competitors, having no relation to the technology and organisation itself. For example, pressures from business partners or competitors have been found to be an important factor in the adoption of integration technologies [20] [28] [35]. Since SMEs are usually the weaker partners in inter-organisational relationships, small businesses are susceptible to impositions by their larger partners [40]. Therefore, SMEs

are under pressure to adopt integration technologies if its business partners request or recommend it to do so.

- **Internal Pressures:** Internal pressures include both the financial and technological resources of the firm. Financial resources are related to the financial resources available to pay for the integration technologies installation costs and for the implementation of any subsequent enhancements, as well as for ongoing expenses during usage. Technological resources refer to the level of sophistication of IT usage and IT management in an organisation. As mentioned before, SMEs need to control their cash flows carefully, as they do not have unlimited funds for their IS projects. Thus, smaller firms tend to choose the cheapest system which may be adequate for their purposes [47]. In addition, Thong [47] also reported that small businesses tend to have insufficient knowledge to implement IS successfully, thus, SMEs might need to seek external expertise (e.g. IT vendors etc.). These all indicate that SMEs' need for integration technologies might be based on their internal resources/pressures. Since SMEs are normally lacking in internal resources, when compared to large companies, it was thus argued that SMEs might make different adoption decisions than their larger counterparts [28].

- **Competition:** The main reason SMEs adopt IT is to enhance their competitiveness [23][34]. Therefore, SMEs may feel the pressure when they see more and more companies in the industry adopting the integration technologies to solve the technical difficulties caused by the incompatibility of systems, especially if it is their business partners, competitors or larger trading partners. Thus, SMEs will feel under pressure and the need to adapt to the IS integrated environment to remain competitive. According to various literature, like Iacovou et al's.[23], the most significant reason that pushes SMEs to adopt integration technology is to gain a competitive advantage.

Based on the discussion above, the authors found that firstly, due to SMEs' resource poverty, SMEs' motivations to turn to adopting integration technologies mostly comes from external forces. This is different from large organisations, as their motivations mostly arise from their technical, financial, strategic and managerial needs [45]. Secondly, the different integration needs between SMEs and large organisations might be caused by their different business complexity [43]. The interpretation of business complexity here means whether the condition of being a complex organisation is related to their adoption of integration technologies. After years of different technological purchases, enterprises have ended up with disparate systems spread throughout different units. However, the number of systems to be managed (i.e. disparate systems) is different between SMEs and large companies. For example, SMEs may only have a few systems, whereas large organisations may have many. Therefore, some SMEs (with only 10 employees or less) may find it ineffective to adopt integration technologies since there are not many disparate systems within the organisations. In this case, adopting integration technologies

to support SMEs' IS integration will only increase their capital or maintenance costs and add complexity to their existing operations, unless there are some irresistible reasons. For example, an SME's trading partners might require them to do so, or pressure from the government may make them act. As for larger organisations, since they are relatively complex organisations compared to SMEs (e.g. with many disparate systems within the organisation), adopting integration technologies can help them solve their integration problems, increase effectiveness, and speed up transactions, etc.

Thus, the discussion in this section demonstrates that different sized companies might have different needs and ways of managing their adoption of integration technologies. Hence, the researcher suggests that SMEs' integration needs might be different from those of large companies, and this might affect their adoption decisions. Therefore, the following research question is formed:

RQ3: *In what ways does SMEs' integration needs differ from large companies?*

II. 4 Integration Technologies Adoption by SMEs and Large Organisations

Due to SMEs' inadequate resources, limited knowledge, lack of 'know-how' about IS, and several other constraints, some researchers have found that small businesses generally face greater risks in IS implementation and the use of information technology than large businesses [12][13][23]. Thus, managers in SMEs have been characterised as having reservations about the adoption and use of information systems [6][46]. However, these reservations have not always obviated the benefits and successes such organisations can achieve from IS. In the early days, SMEs tended to use IS as tools to automate their standard administrative functions, e.g. accounting, budgeting and inventory control, etc. Until recently, there has been growing literature addressing the issue of using IS for a competitive advantage amongst SMEs [34]. According to Lin *et al.*, [30], the increasing interest in the strategic use of IS by SMEs is based on three factors: (a) the increased adoption of IS and its effective use by competitors, (b) a decrease in the cost of IS so that it is accessible to SMEs, and (c) the ability for IS to allow SMEs to mask their size from their external partners. Due to these reasons some SMEs have turned to the adoption of integration technologies as a new strategy to improve their competitiveness.

The review of the literature has shown that some SMEs adopt ERP and EDI to automate their business processes, as well as showing that there are only a few prior studies that have focused on EDI and ERP in small businesses. These studies include those by Iacovou *et al.* [23], [23], Daniel [14], Hughes *et al.*, [22], Kuan and Chau [28], Waarts *et al.*, [48], Ravarini *et al.*, [36] and Tagliavini *et al.*, [43]. Among these studies on adoption, the model proposed by Iacovou *et al.*, [23] presents the most comprehensive research that focuses on the adoption of integration technologies (EDI) in small

businesses [28]. Most of the literature on this subject that has been reviewed mainly focuses on the adoption of EDI and ERP, with studies related to EAI and Web Services adoption in SMEs proving to be largely lacking. This might be due to the fact that EAI and Web Services are only beginning to emerge and it is in the early stages of adoption [19]. Another reason might be that SMEs feel it unnecessary to adopt EAI or Web Services due to the extra costs and expertise required to implement these integrative technologies.

Opposite to studies on SMEs, EAI and Web Services adoption models and studies for larger organisations are available. Many studies have focused on different aspects of adopting EDI, EAI and Web Services in terms of supporting IS integration in large organisations. To better understand these factors reported in the literature, the authors analyse them and this is shown in Table 1. Factors like competitive pressure, Dependency on Partners/ Trading Partners Readiness/Pressure, External Pressure, Perceived Financial Cost/ Financial Resources and Perceived Governmental Pressure that particularly focus on SMEs are highlighted.

Table1. Summary of Factors that Influence Organisations' Integration Technologies Adoption Decision

From Tables 1, the authors found that firstly, similar factors are sometimes used to explain different adoptions of integration technologies (i.e. common factors). For example, IT sophistication, perceived benefits, technical competence, support and financial resources (i.e. cost) factors were applied to explain EAI, EDI and Web Services adoptions in many studies. Therefore, these factors can be considered as the most important factors for explaining the adoption of integration technologies.

Secondly, the authors found that only a few factors were used to explain both the adoption of integration technologies by SMEs and large organisations. For instance, factors like perceived benefits, perceived financial costs and external pressures were used to explain the adoption of integration technologies by SMEs as well as large organisations. However, among these research papers, there was only one of the papers in which the authors referred to this research concerning the EAI and Web Services adoption in SMEs. This indicates that (a) there is a lack of literature on EAI and Web Services adoption in SMEs; and (b) most of the factors identified from the normative literature can not be equally applied to both SMEs and large companies to interpret their

decision whether to adopt integration technologies because having one piece of evidence is not enough to represent every example.

Thirdly, similar factors were highlighted in many research papers to explain the adoption of integration technologies by SMEs. For example, *competitive pressures*, *dependency on partners*, *external pressure*, *perceived financial cost*, *prior EDI experience* and *perceived governmental pressure* were used in many studies to explain the adoption of integration technologies by SMEs. This indicates that the aforementioned factors here are the main/important factors for the adoption of integration technologies by SMEs. However, these factors can also be used to explain the adoption decision by large organisation, even though it may not necessarily be a good one. For example, the perceived governmental pressure might not be a factor that assists the studying of adoption decisions in large organisations, as this factor is particularly used to explain the adoption decision by SMEs. The reason for this is that large organisations like SMEs often find it hard to adopt integration technologies without any kind of support (e.g. not only support from vendors and consultants but also from the government and their suppliers, etc) due to their natural resource constraints. Moreover, as mentioned in the literature review, SMEs might be forced to adopt integration technologies as their business partners or governments require them to do so [8]. This situation might not be appropriate for their larger counterparts as they are usually the stronger partners in inter-organisational relationships, when compared to the SMEs [40][42]. Another explanation is that most of the research papers that focused on the adoption of integration technologies in large companies did not include *perceived governmental pressure* as a factor that might explain or influence their adoption decision.

In accordance with the above considerations, the researcher proposes that there is a high possibility that SMEs and large companies take their decision for the adoption of integration technologies by mostly focusing on different factors (as shown in Tables 3.1, 3.2 and 3.3). This will be illustrated in more detail in Sections 3.3 and 3.4. This assumption matches with the literature, where it is reported that the adoption of integration technologies is different for both large and small companies [23][28]. Thus, the following research question is raised for further investigation:

RQ4: *Do SMEs and large companies consider different factors when taking decisions for the adoption of integration technologies?*

II. 5 Time

In addition, according to the literature, the authors found that most of the factors that focused on the adoption of integration technologies by SMEs are mostly external forces e.g. governmental support, external pressures, pressure from trading partners, etc. This indicates that in many situations SMEs are forced to adopt integration technologies as their

partners require them to do so [23][28]. Thus, to remain competitive, SMEs have no choice but to adopt integration technologies. Due to these reasons, when referring to the adoption life cycles, some literature suggest that SMEs tend to be the late adopters (late majority/laggards) in the adoption of new technology/innovation, rather than the early adopters [23] [28] [31].

Laggards can be summarised as those who only adopt a technology when they have no choice. In fact, many laggards do not explicitly adopt technologies at all but rather acquire them accidentally when a particular technology is a component of a packaged solution [39]. Laggards' innovation-decision process is relatively lengthy, with adoption and use lagging far behind the awareness-knowledge of a new idea. Resistance to new technologies on the part of laggards may be entirely rational from the laggards' viewpoint, as their resources are limited and they must be certain that a new idea will not fail before they adopt it. Kirby [27] and Storey [42] are among those others who claim that SMEs can not afford to fail due to their limited resources. Therefore, most SMEs can be categorised as laggards.

The adopters in the late majority group not only want to be certain that the new technology works, they also want to wait until it's been widely adopted and standardised. They do not consider that the technology offers them any competitive advantage, even though they recognise that they can not live without it once their partners or competitors have adopted it. The pressure of peers is necessary to motivate adoption. In accordance with this point, as mentioned before, sometimes SMEs are forced to adopt integration technologies as their partners require them to do so (e.g. external pressure). Thus, SMEs can also be categorised in the late majority group.

However, there might be an exceptional case where SMEs might be considered as innovators, such as when SMEs are Hi-technology firms. Hi-technology SMEs might use more advanced or sophisticated information technologies for their production or information systems management than those SMEs from other sectors.

Nevertheless, most large companies tend to be in the early adopters/early majority group, with even some of them being classified as innovators. Early adopters are more interested in the business and competitive advantages of a new technology rather the technology itself, but they are still risk-takers since they are willing to adopt a new technology before it has been proven or widely accepted. Those in the early majority group are the pragmatists [39]. They do not want to take the risk of adopting a technology too early, even though they also recognise that waiting too long can put them at a substantial disadvantage. They want to make sure the technology works for others before they invest [26].

Thus, based on the above discussion, it suggests that time plays an important role in terms of integration technologies adoption, as late adopters may find that they have a competitive disadvantage [26]. Kaye [26] suggested that by extending the middle of the early-adopter phase into

the start of the late-majority phase, this period may offer a competitive advantage to the adoption of integration technologies. However, at some time early in the late majority phase, having implemented integration technologies ceases to offer any competitive advantage, and not having implemented anything begins to be a problem. To this end, the following research question is raised:

RQ5: *Can early adoption of integration technologies by the organisations gain competitive advantages?*

III. Conceptual Framework

Based on the discussion and identified research questions in Sections 2.1, 2.2, 2.3, 2.4, and 2.5, the authors identified the potential parameters that can be used to explain the adoption of integration technologies by SMEs and large companies. These adoption parameters are *company size*, *time*, *nature*, *integration needs*, *adoption factors for large companies* and *adoption factors for SMEs*, which are then illustrated in a cube diagram in Figure 1, which shows the dimensions for the integration technologies adoption between SMEs and large organisations.

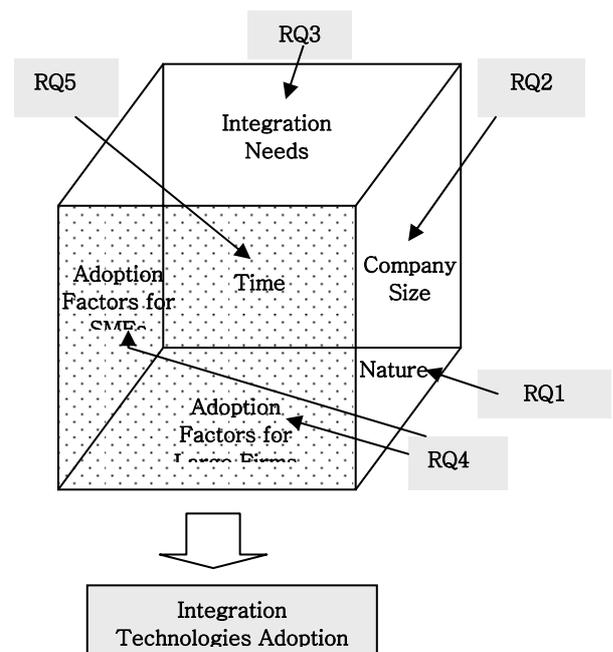

Figure1. Dimensions for Adoption of Integration Technologies between SMEs and Large Organisations

IV. Methodology

The questionnaire contained two sections regarding: (1) general company information, and (2) integration technologies adoption. The questions in this section were categorised into 5 parts according to the parameters identified in Chapter 3, Figure 3.2: *nature*, *integration needs*, *company size*, *adoption factors* and *time*. The questionnaire was validated by two MIS managers from an IT

manufacturing company in Taiwan. They were asked to identify questions, and any for which answers may not be easily available. The questionnaire was then mailed to computer professionals of 500 firms of any size and industry in Taiwan. Enterprises were categorised as SMEs in Taiwan if their paid-in capital was less than NT\$60 million (US\$1.8 million), or the number of regular employees did not exceed 200. The firms were chosen randomly from the database provided by the Industrial Bureau of Ministry of Economics (MOE) in Taiwan. The respondents were asked: (1) to complete if they are using integration technologies, (2) to complete it if they had evaluated integration technologies in the past and had chosen not to use them, and (3) to ignore the questionnaire if the firm does not belong to either category, but to explain their reasons.

A total of 101 responses were received and 68 of them were useable. 40 (58%) responses were from large organisations and 28 (42%) were from SMEs. 59 (87%) of the responding firms were integration technology users (this includes ERP, EAI, EDI and Web Services), and 53 of these were IT manufacturing/high-technology firms. The remaining 9 of the responding firms were non-users, and 4 of these were IT manufacturing/high-technology firms. The responding firms represented diverse industries, such as manufacturing, IT industry, high-technology industry, services sectors and merchandising. The survey results were then analysed by descriptive statistical method and are analysed in the following sections.

V. Survey Results Analysis

V.1 Nature of Organisations

Integration technologies implementation requires capital investment and may involve other expenditure in upgrading the computer and integrating some systems. It seems that large firms should be able to afford such investments more easily than smaller ones, and therefore integration technologies users' firms are expected to be the larger ones. According to the data, among the 9 non-users, 8 are SMEs, (see Table2). The reasons for not adopting integration technologies are shown in Table 3. In addition to those reasons, further reasons for not adopting integration technologies were found to be: (1) that most SMEs do not fully understand what integration technologies (EDI, ERP, EAI and Web Services) are, and (2) that some SMEs find it unnecessary to adopt integration technologies as they are satisfied with the current technologies they are using (e.g. the Internet is good enough for their daily operations). In this research, the author is particularly interested in the integration technologies adopters (in total, 59 adopters).

Moreover, Table 4 shows that EAI has not been popular among SMEs compared to other integration technologies. The possible explanation for this is that the high investment cost and complexity associated with EAI might cause concern to many organisations, especially SMEs. According to Charlesworth and Jones [7], integration technologies need to be "dumbed-down" to effectively communicate the

benefits and issues at the most appropriate level within the organisation.

	Responses	User Firms	Nonuser Firms
SMEs	28	(20) 71.4%	(8) 28.6%
Large	40	(39) 97.5%	(1) 2.5%
Total	68	(59) 86.7%	(9)13.2%

Table 2. User and Nonuser Percentage

Reasons	Responses
Costs	33.3%
Security	11.1%
Uncertainty	11.1%
Financial resources	11.1%
Skills	11.1%
Others	22.3%

Table3. SMEs' Reasons for not Adopting Integration Technologies

	EAI	EDI	ERP	Web Services
SMEs	0	35%	50%	15%
Large	5.1%	51.3%	90%	38.5%

Table4. Integration Technologies Adoption Percentage

Therefore, based on the survey results, the researcher suggests that the nature of SMEs might be an obstacle to their adoption of integration technologies. The reasons for this are: (1) the results indicate that cost is still an obstacle to SMEs, as they cannot really afford to spend extra money on R&D investment; (2) some SMEs still find it unnecessary to implement integration technologies, as there are not that many employees within the organisation; and (3) most SMEs still lack knowledge regarding integration technologies compared to large counterparts.

V.2 Company Size

The survey results reported in Table 5 suggest that SMEs and large organisations manage their IS in different ways. The majority of the integration technologies users in large organisations (71.4%) reported that the MIS department is in charge of the companies' information systems. As for SMEs, there were only around 40% that reported this. The remaining 60% indicated that their IS are often managed under managers or are outsourced. The possible explanations are that, firstly, the culture of a small enterprise is tied in with the needs, desires and abilities of its owner [3]. The owners of SMEs often like controlling their own destiny and doing things differently. Thus, the managers like to manage the IS on their own. Secondly, according to Carter and Evan [5], due to the lack of financial resources and expertise in IT, SMEs usually do not develop IS on their own. Instead, they rely more on standardised and *off-the-shelf* software packages, and normally seek external support for their IT problems, such as friends, vendors or consultants. Thus, many SMEs like to outsource their systems. This shows that companies of different sizes manage their IS and integration technologies differently.

	MIS Dept	Managers	Outsourcing	Others
SMEs	40%	33.3%	20%	6.7%
Large	71.4%	14.3%	9.5%	4.8%

Table 5. Information System Management in Organisations

V. 3 Integration Needs

Table 6 shows that the reasons that push SMEs and large firms to turn to integration technologies are different. The majority of large organisations reported that integration technologies can provide real-time data which can help them to eliminate: (1) systems heterogeneity, (2) data redundancy, and (3) low data quality. For example, multiple applications store data for the same entity (e.g. orders), but there is often an inability to combine data and take decisions, since there is: (1) data incompatibility, (2) confusion regarding data latency, or (3) communication problems. As for SMEs, the majority reported that external pressure and competition are the main reasons that push them to adopt integration technologies. There are only 2.6% and 7.7% of large organisations which reported this. Thus, it clearly shows that integration needs are different between SMEs and large organisations, and this can influence the ways they approach integration technologies.

Additionally, Table 4 shows that the newer the technologies, the less likelihood that SMEs will adopt them. For instance, the adoption rate for EAI and Web Services among SMEs is relatively low compared to their large counterparts. This suggests that the more complex and expensive the integration technologies are, the less likelihood that SMEs will adopt them. For large organisations, they will use the integration technologies in a circumstance it will help them to increase their competitiveness or solve a particular problem. This also shows the different motivations towards integration technologies adoption between SMEs and large organisations.

Integration Needs	SMEs	Large Firms
External pressure	45%	2.6%
Competition	40%	7.7%
Technical reasons	10%	2.6%
Financial reasons	10%	5.1%
Provide solution to the existing problem	20%	12.8%
Managerial reasons	35%	43.6%
Strategic reasons	20%	7.7%
ERP can not fully automate and integrate business process	10%	2.6%
Others	0	2.6%

Table 6. Integration Needs Related Factors

V. 4 Time

Table 7 demonstrates that the timing of integration technologies adoption is different between SMEs and large organisations. For instance, the majority of large

organisations reported that they have adopted integration technologies for more than 10 years. As for SMEs, this only applies to around 15% of them. The majority of SMEs lie between 5 to 10 years. This indicates that SMEs tend to be later adopters compared to large organisations.

	Test Value = 0					
	T	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference	
					Lower	Upper
SMEs Adopted	6.848	67	.000	.412	.29	.53
Competitive advantages	16.836	67	.000	.809	.71	.90
Don't know	1.000	2	.423	.333	-1.10	1.77
	2.000	2	.184	.667	-.77	2.10

Table 7. Timing and Competitive Advantages

Table 8 shows that the early adoption of integration technologies can help organisations to gain some minor competitive advantages. However, many of the respondents claimed that it is hard to tell whether adopting integration technologies gives them a major competitive advantage or not. Nevertheless, they were sure that not having implemented any of these integration technologies may become a problem for their companies.

	< 10 Years	5-10 Years	> 5 Years	Very Recently	-	Planning
SMEs	15%	35%	25%	15%		10%
Large	35.9%	23.1%	10.3%	5.1%		2.6%

Table 8. Timing for Integration Technologies Adoption

V. 5 Adoption Factors for SMEs and Large Organisation

Table 9 shows that SMEs and large organisations face different problems when integrating their IS. The majority of SMEs reported that due to their lack of technical skills they have encountered many technical problems. As for large firms, they reported that they have encountered many strategic problems when integrating their information systems (around 33.3%).

Problems Faced When Adopting Technologies	SMEs	Large Firms
Financial problems due to the limited resources	35%	10.3%
Technical problems due to the lack of expertise's support and technical skills	60%	12.8%
Organisational change	20%	17.9%
Managerial problems	25%	25.6%
Strategic problems	15%	33.3%

No problem at all	0	10.3%
Others	5%	2.6%

Table 9. Problems Faced When Adopting Integration Technologies

Adoption Factors	SMEs	Large Firms
Availability of standards	70%	56.4%
Barriers	20%	7.7%
Perceived industry pressure	15%	2.6%
Business complexity	5%	7.7%
Customer power	35%	5.1%
Internal pressure	10%	2.6%
IT infrastructure	20%	12.8%
Technology characteristics	15%	5.1%
Organisational readiness	20%	10.2%
Extent of organisational change	30%	12.8%
IT infrastructure	10%	12.8%
Security Technical factors	5%	10.3%
Competitive pressures	20%	12.8%
Dependency on partners	25%	7.7%
External pressure	5%	5.1%
IT sophistication	25%	7.7%
Support	20%	17.9%
Perceived financial cost	20%	12.8%
Perceived benefits	40%	35.9%
Perceived technical competence	30%	5.1%
Perceived government pressure	15%	2.6%
Others	0	2.6%

Table 10. Integration Technologies Adoption Factors

Table 10 indicates that SMEs and large organisations take decisions for the adoption of integration technologies, mostly focusing on the different factors. For example, around 35% of SME respondents reported that customer power influences their adoption decisions, but only 5.1% of large organisations reported this. Another example is that 25% of SMEs claimed that dependency on partners is a factor that influences their adoption decisions, but only 7.7% of large organisations reported this.

VI. Conclusion

This research has attempted to study the factors affecting the integration technologies adoption in SMEs based on comparative analysis between SMEs and large companies. In doing so, the authors critically analyse the normative literature regarding the integration technologies adoption in both SMEs and large organisations with number of research questions raised. These research questions are: (1) In what ways does SMEs' integration needs differ from large companies, (2) Is the nature of SMEs a real obstacle to the adoption of integration technologies, (3) What is the relationship between integration technologies and their adoption in companies of different sizes, (4) can early adoption of integration technologies by organisations gain

competitive advantages, (5) Do SMEs and large companies consider different factors when taking decisions for adoption of integration technologies, and (6) if the adoption factors for SMEs and large organisations are thought to be different, to what extent do: (1) integration needs, (2) nature of organisations, (3) company size, and (4) time, influence the different adoption factors.

Based on these research questions and the analysis of the literature, the authors found that the differences between SMEs and large companies on their *nature of organisations, integration need, company size, adoption factors and their timing of adoption* are important parameters affecting integration technologies adoption.

The data for the current study were collected using a postal questionnaire, which limited the ability to include important variables or information regarding the adoption of integration technologies. Therefore, it would be useful to collect in-depth data by conducting interviews that examine more information regarding the differences between SMEs and large organisations in relation to their integration technologies adoption. This will provide a clearer and more complete picture of different integration technologies adoption between SMEs and large organisations.

Credibility Theory: A New Branch of Mathematics that Studies the Behavior of Fuzzy Phenomena

Baoding Liu

Uncertainty Theory Laboratory, Department of Mathematical Sciences

Tsinghua University, Beijing 100084, China

liu@tsinghua.edu.cn

http://orsc.edu.cn/~liu

Abstract: Fuzzy set was initialized by Zadeh via membership function in 1965, and was well developed and applied in a wide variety of real problems. In order to measure a fuzzy event, Zadeh proposed the concept of possibility measure in 1978. Although possibility measure has been widely used, it has no self-duality property. However, a self-dual measure is absolutely needed in both theory and practice. In order to define a self-dual measure, Liu and Liu presented the concept of credibility measure in 2002. Credibility theory is a branch of mathematics that studies the behavior of fuzzy phenomena. An axiomatic foundation of credibility theory was given by Liu in 2004. In fact, the whole credibility theory was derived from the following five axioms:

Axiom 1. $\text{Cr}\{\Theta\} = 1$.

Axiom 2. $\text{Cr}\{A\} \leq \text{Cr}\{B\}$ whenever $A \subset B$.

Axiom 3. Cr is self-dual, i.e., $\text{Cr}\{A\} + \text{Cr}\{A^c\} = 1$ for any $A \in \mathcal{P}(\Theta)$.

Axiom 4. $\text{Cr}\{\cup_i A_i\} \wedge 0.5 = \sup_i \text{Cr}\{A_i\}$ for any $\{A_i\}$ with $\text{Cr}\{A_i\} \leq 0.5$.

Axiom 5. Let Θ_k be nonempty sets on which Cr_k satisfy the first four axioms, $k = 1, 2, \dots, n$, respectively, and $\Theta = \Theta_1 \times \Theta_2 \times \dots \times \Theta_n$. Then

$$\text{Cr}\{A\} = \begin{cases} \sup_{(\theta_1, \theta_2, \dots, \theta_n) \in A} \min_{1 \leq k \leq n} \text{Cr}_k\{\theta_k\}, \\ \quad \text{if } \sup_{(\theta_1, \theta_2, \dots, \theta_n) \in A} \min_{1 \leq k \leq n} \text{Cr}_k\{\theta_k\} < 0.5 \\ 1 - \sup_{(\theta_1, \theta_2, \dots, \theta_n) \in A^c} \min_{1 \leq k \leq n} \text{Cr}_k\{\theta_k\}, \\ \quad \text{if } \sup_{(\theta_1, \theta_2, \dots, \theta_n) \in A} \min_{1 \leq k \leq n} \text{Cr}_k\{\theta_k\} \geq 0.5 \end{cases}$$

for each $A \in \mathcal{P}(\Theta)$. In that case we write $\text{Cr} = \text{Cr}_1 \wedge \text{Cr}_2 \wedge \dots \wedge \text{Cr}_n$.

Let Θ be a nonempty set, $\mathcal{P}(\Theta)$ the power set of Θ . The set function Cr is called a credibility measure if it

satisfies the first four axioms. The triplet $(\Theta, \mathcal{P}(\Theta), \text{Cr})$ is called a credibility space.

A fuzzy variable is defined as a function from a credibility space $(\Theta, \mathcal{P}(\Theta), \text{Cr})$ to the set of real numbers. Then its membership function is derived from the credibility measure by

$$\mu(x) = (2\text{Cr}\{\xi = x\}) \wedge 1, \quad x \in \mathfrak{R}.$$

Conversely, let ξ be a fuzzy variable with membership function μ . Then for any set B of real numbers, we have

$$\text{Cr}\{\xi \in B\} = \frac{1}{2} \left(\sup_{x \in B} \mu(x) + 1 - \sup_{x \in B^c} \mu(x) \right).$$

The expected value of ξ is defined by

$$E[\xi] = \int_0^{+\infty} \text{Cr}\{\xi \geq r\} dr - \int_{-\infty}^0 \text{Cr}\{\xi \leq r\} dr$$

provided that at least one of the two integrals is finite.

This talk will introduce the concepts of credibility measure, credibility distribution, expected value, variance, entropy, characteristic function, convergence almost surely, convergence in credibility, convergence in mean, convergence in distribution, and show the credibility subadditivity theorem, credibility extension theorem, credibility semicontinuity law, sufficient and necessary condition for credibility distribution, linearity of expected value operator, inversion formula. The interested reader may download the book from <http://orsc.edu.cn/~liu>.

Abstract: With emerging e-business models in a global supply chain, the components or parts of a product may be distributed and produced at various plants in a collaborative way for the purpose of expanding capacity and reducing costs. For an assembled product, the assembly operations for assembling the product may be performed at different assembly plants at various geographical locations. In the collaborative commerce environment, it is required to develop a multi-plant assembly planning model for organizing and distributing the assembly operations to the suitable plants for completing the final product. In this research, a multi-plant assembly planning model for generating and evaluating the multi-plant assembly sequences is presented. A graph-based model is developed to model and generate the assembly sequences. The feasible assembly sequences are analyzed and evaluated based on several cost objectives. The multi-plant assembly planning model is formulated with an aim of minimizing the total of assembly costs and multi-plant costs. As a result, the optimized multi-plant assembly sequences can be obtained and each of the assembly operations is assigned to the suitable plant with a minimized cost. Example parts are tested and discussed.

Keywords: Collaborative commerce; SCM; Collaborative manufacturing; Assembly planning; Multi-plant.

I. Introduction

The main purpose of assembly planning is to organize a proper assembly sequence with which the components can be grouped or fixed together to construct a final product. A component is a basic part where no assembly operation occurs. A subassembly is a group of assembled components built for certain functional or manufacturing purposes, but a subassembly is not a final product. An assembly is a final product in which all the components are assembled. An assembly sequence is an ordered assembly operations for grouping and fixing the components and subassemblies to create the final product.

In the related research for assembly planning, it can be summarized that assembly planning can be performed in three stages: (1) assembly modeling and representation, (2) assembly sequence generation, and (3) assembly analysis and evaluation. A recent review can be found in Abdullah *et al.* (2003) in which the research into software and other tools

Proceedings of the Fifth International Conference on Electronic Business, Hong Kong, December 5-9, 2005, pp. 851 - 855.

to support the closely related methodologies of assembly system selection, design for assembly, and assembly planning is reviewed. The previous research in assembly planning can be classified into three categories based on different approaches and purposes. The first category uses rules or knowledge bases to perform generation of different assembly sequences such as developed in Baldwin *et al.* [1], Tonshoff [12], Ye and Urzi [14], and Swaminathan and Barber [11]. The second category presents automatic generation of feasible assembly sequences using graph representation forms. Various graph-based representation schemes are presented in Homem de Mello and Sanderson [7], Santochi and Dini [10], and Lin and Chang [9], and Choi *et al.* [5]. The third category focuses on assembly analysis and evaluation for searching the better or the optimal assembly sequence. The research in this class includes Homem de Mello and Sanderson [7], Ben-Arieh and Kramer [3], Laperriere and ElMaraghy [8], , Gottipolu and Ghosh [6], Zha *et al.* [15], Zhao and Masood [16], Tseng and Liou [13], and Chen *et al.* [4].

In a typical assembly planning scheme, the assembly sequences for producing a product are designed and arranged to be performed in a single plant. The available assembly operations and assembly workstations are restricted in a single plant. Also, the assembly costs associated with the assembly operations are constrained in a specific plant location.

In a multi-plant collaborative commerce model, a product can be designed and manufactured at different plants at multiple locations. Due to the increasing product complexity and increasing production scale, a multi-plant manufacturing scheme is usually adopted to reduce production costs, enhance product variety, and to expand production capacity. For an assembly product, the multi-plant system may be composed of several manufacturing plants and multiple assembly plants located at different geographical locations. It is important to find the best place to manufacture each component, the best place to assemble the components and subassemblies, and the best place to assemble the final product. Therefore, it is required to develop a multi-plant assembly planning model to integrate the cross-plant resources and costs.

In this research, a multi-plant assembly planning model is presented. In this multi-plant model, the components and subassemblies are distributed and assembled at different

plants. In a multi-plant assembly sequence, each plant is assigned and arranged to perform a portion of the assembly operations to complete the product. At the final step, the components and subassemblies are gathered and assembled to build the final product at the final plant.

A graph-based model is developed to formulate the multi-plant assembly sequences. The assembly sequences are analyzed and evaluated based on assembly operation costs and multi-plant costs. The following model Assembly Sequence Tree (AST) describing the relationship between components and subassemblies of a product is introduced. The graph-based tree representation model is developed to generate and represent the feasible assembly sequences. With the feasible assembly sequences as input, a linear programming model is formulated to evaluate all the feasible assembly sequences. The objective attempts to find the optimized multi-plant assembly sequences with the lowest cost. As a result, the multi-plant assembly sequences can be evaluated and the assembly operations are assigned to the most suitable plants.

II. Graph-Based Model for Eprese-Nting Assembly Sequences

In this research, a graph-based model is developed for representing the components and the assembly operations. The graph-based model is used as input for generating the feasible sequences. The feasible sequences are then evaluated in the next section.

A graph-based tree called Assembly Sequence Tree (AST) is developed to represent the feasible assembly sequences. A directed graph $G = (E, P)$ is used to represent an AST where E is the set of component nodes and P denotes the set of linking arcs between nodes. A linking arc from node i to node j is represented by an operation arc in P and is denoted as pk . An operation arc represents the assembly operation required to assemble the two component nodes. The precedence is represented by the directed linking arc from node i to node j . Each graph contains a single source node and a destination node and the graph is called a feasible assembly sequence. A feasible sequence can be generated by traversing the component nodes through the operation arcs.

Using the subassembly information of a product as input, a feasible assembly sequence can be generated and represented as an AST. A search can be performed starting from the base component node to traverse all the component nodes until all the nodes are visited and all the assembly operations are executed. By traversing the nodes and arcs in a systematic way, all the feasible assembly sequences can be generated. As an illustrative example, the component and subassembly information of an example product is shown in Figure 1, the generated AST is shown in Figure 2.

III. Formulation of Multi-Plant Assembly Planning Model

Since the feasible assembly sequences may be combinatorial, the focus of the research is on developing a new model for finding the optimized multi-plant assembly sequence with a minimized cost. To formulate the problem under investigation, the following notations are used.

- E_G : set of subassemblies,
- F : set of manufacturing plants,
- Y : set of assembly plants,
- E : set of components,
- B : set of feasible assembly sequences,
- X : set of assembly operations,
- $As_{[E_R]bx}$: assembly operation time,
- $Num_{[E_R]efy}$: number of components needs to be transported from a manufacturing plant to an assembly plant,
- C : manufacturing cost for components,
- $Co_{[E_R]y}$: assembly operation cost for a subassembly group,
- $Cr_{[E_R]dfy}$: transportation cost for component from a manufacturing plant to an assembly plant,
- $Ct_{[E_R]y}$: transportation cost for transportation to the next assembly operation,
- Cp_y : assembly operation cost at an assembly plant,
- $Q_{[E_R]b}$: decision variable of feasible assembly sequence in E_g and $Q_{[E_R]b} \in (0,1)$,
- $E_{[E_R]efy}$: decision variable representing component e of E_g transported from f to y in E_g ,
- $H_{[E_R]y}$: decision variable representing E_g assembled at the assembly plant y .

The problem formulation is as follows.

1. Assembly costs:

$$Co_{[E_R]y} = \min \sum_{b=1}^B \sum_{x=1}^X (As_{[E_R]bx} \times Cp_y) \times Q_{[E_R]b}$$

$$s.t. \sum_{b=1}^B Q_{[E_R]b} = 1 \quad (1)$$

The objective function attempts to minimize the total cost of assembly operations.

2. Multi-plant assembly costs:

$$\min \sum_{E_R=1}^{E_G} \sum_{y=1}^Y Co_{[E_R]y} \times H_{[E_R]y} +$$

$$\sum_{E_R=1}^{E_G} \sum_{e=1}^E \sum_{f=1}^F \sum_{y=1}^Y C_{r_{[E_R]efy}} \times Num_{[E_R]efy} \times E_{[E_R]efy} + \sum_{E_g=1}^{E_G} \sum_{y=1}^Y C_{t_{[E_g]y}} \times H_{[E_g]y} \quad (2)$$

$$s.t. \sum_{f=1}^F \sum_{y=1}^Y E_{[E_R]efy} = 1$$

$$\sum_{y=1}^Y H_{[E_g]y} = 1$$

The cost objective is the total of the total assembly operation cost, the transportation cost from a manufacturing plant to an assembly plant, and the transportation cost for delivering a subassembly from one assembly plant to the next assembly plant. The constrain ensures that each component in a subassembly can be transported only one time from one plant to the next plan and each subassembly is assigned only one time to the plant with the lowest cost. With the above formulation, the optimized output of the model including the assembly sequence, the assembly time, the assembly cost, and the assembly plant location can be obtained.

IV. Test Result and Discussion

In this section, a wireless mobile phone is used as an example product to show the models and the tested results. The optimized solution of the linear programming problem is obtained using the Lingo software.

The part definitions and the product information are given as input. A description of the components of the product is shown in Table 1. It is assumed that for the purpose of reducing cost and expanding capacity, the seven manufacturing plants and three assembly plants need to be considered. There are fifteen components in the product given as {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15}. There are seven manufacturing plants {F1, F2, F3, F4, F5, F6, F7} as shown in Table 1. There are three assembly plants {Y1, Y2, Y3} as shown in Table 2. Figure 2 illustrates the component and subassembly structure of the product. The AST list is shown in Figure 3. The three assembly plants and the assembly operation cost for each assembly plant is listed in Table 2. The transportation cost for transporting a component from a manufacturing plant to an assembly plant is shown in Table 3. The transportation cost for transporting a component from an assembly plant to the next assembly plant is shown in Table 4. The subassembly information is described in Table 5. With the formulation, the feasible sequences are evaluated based on cost objectives.

The optimized result of the multi-plant assembly sequence with the lowest cost is shown in Table 6. It shows that the E1 subassembly is assembled at plant Y1 and the assembly sequence is from component 1, 2, to 3. The E2

subassembly is assembled at plant Y3 and the assembly sequence is from component 4 to 5. The E3 subassembly is assembled at plant Y2 and the assembly sequence is from component 8, 7, to 6. The E5 subassembly is assembled at plant Y1 and the assembly sequence is from subassembly E1, E2, and E3, to component 9, 10, 11, and then to subassembly E4, and finally to component 14 and 15. This sequence shown in Table 7 represents the optimized multi-plant assembly sequence with the lowest cost.

Based on the formulation, the sum of two main cost factors, assembly operation cost and multi-plant transportation cost, is minimized. It is observed that, in a multi-plant environment, if the assembly operation cost of a plant is too high, then the assembly operation will not be assigned to the plant. Also, if the assembly operation cost of a plant is low enough to cover the transportation cost, then the assembly operation can be assigned to that plant. This is a practical situation in the collaborative manufacturing environment in the current global supply chain in which the manufacturing and assembly operations are distributed with justified transportation costs to the plants with low operation costs.

Since this modeling and solution method is performed with a combinatorial programming approach, a larger size of problem might lead to a complex calculation process. At this stage of the research, a model with a systematic method is provided, but the complexity problem is not further explored.

V. Conclusion

With the developing collaborative commerce and e-business models in a global logistic supply chain, a product can be designed and manufactured at different plants at multiple locations. In a multi-plant assembly sequence, the assembly operations can be performed at various assembly plants at various geographical locations. In this paper, the problem of multi-plant assembly planning is identified. A graph-based representation model is developed for representing the multi-plant assembly sequences. A mathematical programming model is formulated to evaluate all the feasible multi-plant assembly sequences. The formulated model is aimed at minimizing the total cost of assembly cost and multi-plant cost. The results present an optimized multi-plant assembly sequence in which all the components, subassemblies, and product are manufactured and assembled at the most suitable plants with the lowest cost. It can be concluded that the proposed multi-plant assembly planning model is an effective approach to solve the multi-plant assembly planning problem. Further research should be concerned with the additional cost functions such as activities generated due to the different plants located at different countries and other cost issues.

Abstract: This paper is a discussion of reverse logistics management literature, a conceptual model showing the recovery processes and their relationships, preliminary research data, analysis and implications for the manufacturing organisations. A discussion of the findings and their implications highlighting the important role of information technologies for efficient data collection and processing of recovery operations lead to capturing value from effective management of reverse logistics.

I. Introduction

Reverse logistics is planning, implementing and controlling the efficient and cost effective flow of raw materials, in-process inventory, finished goods and related information from the end user to any previous point closer to origin, which may be in or out of the original supply chain. Similarly reverse logistics can be considered as an essential feature of strategic marketing and effective customer relationship management, as well as environmental protection and sustainable development of manufacturing organizations. It entails processing returned merchandise due to damage, seasonal inventory, restock, salvage, recalls, and excess inventory. Further reverse logistics management also includes recycling programs, hazardous material management programs, obsolete equipment disposition, and asset recovery. Although there are numerous reasons for goods to be returned, Dekker and Brito (2002) have categorised returns into few groups such as manufacturing returns, commercial returns, product recalls, warranty returns, service returns, end-of-use returns and end-of-life returns. On the other hand Roy (2003) described numbers of opportunities of reverse logistics such as economical gains by recapturing some of the costs of raw materials, used components, used products and rejects and reuse of discarded products from commercial returns and excess inventory of products and materials (Bayles 2001). Similarly Kokkinaki, Dekker, Lee and Pappis (2001) identified number of direct and indirect benefits of reverse logistics such as regaining value, achieving a competitive advantage and a positive impact on the environment.

So it is important to perform reverse logistics efficiently and effectively to obtain maximum benefits of its opportunities. Therefore the research is focused on investigating how

information technologies can be useful to improve performances of the reverse logistics. The study was included identification of processes in reverse logistics, parties of performing the processes, and then impacts of information technologies on performing reverse logistics processes and associated operations.

This paper presents preliminary findings on reverse logistics with original equipment manufacturers. The data were collated through a postal questionnaire survey with randomly selected 310 original business machine and equipment manufacturers in Australia.

II. Literature Review

According to Logistics Management Council reverse logistics is the process of planning, implementing, and controlling efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal (Rogers and Tibben-Lembke, 1999). Considering both upstream and downstream production operations, Fernandez (2003) suggests that reverse logistics can apply to different types of items such as used products, unused products, components, parts and raw materials. On the other hand Dekker and Brito (2002) categorised the returns into number of groups based on the reasons for returning such as manufacturing returns, commercial returns, product recalls, warranty returns, service returns, end-of-use returns and end-of-life returns. However Morrell (2001) is of the opinion that reverse logistics is "the forgotten child of the supply chain" since many organizations do not treat reverse logistics with the same care as traditional (forward) logistics.

Opportunities and reasons for reverse logistics according to Andel (1997) include profits while Roy (2003) suggests economical gains from recapturing some value from raw materials, used components, used products and rejected goods. On the other hand Bayles (2001) explicated reuse of discarded products from commercial returns and excess inventory of products also as opportunities from reverse logistics.

On the other hand, due to emergence of e-business, where customers purchase goods without trying and without touch or feel, more flexible return policy and an efficient reverse logistics system are essential. Smith, Bailey and Brynjolfsson, (2000) and Boyer, Hallowell and Roth (2002) explain that invisibility and physical distance between customer and seller, lack of face to face interaction with customers in electronic businesses and inefficient reverse logistics can destroy customer trust in electronic businesses. Average percentage of customer returns from Internet sales range from 30 to 50 % (Nairn, 2003). Economic gains are important reverse logistics management issue suggested by Roy (2003). This is supported by Kokkinaki, Dekker, Lee and Pappis (2001) who are of the opinion that number of direct and indirect benefits of reverse logistic such as regaining value, achieving a competitive advantage and a positive impact on the environment, are making organizations consider reverse logistics as an essential feature of strategic marketing, effective customer relationship management, as well as environmental protection and sustainable development of manufacturing organizations.

II. 1 Reasons for Performing Reverse Logistics

Important reasons for managing reverse logistics management identified from literature are discussed below.

II. 2 Electronic Business

Electronic business is sale of goods via electronic channels such as the Internet. Customers purchase goods by virtual conceptualisation of size and quality in most online shops. This definitely warrants a large amount of returns forcing organization to have efficient reverse logistics system (Trebilock, 2002). Similarly Sarkis et al (2004) suggest that growth of electronic business has precipitate the need of efficient and effective reverse logistics management. On the other hand Bizrate.com (1999) reported that 94% of online buyers commit to purchase due to protection of product return policy. This is astonishing as estimated average percentage of customer returns in Internet sales is accounted for 30 to 50 percent (Nairn, 2003; Mason, 2002; Sharma, Wickramasinghe and Singh 2005; Rogers and Tibben-Lemke, 1999). Predicted business to customer [B2C] Internet sale in the Asia Pacific region in 2006 is estimated to be US\$ 210 Billion. Jupiter Communication on the other hand estimates a tremendous growth in B2B online transaction, US\$ 6 trillions by 2005 within the USA market, where as described by Brito, Flapper and Dekker (2002) in B2B e-business, the products come back in bulk.

Other reasons for e-business returns according to Lee (2002) are due to errors in ordering, picking or shipping, damages due to transportation handling or cancellation of orders. This is further supported by Haris and Goodman (2001) explaining that growing frustrations among e-business customers over, unfulfilled promises, indifference, unrealistic response time, and poorly trained workers are also reasons for higher returns. However, the quantity and

time of the returns arrival are key-questions of both business-to-business and business to customer e-businesses. According to Pan, Ratchford and Shankar (2001) online sales processes comprise pre-sales service, transactions, physical order fulfilments and after sales services. Last two processes are mainly concerned on logistics activities while the last is mostly depended on reverse logistics management.

II. 3 Strategic Marketing and Liberal Return Policies

Strategic marketing and liberal return policies are also major contributors to the growing need for efficient reverse logistics management (Krumwiede and Sheu, 2002). These policies are essential for sales from direct store, catalogue, telephone, television and electronic business etc. Accordingly customers have some control of the product they purchase and develop trust. Higher customer protection legislations allow customers to return products if they are not satisfied Brito and Dekker, (2003) and Krumwiede and Sheu (2002). Customers rightfully, and sometimes wrongfully, take advantage of this opportunity. Therefore businesses are highly vulnerable for higher return rates both online and offline. Dekker et al (2002), identified returns from retail outlets to be 10%, catalogs, telemarketing and the television sales to be 35 percent (Trebilcock 2002) and Internet sales returns to be 30 to 50 percent (Nairn 2003; Mason 2002; Sharma et al 2005). Similarly customer protection regulation and competition among vendors, also lead unlimited returns, which require additional logistics management strategies (Rogers and Tibben-Lembke, 1998).

II. 4 Commercial and Warranty Returns

Commercial returns in reverse logistics denote product returns due to non satisfaction with business transaction process or product quality (Lee, 2002). The commercial returns start from two destinations. Retailer returns products to manufacturers and customers return products to manufacturer via a retailer. Brito et al (2002) described that, financial risk transferability from the buyer to the seller and roles and position of different parties in the supply chain are the key factors, which control volume and quality of commercial returns. Warranty returns include products that failed during use or damaged during delivery from manufacturer to buyers. Similarly commercial and warranty returns include returns due to product mismatch, safety concerns and manufacturer recalls.

II. 5 End of Life and End of Use Returns

Brito et al (2002) suggest that end of use or end of scheduled life returns also require efficient reverse logistics management. This occurs once a product's scheduled life is complete which may include such as end of lease or contract and end of life of a product, or when the product can't be used for primary function. For end-of-use returns, the challenge is determining the match between demand for used products and the supply, impacted by time, quantity and quality. Therefore Sarkis, Meade and Talluri, (2004) suggest an effective and efficient reverse logistics

management system, which provide information through the Internet channel.

II. 6 Environmental Protection and Legal Regulations

Returns have triggered a growing interest in reverse logistics in recent years due to environmental protection, competitive advantage and for regaining value (Brito et al, 2002). Legal regulations in returns management are becoming strict in countries like Germany, Netherlands, Europe, USA and Japan are due to negative effects of wasting energy and resources, pollution of air, water and environment (Fernandez, 2003). As a result, these governments have imposed disposal tariffs and bans, placed restrictions on waste transportation, waste prevention and emission which have increased producers' responsibility to manage returns effectively (Krikke, Pappis, Tsoufias and Bloemhof-Ruwaard, 2001). The challenge here is managing of upcoming out-dated computers for example. The number of personal computer returns is predicted to be 500 million units by 2007 in the U.S.A. As electronic products are the source of many toxic substances such as lead, mercury, cadmium, chromium and bromine these products are ranked as the fastest-growing category of solid waste by the Environmental Protection Agency (Kokkinaki et al, 2001; Europa, 2000). Accordingly, disposing of returned personal computers has become a good example of a product for which reverse logistics is essential for protecting environmental as well as recapturing value or asset recovery, however, more importantly for environmental protection.

II. 7 Economic Gains

According to Brito et al (2002) effective reverse logistics management support economic gain or regaining value from reuse of products or parts or recycling materials. Lund (1998) and Roy (2003) described that over 70,000 re-manufacturing firms in the U.S.A. typically for jet and car engines, auto parts and copiers are relying on reverse logistics to recover value from the reuse of products, modules, parts, components or recyclable raw materials. As a result manufacturers are able to provide quick and better customer service with a shorter lead-time and lower operating margin using the recovered material, part, component and modules (Roy 2003). The increased emphasis on new products and product "freshness" also warrant a clear distribution channel requiring an efficient means of bringing back obsolete, outdated and clearance items. This according to Roy (2003) is seen with Xerox replacing or upgrading hundreds of office printing machines every month. As a result, Xerox is able to act quickly to provide state of the art technology so as to retain their customers.

II. 8 Customer Loyalty and Retention Rate

Potential benefits of strategic reverse logistics management identified by Jiang et al (2005) and Sharma et al (2005) are increased customer retention rates, increased customer loyalty which leads to positive word of mouth, increased exist barriers for their customers. Jiang et al further illustrate

that a customer retention rate of 5% could increase company profit to from 25 to 95 percent. Retention of online customers especially is highly important because online shoppers can a new shopfront with the click of a mouse. As cited in Jiang et al (2005), Boston Consulting Group estimates acquiring a new customer to online channel cost US \$82 compared to US\$38 for store based sale and US\$11 for catalogue-based sales. Further, They emphasised that excellence in physically delivery of services in forward logistics and reverse logistics of an electronic businesses could create a powerful competitive differentiation. It is therefore important to investigate how organizations can strategically manage this increased volume of returns.

II. 9 Barriers of Reverse Logistics Management

Although the importance of reverse logistics is clearly highlighted in the discussion above, there a number of barriers identified from literature. These are discussed in the following section.

Firstly reverse logistics has not been given the same importance as forward supply chain due to a lack of understanding about return management benefits by the organizations (Lee, 2002). Accordingly companies ignored allocating necessary resources for proper management of reverse logistics. Tibben-Lembke (2002) touted that electronic businesses have suffered greatly due to an under estimation of difficulties in determining the physical and psychological values of reverse logistics. This view is supported by Spiegel (2000) describing that some electronic businesses lose 70% of their time due to lack of technologically advanced collaboration and automation of all aspects of logistics operations. In addition Rogers et al (1998) identified reverse logistics barriers to be a lack of importance of reverse logistics relative to other issues, company policies, a lack of information systems, competition, management inattention, financial resources, personnel resources and legal issues.

II. 10 Lack of Modern Information Systems

Commercial software specifically designed to support reverse logistics is not yet available (Caldwell 1999). Similarly Nagel and Meyer (1999) emphasized that a lack of information causes bottlenecks, which leads to difficulties in systems resulting in substantial loss to companies. Zhao (2001) highlighted that a lack of technology-supported systems for reverse logistic processes result in delays, higher costs for operations, invisibility of returned products handled by third parties, repeat operations leading to additional cost to manufacturer and, unawareness and inattention of partner process. Due to the unavailability of dedicated information systems to identify validity of returned products at the point of entering leads to some illegal returns. For example, "non-defective returns" can actually account for 55% or more of the total returns (Lee, 2002). An ill-managed reverse logistic operation can have substantial adverse effect on the profit margin due to waste of resources for process management and rework.

Jiang et al (2005) and Sarkis et al (2004) pinpoint that properly integrated web base information system could link all departments including reverse logistics of electronic businesses as a value network to share information and communication accurately, in a timely manner and rapidly with little effort. Consequently these businesses could manage replicating efficiency in reverse logistics with the speed, accuracy and convenience so as to maintain higher reliability, resilience and innovativeness. Increasingly, pervasive, collaborative communications and information sharing and transparent multi-enterprise network could help to minimize the drawbacks experienced in the reverse logistics management processes (Harris and Goodman, 2001). Sharma et al (2005) also suggest that developing a web based information system for reverse value chain is a challenge that will entail essential competitive advantages as it could integrate many different business processes and stakeholders.

II. 11 Poor Management of Intermediaries

Since returns are mostly handled by third parties differences with reverse transportation and in-house carriage lays difficulties to schedule the best trip for vans, trucks or other means of conveyance, both in terms of money and time. Similarly it is also not always easy to predict the exact amount of material in a certain collection center (Carella et al, 2002). However Krumwiede and Sheu (2002) emphasized that lack of guideline and lack of collaborative information sharing facilities are barriers for effectively manage intermediaries of reverse logistics. Therefore the returns are invisible from the information systems, they are not fully utilized and/or not considered for next business operations till physically arrived to store in unknown time. But the manufacturer has to bear all costs and loses involved in holding, and lost opportunity during this period (Zhao 2001).

II. 12 Meeting Recovery Deadline

According to Carella, et al (2002) an efficient model of reverse logistics is vital for companies that produce for make-to-order contract or repair large industrial machineries, like conditioner, heating plants, train, ship, airplane or its components for their clients. Because without a better model they are unable to respond to their customers in a timely manner and help them avoid shortages. However, failing to do so could lead to huge penalty costs to the company.

II. 13 Conceptual Model for Reverse Logistics Management

Based on the issues discussed above, it is apparent that an effective reverse logistics model is essential. To capture business value and efficiencies in reverse logistics it is important to understand the processes of reverse logistics. It was noted that although different aspects of reverse logistics were mentioned in different publications, a logical and comprehensive presentation of the processes showing the logistics of returned goods has not been addressed.

Therefore from the review of literature a conceptual model for the management of reverse logistics is developed and presented as Figure 1. It provides a comprehensive illustration of reverse logistics management processes and operations.

The reverse logistic processes and their relationships, included in figure 1 have been identified from literature and by analyzing previous models addressing certain aspects of reverse logistics. The conceptual model is a comprehensive model for reverse logistics management.

Recovery processes included the conceptual model were identified from previous models. Kokkinaki, Dekker, Nunen and Pappis (1999:2000) included four recovery operations; redistribution, reuse, remanufacture and recycle. Thierry et al (1995) presented a model with resale, reuse, repair, refurbish, remanufacturing, cannibalization, recycling, landfill, and incineration recovery processes. Fleischmann et al (2002) identified the processes of redistribution, reuse, repair, refurbish, recycle and landfill in their reverse logistics model. Lee (2002) discussed resale, reuse, refurbish, and retrieval as return recovery options of his model. Krikke et al (2001) and Roger et al (1998) identified redistribution, resale, reuse, upgrade, remanufacture, refurbish, recycle and landfill as recovery operations of their models. Brito et al (2003) recognized seven recovery operations for their model; redistribution, reuse, repair, remanufacture, refurbish, retrieval and recycle. De Koster, de Brito and van de Vendel (2002) included repair, remanufacture, refurbish, retrieval, recycle and landfill as recovery operations of their model. The reverse logistics model of Lonn and Stuart (2003) described redistribution, resale, repair and landfill as recovery operations while Meade and Sarkis (2002) models consists reuse, remanufacture, recycle and landfill recoveries. Kokkinaki, Dekker, Koster and Pappis (2001) and Kokkinaki, Dekker, Lee and Pappis (2001) included redistribution, resale, reuse, remanufacture, recycle and landfill as recovery operations in the reverse logistics model. Accordingly a conceptual model for reverse logistics management (Figure 1) was developed.

This model (Figure 1) includes three main sections:

- forward logistics operations,
- preliminary reverse logistics operations and,
- Reverse logistics recovery operations.

Forward logistics section;

This is basically the traditional supply chain through which finished products are passed from manufacturer to final customer.

- production [u], warehouse [v], distributor [w], wholesaler and retailer [x] and, customer [y].

Preliminary reverse logistics operations;

This represents the preliminary operations, which take place from the time a customer or dealer decides to return a product or products till the product(s) are to be reprocessed through one or more recovery processes. Seven preliminary recovery processes were identified from the literature.

- inform [a], return authorization [b], gate keeping [c], collection [d], inspection [e], selection [f] and, sorting [g].

Reverse logistics recovery operations;

Methods of returned products reprocessed are considered as recovery processes. Thirteen recovery processes were identified from the literature review based on the level of changes made on and methods of handling of the returned product(s).

- redistribution [h], resale [i], reuse [j], donate [k], upgrade [l], repair [m], refurbishing (module level recovery) [n], remanufacturing (component level recovery) [o], retrieval (selective part level recovery) [p], recycling (material level recovery) [q], hazard waste management (material level recovery) [r], incineration (energy level recovery) [s] and, landfill (environment recovery) [t].

Arrows in Figure 1 show the flow of returned goods. Returns commence at point [a] and flow to [g]. From [g] the returned goods flow to points [h], [i], [j], [k], [l], [m], [n], [o], [p], [q], [r], [s] and, [t] according to recovery decisions made in the first five preliminary operations [a, b, c, d, e, f and g]. From product recovery operations [h], [i], [j], [k] [l] and, [m] goods flow to [v] [w] [x] and [y]. Outcomes of module, component, part, material and hazard waste recovery operations flow to [u], [m] and [l] via the warehouse. This indicates that any part recovered from reverse logistics is either used for the production of other goods or used to repair or upgrade products. Some goods may be selected for [s] and [t].

The above ideas have been put together in figure 1 to show the sequence the processes occur. As shown in the proposed model (figure 1), reverse logistics begins at point [a]. Any partner of the forward supply chain [u, v, w, x and y] can take the decision to return goods due to commercial and warranty issues, end life and end of use issues, environmental issues, sustainable development issues and strategic marketing and retailing policies. The partner or the customer then informs the manufacturer or its agent of the decision.

All of the above discussed recovery operation depends on product life and the level of depreciation. Brito and Dekker (2003) identified three kinds of product depreciation; intrinsic, homogeneity and economic. Intrinsic deterioration is age of the product. Homogeneity deterioration is age of a product's parts and economic deterioration is value of depreciation.

As suggested by Croxton et al, (2001) managing all the above recoveries is a complex task that consists of a number of sub processes. These sub processes can be divided into two groups such as strategic processes and operational processes. Strategic processes address environment and legal, gate keeping, disposition guidelines, manage return flow, credit handling and secondary markets. Operational sub processes manage returns on ground such as preparing to accept returns, receiving returns, recovery decisions,

customer and supplier credit management and analyzing returns. Further according to them these two groups of processes require an interface to cover customer service and relationship management, demand management, order fulfillment, manufacturing management, supplier relationship management and product development management. All this processes and their relationships emphasize the importunacy of having very effective and efficient information management system.

The conceptual model also includes issues identified from literature such as information management (Zhao 2001; Spiegel 2000; Lee 2002; Caldwell 1999; Brito et al 2002; Sarkis et al 2004), strategic marketing, liberal return policies and customer management (Brito et al 2003; Krumwiede et al 2002; Rogers et al 1998), environment protection and legal regulation (Brito et al 2002; Fernandez 2003; Krikke et al 2001; Kokkinaki et al 2001; Europa 2000; Yeldham 2003), intermediaries management (Carella et al 2002; Krumwiede et al 2002; Zhao 2001), meeting recovery deadlines (Carella et al 2002), economical gains (Andel 1997; Brito et al 2002; Lund 1998; Roy 2003) and higher customer or dealers loyalty and retention rate (Jiang et al 2005; Sharma et al 2005, Roy 2003, Brito et al 2002). Further it also aimed to investigate how modern information technologies can be useful to provide better service in reverse logistics management in all types of business models specially which has higher return rate such as retail store and off line business models returns 10 percent (Dekker and Van der Laan, 2002), catalogs, telemarketing and the television models returns 35 percent (Trebilcock 2002) and Internet sales returns 30 to 50 percent (Nairn 2003; Mason 2002; Sharma et al 2005).

Instead of considering all varieties of products together the research is focus on computers and business machines and equipments due to a number of reasons such as comparatively higher percentage of return as a product category 8.5 percent (Rogers and Tibben-Lembke 1998) and nature of machine and equipment such as shorter lifetime of products, higher depreciation rate, high opportunities for secondary market or secondary usage, varieties of basic and additional warranties, huge amounts of used products being disposed, ever expanding market volumes of dealing, perishable nature of goods, high information requirements, high variability and cascade reuse opportunities, and also due to expensive products replacements (Fleischmann et al 2002; Roy 2003; Rogers and Tibben-Lembke 1998; Trebilock 2002; Dekker et al 2002). Therefore this information highly emphasized the necessity of a better reverse logistics system for effective and efficient management of returned machines and equipments. Therefore the research is focused on Australian computer and business machine and equipment manufacturing organizations.

To validate the model research with manufacturing organisations and e-business organisations is undertaken via surveys.

III. Research Approach and Methodology

Research presented in this paper is with manufacturing organisations accomplished via a postal questionnaire survey. The survey questionnaire included a list of carefully structured questions chosen after careful testing for the purpose of eliciting reliable responses (Hussey and Hussey, 1997). It is a positivist methodology whereby a statistical sample is drawn from the population of subjects to make deduction about the population (Collis et al 2003). The survey study was planned to identify and investigate preliminary recovery processes for reverse logistics practiced by the Australian original equipment manufacturers. According to Cavana et al (2001) use of a postal questionnaire survey is more appropriate to gather large amount of data statistically sampled from a survey population, which represent a large geographical area. Therefore the postal questionnaire survey was the most suitable methodology for this research. In addition some other considerations such as budget constraints, time constraints, geographical limitations, and width of the sample frame, were also taken into account when selecting this methodology.

The postal questionnaire was pre-tested with thirty-eight researchers. Based on suggestions of nineteen responses the questionnaire was modified. Modifications included change of question format and the wording for better understanding. The questionnaire survey collated data from a sample of randomly selected 310 Australian original “business machine and equipments” manufacturers which had over Aus\$ 1 million annual income. The manufacturers were randomly chosen from two national business directories (The Business Who's Who of Australia, May 2005, <http://bww.dnb.com.au/> and IBIS World of Australia, May 2005, <http://www.ibisworld.com.au>). A sample of 310 manufacturing organizations was based on the views of Cavana et al (2001), and Sekeran (1992; 2000; 2003) who suggest that sample sizes larger than 30 and less than 500 are appropriate for most research. Original “business machine and equipments” manufacturers were selected as the sample population for this research as they are bound to accept the returned products and provide after sales services due to number of reasons discussed in literature review.

A total of 51 usable responses were received. Response rate 16.45% was contemplated to be reasonable based on the view of Collis and Hussey (2003) that 10% or less response rate of postal questionnaires was not uncommon.

IV. Data Analysis

Data analysis included in this paper was tabulated to show some preliminary findings. The data elicited through the survey were collated from Likert Scales, which are commonly used in business research for useful conclusions (Sekeran 1992; 2000; 2003). Tabular methods of

presentation of the data gathered from the postal questionnaire were summarised and analysed using SPSS, a statistical analysis software package.

V. Findings

Findings of the research date and discussions are presented reflecting issues associated with reverse logistics, information management and information technologies. It also includes findings about reverse logistics performances, market information, product life span and returned products reprocessing time. Some reflections on income and costs are also included. Other issues discussed include business selling models, benefits and barriers of reverse logistics, leadership issues and technologies applied in managing reverse logistics information by the Australian original equipment manufacturers.

Responses were summarised into five categories based on the type of products shown in column one of Table 1. Column two indicates the extent of reverse logistics in each industry. It is clear from Table 1 that large numbers of respondents were electronic and electrical equipment and parts manufacturers, and automotives and parts manufacturers. Both of these product categories represent almost seventy percent of total respondents, while other three categories accounted for remaining thirty percent. Although the numbers of respondents in last three products categories were low, they indicate that reverse logistics is practised in these industries.

From the findings in columns one and two of Table 1, it is apparent that reverse logistics is an important business process. From this information it is clear that nearly 75% of responding manufacturing organizations perform reverse logistics.

Performing reverse logistics could be comparatively easy if the organization's customer base is limited to a smaller geographical area. However from the Table 1, it is clear that large numbers of manufacturing organizations operate globally although they have an important role in the national market of Australia. This indicates that reverse logistics is not only for the local market, but for international returns as well. Therefore management of returned product information is essential for the provision of an effective reverse logistics service.

In Table 2, we present product categories with short and long life spans (three years or fewer and over three years), and the time taken by the organisations to reprocess returned products. It is clear from Table 2 that products with longer life spans are bound to be returned more than those that have a short life span. However, products with shorter life spans are also returned and thus require more stringent reverse logistics management strategy to avoid loss of value from depreciation. Similarly, Table 2 shows that processing time for most of the returned goods is less than a week. However, average return reprocessing time of a returned good just over 3 weeks indicating that a returned product has to spend an average of 2% of its life in reverse logistics processes. While

the goods are in the recovery processes neither manufacturers nor customers receive any benefit or utility from these items, instead it is accounted for depreciation. To achieve value from the returned goods it is essential to minimise the processing time.

Table 3 outlines the cost of reverse logistics by comparing it to organizations' annual income. According to data in Table 3, it is seen that although organizations have annual incomes of up to Aus\$ 100 million, the cost of reverse logistics is only 2% to 3% of annual income. This clearly indicates that reverse logistics is not an important business process in these manufacturing organisations. Findings indicate that the Australian manufacturing organisations are paying poor attention to reverse logistics and thus losing out on substantial opportunities by ignoring reverse logistics.

Table 4 lists the business models that the respondents use to sell their products. The last three columns of the Table 4 show the usage of different business models in each market. It is important to note that the respondents were allowed to select more than one business model if applicable. It is clear from Table 4, that wholesaling (84%), retailing (63%), telephone (63%) and catalogue (57%) business models are largely used by manufacturing organizations in Australia to sell their products in regional, national and global markets. It is important to note that, B2B and B2C e-business business models are not as popular as expected, especially to reach out to global customers.

The respondents were allowed to select more than one business models if applicable. From the data, it is shown that 89% use two or more business models to distribute their products while 55% use four or more strategies. Therefore it is inferred that for all business models reverse logistics processes have to be put in place to manage returns. To manage returns from several selling models an efficient information management system would be useful.

Reasons for performing reverse logistics and their importance indicated in percentages are presented in Table 5. It is important to note that the respondents were allowed to select more than one reason for reverse logistics if applicable. According to data in Table 5, the two most important reasons for reverse logistics are customer service (84%) and strategic (73%) such as goodwill and brand image. Competition is another reason, while some less important ones are law, legal disposal requirements, recapturing value and assets and a clean channel.

Company image and goodwill are the most important benefits of reverse logistics identified from this research. Other reasons are competitive advantage, recapturing value from components and legal obligations. As seen in Table 6, recapturing value is important for only half the respondents, and this could be the reason for the less importance given to reverse logistics, or on the hand this could also indicate that if the reverse logistics processes are better managed, more value could be captured from returned goods.

In Table 7 we present a list of barriers for reverse logistics and percentage as indicated by the respondents. The

respondents were allowed to select for more than one barrier for reverse logistics if applicable. According to Table 7 the three main barriers for reverse logistics are low importance compared to other business processes, improper information management and a lack of personnel resources. It is imperative to note that the barrier of unavailability of efficient and effective reverse logistics information management systems has been identified as the second most important barrier for reverse logistics by the manufacturing organizations in Australia. This finding is supported by the literature (Zhao 2001 Lee 2002; Sarkis et al 2004; Spiegel 2000 and Rogers et al 1998) which identified that a lack of information system as a main barrier. This implies that application of effective information systems will drastically improve the reverse logistics information management for capturing value.

Other less important reasons are a lack of interest from the management, not having company policies in place to support reverse logistics, and poor partnerships to manage the processes.

According to data in Table 1 it is apparent that reverse logistics in most organisations is the responsibility of the operations manager. Manufacturing managers and marketing managers also are given the responsibility in some cases. However, a dedicated reverse logistics manager is not a position in any of the organisations implying that it is not very important.

List of technologies used in reverse logistics management are shown in Table 9. According to Table 9, the most important technologies supporting reverse logistics are telephone, fax and computers. Mobile technologies are being applied as well together with other technologies.

This implies that information technologies have a very important role in collating and processing reverse logistics information.

However according to Table 9, it is clear that most of the information technologies such as Internet, extranet, ERP, barcode and EDI, are not fully exploited for reverse logistics management. Therefore the responded manufacturing organizations have to take strategic action for incorporating these technologies that could facilitate online real time reverse logistics information management. Because it could help manufactures to receive number of benefits of efficient information management such as minimum waiting time for information, minimum use and waste of resources [such as papers, envelopes, money and labour], higher efficiency in information sharing and exchange, online conference and decision making. Similarly implementation of online real time reverse logistics information updating, managing, updating and sharing system will enhance quality of managing customer service and reverse logistics.

VI. Discussion

From the data presented above it is clear that reverse logistics is important for industries manufacturing electrical and electronic goods and automotive parts more than other

industries. It also highlights that reverse logistics is an important business process for goods sold in regional, national and international markets. Findings indicate that products with a longer life span are more likely to be returned and require reverse logistics management more than products with short life spans. The most important reasons identified for reverse logistics are customer service, strategic and competitive reasons.

Although anecdotal evidence indicates recapturing value from returned goods to be an important reverse logistics benefit, this research indicates that company image and goodwill to customers are more compelling benefits. The most important barrier identified is the diminutive role of reverse logistics in companies. Ad hoc information management methods, a lack of resources and top management support are other important barriers to reverse logistics in the Australian manufacturing industries.

This research highlights that in most organisations reverse logistics is the responsibility of the operations manager. This implies that reverse logistics is not important or large enough to warrant a role for its management or department. It is very clear from this research that a large number of technologies are used to manage reverse logistics in Australia. This implies that at this stage there is no dedicated system for the management of reverse logistics.

VII. Conclusion

This is a research in progress paper, which has discussed some preliminary findings. Issues identified from a review of literature on reverse logistics have highlighted its importance and ability to capture value. An analysis of models addressing different aspects of reverse logistics have been comprehensively put together to show the flow of processes and information to maximise value. However, research findings indicate that manufacturing organisations have not realised the value of reverse logistics and have not given it the same importance as other processes. Hence to some extent it still is 'the forgotten child of supply chain'.

The next phase of this research will explore reverse logistics in the e-business space as literature indicates that returns from e-business purchases are very high.

Abstract: This study identifies the factors that influence supply chain integration between manufacturer and suppliers and develop the measurement instruments for them. The factors influencing supplier integration include mediated power, non-mediated power, normative relationship commitment, and instrumental relationship commitment among the trading partners. This study empirically investigates the relationships between the factors that influence supplier integration, the degree to which the suppliers are integrated, and supplier and manufacturer's performance within the supply chain using data collected from manufacturing companies within the supply chains from Mainland China and Hong Kong. This study also empirically tests the reliability and validity of the instruments. The results show that two types of power impact relationship commitment significantly. Relationship commitment has a positive influence on supplier integration and supplier's performance. Supplier integration leads to manufacturer's financial performance. This study provides important insights for future researchers to understand power, relationship commitment and supplier integration from various perspectives. Findings from the study can help companies enhance their global competitiveness by developing and managing relationships with their trading partners that will enable them to have effective integration of key processes within the supply chain.

Keywords: SCM; Power; Relationship Commitment Supplier Integration; Performance; China.

I. Introduction

Though the fundamental concept and importance of supply chain management are widely accepted by both the scholars and the practitioners, some important areas about supply chain integration are still not described theoretically and processed practically well. For instances, there is no commonly accepted scales on the term "supply chain integration" and there is no concrete descriptions on the factors affecting the supply chain integration. In addition, there is not much research findings on how the initiators affect the supply chain integration, and in what extent the supply chain integration could affect the performance of the

manufactures.

Many papers identified different types of integration of supply chain [33;46;57;62;78;78], Some papers analyzed the relationship between supply chain integration and supply chain performance [62], However, only a few papers explained the initiators of the supply chain integration and the functions of them, and these papers only sited several initiators of the supply chain integration without detailed explanation about the relationships among the initiators, supply chain integration and performance.

Researchers in marketing and management have investigated power and relationship commitment issues within and between organizations over the last decade. Brown, Lusch, & Nicholson [12] empirically tested the impact of power and relationship commitment on marketing channel member performance from the relationship marketing perspective. Maloni & Benton [53] found that power plays a significant role in the supply chain management, and the different sources of power have different impacts on inter-firm relationship in the supply chain. A stronger buyer and supplier relationship can enhance the performance of the companies in a supply chain. Cox [23] illustrated that power is at the heart of the trans-organizational relationships and captive suppliers are conditioned by powerful buyers to make substantial investment (commitment) to sustain the business relationships. Benton & Maloni [6] investigated the supplier satisfaction in power driven buyer-supplier relationships. However, there are few studies investigated the influence of power or relationship commitment in SCI area. Beth et al [7] advocated that relationship commitment are placed in the highest priorities in achieving "supply chain integration", a significant concept that promotes collaboration between supply chain partners for values and competitiveness.

We aim to find the factors that play an important role integration of the enterprises, Such as power, and relationship commitment. This study identifies the key factors that influence supplier integration, develops and tests a conceptual framework that can explain the relationships among the key driver variables and process integration, and the performance of the firms within the supply chain. So, the objective of our study is to build a model to identify the relationships among power, relationship commitment, supplier integration, and company performance. It also presents an overview of the manufactures in Mainland China and Hong Kong. Specifically, the objectives of this study

are: 1). to offer a comprehensive review of power, relationship commitment, supply chain integration with supplier, and company performance. 2). to identify the key factors that influence supply chain supplier integration. These factors include power, and relationship commitments, etc. 3). to develop a measurement instrument for the above factors, supplier integration, and the performance of the firms within the supply chain. 4). to propose and test a model that represents the relationships among the factors that influence supplier integration, the degree of supplier integration, and firm performance. 5). to provide guidelines for companies to enhance their performance through better relationship management and process integration.

The paper is organized as follows: firstly, we review some related literatures related to power, relationship commitment, supplier integration, and performance; this is followed by the development of a conceptual model with hypotheses and the explanation of research methodology. The hypotheses are tested, followed by the discussion of the findings. Finally, the conclusions and the limitations of the study are presented, together with suggestions for future research.

II. Literature Review

II.1 Supply Chain Integration

Extensive literature has attached great importance to supply chain integration for achieving comparative advantages [9;22;32;52;56;59;72], as well as operational performance [1;3;33;46;61;78]. Various literatures [9;41] suggested that supply chain integration are to integrate the relationships, activities, functions, processes and locations among all channel members in the supply chain. Stevens [80] proposed that integrating the supply chain is primarily involved in planning, coordinating and controlling materials, parts and finished goods from suppliers to customers at all different strategic, tactical and operational levels. In addition, Naylor et al [64] demonstrated that the goal of integration is to eliminate all the boundaries to smooth the flow of material, cash, resource and information. Based on this line of thought, supply chain integration should be strategically managed as a single system as opposed to individually optimizing fragmented subsystems [85]. But, one of the limitations of the earlier explanations is that they may not be systematic enough to differentiate integration from supply chain management.

Supply chain integration could be illustrated as the degree to which the firm can strategically collaborate with their supply chain partners and collaboratively manage the intra- and inter-organization processes to achieve the effective and efficient flows of product and services, information, money and decisions with the objective of providing the maximum value to the customer at low cost and high speed [8; 33; 80; 82; 83]. The objective of supply chain integration is to provide the maximum value to the customer at low cost and high speed. Customer orientation is exceptionally important in current business world.

Without the customer-oriented initiatives, we couldn't expect a successful implementation of supply chain integration.

Supply chain integration could be further identified into six types: strategic integration, relationship integration, internal integration, external integration, information integration and measurement integration. Strategic integration refers to the degree to which a firm can structure the strategic goals and objectives, as well as the sharing of resources, rewards and risks across organizations into consensus and contractual agreements in order to achieve competitiveness [14; 34; 46]. Relationship integration refers to the degree to which a firm can structure the formation, commitment, maintenance and exit of relationships across organizations into consensus and contractual agreements in order to achieve competitiveness [8; 78]. Internal integration refers to the degree to which a firm can structure its organizational practices, procedures and behaviors into collaborative, synchronized and manageable processes in order to fulfill the customer requirement [16; 18; 48; 50]. External integration refers to the degree to which a firm can partner with its key supply chain members (customers and suppliers) to structure their inter-organizational practices, procedures and behaviors into collaborative, synchronized and manageable processes in order to fulfill the customer requirement [79]. Information integration refers the degree to which a firm can coordinate the activities of information sharing and combine core elements from heterogeneous data management systems, content management systems, data warehouses, and other enterprise applications into a common platform in order to substantiate the integrative supply chain strategies [45; 74]. Measurement integration refers to the degree to which a firm can structure the measurement systems and manage the measurement activities with its key supply chain members in order to substantiate the integrative supply chain strategies [8].

Frohlich et al [33] investigated supplier and customer integration strategies in a global sample of 322 manufacturers. Scales were developed for measuring supply chain integration, and five different strategies (inward-, periphery-, supplier-, customer-, and outward-facing) were identified in the sample. Morash et al [57] investigated and compares 3 major forms of supply chain integration for approximately 2 thousand global firms. The 3 forms of supply chain integration include intra-organizational process integration, inter-organizational collaborative integration including strategic alliances, and operational excellence. This paper identified two types supply chain integration: external (customer and supplier) and internal (process reengineering) integration.

The measurement and empirical studies of supply chain integration can be further divided into two prevalent perspectives. These are 1) as a series of interactions between the competitive environment and the organization and 2) as collaborative behaviors that happened within and across supply chain organizations. In line with the first perspective,

Johnson [46] developed an instrument using data from industrial equipment distributors and empirically validated strategic integration as a center of gravity for building up sustainable integration. The findings revealed that dependence, flexibility, continuity expectations, and relationship age have positive effects on a distributor's strategic integration with its suppliers. Moreover, strategic integration enhanced the distributor's financial performance. However, contrary to common belief, the result suggested that uncertainty did not have a significant effect on the distributors' strategic integration with their suppliers or on performance. Following a second line of thought, Stank et al [79] emphasized internal and external collaboration. On the basis of their findings, it has been suggested that collaboration with external supply chain entities increased internal collaboration, which in turn improved service performance. Although both dimensions can provide insights for managers and researchers in establishing supply chain integration, it is reasonably believed that a composite of the two may better describe supply chain integration in a highly dynamic environment.

II. 2 Power

Category management has been promoted as a mechanism to achieve closer working relations between suppliers and retailers. The premise has been that category management should result in a reduced reliance on the use of power as an element of the relationship and increased levels of cooperation. However, Dapiran & Hogarth-Scott [24] suggested that power is an element of any relationship and exists even when not activated and the premise rests on the notion that cooperation is a polar opposite of power. This research confirms that UK and Australian food industry managers perceive the use of power in solely negative terms. Power can be defined operationally as the ability of one channel member to influence the marketing decisions of another channel member and hence must be related to cooperation. This paper reviews the nature of dependence, power and cooperation and explores the role of these constructs in the practice of category management. And a model was suggested that shows the linkages between power, cooperation, capitulation, and trust. The use of mediated power bases of reward and coercion was likely to lead in the immediate term to capitulation. The non-mediated bases of power - expert/ information, referent, legitimate - were likely to lead to the state of existence called cooperation.

Cox [23] illustrated that power is at the heart of the trans-organizational relationships and captive suppliers are conditioned by powerful buyers to make substantial investment (commitment) to sustain the business relationships. The study explained why competence in procurement and supply management must start from an understanding of the bases of supplier power and business strategy and how the power perspective can enhance effective procurement and supply management. The basic power matrix that is essential in understanding the exchange relationship between buyers and suppliers is outlined, so that

buyers can understand the circumstance they are in and what scope exists for them to augment their power relative to suppliers. The study also investigated that procurement and supply competence must involve the buyer seeking ways to eradicate augment the power of the supplier over the buyer, as well as seeking at all times to ensure that its suppliers operate only in highly contested markets and earn only normal returns. It was important to understand that the power attributes that may be available to buyers and suppliers can be double-edged. This was because a power attribute may favor the buyer and sometimes it may favor the supplier. The paper also explained how regulation can be an attribute that augments the power of both the buyer and the supplier.

Benton et al [6] investigated the supplier satisfaction in power driven buyer-supplier relationships. They examined the influences of supply chain power on supplier satisfaction and the impact of buyer-seller relationship on supplier satisfaction. Three primary objectives were achieved in this study: 1) how the different "bases of power" affect the satisfaction of selling firms? 2) how power driven relationships affect supplier satisfaction, and 3) how to measure the effect of power influences on supplier satisfaction in the automobile industry. The power-affected buyer-supplier relationship was found to have a significant positive effect on both performance and satisfaction. But they failed to find the casual relationship between performance and satisfaction.

Maloni et al [53] examined the detrimental and beneficial effects of power on the ability to build integrated, high-performance buyer-supplier relationships in the supply chain. The study found that power plays a significant role in the supply chain management, and the different sources of power have different impacts on inter-firm relationship in the supply chain. A stronger buyer and supplier relationship can enhance the performance of the companies in a supply chain. Study also validates that supply chain integration is a key element of cooperate strategy and it is very important to understand the process of supply chain integration.

Brown et al [12] empirically investigated the impact of power and relationship commitment on marketing channel member performance from the relationship marketing perspective. They found that in marketing channels for farm equipment, the supplier's use of power may bring two 2 key outcomes: 1). the retailer's commitment to the channel relationship and 2). both supplier and retailer performance within the channel. They also investigated how retailer commitment affects channel members' performance in terms of both supplier's performance and retailer performance. They argued that key linkages are moderated by the symmetry of power within the channel (i.e., whether the retailer is more powerful, power is somewhat balanced between the two channel members, or the supplier is more powerful). Their results partially supported both the primary construct linkages as well as the moderating effect of power symmetry upon them. The study demonstrated that power and its usage can have a pivotal impact on the working

relationships in marketing channels and under certain conditions, the use of power in the channel can enhance performance for all channel members.

Goodman & Dion [37] argued that since Industrial distributors were carrying an increasing percentage of industrial goods in the ways of mergers and acquisitions, they became larger and more powerful. This constrained the ability to product line manufacturers to exercise power over their distributors. But the manufacturers still require commitment from their distributors in order to carry out a coordinated marketing program. Power was becoming one of the important determinants of relationship commitment in the distributor-manufacturer relationship. A model of distributor commitment was developed in this study based on the high-tech distributors surveyed.

Chris [21] stated that the balance of power in an exchange relationship can shift over time to favor the supplier. This paper investigated the importance of asset specificity for buyer-supplier exchange relationships in outsourcing decisions. Emphasis was placed on the need for buyers to understand pre- and post-contractual risks and how asset specificity can lead to post-contractual lock-in or dependency was discussed. The concepts of asset specificity, uncertainty, and information asymmetry were outlined as they relate to the scope for improvement in supplier power.

Watson [86] presented that supply chains are complex power structures in which participants have very definite interests that go beyond cost control through waste management. These interests extend into areas such as that wins from the process of coordination and whether the benefits of coordination fully cover the managerial costs incurred. Customers and suppliers enjoy the power to veto an organization's integrated supply chain management initiative and, as a result, the chances of achieving supply chain integration are reduced. But even in the relationship between the insurers and their preferred car repairers, these preferred suppliers have little scope to leverage value from the branded parts suppliers that dominate the relationship between quality and cost in this sub-regime of the overall power regime.

II. 3 Relationship Commitment

Morgan & Hunt [58] suggested that the propensity for relational continuity and the establishment of long-term relationship are primarily in the theme of "relationship commitment". Relationship commitment can be defined as the willingness of a party to invest resources into a relationship [27; 58]. Gundlach et al [39] further pinpointed its importance for developing and sustaining successful relational exchange.

Relationship commitment can be identified into two levels: interpersonal commitment and organizational commitment. Interpersonal commitment refers to the individual's willingness to contribute considerable time, work and energy for another individual [43]. Organizational commitment could be further categorized

into two: Intra-organizational and inter-organizational commitment. Intra-organizational commitment refers to employee's identification with and acceptance of their organizational goals and values, as well as his willingness to make considerable effort to his organization for a desirable outcome [60; 69]. Inter-organizational commitment is defined as the willingness of a focal organization to invest in the relationship with its partners based on the favorable outcomes [19]. With increased inter-organizational commitment, supply chain organizations would develop closer relationships with their supply chain partners; therefore, it enhances the implementation of supply chain integration. Two types of relationship commitments were identified by Mathieu & Zajac, and Penley & Gould [55; 68]: affective commitment and calculative commitment. Affective commitment can be defined as one party's identification with and emotional attachment to the goals and values of another party, and willingness to secure the relationship [58; 87]. Calculative commitment can be viewed as one party's identification with the benefits and costs of the relational exchange, and willingness of maintaining the relationship for satisfying his needs [36].

Because supply chain integration is created by cooperative, mutually beneficial partnerships with supply chain members [88], there has been an increasing research emphasis on power and relationship commitment in recent years.

II. 4 Performance

As cited by Chen et al [18], a common measure of business performance is financial performance because the primary goal of business organization is to make profits for the shareholders. Financial performance has been widely used as a key measure of firm performance [10; 11] and is evaluated in different dimensions. However, much literature [28; 29; 77] has pinpointed the limitations in relying solely on financial performance measures in supply chains. van Hoek [84] further advocated the supply chain firms to devise innovative measurement system as opposed to the traditional ROI-based system. A broader conceptualization of performance measures includes customer service and other operational indicators. Neely et al [65] presented a few of the categories of performance: comprising quality, time, flexibility, and cost. Vickery et al. [85] included the dimensions of service performance in their customer service construct that are general, and these customer service items include pre-sale customer service, product support, responsiveness to customers, delivery dependability, and delivery speed. Benita [4] presented an overview and evaluation of the performance measures used in supply chain models and also presents a framework for the selection of performance measurement systems for manufacturing supply chains. Three types of performance measures are identified as necessary components in any supply chain performance measurement system, and new flexibility measures for supply chains are developed.

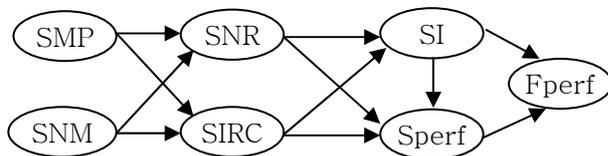

Various literatures [38; 38; 49; 54] suggested that a

balanced approach for the performance measurements is essential to present a clear picture of organizational performance. Actually, some recent supply chain integration studies [81; 85] have used both operational and financial performances as indicators for the organizational performance. However, many supply chain integration studies have measured either operational [75; 78; 79] or perceived financial performance outcomes [73].

In summary, previous research has shown that supply chain integration with suppliers is very important for achieving superior supply chain performance. Additionally, power and relationship commitment have become a promising area of research in supply chain integration literature. However, much of the previous work regarding supply chain integration is U.S.-oriented and has not identified a comprehensive model for business process integration. There is a need for further research to investigate the relationships between the various factors that influence business process integration, the degree to which processes are integrated, and the performance of the firms within the supply chain.

III. The Proposed Model and Rese-Arch Hypotheses

Based on an the literature reviewed and the in depth interviews with more than 15 practitioners who are in charge of supply chain management in Hong Kong and Mainland China, we propose the following theoretical framework for supply chain supplier integration.

Within this framework, we have included the following seven theoretical constructs: (1) Perceived Supplier Mediated Power (Smp), Mediated power, which includes reward, coercive, and legal legitimate, involve influence strategies that the source (buyer) specifically administers to the target (seller). The intention is to bring about some direct action. Mediated bases represent the competitive and negative uses of power traditionally associated with organizational theory [12; 53]. (2) Perceived Supplier Non-mediated Power (Snp), Compared with mediated powers, Non-mediated power which includes expert, referent, and traditional legitimate are more relational and positive in power orientation [53]. (3) Normative Relationship Commitment to Supplier (Snrc), Normative relationship commitment refers to one member's identification with another member and its internalization of common norms and values with another member [12] (4) Instrumental Relationship Commitment to Supplier (Sirc), Instrumental relationship commitment is based on compliance (driven by rewards or punishment, etc.) and distinct from normative

commitment [12]. (5) Supplier integration (Si), Supplier integration is defined as the core competence derived from better coordination of all the critical suppliers in a company's supply chain to jointly achieve improved service capabilities at lower total supply chain cost [8]. (6) Supplier's performance (Sperf), Supplier's performance is defined as the company's supplier operational outcome, such as the level of quality, flexibility, delivery, and customer service. It should be noted that supplier's performance is concerning the company's performance with respect to its major supplier. It is not the performance of the supplier companies. (7) Financial performance (Fperf). Financial performance is defined as financial and market measures to evaluate the firm's efficiency and effectiveness. We used financial performance to measure the performance of the manufacturer in the supply chain is for that financial performance is a common measure of business performance [18]. On the other hand, we can find that supplier's performance is based on the operation aspects of the companies. Using financial performance as a common measure of the performance of the manufacturer in the supply chain, we can investigate the impacts of supplier's performance on financial performance. These constructs and their relationships were identified based on the results of an extensive review of the related literature and our observations during plant visits and in-depth interviews with executives who are knowledgeable in supply chain management. To identify reliable and valid measurement items for each of the constructs, we have conducted an extensive literature review. Whenever possible, we have adopted from valid measurement items used in previous studies. We have also added some new measurement items and modified some of the measurement items based on the results of our in-depth interviews and observations during the plant visits. The preliminary measurement items for the key constructs and the sources from which these items were adopted are shown in Appendix.

Brown et al.[12] found that in marketing channels for farm equipment, the supplier's use of different power may bring different retailer's commitment to the channel relationship and relationship commitment brings both supplier and retailer performance within the channel. Goodman et al [37] argued power was becoming one of the important determinants of relationship commitment in the distributor-manufacturer relationship. So, we proposed those hypotheses:

H1: Companies with a greater level of perceived supplier mediated power are more likely to have a stronger normative relationship commitment to suppliers.

H2: Companies with a greater level of perceived supplier mediated power are more likely to have a stronger instrumental relationship commitment to suppliers.

H3: Companies with a greater level of perceived supplier non-mediated power are more likely to have a stronger normative relationship commitment to suppliers.

H4: Companies with a greater level of perceived supplier non-mediated power are more likely to have a stronger

instrumental relationship commitment to suppliers.

With relationship commitment, supply chain partners become integrated into their key suppliers' business processes and more tied to established goals [18; 58]. Working in this same vein, Prahinski & Benton [70] developed and empirically tested a model that explained how suppliers perceive the buying firm's supplier evaluation communication process and its impact on suppliers' performance. Johnson [46] investigated the strategic role of inter-firm relationships through the concept of strategic integration. Narasimhan & Kim [63] investigated a set of strategies for information systems utilization in supply chain integration initiatives. It is argued that there might be a recommended sequence in using information systems for supply chain integration. Stank et al [79] developed and tested the measures to examine empirically the relationships between internal and external supply chain collaboration and logistical performance. Daugherty et al [26] empirically examined involvement in reverse logistics activities. The research specifically addressed the relationship between information systems support and reverse logistics program performance. The research examined the role of relationship commitment. Relationship commitment implies closer relationships. Such closer buyer-seller relationships are frequently associated with more positive relationships between information systems support and reverse logistics program performance. Brown et al [12] found that relationship commitment brings both supplier and retailer performance within the channel. So we proposed that

H5: Companies with a stronger normative relationship commitment to suppliers are more likely to have to a greater extent of supplier integration.

H6: Companies with a stronger instrumental relationship commitment to suppliers are more likely to have to a greater extent of supplier integration.

H7: Companies with a stronger normative relationship commitment to suppliers are more likely to have to a greater extent of supplier's performance.

H8: Companies with a stronger instrumental relationship commitment to suppliers are more likely to have to a greater extent of supplier's performance.

The relationship between supply chain integration and performance outcomes is discussed over a vast body of supply chain and operations literature [3] [25; 81]. For example, Stank et al [78] developed and tested an instrument for measuring supply chain integration competences as well as determining their relative importance to developing logistics distinctiveness. Stank et al. [79] suggested that collaboration with supply chain partners facilitates internal collaboration, which in turn enhances logistics performance. Frohlich et al [33] examined the simultaneous effects of five different supplier and customer integration strategies on a broad array of operations performance outcomes based on a global sample of 322 manufacturers. The findings demonstrated that supply chain companies with the widest degree of the arcs of integration achieve the highest level of performance improvement involving the customer service,

on-time delivery, delivery lead time, productivity, quality, and cost, in addition to the market share and profitability. Armistead et al [3] identified the extent to which greater integration along the supply chain leads to improved operating performance. A survey was conducted of managers from companies that participated in the UK Best Factory Audit conducted by Management Today and Cranfield School of Management. So we proposed those hypotheses

H9: Companies with a greater extent of supplier integration are more likely to have a greater extent of supplier's performance.

H10: Companies with a greater extent of supplier integration more likely to have a greater extent of financial performance.

H11: Companies with a greater extent of supplier's performance more likely to have a greater extent of financial performance.

IV. Research Methodology

IV.1 Sampling and Data Collection

To test the above hypotheses, we collected data from manufacturing companies in Hong Kong and Mainland China. Since China is becoming the global factory of the world, manufacturing companies in China play a very important role in many supply chains. To our knowledge, there are no solid empirical studies of supply chain management issues using data from China. Therefore the data collected and the results found from China can be of great value. We use a mail survey combined with telephone calls to maximize the return rate.

As an exploratory study, the method of simple random sampling is used to collect the data. Since China is a big country, we will strategically choose four cities representing the whole economy of China: Chongqing, Tianjin, Guangzhou, Shanghai, and Hong Kong as our target samples. Chongqing is a traditional industrial base in the northwestern part of China. It is in at a relatively lower stage of economic reform and market formationization. Tianjin is an industrial base in central China and reflects the "average" stage of economic reform and market formation in of China. Guangzhou and Shanghai are in Southern China and have enjoyed a higher degree of economic reform and marketization. We believe these four cities are representative of the general business conditions in China. Therefore, Tianjin, Guanzhou, Chongqing, Shanghai are the representatives of Chinese economic development with comparably market economy, and therefore were selected as sample cities for our study. Hong Kong is a city with a different manufacturing environment from the other cities of China. We choose both Hong Kong and China because we believed that there would be a significant difference on the power and relationship commitment patterns between these two places, since Hong Kong has already been a well developed business structure, which can facilitate sharing a lot better.

Based on previous studies on from relevant supply chain

management literature, the theoretical framework has been proposed and the questionnaire has been designed. The questionnaire included questions on the demographic profile of the company and the questions relating to the company performance, supplier integration, supplier relationship, and supplier use of power. In all these questions, a Likert scale of 1 to 7 was used. In order to ensure the reliability of the questionnaire, the English version of the questionnaire was first developed and then was translated into Chinese by an operations management professor in China. The Chinese version was then translated back into English by another operations management professor in Hong Kong. This translated English version was then checked against the original English version for question accuracy. In Mainland China, we used the Chinese version of the questionnaire. In Hong Kong, we will use the bilingual version of the questionnaire.

Before we launch the full-scale study, we piloted test the questionnaire using a sample of 15 companies. We revised the questionnaire based on the results of the pilot-test and also decide whether to use a single or multiple informants per company.

Moreover, to get a representative sample of manufacturing companies in these four Mainland China cities, we used the yellow pages of China Telecom in each one of the four cities in Mainland China and Directory of the Chinese Manufacturers Association in Hong Kong as a large sampling pool. We randomly selected some of these companies on the lists to contact with telephone calls. These companies come from a wide variety of industries, such as Food, Beverage, Alcohol & Cigarettes, Chemicals & Petrochemicals, Wood & Furniture, Pharmaceutical & Medicals, Building Materials, Rubber & Plastics, Metal, Mechanical & Engineering, Electronics & Electrical, Textiles & Apparel, Toys, Jewelry, Arts and Crafts, and Publishing and Printing.

One importance important challenge for this research is how to collect reliable data concerning the relationship management and process integration with the supplier and suppliers within the supply chain. After visiting over ten companies, we believe that the best way is to get one key informant who is knowledgeable of about supply chain management within the manufacturing companies. This person is normally knowledgeable about the internal processes, processes for purchasing and distributions, and for supplier relationship management, such as supply chain managers, CEO/presidents, senior/executive, vice presidents, senior/executive directors, directors/managers in the companies. Many studies have used a single informant in studying relationship and trust issues between different organizations [42]. However, some researchers have demonstrated the benefits of using multiple informants [13]. We made telephone calls to these companies to identify the manufacturers, make sure that their addresses were correct and also identified the name and contact information for the most suitable informants who were in charge of supply chain management, purchasing and marketing/sales the operations

function. Then we sent the questionnaire to these key informants. A cover letter highlighted the objectives of the survey and its potential contributions to the respondents.

Respondents were encouraged to participate in the survey with an entitlement to a summary report of the results and a small participation incentive. Self-addressed and stamped envelopes were also included together with the survey to facilitate the returning of the completed questionnaires. Follow-up telephone calls were made to improve the response rate. Follow-up mailings were also done if companies request to do them after we contact them by the phone. Respondents were contacted to clarify missing data in their responses.

617 usable questionnaires were received from the contacted 4569 companies, so the rate was 13.5%. A total of 1356 questionnaires were sent out and 617 returned questionnaires were usable. Some of the questionnaires were not used because they were not properly filled out or had too many missing values. The usable response rate was 19.7 %.

IV. 2 Company Profile

The respondents represent a large variety of the companies from a variety of industries. More than 25.49% of the companies are from metal, mechanical and engineering, 17.86% of the companies produce textiles or/and apparel, 13.15% of the respondents are electronics and electrical companies. In details, 35.61% of the companies from Hong Kong belong to textiles and apparel, but only 9.27% of Hong Kong respondents are from metal, mechanical and engineering. 35.58% of the companies in Chongqing are from metal, mechanical and engineering industry, but only 3.85% of Chongqing respondents are from textiles and apparel. 42.00% of the respondents in Shanghai are from metal, mechanical and engineering industry. We can see that the backgrounds of the industry emphasis are different among the five cities. Over 32% of the respondents have the annual sales of less than HK\$5 million, and 14.99% of the respondents have the annual sales of more than HK\$100 million. But in Hong Kong, only 9.09% of the respondents have the annual sales of less than HK\$5 million, and 30.68% of the respondents have the annual sales of more than HK\$100 million. 56.31% of the respondents in Tianjin have the annual sales of less than HK\$5 million, and 4.85% of the respondents from Tianjin have the annual sales of more than HK\$100 million. 49.04% of the respondents in Guangzhou have the annual sales of less than HK\$5 million. Many of the companies in Hong Kong have a bigger sales scale than those from Mainland China.

IV. 3 The Structural Equation Modeling Method

In the study, we use structural equation modeling to estimate the causal relationships among the different constructs with linear structural relations (LISREL) program and a sample of 617 companies. Kline & Klammer [51] contended that LISREL examines the relationships of the variables as a unit, rather than piecemeal as in a regression approach. The

assumption of perfectly reliable measures in regression is untenable and easily handled by LISREL.

Structural equation modeling is a confirmatory approach to data analysis requiring the a priori assignment of inter-variable relationships. It tests a hypothesized model statistically to determine the extent the proposed model is consistent with the sample data. The measurement models specify how the latent variables are measured in terms of the indicator variables as well as address the reliability and validity of the indicator variables in measuring the latent variables or hypothetical constructs. The structural equation model provides an assessment of predictive validity, specifies the direct and indirect relations among the latent variables, and describes the amount of explained and unexplained variance in the model [15; 76].

LISREL 8.54 was used to analyze the hypothesized model. A two-step model building approach was used, wherein the measurement models were tested prior to testing the structural model. The rationale behind this two-step approach is discussed in Joreskog & Sorbom, and Anderson & Gerbing [2; 47]. The maximum likelihood estimation method was used which has desirable asymptotic properties (e.g., minimum variance and unbiasedness) and is scale-free. This estimation method assumes multivariate normality of the observed variables. Recent research has shown that the maximum likelihood method can be used for data with minor deviations from normality [71]. As a check of normality, the P-P plots for a number of variables were checked in the sample, and the data appeared approximately normally distributed.

IV. 4 Measurement Items

Perceived supplier non-mediated power and normative relationship commitment to supplier are measured by five items respectively. Perceived supplier mediated power is measured by six items and instrumental relationship commitment to supplier is measured by three items. All the items are adapted from the scale developed by Brown et al [12]. These indicators are measured using a 7-point Likert scale, with “1” for “strongly disagree”, “7” for “strongly agree”.

Supplier integration, supplier integration, and internal integration are measured by eight items respectively. Our supplier integration scale and supplier integration scale were largely derived from seven items of Narasimhan et al [62] which emphasized information sharing and collaboration and was further substantiated from Morash and Clinton (1998). We adapted some of these items and devised new ones to depict this construct in a most appropriate way. Eight items of internal integration which are focus on data integration, information integration as well as process integration were modified from the scales developed by Narasimhan et al [62]. All indicators are measured using a 7-point Likert scale, with “1” for “strongly disagree”, “7” for “strongly agree”.

Supplier’s performance is measured by five items, which were partly derived from the measurements used by

previous studies. These indicators are measured in the 7-point Likert scale, with “1” for “much worse”, “7” for “much better”.

Financial performance is measured by five items, which were partly derived from the measurement items of “firm performance” in Narasimhan et al [62]. These indicators are measured in the 7-point Likert scale, with “1” for “much worse”, “7” for “much better”.

IV. 5 Construct Validity and Reliability Analysis

Since the data for this research was generated using scaled responses, it is necessary to test for reliability. Reliability is an assessment of the degree of consistency between multiple measurements of a variable [40]. The most commonly used measure of reliability is internal consistency. Flynn et al [30] suggested that the most accepted measure of a measure’s internal consistency is Cronbach’s Alpha. Cronbach’s Alpha coefficient is used [66] to measure the internal consistency of the items included in each of the constructs. The generally agreed lower limit for Cronbach’s Alpha is 0.50 to 0.60 in exploratory research [30; 66]. We followed the two-step method used in Narasimhan et al. [61] to test the construct reliability. First, we did an exploratory factor analysis to ensure the unidimensionality of the scales. Second, we used Cronbach’s alpha to assess the reliability of each construct. Table 1 shows the results of principal components factor analysis with varimax rotation. Cronbach Alpha tests were performed on the constructs (Table 2). Based on the coefficient values, the items tested were deemed reliable for this type of exploratory research [66].

A structural equation model is only reliable if its parameter values can be estimated [71]. Sample size affects the ability to correctly estimate parameter values and determine model fit [76]. Anderson et al [2] suggested a minimum sample size of one hundred and fifty. So, 617 samples are sufficient for the model to be tested in this study.

Construct	No. Of questions	Cronbach's Alpha
Financial performance (Fperf)	5	.905
Normative Relationship Commitment to Supplier (Snrc)	5	.900
Instrumental Relationship Commitment to Supplier (Sirc)	3	.694
Perceived Supplier Non-mediated Power (Snmp)	5	.822
Perceived Supplier Mediated Power (Smp)	6	.883
Supplier integration (Si)	8	.904
Supplier's performance (Sperf)	5	.875

The data collected by surveys and other empirical designs is of little use unless its reliability and validity can be demonstrated [30]. O'Leary-Kelly et al [67] mentioned that the methodological issue of construct is generally ignored in most of previous empirical researches in operations management area. There are two dimensions of construct validity: discriminant validity and convergent validity. Discriminant validity is the degree to which measures of different latent variables are unique [67]. Convergent validity relates to the degree to which multiple methods of measuring a variable provide the same results [67]. In our study, we try to assess those two kinds of validity by CFA models in structural equation models. O'Leary-Kelly et al [67] suggested that the confirmatory

factor analysis (CFA) method of assessing convergent and discriminant validity is a more powerful tool and requires fewer assumptions than the traditional MTMM matrix method.

At the beginning, we construct the CFA model using LISREL program. In the model, each item is linked to its corresponding construct and the covariances among those constructs are freely estimated. The model fit indices are Chi-Square = 2379.21 with Degrees of Freedom = 603, RMSEA=0.069, which indicate that the model is acceptable [44]. Generally, a construct with either loadings of indicators of at least 0.5, a significant t-value ($t > 2.0$), or both, is considered to be convergent valid [17; 31]. For our model, most of the factor loadings are greater than 0.50 and the t-values are all greater than 2.0 (Table 1). Therefore, convergent validity is achieved in our study.

In order to assess the discriminant validity, we build a constrained CFA model, in which the correlations among constructs are fixed to 1. This model will be compared with the original unconstrained model, in which the correlations among constructs are freely estimated. A significant difference of the Chi-square statistics between the fixed and unconstrained models indicates high discriminant validity [17; 31]. In our study, the difference of χ^2 is significant at 0.05 significant level. Therefore, the discriminant validity is ensured in our study.

IV. 6 Structural Model and Hypotheses

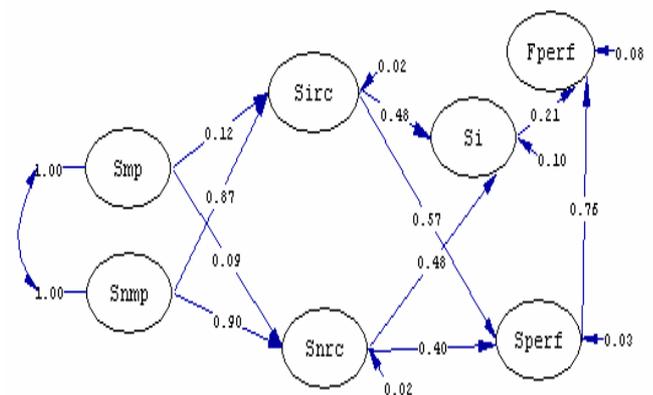

FIGURE 2. Structural Equation Model

The structural model was analyzed based on the modified measurement models using the maximum likelihood estimation method. Figure 2 shows the modified structural equation model and standardized coefficients. All coefficients shown were significant at 0.05 levels except for H9. The initial model as shown in Figure 1 was tested, resulting in ten significant path coefficients (H1-H8, and H10-H11), suggesting the support in the data for the relationships. The data supported hypotheses H1- H8, H10-H11, namely, that companies with a greater level of mediated power with suppliers are more likely to have a

stronger normative relationship commitment and instrumental relationship commitment with suppliers. Companies with a greater level of non-mediated power with suppliers are more likely to have to a stronger normative and instrumental relationship commitment with suppliers. Companies with a stronger normative or instrumental relationship commitment with suppliers are more likely to have to a greater extent of supplier integration. Companies with a stronger normative or instrumental relationship commitment with suppliers are more likely to have to a greater extent of supplier's performance. Companies with a greater extent of SC performance are more likely to have a greater extent of financial performance. H9 is not supported by the data. That means that supplier integration has no significant influence on supplier's performance.

In structural equation modeling, there is no single test of significance that can absolutely identify a correct model given the sample data [76]. Much goodness of fit criteria has been established to assess an acceptable model fit. Consequently, several authors recommend presenting a number of indices to support model fit [5; 35]. This paper presents and discusses a number of fit indices with the results. The goodness of fit indices for our model are $\chi^2(612) = 2631.78$, NFI = 0.99, NNFI = 0.99, CFI = 0.99, RMSEA = 0.073, Standardized RMSE = 0.016. These indices are better than the threshold values suggested by Hu et al [44]. In particular, Cheung & Rensvold [20] argued that the more complex models should be evaluated using lower cutoff values and the simpler models should be evaluated using higher cutoff values. Therefore, our model can be accepted for future discussion.

V. Discussion

V.1 Supplier Integration and Performance

Supplier integration significantly impacts financial performance of the manufacturers. Manufacturers' supplier's performance has a positive influence on financial performance of the manufacturers. Supplier integration has no significant influence on supplier's performance. That maybe for that we selected the data sample pool from the manufacturers in Mainland China and Hong Kong. For the manufacturers we surveyed, they paid more attention to the customers because that usually they have more problems for marketing. In order to sell their products; they integrated the customers with their internal operation process according to the "customer focus" operation strategy. But for suppliers, the manufacturers are their buyers or customers. The supplier usually were ignored or emphasized by the manufacturers. So the extent of supplier integration is not so high as to have a significant influence on supplier's performance of the manufacture.

The relationship between supply chain supplier integration and performance has been discussed over a vast body of supply chain and operations literature. For example,

Stank et al [78] developed and tested an instrument for measuring supply chain integration competences as well as determining their relative importance to developing logistics distinctiveness. Supplier and internal integration are considered the most important differentiators of overall firm performance. Stank et al [79] suggested that collaboration with supply chain partners facilitates internal collaboration, which in turn enhances logistics performance. Besides, Frohlich et al. [33] demonstrated that supply chain companies with the widest degree of the arcs of integration achieve the highest level of performance improvement involving the supplier service, on-time delivery, delivery lead time, productivity, quality, and cost, in addition to the market share and profitability. Most previous researchers only tested the association between integration and supply chain performance, while in practicality, business executives will primarily concern about the financial performance. The last supported hypothesis grasps the true relationships between supply chain performance and financial performance.

V. 2 Relationship Commitment and Supply Chain Supplier Integration

Both manufacturers' normative and instrumental relationship commitment to suppliers significantly impact supply chain supplier integration and supplier's performance. That means that companies with a stronger relationship commitment to suppliers are more likely to have to a greater extent of supplier integration and achieve the better supplier's performance. We can see that manufacturers' normative relationship commitment to suppliers has the same influence on supplier integration as manufacturers' instrumental relationship commitment to suppliers does (both the standardized coefficients are 0.48). And manufacturers' instrumental relationship commitment to suppliers has a higher influence on supplier's performance (standardized coefficient: 0.57) than manufacturers' normative relationship commitment to suppliers does (standardized coefficient: 0.40). From the relationship of supplier integration and supplier's performance and financial performance we discussed in last section, we know that manufacturers' instrumental relationship commitment to suppliers also has a higher influence on manufacturers financial performance than manufacturers' normative relationship commitment to suppliers does. The manufacturers should commit more instrumental relationship to the suppliers to pursue the high performance. From the relationship between relationship commitment and supplier integration, we can find one of the important drivers for supply chain integration.

Based on the high and good relationship commitment, the suppliers are very likely to cooperate with the partners in the same supply chain. The results of this study are agreed with the results of the previous studies. Prahinski et al [70] developed and empirically tested a model that explained how suppliers perceive the buying firm's supplier evaluation communication process and its impact on suppliers' performance. The results indicated that buyer-seller

relationship influences supplier commitment, which eventually yields better supplier's performance. Unless the supplier is committed to the buying firm, the supplier evaluation communication process doesn't ensure better supplier's performance. Furthermore, it has been suggested that the buying firms should increase their efforts on cooperation and commitment in order to augment the supplier's commitment.

Today, the competition is not amongst the companies, but amongst the supply chains. Supply chain supplier integration is getting more and more attention from both the academicians and the practitioners. Based on a high relationship commitment, the suppliers are more likely to cooperate with the manufacturers. So the manufacturer will have less difficulty to integrate the suppliers with its own operation process in the supply chain to achieve the competitive advantages. Many previous papers failed to find out the impacts of relationship commitment on the supply chain supplier integration.

V.3 Power and Relationship Commitment

Power has the positive influence on relationship commitment. That means that the suppliers' use of both mediated and non-mediated power have the positive impact on both normative and instrumental manufacturers' relationship commitment to the suppliers. Supply chain organizations must evaluate their supply chain partners by different perspectives and develop an appropriate level of power in response to perceived risks in different scenarios. Based on power, commitment is formed to extend the relationships. Power as a business decision must precede the committed investment. This conclusion has also been tested by some other researchers. Brown et al [12] found that the supplier's use of different power may bring different retailer's commitment to the channel relationship. Goodman et al [37] argued power was becoming one of the important determinants of relationship commitment in the distributor-manufacturer relationship.

From the results of the model, we can also find that, the influence of suppliers' use of mediated power on manufacturers' instrumental relationship commitment to suppliers (standardized coefficient: 0.12) is nearly equal to the influence of suppliers' use of mediated power on manufacturers' normative relationship commitment to suppliers (standardized coefficient: 0.09). The influence of suppliers' use of non-mediated power on manufacturers' instrumental relationship commitment to suppliers (standardized coefficient: 0.87) is nearly equal to the influence of suppliers' use of non-mediated power on manufacturers' normative relationship commitment to suppliers (standardized coefficient: 0.90). The suppliers' use of non-mediated power has a much higher impact on manufacturers' normative relationship commitment to suppliers (standardized coefficient: 0.87) than suppliers' use of mediated power does (standardized coefficient: 0.12). The suppliers' use of non-mediated power has a much lower impact on manufacturers' normative relationship

commitment to suppliers (standardized coefficient: 0.09) than customers' use of mediated power does (standardized coefficient: 0.90). Non-mediated power has a much higher influence on relationship commitment than mediated power does. From the analysis of last section, we also know that non-mediated power is more powerful to increase the supplier integration. The suppliers' use of more non-mediated power is better for the manufacturers' supplier's performance and financial performance.

The suppliers' use of mediated power can positively and significantly influence both manufacturers' instrumental and normative relationship commitment to suppliers. But the suppliers' use of non-mediated power has little impact on manufacturers' relationship commitment to suppliers. For relationship commitment, manufacturer's instrumental and normative relationship commitment to the supplier has the equal impact. But manufacturer's instrumental relationship commitment has a higher influence on supplier's performance than manufacturers' normative relationship commitment does. That means that, in China, the suppliers have a relative lower power on manufacturers than the power used by the manufacturers on the suppliers.

VI. Conclusions

This study firstly examined the relationships between power, relationship commitment, supply chain supplier integration and manufacturers' performance in the context of a holistic model that allowed for the simultaneous testing of these relationships based on the data from Mainland China and Hong Kong. With the growing awareness of power, relationship commitment and supply chain integration over the past decade, it is an important issue to improve the understanding of these variables and the associated relationships. Our research contributes to the supply chain management literature by proposing and empirically testing a supply chain supplier integration model. The model illustrates the effect of power, relationship commitments on supplier integration within the supply chain and manufacturers' performance. This model can be used as a basis for further empirical work in supply chain management. Moreover, the knowledge of this model should provide some guidelines for managers as to how to direct their improvement efforts to achieve superior manufacturer's performance. In addition to the grounded theoretical benefits of applying our recommended practices, empirical validation enables the managers to adopt the most effective practices of supply chain management for enhancing their competitiveness in today's highly competitive global market place.

In conclusion, our study identified the factors of the supply chain supplier integration and the relationship between the factors and supplier integration. It investigated the relationship between two types of power and two types of relationship commitment and found that both types of power have the positive influence on supply chain supplier integration. Our model also revealed that manufacture

performance is dependent on the extent of the supply chain supplier integration.

There are some limitations in the power, relationship commitment and supply chain supplier integration model. The relationships between the two types of power are not explained. Environmental factors that can have a differential influence on supply chain supplier integration and relationship commitment are not included. Such as that trust is regarded as one important factor impacts relationship commitment by many researches. There should be a classification of the companies from Mainland China and Hong Kong though they share the same Chinese culture and industry background.

The future research directions can be stimulated from the limitations of this research, i.e. the initiators of the supply chain supplier integration demand further research. The relationships between two types of power and between two types of relationship commitment should be identified. Other factors that impact power and relationship commitment should also be tested. Future studies could also focus on a better understanding of the differences between high and low performers from Mainland China and Hong Kong, and the process that can enable a low performer to become a high performer. The similar research about power, relationship commitment, customer integration and manufacture performance can be conducted.

VII. Appendix

VII.1 Construct Measurement

Financial performance (Fperf)

FPERF1: Growth in sales

FPERF2: Growth in profit

FPERF3: Growth in market share

FPERF4: Growth in ROI

FPERF5: Growth in return on sales

Normative Relationship Commitment to Supplier (Snrc)

SNRC1: We feel that our major supplier views us as being an important "team member," rather than our being just another customer

SNRC2: We are proud to tell others that we are a customer of this supplier

SNRC3: Our attachment to this supplier is primarily based on the similarity of our values and those of this supplier

SNRC4: During the past year, our company's values and those of the major supplier have become more similar

SNRC5: What this supplier stands for is important to our company

Instrumental Relationship Commitment to Supplier (Sirc)

SIRC1: Unless we are rewarded for it in some way, we see no reason to expend extra effort on behalf of this supplier

SIRC2: How hard we work for this major supplier is directly linked to how much we are rewarded

SIRC3: Bargaining is necessary in order to obtain favorable terms of trade with dealing with this supplier

Perceived Supplier Non-mediated Power (Snpmp)

SNMP1: The people in the supplier's organization knew what they are doing

SNMP2: We usually got good advice from our major supplier

SNMP3: The supplier had specially trained people who really knew what had to be done

SNMP4: We really admire the way our major supplier runs their business, so we tried to follow their lead

SNMP5: Our major supplier's business expertise made them likely to suggest the proper thing to do.

Perceived Supplier Mediated Power (Smp)

SMP1: We had an obligation to do what the major supplier wanted, even though it wasn't a part of the contract

SMP2: Since they were the supplier, we accepted their recommendations

SMP3: We felt that by going along with the major supplier, we would have been favored on some other occasions

SMP4: By going along with the major supplier's requests, we avoided some of the problems other companies face

SMP

5: Our major supplier often rewarded us to get our company to go along with their wishes

SMP

6: The major supplier often hinted that they would take certain actions that would reduce our profits if we did not go along with their requests

Supplier integration (Si)

SI1: The level of information exchange with our major supplier through information network

SI2: The establishment of quick ordering system with our major supplier

SI3: The participation level of our major supplier in the process of procurement and production

SI4: The participation level of our major supplier in the design stage

SI5: Our major supplier shares their Production Schedule with us

SI6: We share our production plan with our major supplier

SI7: We share our demand forecast with our major supplier

SI8: We help our major supplier to improve their process to better meet our needs

Supplier's performance (Sperf)

SPERF1: Our major supplier can quickly modify products to meet our company's requirements

SPERF2: Our major supplier can quickly introduce new products into the markets

SPERF3: Our supplier has an outstanding on-time delivery record to our company

SPERF4: The supplier's lead time for fulfilling our company's orders (the time which elapses between the receipt of our order and the delivery of the goods) is short

SPERF5: Our major supplier provide high level of customer service to our company

Abstract: Information and communications technologies (ICT) can be used to improve the efficiency of field service processes. The role of ICT in assisting the planning process of preventive equipment maintenance has been abundantly discussed in the literature, but the actual on-site maintenance execution and the value of information have escaped the attention of most researchers. This gap in research has been pointed out by a few authors [4][25]. Due to the scarce literature on ICT support for maintenance operation execution, we pose the following research problem: How can maintenance execution be helped with better information? This problem is approached by examining how the unavailability of information does affect maintenance execution performance, and what the most often required pieces of information are.

This study includes a literature part and a case study. In the literature part, we first examine the maintenance environment where breakdown maintenance policy and field service are distinguished as the most challenging environments in terms of managing equipment down-time. After that, we examine equipment down-time and uses of ICT systems in accordance with a framework for the components of defect rectification time that is built upon a model according to Knotts [21]. In the case study, we examine the service company network of a Finnish capital goods manufacturer. We use interviews, survey of service companies, and data analyses to examine the case in accordance with the framework developed in the literature part.

The study revealed that about 40% of the failed service visits are caused by the unavailability of information. In addition, almost a third of the service visit's duration is used to inquire for equipment details and to diagnose the problem. We conclude that better information would increase the service call success ratio and would cut down the duration of the on-site service operations.

Keywords: SCM & E-logistics; Case study in E-business.

I. Introduction

The benefits of information and communications technologies (ICT) in maintenance services are widely recognized. As early as in 1988 Ives and Vitale claimed that ICT could be a significant factor in leveraging investments in maintenance and in directing a company's overall approach to the maintenance issue. More recently, Agnihotri et al. [4] among others have pointed out the usefulness of ICT in maintenance. In the literature of ICT facilitated maintenance, the focus seems to be on the sophisticated maintenance solutions, such as condition-based maintenance [18][34], problem diagnosing tools [18][28] and life-cycle information acquisition [25][30][31]. While the value of these sophisticated systems must not be understated, we find it surprising that the information needs in performing the actual service operations are scarcely addressed in the literature. Marsh and Finch [25] have pointed out the same issue by claiming that there still are problems in providing the basic product information for the service personnel. We argue that this is a notable deficiency since the on-site operations are the most critical element in providing effective field-service. Whether the service call is triggered by the decreased condition of the equipment, a maintenance schedule or an equipment breakdown, it always comes down to fixing the problem on-site. Moreover, the on-site operations are the most visible element of field-services for the customers.

Based on a survey of field-service companies in an industry of electrical investment goods, we present effects that information availability has on field-service execution in terms of service call accomplishment ratio and on-site time usage. Our research problem is how maintenance execution can be helped with better information. The paper is structured as follows. In the first part, we discuss relevant maintenance literature addressing maintenance policies, equipment down-time and information needs in maintenance operations. In the second section, we give the research design of this study. The third part presents the results of the study, followed by discussion and further research suggestions.

II. Literature Review

First, we give background and motivation for studying and developing maintenance operations. We do this by analyzing maintenance policies and presenting the restrictions in their

applicability. In the second section we exhibit a framework for analyzing service operations in terms of process steps and the possibilities of influencing the steps with better information availability. In addition, reported ICT tools for maintenance operations are reviewed in light of the framework.

II. I Maintenance Environment

The primary objective of equipment maintenance is to preserve system functions in a cost-effective manner [34]. Under this general goal, different parties have their own objectives for maintenance and that is why maintenance performance should be measured from several viewpoints. Consequently, maintenance performance measures can be divided into three common categories [33]: equipment performance, cost performance, and process performance. From the equipment user's viewpoint, the most important goal of maintenance is to minimize the down-time of equipment. This is the equipment performance standpoint. For a manager of a maintenance organization, the interests are also in maintenance costs and efficient execution of the maintenance process. These represent cost performance and process performance standpoints. In this paper, the focus is on maintenance process performance since it delineates the maintenance execution performance. In addition, improving process performance typically enhances also cost performance and equipment performance and is therefore a very important measure for a field-service organization.

The objectives of maintenance can be pursued using different maintenance policies which all aim at reducing the equipment down-time. These policies can roughly be divided in corrective maintenance and preventive maintenance. In the former case, maintenance operations are carried out after an equipment failure has been identified, while in the latter group the goal of operations is to replace equipment or return it to good condition before failure occurs [15][34].

Preventive maintenance methods are further divided to scheduled maintenance methods and condition-based maintenance methods [36]. Scheduled maintenance is achieved when maintenance tasks are performed following a time or usage based schedule. Optimal schedules can be determined using quantitative decision models, but usually they are only drawn up on the supplier's recommendations on mean failure times [15][34].

Condition-based maintenance (CBM) is a more sophisticated type of preventive maintenance. The condition of the item is monitored continuously or intermittently to carry out preventive maintenance actions only when failure is judged to be imminent. Thus, replacing or servicing equipment prematurely can be avoided. Decision when the maintenance task is carried out is made based on the condition monitoring techniques, as vibration monitoring, process-parameter monitoring, thermography, and tribology [34].

However, despite that the preventive maintenance policies are designed to reduce the number of equipment

breakdowns and reduce the uncertainty of down-time by planning in advance, equipment breakdowns cannot be totally eliminated.

First, there are trade-offs between the costs of scheduled maintenance or condition monitoring and the costs of a breakdown. The aim of maintenance policy selection is to find the most cost-effective strategy [24][34]. When striving for optimal maintenance costs, different parts of a production facility most likely require different maintenance policies [36], thus potentially leaving some equipment to be serviced only in cases of breakdown.

Second, breakdowns cannot wholly be eliminated with preventive maintenance measures. Scheduled maintenance is often based on either measured or supplier specified equipment mean-time-between-failures, but in reality the failures take place at random times, and therefore breakdowns will at times happen between scheduled maintenance actions [27]. Also, with condition-based maintenance it is to be noted that no inspection or monitoring can be 100% effective, as the condition needs to be identified correctly, and the symptoms of a failure are not always noticed [13]. Further, the opportunity window between the emergence of abnormalities and consequent failure may be too short for the symptoms to be recorded in an inspection or monitoring process [27].

Third, the implementation of sophisticated maintenance strategies can be difficult in companies with established maintenance traditions. A study of four manufacturing firms in the UK indicated that in practice many advanced maintenance philosophies are not adopted fully in organizations, as the service technicians may remain unfamiliar with the concepts. As a result, planned maintenance activities give way to short-term needs of keeping the plant running, which results in firefighting activities and breakdown maintenance [12]. Thus, corrective maintenance in the form of breakdown repairs is not always a deliberate choice, but rather results from ignorance towards maintenance planning [16].

As we presented, equipment breakdowns cannot be totally eliminated. What makes this notion important is that down-time is especially problematic for equipment that relies on corrective maintenance or otherwise breaks down. First, such equipment easily experiences a longer down-time than equipment with preventive maintenance, which is demonstrated in the following section. Second, the resulting unplanned down-time of equipment is far more costly than planned stoppages due to loss of committed production, decrease in quality, and inefficient use of facilities, equipment and personnel [7]. Examples of down-time costs per hour have been quoted as 1.000 EUR in the energy industry to 13.000 EUR in the chemical industry [24]. Due to these reasons, reducing down-time for equipment breakdowns is especially important.

Before examining the components of down-time in detail, we present the concepts of field-based and facility-based maintenance that also have an impact on the down-time components. In field-based maintenance i.e. field-service, it

is the responsibility of the service provider to perform maintenance operations to the equipment located at a customer's site [4]. The opposite approach is facility-based service, where customers access the service facility [4]. In this study, we focus on one sub-category of field-service that is after-sales service support. Agnihothri et al. [4] point out that after-sales service support is the most problematic in terms of down-time. For companies engaged in after-sales service support, it is important that they manage both service response time, i.e. time it takes to access the service site, and on-site time, i.e. time it takes to carry out the on-site operations.

To summarize the main findings, it seems that in terms of maintenance policy, it is corrective maintenance that poses the greatest challenges for managing equipment down-time. In addition, the most challenging type of field-based maintenance, in terms of down-time, is after-sales service support. The case study presented in this paper comes from an environment where both of these challenges are realized, and therefore it provides a good research platform to study this phenomenon.

II.2 Equipment Down-Time and Uses of ICT Systems

According to Knotts [21], the time it takes to rectify a defect consists of four main phases: identification that a problem exists, gaining access to the equipment, diagnosing the problem and locating the cause, and taking necessary corrective action. Knotts argues that there are differences in the predictability for the durations of the different steps of defect rectification time. He explains that time covering access, defect rectification, and test and close up can be forecasted based on either experience or predictive techniques using time standards. On the contrary, the problem identification and fault diagnosing times are difficult to predict. Knotts argues that the unpredictability arises from non-standardized procedures and lack of time prediction techniques covering fault diagnosis and isolation. His presentation of down-time is especially useful, when evaluating the impact of different ICT systems on the maintenance execution process.

The context where Knotts applied his framework was that of facility-based maintenance [21], where it is possible to warehouse scores of spare-parts as back-up and have a variety of tools and documentation available at the service facility. This is not possible in field-based service, which makes it necessary to prepare in advance for the operations [8]. Consequently, we add an additional step "preparation" and a possible return loop that results from failure to deal with the defect (Figure 1). The importance of this addition is highlighted by statements that the probably most typical problem in field-service is not having the correct spare-part available on site [26]. For comparative purposes between maintenance policies, we also distinguish between three different initial stages for the defect rectifying process (Figure 1). Next, the information needs and utilization of ICT in different phases of the maintenance process is examined through a review of reported ICT systems. In

general, it seems that the ICT solutions in field-service have not been the focus research area of academics. Nevertheless there are reports of maintenance support systems used in various field-service organizations published mainly in non-academic trade journals. This literature review aims at enlightening the different kinds of maintenance support tools that are adopted in field-service, but it is not intended to be inclusive. Appendix 1 summarizes the example cases of ICT tools used in the field-service execution.

II.3 Problem Identification

The uncertainty for the duration of the first phase, problem identification, relates to the need of timely and correct information that the equipment is performing at an unacceptable level. For equipment run under breakdown maintenance policy, the problems are identified after the failure has occurred and the down-time timer has started ticking. This does not hold true in preventive maintenance where the problem identification is carried out using non-intrusive techniques while the equipment is operational or during planned stoppages, thus the time required for identification does not result in additional and unexpected downtime for the equipment.

The most typical ICT tools in the failure reporting and confirmation phases are condition monitoring tools. These facilitate automatic identification of the occurring and upcoming problems and thus reduce the uncertainty related to the prediction of the duration of these phases. The earliest case-reports come from the 1980's and the reported utilization cases of condition monitoring and CBM have become more frequent since. Today, condition-based maintenance encompasses several techniques and it is used in various industries including automobile manufacturing [3], power industry [2][23], aircraft engine maintenance [22], and ship engine maintenance [19]. There is some variation in the terminology of the CBM systems, for example term *Built-in-test-equipment* (BITE) is commonly used in the aircraft industry [20], but the operating principles are the same.

II.4 Preparation

The preparation step is critical for successful accomplishment of a service call, especially in field-based service. The objective of this phase is to ensure that the correct maintenance resources, the required documents and spare-parts, and the subject of maintenance operations i.e. the equipment will all be available during the service visit. Inadequate preparation may denote that the service technician is unable to rectify the defect, which leads to a failed service visit and a need for a follow-up visit, indicated as the return loop in Figure 1. In facility-based maintenance [4], the role of the preparation phase is less important, since the maintenance resources, documents, spare-parts, and subject of maintenance are all located in the service facility. If a service call cannot be accomplished in facility-based maintenance the servicing is postponed but there is no need for additional preparation and access gaining phases.

The effectiveness of the preparation phase depends strongly on the advance information available on the identity of the equipment and the type of failure. Identifying the

will the most likely be needed during the service visit [18], and thus reducing the number of return visits and increases field-service function’s efficiency. One example of

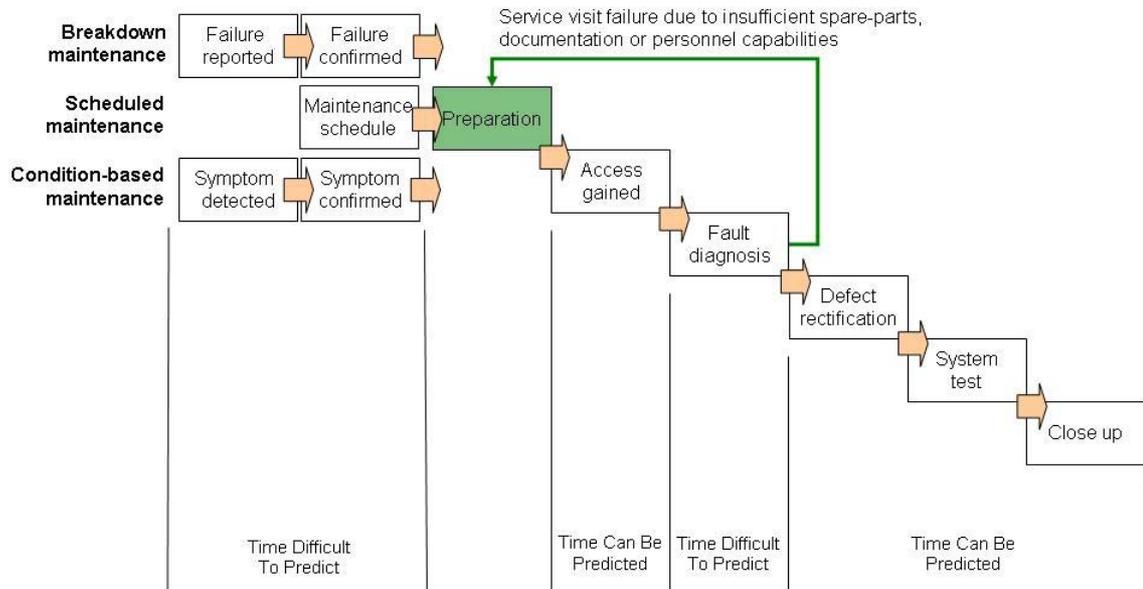

FIGURE 1 COMPONENTS OF DEFECT RECTIFICATION TIME (APPLIED FROM KNOTTS, 1999)

equipment based on e.g. its model or serial number allows the selection of the right kind of maintenance resources, spare-parts, and documentation for a service call. Advance information on the failure type may make this more efficient if the possible problem can be hypothesized.

The amount and quality of advance information varies among the maintenance policies. In breakdown maintenance the available information is most uncertain: the identity of the equipment and description of the failure rest on the expertise of the person reporting the failure. With scheduled maintenance, the service technician knows the identity of the equipment, but there is no information available on the equipment condition. However, in scheduled maintenance there typically are predefined periodic maintenance tasks that are to be carried out. For example, in case of elevator maintenance, the periodic maintenance tasks may include adjusting equipment, examining and repairing or replacing worn components, and lubricating parts and cleaning certain areas [9]. The periodic maintenance operations can be used to determine the necessary tools and the spare-parts most likely needed. In principle, the situation is best when using condition-based maintenance where the equipment identity and symptoms are known in advance and thus the failure type can be hypothesized.

Besides the condition-monitoring devices listed above, the ICT tools designed for the preparation phase assist in ensuring that the correct maintenance resources, the required documents and spare-parts, and the subject of maintenance operations will all be available during the service call. Xerox has been reported to use a system telling which spare-parts

preparation in facility-based maintenance is a system that determines spare-part needs for a damaged ship-engine, identifies the nearest repair facility, and guides the ship crew to prepare the engine for the repair [18]. Preparation can also be done for the follow-up service visit if such is needed. For example, Sears Roebuck & Co. is using a wireless support system to order a spare-part and schedule a second visit for the service technician to install the part [6]. This kind of system provides assistance when it is not possible to predict the spare-part needs before the service technician analyses the problem on-site.

II. 5 Gaining access

The next step in the defect rectification classification is gaining access to the equipment, which in field-based service is carried out so that the service technician moves to the equipment. In this phase, the service technician needs to know where, when and how the equipment should be accessed. In principle, the selected maintenance policy does not affect the access gaining phase. Instead, service response times are typically determined in maintenance contracts and service-level agreements (SLA) [35].

The ICT solutions available for the access gaining phase are related to routing the service resources. The most modest systems provide service technicians with information on available service calls [14]. In order to gain scale benefits, the systems can be used to route the field-service workforce more efficiently to complete more service calls a day. Several example cases can be found for using wireless field-service support systems for routing and service call

management [6][9][32]. The factors considered in assigning routes can be geographic proximity, technician workload, necessary skills, and customer relations [9]. One significant benefit of these systems is that the service technicians can acquire new job orders online, without returning to the workshop, which increases service responsiveness and efficiency. Because a routing system can take into account the skills of the workforce, they may also assist in correct preparation.

II. 6 Diagnosis

The fault diagnosis phase aims to identify the problem and determine the required corrective actions. It is an information intensive phase, where maintenance technicians traditionally rely on technical publications for information covering fault diagnosis procedures, configuration details, and functionality descriptions [21].

There are some reports on ICT tools used in the fault diagnosing & isolation phase, which aim at aiding the service technicians to locate the problem quickly and properly. Automatic failure diagnosing tools take symptoms and some other parameters as input information, and based on a knowledge base, suggest what the probable failure reason is [18]. In addition, there are tools to provide the service technicians with information that might help in their decision making [25][37]. The pieces of information that seem to be valuable in the fault diagnosing & isolation phase are service history for the serviced equipment, service call reports for similar cases, and schematics [6][25][37].

II. 7 Failure loop

The fault diagnosis phase continues with defect rectification step. However, it might turn out that – for a reason or another – the service technician is unable to rectify the defect and has to return with the proper utensils to access the equipment again (indicated as the return loop in Figure 1). This increases the need for accurate information for service personnel to ensure they have all the necessary documentation, tools and parts with them for the first time. It is especially critical in breakdown maintenance, where the down-time continues if the first service visit fails. In addition, an unaccomplished service visit decreases customer satisfaction, and a follow-up visit to the facility decreases operational efficiency of the maintenance personnel. It comes as no surprise that reducing the requirement for repeat or follow-up service calls has been commented to be one of the largest cost-saving opportunities for companies engaged in field-service [10].

II. 8 Rectification and reporting

The final steps are defect rectification, system testing and close up. These steps include adjusting, repairing or replacing equipment and ensuring that the resulting configuration is operating as it should. Finally, the required documentation, e.g. service report and invoice, is produced. [21]

The supporting ICT tools include means for accessing

technical documentation in electronic form and for generating service reports and invoices. The productivity improvements in defect rectification from having technical information available via a wireless computer compared to paper-based systems may be significant, since all the information can be accessible through one interface. In the case of SkyWest Airlines Inc. [29], this time saving was anticipated to be as much as 1,5 hours a day for one service technician. The role of accurate information in defect rectification is emphasized by the fact that there are reports on maintenance induced failures, where subsequent equipment failures have been pinned down to be caused by mistakes of service technicians due to lack of information on correct procedures and parts [13].

Finally, during the system testing and close up phases, the most important tasks for the service technician are to make sure the equipment is in order, and to invoice the customer. Automatic diagnosing systems and condition monitoring tools may help the service technician in the system testing phase, but there seems to be no case examples in that area. However, automatic test equipment have been reported to reduce test times by more than 60% in factory production environment [17], so evidence for increasing testing efficiency with ICT tools exists.

In field-service context, there exist reports on ICT tools for creating and managing service reports and invoices. Brown [10] and Albright [5] stress that by using wireless computers to create the service reports on-site it is possible to reduce the amount of paperwork and improve data accuracy. In addition, one significant benefit of making the invoice on the site is that the payment cycle starts immediately.

As a conclusion from the down-time examination, the down-time of equipment is likely to be the longest with breakdown maintenance, and the information for identification and rectification the scarcest. While condition-based maintenance is designed to inherently provide the best information to carry out maintenance operations effectively and efficiently, there is no reason why information availability should not be secured for less sophisticated maintenance approaches, especially as shown, it is not possible to completely avoid breakdowns.

Summarizing the ICT review, there clearly seems to be indications that ICT can provide great assistance to the different phases of field-service execution. The exemplary ICT use cases are summarized in Appendix 1. Unfortunately, it seems that the support that ICT might give to the effectiveness of field-service operations has been scarcely studied [4]. Especially the magnitudes of the impact or the types of information making the impact have not been evaluated. Understanding the potential implications and sources of impact is especially important in the evaluation of the feasibility of different ICT systems, and therefore we address this as a notable gap in the literature.

III. Research design

Despite the reported ICT solutions, the implications of information availability in maintenance have not been addressed in such a level that it would be possible to assess the benefits of implementing ICT solutions. Therefore we pose the following research problem: How can maintenance execution be helped with better information? To approach this problem, we seek for answers for the following research questions:

How does the unavailability of information in field-service affect maintenance execution performance?

What are the most critical pieces of information required in different process phases?

The purpose of the first research question is to determine how big performance efficiency losses the unavailability or incorrectness of information may incur. The efficiency losses will be quantified in terms of service call accomplishment ratio and service visit time usage. With service call accomplishment ratio we mean the share of service calls that are accomplished during the first service visits. The second research question seeks to define the unavailability of which particular pieces of information is causing the problems. That way it is possible to give recommendations on how the information availability could be improved.

As was discussed before, breakdown maintenances and field-based maintenance service form a challenging environment where the requirements for information to manage and reduce down-time are high. On the other hand, such an environment provides a good research platform to study how maintenance execution can be helped with better information, and thus our study was conducted with a manufacturer whose service company network is operating in such a challenging environment.

The focal case company of the study is a capital goods manufacturer. Its customer base includes hundreds of companies of various sizes who utilize the case company's products in their own operations. In practice, the equipment manufactured by the case company are located in customer sites scattered to various locations.

IV. Research Methods

The study included interviews, a survey, and database analyses. The case setting was first studied in detail with initial interviews including 14 interviewees at the focal company, 3 interviews with service companies, and 2 interviews with customers of the focal company. Most of the interviews were performed with two researchers to guard for interviewer bias by allowing comparisons of interview notes and perceptions. After agreeing on all interview items, the interview memorandums were stored in a case study database for easy later access.

To answer the research questions, we performed an industry-wide survey of maintenance companies. The initial interviews with representatives from the manufacturer, maintenance companies, and customer organizations were used as input while designing the survey questionnaire. The

survey was targeted to the service company network of the focal capital goods manufacturer including 56 service companies with a geographical coverage of the entire Finland.

The questionnaire used in the survey consisted of open-ended questions and multiple choice questions which were used to collect both qualitative and quantitative data. The questionnaire had two main parts. The first part concentrated on the service operations and the implications of poor availability of information. The second part aimed to solve what information would be needed for better operations. Before launching the survey, the questionnaire was tested with three service companies whose feedback was used to reform the questionnaire. Each company was contacted by phone beforehand and the questionnaire was delivered by mail, e-mail, or fax, based on each the respondent's preference. All non-respondents were contacted again after the initial deadline for returning the questionnaire. The response rate turned up to be 55% with 31 responses, and the respondents were mainly service managers and company owners.

The respondent companies diverge, to some extent, in terms of their scope of servicing activities and the company specialization. The respondents are mostly small companies with only a few service technicians; 75% of them have from one to three service technicians, while the largest respondent has from 50 to 80 service technicians. Respectively, the number of service calls the companies are managing per week is quite modest: 64% of the companies have ten or less service calls per week and the median number of service calls is eight. 14% of the respondents have over twenty service calls per week. In addition to the differences in the scope of the servicing activities, some of the respondents seemed to be focusing on other lines of businesses than field-service of the focal type of capital goods. Based on the survey, servicing is an important of very important line of business only for 71% of the respondents. Some of the remaining 29% respondents informed that they were mainly involved with the installation works of the capital goods.

After the survey was carried out, the results were validated in discussions with experts from the manufacturing company, and compared with warranty invoicing data from the equipment manufacturer where applicable. All the service invoices and reports from a five-month period in 2004 were analyzed, including 83 invoices from 23 service companies.

V. Results

V.1 Introduction to the Case Company

The equipment manufactured by the case company can be divided into two categories which in this study are called small-scale and large-scale products. The large-scale products are fixed equipment which are fitted to a particular site and have a large capacity. On the contrary, the small-scale products have a smaller capacity but they are not fixed and thus can be transferred to another site if required. In addition, the large-scale products can be equipped with

electronic controller systems that enable remote diagnostics and condition-based maintenance functionalities.

Based on the initial interviews, it was identified that the most used maintenance method in the examined line of business is breakdown maintenance, i.e. the customer site personnel order a service after the equipment is not working properly. Therefore, the context of this case setting enabled us to examine the effects of the unavailability of information in an environment where the maintenance execution is highly time-critical. In some individual situations, there is a maintenance agreement between the customer and a service company, where condition-based maintenance or scheduled maintenance is practiced, but this is more uncommon.

Next, the typical maintenance process in context of the case is examined following the components of defect rectification time.

V. 2 Problem Identification Phase

According to the interviews, the defect reporting and confirmation phase is carried out following one of the three possibilities in Figure 1. The most common means is breakdown maintenance, where plant personnel observes that the equipment is not working properly. After that, a service is ordered either by contacting the equipment manufacturer or by contacting a service company. In some cases, a customer plant and a service company have signed a service contract which obliges the service company to regularly, e.g. once a year, service the plant equipment. This is scheduled maintenance, but it is rather rare in the examined industry. The third possibility is condition-based maintenance, where automatic condition monitoring devices set off an alarm that notifies the plant personnel of improper operation. In addition, the service companies have the prospect to take a remote connection to the plant's condition monitoring system in order to gain run-time information of the equipment in the plant. This is, of course, possible only if both the plant equipment are connected to the remote monitoring system and the service company has the required terminal equipment.

In the interviews, the service technicians commented that by using the remote condition monitoring system, the upcoming problems may be recognized before the breakdown occurs. Therefore, in the examined case, it seems that information on the condition of the equipment i.e. pressure and temperature readings provides great assistance to the problem identification phase. The survey was used to determine how often this information is available. Based on the answers, 41% of the service companies have access to remote monitoring information. For two companies, this information is available for over 70% of the equipment serviced, and for the rest of the companies gaining this information, it is available from 4% to 25% of the equipment serviced. As a result, despite the value of remote monitoring information, it seems to be available not too often. In addition, for the equipment not under condition monitoring, the unavailability of information on the failure leads to longer downtimes by increasing the problem

identification time. Nevertheless, the defect identification time is not included in scope of the study, as data on the duration of this phase should be interrogated from site owners that could not be included in the study.

V. 3 Preparation Phase

The second step in the defect rectification process is preparation. According to the interviewees, this means that the service technicians load the necessary spare-parts and documents to the service vehicle when leaving from the workshop. As was discussed before, this is a highly information critical phase where gaining advance information on the identity of the equipment and the type of failure are important for effective and efficient preparation. However, based on the survey, there seems to be inadequate data available in this phase. By using the survey, we determined what advance information the service technicians currently have for preparation.

In addition to remote monitoring information, one information source is the customer who orders the service. In the survey, we enquired how often different pieces of information are gained from this source. We found out that information on the type of the product, i.e. whether it is a small-scale or a large-scale product, is acquired the most often, in 66% of the service orders. Description of the failure is gained in 51%, and equipment's manufacturer in 44% of the service orders. Other information pieces are gained much less frequently. Information on the equipment's service history, previously installed spare-parts, and model are gained in about every fifth service order, and equipment's serial number is gained less than in every tenth service order.

The third information source in the preparation phase is the service companies' own records. In the survey, 71% of the companies responded to hold paper records and 11% responded to hold electronic records on equipment locations. Especially the companies that have installed 40% or more of the equipment serviced were all holding records on equipment locations. In principle, these records could be used to identify the piece of equipment to be serviced and thus help in effective preparation, but the research material gave no indication of this. The companies holding records on item locations were not showing better performance than the companies not holding records.

As a result, identification of the equipment to be serviced can take place based on remote monitoring information, customer information, or companies' own records. However, it seems that not one of these means can provide comprehensive information in all situations, or even used together, identity of the product serviced remains a mystery in the preparation phase. In addition, only remote monitoring can provide the technicians with accurate advance information on the condition of the equipment, but this information is gained quite seldom. The implications of improper preparation can be detected in the later steps of the maintenance process.

V. 4 Access Gaining Phase

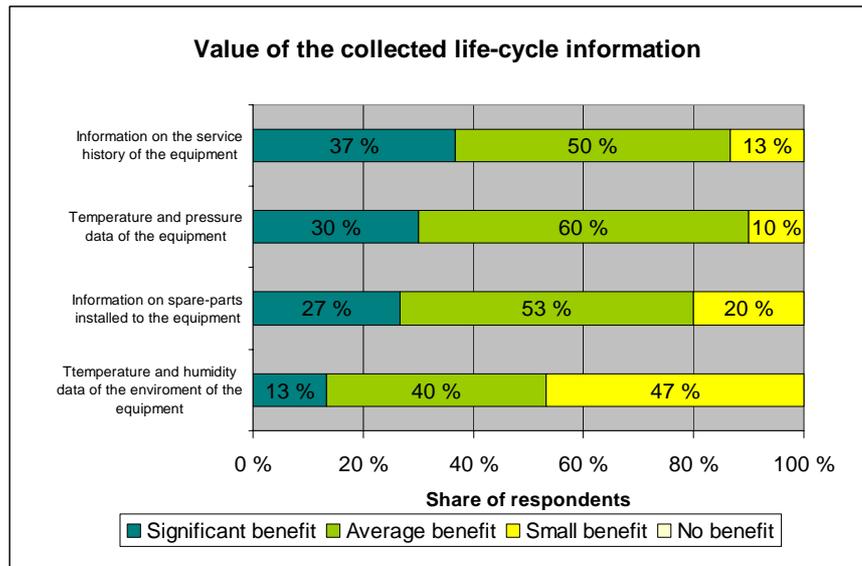

FIGURE 2 THE VALUE OF INFORMATION IN SERVICING OPERATIONS

The third component of the defect rectification process is gaining access to the equipment. In practice, this means that when the maintenance resources are available, a service technician drives to the customer site with his service vehicle and locates the equipment to be serviced. In the examined field-service organizations, this time depends on the service level that the companies are offering and it is agreed upon in the service contract. The response time is regulated also by the service pricing so that the service visits that are carried out during nights and weekends are more expensive than the ones during the office hours. Since the duration of gaining access is controlled by contractual issues, it is not relevant to examine in this context the effects of unavailability of information to the performance of gaining access to the equipment.

V. 5 Diagnosing Phase

After arriving at the customer plant, the service technician seeks to isolate and diagnose the fault. This is an information intensive phase and in addition to doing the diagnosing activities, the service technicians need also to acquire information to support the problem diagnosing. The duration of this phase was determined in the survey by inquiring the average on-site duration of a service visit and the share of on-site time used to problem diagnosing activities, problem fixing activities and inquiring for information. Based on the answers, the average duration of the diagnosing phase is 45 minutes, corresponding to 36% of the average total service visit duration. On average 14 minutes (11% of the total service visit duration) of this time is used for acquiring additional information. The standard deviation for the duration of the diagnosing phase is 27 minutes.

In practice, there are several sources from where to look for information. First of all, there are three possible information

sources on-site. Some pieces of product information can be found from the product itself e.g. information on the type of lubricant is attached to every new product manufactured. In addition, some documents such as electric diagrams are delivered with the product to the site of usage. The problem with these documents is, as the service technicians pointed out in the interviews, that they are seldom found from the plant when needed. The third source of on-site information is the paper documents stored in the service vehicle. However, due to the large number of different products serviced, it is not possible to carry all the required documentation in paper format. Due to these issues, service technicians need to inquire for information from outside the service site. Based on the survey, we determined that the service technicians most typically contact their own office, if information is missing. Most often used medium for transferring information is telephone, but also fax and e-mail are used for transferring technical drawings. However, the service technicians contact the focal manufacturing company on average 0.7 times a month to inquire for information. In total, this encumbers the case company’s technical support staff with hundreds of technical inquiries a month that are due to the poor availability of information.

In addition to having technical documents available in problem diagnosing, the literature review revealed that service technicians may benefit from collected life-cycle information. Therefore, the value this information was examined in the survey with a multiple choice question. The service companies were to estimate how beneficial the given pieces of information are. This question included all the pieces of lifecycle information on the devices and their value was estimated in a scale of significant benefit, average benefit, small benefit, and no benefit. The results of this question are presented in Figure 2. The most valuable piece

of life-cycle information seems to be the equipment service history. It was responded to bring significant benefit by 37% and average benefit by 50% of the service companies. About as valuable piece of information seems to be equipment's temperature and pressure data, which was responded to bring significant benefit by 30% and average benefit by 60% of the companies. It was evaluated as a small benefit only by 10% of the respondents. Information on spareparts installed to the equipment was estimated to bring significant benefit by 27% of the respondents. Temperature and humidity data of the environment of the equipment was the least valuable of the given information pieces, almost half of the companies responded that it brings only small benefit to servicing operations. In general, the collected lifecycle information seems to be at least somewhat valuable to all the service companies, as no one answered that some piece of information would not be beneficial at all.

In the survey, the means to improve the fault diagnosing were inquired with an open-ended question. Subjects of improvement for failure diagnosing included information, technology, and training related issues. Information related development needs were dominant and comprised of better availability of existing documentation and needs for currently non-existing documents as trouble shooting diagrams and typical failure documents. Technology related improvement suggestions were automated failure diagnostics tools and remote monitoring devices, which already are in use to some extend. In addition, training held by experienced service technicians was mentioned as a way to improve fault diagnosing. Based on these answers, it seems that better availability of information would indeed improve the fault diagnosing phase. Currently, the service technicians have to work with incomplete information on the serviced equipment, which reduces their efficiency to locate quickly and reliably the problem at hand.

V. 6 Return loop

If the defect cannot be rectified during the service visit, the process returns back to the preparation step which is indicated as the return loop in Figure 1. The problems related to a failed return visit were discussed before, and next we dig deeper into the reasons behind the failing service visits in this case in order to be able to quantify the problems caused by poor availability of information.

An overview of the average situation for a service company in a month is given in Figure 3. Based on the survey answers, the average service call accomplishment ratio for the service companies is 79% (Figure 3: Accomplishment ratio). That means, on average 21% of the service visits go to the return loop. Only for 17% of the respondents the accomplishment ratio was 70% or less, so based on this measure, the maintenance performance of the service companies is somewhat uniform. To assess the reliability of this result, the service call accomplishment ratio was determined based on the warranty service invoice data as well. The survey result received modest support, as the average accomplishment ratio for the services made

under warranty was 75%.

From customer perspective, the down-time continues in breakdown maintenance until the service technician returns for a follow-up service visit to rectify the defect. The time customers have to wait for the follow-up service visit was determined based on the warranty service invoice data. On average, it takes three days for a follow-up visit but the spread is quite large. For 19% of the cases it takes longer than a week and 19% of the follow-up visits can be accomplished during the same day. Therefore, for a customer a failed service visits means several days more of unplanned downtime that cannot be from affecting the customer's perception on the reliability of the manufacturer's products.

To find out why some service visits fail, the failure reasons and their significances (Figure 3: Failure reason) were inquired in the survey. The respondents had to estimate weights for the given failure reasons: lack of spare-parts, lack of documents or information, and lack of tools. In addition, the respondents could fill in other failure reasons and their weights as well. It turned out that the main failure reason is the lack of spare-parts, which causes two thirds of failed service visits. Lack of information or documents is the reason behind 14% of the failed service visits while the lack of tools is the reason in only 3% of the cases. The last 16% is caused by other reasons, which were mainly customer-related and service process-related reasons, such as the customer's contact person being unavailable at the time of visit.

There are several reasons why the service technicians may be lacking of the needed spare-parts while on-site (Figure 3: Spare-part problem reasons). Therefore, the survey was used to determine what the relevant reasons in this particular case are. As a result, the two main reasons for missing spare-parts are that it is not known which parts should be taken with when leaving for service site, and that the spare-part is not stored and it must be ordered. These both account for 35% of the cases when a spare-part is missing. The next significant reasons are that the spare-part is temporary lacking from the service vehicle, and that the spare-part is out of stock. Other reasons account for the remaining 2%.

The service technicians have a need for a great deal of information when carrying out the on-site operations. In the examined case, the information is not always available due to the characteristics typical of most field-service organizations: paper-based documentation is poorly portable, and the amount of documentation is very large [25]. Based on the survey answers, the lack of information is the reason behind 14% of the failed service visits. In order to better understand this failure reason, the respondents were asked to specify the missing of which particular document or piece of information typically prevents from completing a service call. The answers to this open-ended question and their frequencies are presented in Table 1.

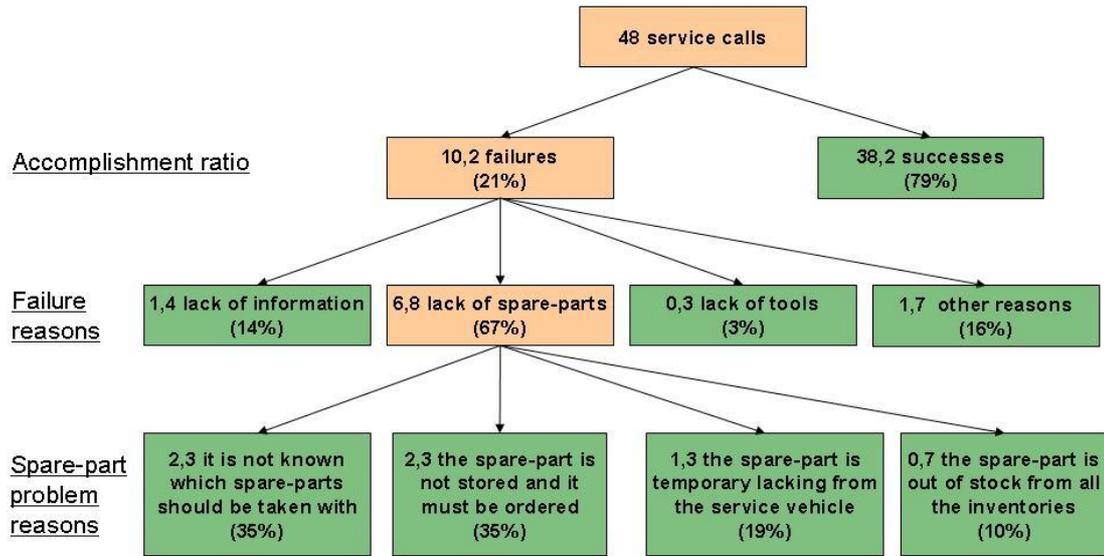

FIGURE 3 SERVICE COMPANIES' AVERAGE SITUATION IN ONE MONTH PERIOD

Table 1 Typically missing documents or information

Document or piece of information	Mentioned in the survey
Electric diagram	11
Electronic controller's instructions or settings	4
Adjuster's instructions or settings	3
Control settings or parameters	1
Instructions	2
Equipment's special parts	1
Type of lubricant	1
Electrotechnical information	1
Equipment's power	1
Inadequate failure description by the customer	1
Information on is it allowed to maintain the equipment and who will pay for it	1
Inadequate equipment's operating report	1
False information from the customer	1
Total	29

The most typically missing document is electric diagram which was mentioned by 11 of the total 24 respondents to this question. Although this document is delivered to the plant with the equipment, the electricians often lose it during the installation works and therefore it is missing when needed. Other typically missing documents are instructions or settings for the electronic controllers and adjusters. Information on equipment's special parts, type of lubricant, electrotechnical attributes, and equipment's power were all mentioned once as typically missing pieces of technical information. Inadequate failure description by the customer, equipment's operating report, false information from the

customer, and missing of information on typical failures were mentioned as other causes for failed service visits.

One important factor that causes the unavailability of information seems to be the observation that the current availability of documents and information is inadequate for the service companies. Service companies' preferences for the locations where different pieces of information should be available were inquired in the survey. When these results are compared to the current availability of documents, some rather large discrepancies in information's current availability and the wanted availability can be recognized. For the most typically missing document, electric diagram, 80% of the respondents wanted it to be physically attached to the equipment. For the settings and service instructions for electronic adjusters, the second typically missing document, 63% of the respondents wanted it to be available in the service instructions located at the customer plant. In addition, almost half of the respondents wished that at least one of the document types would be available in the Internet. The manufacturer is currently not satisfying these needs and therefore the service companies are facing problems in the information availability.

The observations from the return loop indicate that several of the current failure reasons are related to the unavailability of information. In fact, the study revealed that about 40% of the failed service visits are either directly or indirectly caused by the unavailability of information. Missing document or piece of information is the reason behind 14% of the failed service visits. With better availability of information on the service site, these failures could be eliminated. The single most important reason for a service call failure is insufficient advance information on the spare-parts that will be needed during the service visit. This means the service technicians do not know which spare-parts

should be taken to the service site, and it is the reason behind 24% of the failed service visits. If the service technicians would have advance information on the model of the equipment and possibly on the failure type, they could be better prepared with the proper spare-parts when arriving for the service site for the first time. Having all the possible spare-parts in the service vehicle is not achievable due to the large variety of spares and due to the large size the most often missing component. Therefore, the solution would be advance information that would allow more accurate preparation for the service calls. That way, the service technicians would also be able to prepare themselves with the required tools, the lack of which is currently the reason behind 3% of the failed service visits. These improvements in information availability would ultimately allow the service companies to accomplish 40% of the currently failing service calls, and thus increase the accomplishment ratio from the current 79% to around 87%.

V. 7 Defect Rectification

After a successful failure analysis, the service technician can rectify the defect. According to the service technicians, this can involve cleaning, adjusting, repairing, or component changing activities. According to the survey, this phase takes on average 1 hour 19 minutes corresponding to 64% of the service visit duration. The service technicians commented that the duration of this phase varies a lot, and consequently the results showed rather big variance with a range of 27 minutes to 240 minutes and a standard deviation of 42 minutes.

The defect rectification step can be argued to be the most important phase of the whole defect rectification process. The information needs during the rectification consist of product documentation on product structure, such as diagrams, and settings. The availability of these documents and consequences of non-availability have been included in the above sections addressing diagnosis and the reasons for failed service calls, while the defect rectification phase was measured to identify the share of time used to the corrective work with the equipment.

V. 8 Testing and close-up

The final phase in the defect rectification process is testing and close-up. In the interviews, the service technicians commented that testing is carried out only briefly. In most of the cases this is sufficient, but sometimes the failure recurs quickly because the actual defect was not rectified. Close-up of a service call means creation of a service report and an invoice. There is no standard format for a service report, and typically a service report means information on the invoice items of a service call: number of billed hours, traveling expenses, and cost of spare-parts. However, customers can require more detailed reporting. The manufacturer requires more information for identifying the service product and description of the type of failure in order to pay the warranty service invoice. However, as Christer and Whitelaw [11] argue, there would be more valuable information available

that is not currently reported. The service technician could report his professional view on the cause of fault, consequences of fault, and means of prevention [11]. This information could be used in prevention of the future breakdowns.

The time it takes to create a service report and an invoice is rather short. However, the time it takes to handle the paperwork is longer. In order to study the duration of the reporting phase, we examined how long it takes for the service companies to invoice their customers. In the survey, we inquired the average duration for invoicing the customer after a service visit. The average result for the respondents is 7 days with a range from 1 to 20 days. This result is compared with the invoicing data. From the warranty service invoices, we could determine how many days it has taken from completion of the service call to the creation of the invoice. According to this data, the average duration for invoicing has been much longer – 17 days – and for 12% of the invoices the duration is 30 days or more. Therefore, it seems that the survey results do not reliably represent the actual operations of the service companies in terms of reporting duration. In addition, this indicates that there are inefficiencies in the close-up reporting process that can affect the value of data gathered.

V. 9 Discussion of the results

To provide answer for the first research question, we examined the maintenance execution process of the case in the light of the framework for defect rectification process (Figure 1). Based on our findings, there are several ways how the unavailability of information in field-service affects maintenance execution performance. In terms of maintenance efficiency, the most significant implication is that due to the unavailability of information in the preparation phase, the current service call accomplishment ratio is below 80%. We argue that with better information in the preparation and fault diagnosing phases, the service companies could accomplish up to 40% of the currently failing service calls, and thus increase the accomplishment ratio to around 87%. We emphasize that this improvement can be attained just with better preparation and better availability of information – without affecting the service companies' current spare-part ordering and inventory holding practices.

The second important implication of the unavailability of information is that valuable onsite time has to be spent to acquire information from several sources. Currently 36% of onsite time is spent with problem diagnosing and searching for information. We conclude that the information unavailability in this case was caused by nonconformity of means requested and provided. Better data could help to reduce the problem diagnosing time, and better availability of information could help to reduce the information acquiring time. Therefore, proper tools to access or other arrangements to make relevant information available could cut down the duration of the on-site service operations.

The objective of the second research question was to

find out what are the most critical pieces of information required in the different process phases. We argue that the biggest benefits could come from increasing the effectiveness of the preparation phase. That could be done with information on the identity or type of the equipment to be serviced. If the service technicians knew which equipment they will service, they could prepare better in terms of spare-parts, documents and tools. That would improve effectiveness of preparation. In addition, advance information on the type of the failure would make the preparation more efficient. To improve the on-site operations, product documentation should be better available. In this case, especially electric diagrams and settings for adjusters and controllers are typically missing documents. Based on the results, the problem diagnosing activities could be made more efficient with life-cycle information such as service history and temperature and pressure data for the equipment.

The examined ICT-solutions in the literature part give indication on the means how information could be made better available. For the preparation phase, a system that takes product type and symptoms of the failure as input and propose the likely needed spare-parts would provide considerable assistance, corresponding to case Xerox [18]. To improve the availability of information in the on-site phases, it seems that portable computers could be the solution to ensure the availability of comprehensive product documentation. In addition, there is evidence that portable computers can help also in the reporting phase, where the service companies are currently facing long lead times in invoicing.

Our findings concerning the predictability of duration for the different phases of the defect rectification framework are somewhat contradictory to Knotts's statements. Knotts argues that the duration of problem diagnosing phase is difficult to predict, but the duration of defect rectification phase can be predicted [21]. However, our research material showed the opposite since the standard deviation for the duration of the diagnosing phase is 27 minutes but for the defect rectification phase it is 42 minutes. Greater deviation makes it harder to predict the duration of the defect rectification phase. We contend that the main reason for this poor predictability is the variance in rectification times for different failure types. For example, some service technicians commented that replacement of certain components is exceptionally time-consuming since it requires breaking down the whole equipment.

On the validity of the findings, the set-up of the study with service companies separate from the manufacturer is one factor that reduces the quality of information available to the service providers. Nevertheless, our discussions with representatives from investment goods manufacturers with own service organizations indicate that the results are not far from their experiences. The use of several sets of research material enables assessment of the reliability of the results. For the service call accomplishment ratio and invoicing lead time, the survey results gave a better image of the service

companies' performance than the warranty invoicing data did. This indicates that the service companies may have answered overly optimistically, and it means that the potential of improvement may be even higher than the results point out.

.VI Conclusions

When selecting ICT tools for maintenance operations, it is important to understand which phases in the service process currently lack information and what the potential impact of better information could be. We have 1) demonstrated the magnitude of impact on process performance that unavailable information may have in the context of one case and 2) developed the framework presented by Knotts [21] further to enable analyzing the information needs in and impacts on distinct process phases. Based on our findings, the single most important means to improve the defect rectification process performance can be to provide better information for the preparation phase, which can yield considerable benefits in terms of improved service call accomplishment ratio.

The total improvement potential of better information is considerable especially from the customer viewpoint, as it would be possible to significantly reduce the equipment downtime that the customers are experiencing. Especially, making sure the equipment can be put into condition during the first service visit has a huge effect on the service level experienced by a customer, since she does not have to wait for the second service visit.

The realization of the improvement potential by means of ICT is in the interest of the manufacturer as well, since it ensures more reliable customer service that can increase both customer satisfaction and the company's brand image. From the service company viewpoint, better information would increase operational efficiency of the defect rectification process, which can turn into more business.

Our study proved that the lack of very basic information, here electric diagrams, may be a major reason for service delays, not necessarily the lack of sophisticated tools. Therefore, when selecting ICT tools for maintenance operations, it is important to understand the service technicians' real information needs and fulfill them.

Component of defect rectification framework (Applied from Knotts, 1999)	Example case	System description	Author
Symptom/failure/defect reported and confirmed	Palomar Technology International Inc.	Condition-based maintenance system. The maintenance engineer enters temperature and pressure readings from gauges associated with the equipment and vibration information gathered with a magnetic probe. Data is compared with historical data stored in the computer and the system identifies required repairs.	Ives and Vitale, 1988
	Light aircraft manufacturer	A condition-based maintenance system used to monitor the condition of the aircraft engine	Ives and Vitale, 1988
	Otis Elevator Inc.	A self diagnostics control systems that inform the company when maintenance is required.	Ives and Vitale, 1988
Preparation	Xerox	The customer support service system tells the maintenance personnel which spare parts will most likely be needed.	Ives and Vitale, 1988
	A ship engine manufacturer	Diagnostics tool to determine product service and spare-part needs after the failure has occurred. Data about the damaged engine and ship location are transmitted to the manufacturer's headquarters, where the nearest repair facility is identified, and replacement engine or spare-parts are dispatched. The system also guides the ship's crew to prepare the engine for subsequent repair.	Ives and Vitale, 1988
	Sears Roebuck & Co.	The field service personnel can check spare-part availability and place orders using wireless computers. The back-end system schedules a second visit for the service technician to install the part. Previously the technicians had to call the headquarters for availability information and to order the spare-parts. The system has yielded 70% decrease in the back-office support.	Albright, 2000
	An electronic products manufacturer	A centralized diagnosis support system that is used by the call center employees. It advises customers to make small repairs themselves and dispatches a service technician for complex cases.	Pintelon et al., 1999
	Access gained	Maytag Corp.	A mobile computer system provides repair workers with updates on the available service calls. The service vehicles can be tracked via the GPS. Since the rollout, the average number of service calls completed by the service persons has increased.
Schindler Elevator Corp.		A routing system to assign routes for field service workforce that carries out periodic maintenance operations, breakdown maintenance operations and emergency services. Optimal routes are found by minimizing operational costs while taking into account geographic proximity, technician workload, necessary skills and customer relations.	Blakeley et al., 2003
Sears Roebuck & Co.		Wireless computers are used to route the field-service personnel. The back-end system forecasts the proper number of technicians needed to serve each day's route and matches each technician's skill set with the jobs on the route.	Albright, 2000
Southern Co.		Field service personnel get work orders and mapping information to their laptop computers using a wireless connection. Back-end systems take care of routing by taking into account the available workforce, materials and equipment. Imbedded GPS tracks the location of the service call and the crew, which is captured and mapped.	Townsend, 2004
Fault diagnosed & isolated	Honeywell Inc.	Portable diagnostic tool to help the service technicians locate the problem	Ives and Vitale, 1988
	Worthy Down Centre	Provide product information and maintenance history by means of 2D bar-coding. Benefits: faster data entry, improved decision making when carrying out the servicing activities, and reliable identification of serviced equipment.	March and Finch, 1998
	Sears Roebuck & Co.	The company's field service technicians are using wireless computers with the following applications: diagnostic tools, schematics and training materials.	Albright, 2000
	A capital goods company	The company is collecting service call reports to a centralized database. This database serves as a resource for unusual, or first-time, repairs	Zackariasson and Wilson, 2004
Defect rectified	SourceOne Healthcare Technologies	A wireless field service support system to provide to technicians with equipment and site history, parts and customer information, automatic time sheets, e-mail messaging, and inventory management functions.	Anonymous, Wireless News 2004

Abstract: The performance of supply chain is an important factor for the success of a company since it greatly affects the ability to provide customer value. Therefore, it is very important for a company to develop independent criteria to evaluate the performance, compare with competitors, and monitor the operation of a company. In the past, many companies tried to develop criteria for measuring their performance of supply chain. However, suitable criteria are hard to develop since the supply chain is generally very complex. The purpose of this study is to develop criteria to measure the performance of supply chain by using the Supply Chain Operations Reference Model (SCOR), which was shown by several previous studies to be an effective tool to develop criteria for measuring performance in diverse industries. To investigate the effectiveness of SCOR, we use the process reference model in SCOR to analyze the current state of a famous garment company's processes and its goals, and quantify the operational performance. Results from this study show that SCOR is a very effective tool to develop performance metrics of the supply chain. Through the use of SCOR, a company can clearly define key performance indices (KPI) to improve their performance.

Keywords: SCOR; Supply Chain Performance; Garment

I. Introduction

There are several obstacles when developing an evaluation system of the supply chain performance (CSC, 2004). First, the evaluation is very hard to execute. Second, functions and processes are usually very complex and lack consistency across a supply chain. Third, supply chain members who have been evaluated are usually not willing to provide true information. Fourth, definitions of evaluated items are different for different supply chain members. In addition, the communications between supply chain partners are usually time-consuming and with low efficiency. Hence, there is a requirement for well-defined metrics and a common language for evaluating the supply chain performance.

Hammer and Champy (2004) stated that we should employ a macroscopic perspective to view a supply chain. The optimization of each member of a supply chain is not

the optimization of the whole supply chain. The main purpose of the supply chain management is integration of these activities through improved supply chain relationships to achieve a global optimization and sustain competitive advantages. Formerly, a company only has to consider their own performance within an organization and focus on processes in their department. However, in recent years, the industry has developed a number of strategies to allow supply chain partners to replace sequential planning, or sequential optimization, with global optimization (Simchi et al., 2003). In sequential planning, each member optimizes its own profit with almost no regards to how its decisions impact other supply chain partners. By contrast, the goal of global optimization is to find what the best for the entire supply chain is.

As we know, companies need a standard model to establish their own metrics of performance, analyze the values of indicators, and improve their supply chain efficiency. Moreover, a common language can improve the communications between the members of the entire supply chain. Recently, the SCOR model (SCC, 2005) is emerging as a powerful and potential tool to analyze a supply chain. It uses a process reference model that can analyze the current state of a company's process and its goals, evaluate operational performance, and compare it with benchmark data. To measure the performance of supply chain, SCOR has developed a set of metrics in five perspectives, including reliability, responsiveness, flexibility, cost, and, assets, which were successfully applied to many industries, such as car, electronics, and so on. In this study, we will also use the SCOR to develop the criteria for the performance of supply chain.

The remainder of this paper is organized as follows. Section 2 gives a brief overview of the structure for measuring the performance of supply chain based on SCOR. The case study is described in Section 3. Finally, conclusions are presented by summarizing the findings in Section 4.

II. Procedure for Measuring Supply Chain Performance

The procedure for measuring the performance of supply chain is shown in Fig. 1.

Fig. 1 The Steps of supply chain performance analysis

The first step is to choose performance metrics. There are five perspectives of metrics in SCOR: reliability, responsiveness, flexibility, cost, and assets. After choosing the metrics, the metrics are defined. Interviews on top managers are performed to ensure that the definitions of the metrics are the same for members within the supply chain. Comparison is made by benchmark data in the third step to find the gap rate. Finally, results are obtained by checking the gap rates and used to improve the performance. The details are mentioned as follows.

1) Choose Performance Metric

There are five perspectives in SCOR and in each perspective a SCOR card can be established. Table 1 illustrates the SCOR card. In the third column, the metric is categorized according to the type of the activity. For example, M1 stands for make-to-stock, M2 represents make-to-order, and so on. The actual and target values are shown in the fourth and the fifth columns, respectively. The gap, i.e., the difference between the actual value and the target value, is shown in the sixth column. Finally, the gap rate is calculated in the last column.

Table 1 SCOR card

SCOR card - (Type Name)						
Metric	Metric Definition	SCOR Categories	Actual	Target	Gap	Gap Rate
...
...

2) Define Performance Metric

A key point for a successful SCOR card is clear definitions of metrics. Therefore, each metric is clearly defined in the second column to avoid confusion between supply chain members. Only an appropriate definition is given is the information helpful. Interviews with managers in the supply chain must be performed to ensure a suitable definition is described.

3) Benchmarking

Most organizations tailor definitions of benchmarking to suit their own strategies and objectives (Shoshanah and Joseph, 2005). In practice, benchmarking usually includes

regularly comparing perspectives of performance (functions or processes) with best practitioners, recognizing gaps in performance, seeking new approaches to bring about improvements in performance, following through with implementing improvements, and following up by monitoring progress and reviewing the benefits. Benchmarking is both internal and external that can give valuable data for improving supply chain performance and has two main benefits (<http://www.benchmarking.gov.uk>, 2005). First, external comparisons place your performance in an industry circumstance, which helps to identify supply chain improvement opportunities. And second, regions, or locations are the best performers. Then you can identify the underlying practices that make the difference and implement those practices across the company.

4) Evaluating and Improving

Benchmarking has been used by managers in different industries to evaluate and improve the quality of their products, work process and procedure, and work performance. By finding those gap rates which are less than a threshold value, managers can understand which metrics have poor performance and should be improved first.

III. THE CASE STUDY

To evaluate the effectiveness of the SCOR model, a garment manufacturing company was selected to do the case study. Garment industry is characterized by high fashion, high creativity, high globalization, low repetition, and low standardization. It is generally difficult to analyze its supply chain and develop its measurements of performance since its processes are very complicated. In addition, it is necessary to use a common language to communicate with each partner across the supply chain as businesses become more and more worldwide. Therefore, an effective tool is much necessary while developing measures for evaluating the performance of the supply chain of garment industry.

The case company (hereafter referred to as J Company) is a holding company with worldwide markets in fabric and garment production. J Company has a capital of about 1 billion and a turnover of about 5.5 billion NT dollars in 2004. J Company is one of the top 500 manufacturing companies and one of the largest manufacturers of knitted fabrics in Taiwan. The headquarters is located in Taipei and it has factories in Mainland China, Vietnam, Thailand, Cambodian, Lesotho, and more. This company has been expanding the overseas undertaking actively all the time in recent years. To meet the change of environment, J Company has been deploying globally and changed its business model. Fig. 2 shows the global deployment of J Company.

Fig. 2 The global configuration of J Company

The as-is and to-be business models of J Company are illustrated in Fig. 3. J Company always tries to employ different e-strategies for improving its operational condition and performance. After employing the supply chain typology analysis, the business model was changed. A global logistics center was set up in charge of integrating two major product business, i.e., fabric division and garment division. Originally, the fabric division and the garment division do business nearly independent, lacking of integration. Its to-be business model integrates the fabric and the garment divisions vertically to take orders jointly to maximize the profit of the company. Once the business model of a company is changed, the processes are also changed. Therefore, it is very important to find appropriate performance metrics. It is important for an enterprise to find out the most appropriate evaluation performance index.

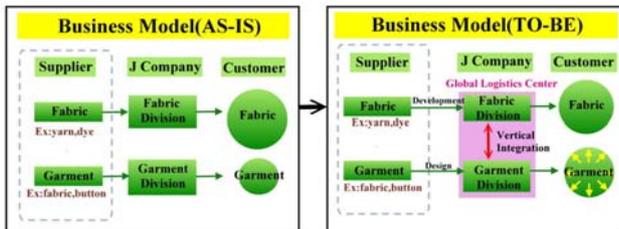

Fig. 3. The as-is and to-be business models of J Company

By using the SCOR model, 3 key performances indicators (KPI) were developed to evaluate the performance, compare with the target value, and to improve the gap between the actual and the target value.

1) Choose Performance Metric

After the interviews with staff in the case company, appropriate evaluation performance indicators from the five perspectives can be selected. The selected indicators are shown in Table 2. The metrics include the cycle time for responding customer's requirements, decision processing time, on-time delivery rate, the supply cycle time of main material, air transportation cost, and order processing cost.

Table 2 The performance perspectives and metrics selected by J company

Perspectives	Metrics
Responsiveness	The cycle time for responding customer's requirements
	Decision processing time
Reliability	On-time delivery rate
	The supply cycle time of main material
Cost	Air transportation cost
	Order processing cost

2) Define Performance Metric

As for the definition of performance metrics, the SCOR model has provided with complete definitions for references. However, to suit the requirements of the practice, the case company had its own definitions for the metrics. After many deep interviews and discussion with some staff of the case company, the definitions of these metrics were finally confirmed. Table 3 shows the definitions of some performance metrics.

3) Benchmarking

Whether its market share, its annual turnover, or its development of own brand, the case company was top in the field of garment industry. As a result, this enterprise was inclined to learn from the precursors to intensify its competitiveness in this field.

The case company selected several similar industries as its models, with an eye to their industrial functioning and results, then evaluate its own characteristics and status quo to set up the most appropriate index for its target.

Table 3 Definitions of performance metrics

Metric	Definition
Cycle time for responding customer's requirements	The time period between on order and responding customer's requirements
Decision processing time	The time period between receiving and dispatching an order to a most suitable factory
On-time delivery rate	The ratio of the number of on-time-delivery orders to the number of orders
Supply cycle time of main material	The cycle time between placing on order to a supplier of fabrics and receiving the fabrics
Air transportation cost	The cost of transportation by air for delivering garment
Order processing cost	The total cost from receiving an order to shipping an order

4) Evaluation and Improving

Following the procedure mentioned above, the SCOR cards in several perspectives were set up. The description is illustrated in Table 4. Companies can fully or partially refer to SCOR in five perspectives. The advantage is that a company can exactly develop its best model on its own. In this case, J Company did not focus on the assets and the flexibility perspectives. Therefore, the metrics concerning the assets and the flexibility perspectives can be neglected.

Table 4 The SCOR card in the responsiveness perspective

Level 1-SCOR Card (Responsiveness)				
Metric	Actual	Target	Gap	Gap Rate
The cycle time for responding customer's requirements	14 Days	7 Days	7 Days	1
Decision processing time	2 Days	0.5 Days	1.5 Days	3

Table 5 The SCOR card in the reliability perspective

Level 1-SCOR Card (Reliability)				
Metric	Actual	Target	Gap	Gap Rate
On-time delivery rate	70%	90%	20%	0.22
The supply cycle time of main material	28 Days	24 Days	4 Days	0.17

Table 6 The SCOR card in the cost perspective

Level 1-SCOR Card (Cost)				
Metric	Actual	Target	Gap	Gap Rate
Air transportation cost	12 Million	6 Million	6 Million	1
Order processing cost	18 Million	6.8 Million	11.2 Million	1.65

Through SCOR card one can understand the gap between the actual value and the target value of specific metrics. It enables a company to manage performance based

on criteria. The case company established several metrics in 3 perspectives by referring to the SCOR model and from the global viewpoint in order to check the effectiveness of 3 overall evaluation performance indicators.

After completing the SCOR card, the company must decide a threshold value of the gap rate according to its operation state. Indicators exceeding the threshold value of the gap rate are considered to have a poor performance. Because the threshold value of the gap rate is determined by high-level administrators' experiences and the culture of an enterprise, the optimistic administrators will generally set up higher values of threshold of the gap rate. For instance, the efficiency of decision-making has a larger gap rate than the required cycle time of customers at the perspective of responsiveness, providing that the threshold value of gap set up by the administrator is 1.5, indicating that the particular enterprise needs to focus on its improvement of efficient decision-making. Similarly, at the perspectives of reliability and cost, when the index has a higher gap rate than the threshold value of gap, the index indeed needs a great deal of adjustment and improvement.

Table 7 Key performance indicators of J Company

KPI	Actual	Target	Rate
Production cycle time	90 Days	45 Days	Reducing 100 %
Joint order-taking rate	8.55 %	17 %	Increasing 100 %
Order cycle time	120 Days	90 Days	Reducing 25%

Table 7 shows 3 key performance indicators that help the case company to observe the performance of the supply chain from a global viewpoint. The elevation of the overall performance indicators shows that the case company is on its right track of improvement or not.

IV. Conclusions

The supply chain performance is one of the most important factors for the success of a company since it considerably affects the ability to provide customer value. It is, thus, very important for a company to develop independent criteria to evaluate the performance, compare with competitors, and monitor the operation. However, suitable criteria are hard to develop since the supply chain is usually very complicated. The purpose of this study is to develop criteria to measure the performance of supply chain by using the Supply Chain Operations Reference Model (SCOR). To investigate the effectiveness of SCOR, we use the process reference model in SCOR to analyze the current state of a famous garment manufacturer's business processes and its goals, and quantify the operational performance. Results show that

SCOR is a very useful tool to develop performance metrics of the supply chain. Through the use of SCOR, a company can define key performance indicators (KPI) to improve their performance.

Abstract: The travelling salesman problem is to find a shortest path from the travelling salesman's hometown, make the round of all the towns in the set, and finally go back home. This paper investigates the travelling salesman problem with fuzzy random travelling time. Three concepts are proposed: expected shortest path, (α, β) -path and chance shortest path according to different optimal desire. Correspondingly, by using the concepts as decision criteria, three fuzzy random programming models for TSP are presented. Finally, a hybrid intelligent algorithm is designed to solve these models, and some numerical examples are provided to illustrate its effectiveness.

Keywords: travelling salesman problem; fuzzy random programming; fuzzy simulation; genetic algorithm.

I. Introduction

The travelling salesman problem (TSP) is to find a shortest path from the travelling salesman's hometown, make the round of all the towns in the set, and finally go back home.

Mathematical problems related to the travelling salesman problem were treated in the 1800s by the Irish mathematician Sir William Rowan Hamilton and the British mathematician Thomas Penyngton Kirkman[3]. The term 'travelling salesman problem' was first used by J.B.Robinson[20] in 1949, which makes it clear that the TSP was already a well-known problem at that time. In 1954, G. Dantzig, R. Fulkerson, and S. Johnson[4] first solved the TSP with 49 cities, which was one of the principal events in the history of combinatorial optimization. Since then, many other researchers have made efforts to find better algorithms to solve large-scale TSP.

Traditionally, the travelling salesman problem considers the distance between two cities as a constant. However, in the real world, uncertainty always exists in travelling salesman problem. Probability theory was introduced into TSP in 1980's. In 1984, M. Mezard[18][21] studied the travelling salesman problem in the case where

the distances are random variables and found the solution under the hypothesis that the replica symmetry is not broken. This kind of TSP was called 'the random link TSP'. Lu presented three types of fuzzy models as fuzzy expected fuzzy expected value model, fuzzy α -path model and most credibility model to solve fuzzy travelling salesman problem in 2005.

While in some cases, we care about the travelling time instead of the travelling distance. Considering the weather or traffic environment, the travelling time from one city to another is uncertain. Sometimes randomness and fuzziness may co-exist in traveling salesman problem in the real world. For instance, the route may change because of the traffic environment, we can assume the distance as a fuzzy variable. Everyday the speed of travel is random in different time and different weather or traffic circumstance. Therefore, we can get the shortest traveling time between two cities by the highest speed in shortest route, but we can't estimate the worst circumstance. In this case, fuzzy random variable can be introduced into optimization problems with mixed uncertainty of randomness and fuzziness. In this paper, the travelling times are assumed to be fuzzy random variables. Fuzzy random variable was first introduced by Kwakernaak[7][8]. And in the next years, Puri[19], Kruse[6], and Liu[16] developed the concept with different requirements of measurability. In this paper, we introduce the concept of fuzzy random variable initialized by Liu[16] and some relevant concepts to prepare for modelling the fuzzy random traveling salesman problem. Numerous numerical experiments have shown that the fuzzy random simulation indeed works very well. In this paper, we use a fuzzy random number to represent the travelling time between two cities, and define three concepts of shortest path in fuzzy random situation: expected shortest path(ESP), (α, β) -path and chance shortest path(CSP). Correspondingly, by using the three concepts as decision criteria, three fuzzy random programming models are proposed.

This paper is organized as follows: In Section 2, the travelling salesman problem is described. After recalling three ranking criteria for ranking fuzzy random variables in Section 3, Section 4 builds three types of fuzzy random models as expected shortest path model, (α, β) -path

model and chance shortest path model. Then in Section 5, some numerical experiments are given to show the effectiveness of a hybrid intelligent algorithm, which is integrated by fuzzy random simulations and genetic algorithm (GA). Furthermore, Section 6 gives some conclusions.

II. Problem Description

The travelling salesman problem may be stated as follows: A salesman is required to visit each of some given cities once and only once, starting from one city and returning to the original place of departure. What route should he choose in order to minimize the total distance travelled?

In order to model the travelling salesman problem, we first introduce the following indices and parameters:

$i = 1, 2, \dots, n$: cities;

d_{ij} : travelling time between city i and j ;

x_{ij} : decision variables, where $x_{ij} = 0$ means that the salesman does not go from i to j , otherwise $x_{ij} = 1$ means that the salesman goes from i to j .

Then in order to minimize the total travelling time, we have the following model:

$$\min \sum_{i \neq j} d_{ij} x_{ij} \tag{1}$$

$$s.t. \sum_{j=1}^n x_{ij} = 1, \quad i = 1, 2, \dots, n \tag{2}$$

$$\sum_{i=1}^n x_{ij} = 1, \quad j = 1, 2, \dots, n \tag{3}$$

$$\sum_{i,j \in s} x_{ij} \leq |s| - 1, \tag{4}$$

$$2 \leq |s| \leq n - 2, \quad s \subset \{1, 2, \dots, n\} \tag{4}$$

$$x_{ij} \in \{0, 1\}, \quad i, j = 1, \dots, n, \quad i \neq j. \tag{5}$$

The constraint (2) requires the salesman just goes out of city i once and the constraint (3) requires salesman just enters city j once. Hence, every city must appear once and only once in the route. The constraint (4) means that there is no circle in the route.

In the above model, d_{ij} denotes the distance between two cities and is deterministic. In the following models, we will consider d_{ij} as the travelling time between two cities and assume it to be a fuzzy random variable. D denotes the feasible set defined by the constraints (2-5).

III. Fuzzy Random Variable

In this section, we will give some basic concepts of fuzzy random theory. The interested reader may refer to Liu[14] to see the fuzzy random theory.

We firstly recall the concepts of possibility, necessity, and credibility of a fuzzy event. Let ξ be a fuzzy variable with membership function μ . Then the possibility, necessity, and credibility of a fuzzy event $\{\xi \geq r\}$ can be defined by

$$\text{Pos}\{\xi \geq r\} = \sup_{u \geq r} \mu(u),$$

$$\text{Nec}\{\xi \geq r\} = 1 - \sup_{u < r} \mu(u),$$

$$\text{Cr}\{\xi \geq r\} = \frac{1}{2} (\text{Pos}\{\xi \geq r\} + \text{Nec}\{\xi \geq r\}).$$

Definition 1 (Liu and Liu[16]) *A fuzzy random variable ξ is a function from the probability space $(\Omega, \mathcal{A}, \text{Pr})$ to the set of fuzzy variables such that $\text{Pos}\{\xi(\omega) \in B\}$ is a measurable function of ω for any Borel set B of \mathcal{R} .*

III.1 Expected Value

Next, we will introduce several concepts as ranking criteria for the preparation of modelling the traveling salesman problem. The first concept is the expected value of a fuzzy random variable. Before we give the first criterion for ranking fuzzy random variables, the concept of expected value of fuzzy variable will be given as follows:

Definition 2 (Liu and Liu[15]) *Let ξ be a fuzzy variable. The expected value of ξ is defined by*

$$E[\xi] = \int_0^{+\infty} \text{Cr}\{\xi \geq r\} dr - \int_{-\infty}^0 \text{Cr}\{\xi \leq r\} dr$$

provided that at least one of the above two integrals is finite.

Based on the concept of expected value of fuzzy variable, the expected value of fuzzy random variable can be shown as:

Definition 3 (Liu and Liu[16]) *Let ξ be a fuzzy random variable. Then its expected value is defined by*

$$E[\xi] = \int_0^{+\infty} \text{Pr}\{\omega \in \Omega \mid E[\xi(\omega)] \geq r\} dr -$$

$$\int_{-\infty}^0 \text{Pr}\{\omega \in \Omega \mid E[\xi(\omega)] \leq r\} dr$$

provided that at least one of the above two integrals is finite.

Let ξ and η be two fuzzy random variables. Liu[14] suggested that $\xi > \eta$ if and only if $E[\xi] > E[\eta]$, where E is the expected value operator of fuzzy random variable.

III.2 Chance Measure

The second concept is the chance measure of a fuzzy random event.

Definition 4 (Liu, Gao and Liu[14]) Let ξ be a fuzzy random variable, and B a Borel set of \mathcal{R} . Then the chance of fuzzy random event $\xi \in B$ is a function from $(0, 1]$ to $[0, 1]$, defined as

$$\text{Ch}\{\xi \in B\}(\alpha) = \sup_{\text{Pr}\{A\} \geq \alpha} \inf_{\omega \in A} \text{Cr}\{\xi(\theta) \in B\}.$$

Let ξ and η be two fuzzy random variables. Liu[14] suggested that $\xi > \eta$ if and only if $\text{Ch}\{\xi \geq \bar{r}\}(\gamma) > \text{Ch}\{\eta \geq \bar{r}\}(\gamma)$ for some predetermined levels \bar{r} and $\gamma \in (0, 1]$.

III.3 Critical Value

Next we will introduce two critical values as optimistic value and pessimistic value to measure fuzzy random variables.

Definition 5 (Liu[14]) Let ξ be a fuzzy random variable, and $\gamma, \delta \in (0, 1]$. Then

$$\xi_{\text{sup}}(\gamma, \delta) = \sup \{r \mid \text{Ch}\{\xi \geq r\}(\gamma) \geq \delta\}$$

is called the (γ, δ) -optimistic value to ξ , and

$$\xi_{\text{inf}}(\gamma, \delta) = \inf \{r \mid \text{Ch}\{\xi \leq r\}(\gamma) \geq \delta\}$$

is called the (γ, δ) -pessimistic value to ξ .

Let ξ and η be two fuzzy random variables. Liu[14] suggested that $\xi > \eta$ if and only if, for some predetermined confidence levels $\gamma, \delta \in (0, 1]$, we have $\xi_{\text{sup}}(\gamma, \delta) > \eta_{\text{sup}}(\gamma, \delta)$, where $\xi_{\text{sup}}(\gamma, \delta)$ and $\eta_{\text{sup}}(\gamma, \delta)$ are the (γ, δ) -optimistic values of ξ and η , respectively. Similarly, Liu[14] suggested that $\xi > \eta$ if and only if, for some predetermined confidence levels $\gamma, \delta \in (0, 1]$, we have $\xi_{\text{inf}}(\gamma, \delta) > \eta_{\text{inf}}(\gamma, \delta)$, where $\xi_{\text{inf}}(\gamma, \delta)$ and $\eta_{\text{inf}}(\gamma, \delta)$ are the (γ, δ) -pessimistic values of ξ and η , respectively.

With the above concepts as different ranking criteria, we can model fuzzy random traveling salesman problem in different forms according to different types of optimization requirements.

IV Fuzzy Random Models

IV.1 Expected Shortest Path Model

Expected value model (EVM), which is to optimize some expected objectives with some expected constraints, is a widely used method in solving practical problems with uncertain factors. In uncertain environments, objective

functions and constraint functions always cannot be compared directly since they always involve uncertain variables. Since in fuzzy travelling salesman problem the shortest path cannot be achieved directly, it may be required to minimize the expected travelling time under the constraints.

Definition 6 A path x^* is called the expected shortest path(ESP) if

$$E \left[\sum_{i \neq j} d_{ij} x_{ij} \right] \geq E \left[\sum_{i \neq j} d_{ij} x_{ij}^* \right]$$

for any path x satisfy (2.2)-(2.5).

In order to satisfy this type of request, we can build an expected valued model as:

$$\begin{aligned} \min \quad & E \left[\sum_{i \neq j} d_{ij} x_{ij} \right] \\ \text{s.t.} \quad & \sum_{j=1}^n x_{ij} = 1, \quad i = 1, 2, \dots, n \\ & \sum_{i=1}^n x_{ij} = 1, \quad j = 1, 2, \dots, n \\ & \sum_{i,j \in s} x_{ij} \leq |s| - 1, \quad 2 \leq |s| \leq n - 2, \\ & s \subset \{1, 2, \dots, n\} \\ & x_{ij} \in \{0, 1\}, \quad i, j = 1, \dots, n, \quad i \neq j. \end{aligned}$$

IV.2 (α, β) -Path Model

Chance-constrained programming (CCP) is a new modelling philosophy deals with uncertainty (traditionally randomness) which is initialized by Charnes[1][2]. It is applied to solve problems with the request that chance constraints should hold with at least some given confidence levels. In travelling salesman problem, a decision-maker may not want to minimize the expected travelling time, but to consider the risk. So we can establish an (α, β) -path model to meet this type of requirement.

Definition 7 A path x^* is called (α, β) -path if

$$\left(\sum_{i \neq j} d_{ij} x_{ij} \right)_{\text{inf}} (\alpha, \beta) \geq \left(\sum_{i \neq j} d_{ij} x_{ij}^* \right)_{\text{inf}} (\alpha, \beta)$$

for any path x satisfy (2.2)-(2.5).

Following the idea of fuzzy random CCP, we can present the CCP models as follows:

(α, β) -path model(minimaxCCP):

$$\begin{aligned}
 \min \quad & \bar{f} \\
 \text{s.t.} \quad & \text{Ch} \left\{ \sum_{i,j} x_{ij} d_{ij} \leq \bar{f} \right\} (\alpha) \geq \beta \\
 & \sum_{j=1}^n x_{ij} = 1, \quad i = 1, 2, \dots, n \\
 & \sum_{i=1}^n x_{ij} = 1, \quad j = 1, 2, \dots, n \\
 & \sum_{i,j \in s} x_{ij} \leq |s| - 1, \quad 2 \leq |s| \leq n - 2, \\
 & s \subset \{1, 2, \dots, n\} \\
 & x_{ij} \in \{0, 1\}, \quad i, j = 1, \dots, n, \quad i \neq j.
 \end{aligned}$$

IV.3 Chance Shortest Path Model

We have built two types of model based on the expected value and pessimistic value. Another useful tool to solve practical problems in uncertain environments is dependent-chance programming (DCP). Because many goals cannot be obtained absolutely in practice, a decision-maker may want to achieve his goal with maximal chance. Dependent-chance programming (DCP) is initialized by Liu[9] to maximize the chance functions of optimization goals. The readers may also refer to Liu[14] to see how DCP is used to solve different problems. Accordingly in fuzzy random travelling salesman problem, a decision-maker may want to maximize the chance that the total travelling time does not exceed some given time under the constraint. First, for a given travelling time \bar{f} , we obtain a fuzzy random event: $f(x, d) = \sum_{i \neq j} d_{ij} x_{ij} \leq \bar{f}$.

Definition 8 A path x^* is called chance shortest path (CSP) if

$$\text{Ch} \left\{ \sum_{i \neq j} d_{ij} x_{ij} \leq \bar{f} \right\} (\alpha) \leq \text{Ch} \left\{ \sum_{i \neq j} d_{ij} x_{ij}^* \leq \bar{f} \right\} (\alpha)$$

for any given \bar{f} and α .

Hence, we can build a chance shortest path model based on fuzzy random DCP:

$$\begin{aligned}
 \max \quad & \text{Ch} \left\{ \sum_{i \neq j} d_{ij} x_{ij} \leq \bar{f} \right\} (\alpha) \\
 \text{s.t.} \quad & \sum_{j=1}^n x_{ij} = 1, \quad i = 1, 2, \dots, n \\
 & \sum_{i=1}^n x_{ij} = 1, \quad j = 1, 2, \dots, n \\
 & \sum_{i,j \in s} x_{ij} \leq |s| - 1, \quad 2 \leq |s| \leq n - 2, \\
 & s \subset \{1, 2, \dots, n\} \\
 & x_{ij} \in \{0, 1\}, \quad i, j = 1, \dots, n, \quad i \neq j.
 \end{aligned}$$

V. Numerical Experiments

In the above three models, there exist several uncertain functions with fuzzy random variables as the expected shortest path $E \left[\sum_{i \neq j} d_{ij} x_{ij} \right]$, the (α, β) -path

$\min \left\{ \bar{f} \mid \text{Ch} \left\{ \sum_{i,j} x_{ij} d_{ij} \leq \bar{f} \right\} (\alpha) \geq \beta \right\}$ and the chance $\text{Ch} \left\{ \sum_{i,j} x_{ij} d_{ij} \leq \bar{f} \right\} (\alpha)$. We use fuzzy random simulations introduced by Liu[13] to estimate the three fuzzy random functions.

To find a shortest path for a salesman, we need to design some heuristic algorithm. We embed the fuzzy random simulations, which are used to simulate the above three types of uncertain functions, into GA to design a hybrid intelligent algorithm. In this section, we will show the effectiveness of the hybrid intelligent algorithm by the following three numerical experiments.

Now let us consider a traveling salesman problem with 10 cities as shown in Table 1, which gives the coordinates of the cities.

Table 2 shows the matrix in which each triple denotes a fuzzy random variable.

Note that the traveling times are assumed to be fuzzy random variables, denoted by a form of triangular fuzzy variable (a, b, ρ) , where a and b are given crisp numbers and ρ is a exponential distributed random variable with the expected value is c .

Before running the hybrid intelligent algorithm, we set the parameters as follows: *pop_size* is 50, the number of generations is 500, the number of stochastic simulation cycles is 1000, the probability of crossover p_c is 0.1, the probability of mutation p_m is 0.7, and the parameter a in the rank-based evaluation function is 0.05.

After a run of the hybrid intelligent algorithm with the parameters above to solve the expected shortest path

model, an optimal path is presented as 7 – 2 – 9 – 4 – 3 – 8 – 5 – 6 – 1 – 10 and the total traveling time is 2050.

For solving the (α, β) -path model with different confidence levels, we run the algorithm with the same parameters. The (α, β) -path with different (α, β) are shown as in Table 3.

Similarly, we run the hybrid intelligent algorithm for chance shortest path model. The chance shortest path with different \bar{f} are presented as in Table 4.

In order to show the effectiveness of the hybrid intelligent algorithm, we solve the (α, β) -path model with $(\alpha, \beta) = (0.8, 0.8)$. We compare solutions when different parameters are taken in the algorithm ($a = 0.05, Gen = 500, Pop.Size = 50$). The errors shown in Table 5 are calculated by the formula as $(\text{actual value} - \text{optimal value}) / \text{optimal value} \times 100\%$.

VI. Conclusion

We introduced fuzzy random theory into traveling salesman problem and solve it with mixed uncertainty of randomness and fuzziness in this paper. After the concepts of fuzzy random theory were presented, three types of fuzzy random models as expected shortest path model, (α, β) -path model and chance shortest path model were built. A hybrid intelligent algorithm integrated by fuzzy random simulations and genetic algorithm was designed and the results of the numerical examples were given to illustrate the effectiveness of the hybrid intelligent algorithm.

Abstract: The quadratic shortest path (QSP) problem is to find a path from a node to another node in a given network such that the total cost includes two kinds of costs, say direct cost and interactive cost, is minimum. The direct cost is the cost associated with each arc and the interactive cost occurs when two arcs appear simultaneously in the shortest path. In this paper, the concept of the quadratic shortest path is initialized firstly. Then a spanning tree-based genetic algorithm is designed for solving the quadratic shortest path problem. Finally, a numerical example is given.

Keywords: graph; network; shortest path; genetic algorithm.

I. Introduction

The shortest path (SP) problem has a long history in the combinatorial optimization. Since the SP problem was initialized, it was studied by many researchers and has been applied in wide varieties. The classical SP is to find the shortest, namely the least cost, path from the origin node to the destination node in a given network, where the cost of the path is defined as the sum of the costs of the arcs in the path and the costs are assumed to be non-negative.

There are varieties of extensions both in models and algorithms of SP after it was initialized and thousands papers with respect to various SPs and algorithms in recent years can be retrieved by a quickly searching in the web. For example, Balachandhran and Randan [2], Pettie [20] studied the all pairs SP; Pattanamekar and Park etc.[3], Frigioni and Marchetti-Spaccamela [5] investigated the dynamic and stochastic SP; Davies and Lingrascite [6] designed a genetic algorithms for the dynamic and stochastic SP; Bousoño-Calzon and Figuiras-Vidal [7] explored an algorithm by using the Hopfield neural networks; Miller-Hooks and Mahmassanicite[8] studied SP in stochastic time-varying networks; Chen and Tang [9] introduced minimum time paths in a networks

with mixed time constraints; Granat and Guerriero [10], Modesti and Sciomachen [11] gave the algorithms of the multi-criteria shortest path, respectively; Chen and Yang [19] introduce the algorithm for finding the first k shortest paths in a time-window network; Bose, Maheshwari and Narasimhan [21] initialized the bottleneck shortest paths; Okada [22] studied the SP with fuzzy arc lengths; Godor, Harmatos and Juttner [24] initialized the inverse SP and Daganzo [25] the time-dependent SP. Some of them are listed in the references [2]–[26]. Some of the extensions are NP-hard. As another extension of the SP, we initialize the quadratic shortest path (QSP) problem and formulate the QSP as a quadratic 0–1 programming in this paper.

This paper is organized as follows. Firstly, we initialize the concept of quadratic shortest path (QSP) problem in the Section . Then a spanning tree-based heuristic genetic algorithm is given in Section by using heuristic approach and a numerical example is given in Section ??.

II. The Preliminaries and the Mathematical Model of QSP

Firstly, let us recall some preliminaries and define some notations. Throughout this paper, all the graphs are simple direct graph. Let G be a graph with $E(G)$ and $V(G)$ as its arcs set and nodes set, respectively. Assume that $E = E(G) = \{e_1, e_2, \dots, e_{|E|}\}$, $V = V(G) = \{v_1, v_2, \dots, v_{|V|}\}$, $m = |E|$, $n = |V|$ and the ordering pair (u, v) , $u, v \in V(G)$ denote the arc from node u to node v . For a node $v \in V(G)$, $d_G(v)$ denotes its degree and $N^+[v]$, $N^-[v]$, $N_e^+[v]$ and $N_e^-[v]$ denote the sets $\{u | (u, v) \in E(G)\}$, $\{u | (v, u) \in E(G)\}$, $\{(u, v) | (u, v) \in E(G)\}$ and $\{(v, u) | (v, u) \in E(G)\}$, respectively. For a subset S of E or V , $G[S]$ and $|S|$ denote the subgraph induced by the subset S and the cardinality of the set S , respectively. Additionally, for a subgraph T of G and an arc $e = (u, v) \in E(G)$, $T + e$ or $T + (u, v)$ denotes the graph obtained by adding arc $e = (u, v)$ to T and $T - e$ or $T - (u, v)$ denotes the graph obtained by removing arc $e = (u, v)$ from T .

The QSP is to find a path from a node to another

node in a given network such that the total cost includes two kinds of costs, say direct cost and interactive cost, is minimum. The direct cost is the cost associated with each arc and the interactive cost occurs when two arcs appear simultaneously in the shortest path. Let d_i and w_{ij} be the direct cost of the arc $e_i \in E$ and the interactive cost of arcs $e_i, e_j \in E(G)$, respectively, $i, j = 1, 2, \dots, |E(G)|$. Assume that the required path P is the path from the node 1 to the node $|V|$ in this paper. The decision variables $x_i = 0$ or 1 , $i = 1, 2, \dots, |E|$, indicate that each arc i is either in the path or not and \mathbf{x} is the vector consists of x_i , $i = 1, 2, \dots, |E|$. Then the path P can also be denoted by such a vector \mathbf{x} and the cost function of the path \mathbf{x} can be defined as

$$f(\mathbf{x}) = \sum_{i=1}^{|E|} d_i x_i + \sum_{i=1}^{|E|} \sum_{j=i+1}^{|E|} w_{ij} x_i x_j. \quad (1)$$

For convenience, we briefly take the index k of arc e_k or node v_k to denote the k th arc e_k in arcs set E or the k th node v_k in the nodes set V in the following process. Then the mathematical model of QSP can be formulated as follows:

$$\begin{aligned} \max f(\mathbf{x}) &= \sum_{i=1}^{|E|} d_i x_i + \sum_{i=1}^{|E|} \sum_{j=i+1}^{|E|} w_{ij} x_i x_j \\ \text{s.t.} \quad &\sum_{i \in N_e^+[v]} x_i - \sum_{j \in N_e^-[v]} x_j = d, \quad v \in V(G), \\ &x_i = 0 \text{ or } 1, \quad i = 1, 2, \dots, |E|, \end{aligned} \quad (2)$$

where

$$d = \begin{cases} 1, & \text{if } v = 1, \\ 0, & \text{if } v \neq 1 \text{ or } |V|, \\ -1, & \text{if } v = |V|. \end{cases}$$

It is clear that the model (2) of QSP is quadratic 0–1 programming. It is well-known that the quadratic programming is NP-hard, especially the quadratic 0–1 programming. So we will focus on the algorithm designing of QSP in the remain parts of this paper. It is also generally accepted that the genetic algorithm is an efficient ways to solve the NP-hard problems. For the SP, the related exposition related to SP is initialized by Cheng and Gen [23]. To design the genetic algorithm of QSP, we introduce a Lemma as follows.

Lemma 0.1 [27] *Let G be a connected simple graph and T be a spanning tree of the graph G . If $(u, v) \in E(G)$ satisfies $(u, v) \notin E(T)$, then there is a unique cycle in $T + (u, v)$.*

On the basis of Lemma 0.1, we design a spanning tree-based genetic algorithm for solving the model (2) in the next Section.

The encode method and evolution operation are the universal problems in the current genetic algorithms for

the SP and its extensions. Firstly, different paths from the origin node to the destination node include a variable number of the nodes and a random arcs series usually does not correspond to a path. Furthermore, the evolution operation such as the crossover and mutation operations can't be performed efficiently because two paths usually haven't had any common nodes or arcs except the end node 1 and n of the paths. For example, Cheng and Gen [23] have designed a comprise approach-based genetic algorithm of the multi-criteria SP. In Cheng and Gen's algorithm, the chromosome is encoded as the path from the origin node to the destination node. In next Section, we explore a completely new encode method and evolution operators.

III. Genetic Algorithm

In the following process, we shall design the representation, crossover, mutation and selection operation of the spanning tree-based genetic algorithm for solving the QSP. As stated in the Section , the encode method and evolution operation are the universal problems in the current genetic algorithm for the SP. Aim at the purpose to solve these problems, we shall design the oriented tree-based crossover, mutation and evaluation operation by encoding the chromosome as a spanning tree. By such an encode method, there is a unique path from the origin node to the destination node and by using some spanning tree-based heuristic evolution operations, the algorithm completely overcome the defects of the current genetic algorithm with respect to SP. Additionally, the merits of such an encode method are that the chromosomes produced by the crossover and mutation are also feasible.

III. 1 Representation

Assume that $m = |E|$ and $n = |V|$. There are many ways to represent a solution of the optimization problem in genetic algorithm. In this paper, we employ a spanning tree-based encoding method to define the chromosomes of the QSP. We employ a spanning tree X which is denoted by an arcs set with fixed set cardinality $n - 1$ to encode a chromosome of the QSP, where $X = \{x_1, x_2, \dots, x_n\}$ and each x_i represents an arc in the spanning tree and its value is equal to the index of the corresponding arc. It is clear that such a chromosome includes a unique path from the node 1 to the node n .

In the evolution process, we must perform some network search operation such as finding the cycle in the graph $T + e$ or the unique path in T from the node 1 to the node n , where T is a chromosome (tree) and $e \in E(G) \setminus E(T)$. So the chromosome is converted to an oriented tree when perform the crossover and mutation operations. Clearly, It is very convenient to find such a

cycle or path by using the oriented tree.

Definition 0.1 *The weight of the chromosome X , denoted by $W(X)$, is defined as*

$$\sum_{i \in P} d_i x_i + \sum_{i=1}^{|E|} \sum_{j=i+1}^{|E|} w_{ij} x_i x_j,$$

where P is the unique path from the node 1 to the node n in X . The optimal chromosome is such a chromosome X that the weight of $W(X)$ is optimal.

By such an encoding method, the crossover and mutation operations are really a set-based genetic operations and the decoding process are also convenient to be realized by finding the path from the node 1 to the node n in the chromosome X .

III. 2 Initialization Process

The initialization is an important process in genetic algorithm serving as the role of initializing the chromosomes. We take pop_size to denote the number of chromosomes. We initialize chromosomes $X_1, X_2, \dots, X_{pop_size}$ by repeating the following algorithm pop_size times, where T denotes a spanning tree of the graph $G(V, E)$.

The initialization algorithm:

- Step 1.** Set $T = \emptyset$. Randomly select nodes $u_0 \in V(G)$, $v_0 \in N(u_0)$. Set $T \leftarrow T + (u_0, v_0)$.
- Step 2.** Randomly select a node $u \in V(T)$ with $N(u) \setminus V(T) \neq \emptyset$. Randomly select a node $v \in N(u) \setminus V(T)$. Set $T \leftarrow T + (u, v)$.
- Step 3.** Repeat Step 2 until $|E(T)| = |V(G)| - 1$.
- Step 4.** Set $X_i \leftarrow T$ and stop.

Theorem 0.1 *The obtained tree in the initialization algorithm is a spanning tree.*

Proof: Because the arc (u, v) in the Step 2 has a common node u with $V(T)$, the obtained graph T is obviously a connected graph. Additionally, the node v in the Step 2 is selected from $N(u) \setminus V(T)$, this implies that T is cycle free. Therefore, a spanning tree is obtained when $|E(T)| = |V(G)| - 1$.

III. 3 Crossover Operation

Let $P_c \in (0, 1)$ be the crossover probability. In order to determine the parents for the crossover operation, we repeat the following process pop_size times: randomly generating a real number r from interval $(0, 1]$, the chromosome X_i is selected to crossover if $r < P_c$. We denote

the selected parents by X'_1, X'_2, \dots and divide them into the following pairs:

$$(X'_1, X'_2), (X'_3, X'_4), (X'_5, X'_6), \dots$$

Based on Lemma 0.1, we take the chromosomes pair (X'_1, X'_2) as the example to illustrate the crossover process. The Figure 1 is a numerical example. Randomly generate an integer k from interval $[1, t]$, where

$$t = \left| E(X'_1) \setminus (E(X'_1) \cap E(X'_2)) \right| = \left| E(X'_2) \setminus (E(X'_1) \cap E(X'_2)) \right|.$$

After that, randomly select two sets $S_1 \subset E(X'_1) \setminus (E(X'_1) \cap E(X'_2))$ and $S_2 \subset E(X'_2) \setminus (E(X'_1) \cap E(X'_2))$ with cardinality k . Follows from Lemma 0.1, for each arc $e \in S_1$ (or $e \in S_2$), there is a unique cycle, says C_e , in $X'_2 + \{e\}$ (or $X'_1 + \{e\}$) with the arc e on it. Then we can perform crossover operation as follows: randomly select an arc $e' \in E(C_e)$ and set $X'_2 \leftarrow X'_2 - \{e'\} + \{e\}$ (or $X'_1 \leftarrow X'_1 - \{e'\} + \{e\}$) (Figure 2, where (a) and (b) are X'_1 and X'_2 before crossover, (c) and (d) are these after crossover).

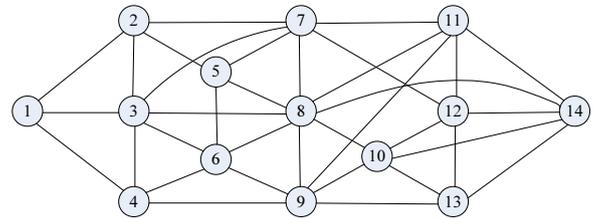

Figure 1: A numerical example with 14 nodes and 35 arcs

Crossover algorithm:

- Step 1.** Convert the chromosome X'_1 and X'_2 to the oriented trees T_1 and T_2 .
- Step 2.** Set $t = |E(X'_1) \setminus (E(X'_1) \cap E(X'_2))| = |E(X'_2) \setminus (E(X'_1) \cap E(X'_2))|$.
- Step 3.** Randomly generate an integer k from interval $[1, t]$.
- Step 4.** Randomly select two sets S_1 and S_2 :

$$S_1 \subset E(X'_1) \setminus (E(X'_1) \cap E(X'_2)),$$

$$S_2 \subset E(X'_2) \setminus (E(X'_1) \cap E(X'_2)),$$

$$|S_1| = |S_2| = k.$$

- Step 5.** For every arc $e \in S_1$, Find the unique cycle C_e in $T_2 + \{e\}$. Randomly select an arc $e' \in E(C_e)$, $e' \neq e$. Set $X'_2 \leftarrow X'_2 - \{e'\} + \{e\}$.

Step 6. Perform the same operations as Step 5 between T_1 and S_2 .

For a spanning tree T , if we indicate a node as the root of T , then the spanning tree can be converted to an oriented spanning tree by using the following method. Let P be a path from the root to a node v . The direction of the path P is defined as the direction go away from the root to the node v in the path P and the direction of an arc in $E(P)$ is defined as the same direction of the path P . By such a way, an oriented spanning tree is defined. Based on such an oriented tree T , we design an algorithm to find the cycle C_e in the Step 5 of the crossover algorithm. For arc $e = (u, v)$, $P_{[s,t]}$ denotes the segment in the path P between the vertices s and t .

The algorithm to find the cycle C_e :

Step 1. Start from the node u , along the predecessor node of u , find the path P^u from the root to the node u . If $v \in V(P^u)$, the cycle C_e is found and set $C_e = P_{[u,v]}^u + \{e\}$, stop. Otherwise, go to next step.

Step 2. Start from the node v , along the predecessor node of v , find the path P^v from the root to the node v . If $u \in V(P^v)$, the cycle C_e is found and set $C_e = P_{[u,v]}^v + \{e\}$, stop. Otherwise, go to next step.

Step 3. Start from the root node, along the path P^v or P^u to find the the last common node s of the path P^v and P^u , set $C_e = P_{[u,s]}^u + P_{[s,v]}^v + \{e\}$.

It is clear that the new chromosome obtained by such crossover operation is also a feasible.

III. 4 Mutation Process

In this section, we will design an oriented tree and knowledge-based heuristic mutation operator. Let $P_m \in (0, 1)$ be the mutation probability. We employ the following operator to select the chromosome to be mutated: for $i = 1$ to pop_size , randomly generate a random number r from interval $(0, 1)$; if $r \leq P_m$, then the chromosome X_i is selected to be mutated. The idea of the mutation operation is also originated from Lemma 0.1. Firstly, randomly select an integer k from interval $[1, |E(G) \setminus E(X_i)|]$. Then randomly select k different arcs e_1, e_2, \dots, e_k from set $E(G) \setminus E(X_i)$. For each arc e_j , $j = 1, 2, \dots, k$, it follows from Lemma 0.1 that there is a unique cycle C_{e_j} in $X_i + \{e_j\}$. The mutation is performed on C_{e_j} as follows: randomly select an arc $e'_j \in E(C_{e_j})$ such that $e'_j \neq e_j$, set $X_i \leftarrow X_i - \{e'_j\} + \{e_j\}$. The mutation operation is summarized as follows.

Mutation algorithm:

Step 1. For $i = 1$ to pop_size , repeat Step 2 to Step 3.

Step 2. Randomly generate a random number r from interval $(0, 1]$. If $r \leq P_m$, then go to Step 3. Otherwise, go to Step 1.

Step 3. Randomly select an integer k from interval $[1, |E(G) \setminus E(X_i)|]$ and randomly select k different arcs e_1, e_2, \dots, e_k from set $E(G) \setminus E(X_i)$. For $j = 1$ to k , repeat Step 4.

Step 4. Find the unique cycle C_{e_j} in $X_i + \{e_j\}$. Randomly select an arc $e'_j \in E(C_{e_j})$ such that $e'_j \neq e_j$, set $X_i \leftarrow X_i - \{e'_j\} + \{e_j\}$.

Clearly, such a mutation can also ensure that the new chromosome is also a spanning trees.

In order to accelerate the convergence speed of the designed genetic algorithm, some heuristic methods can be used in the mutation operator. The base idea is to give each arc in the set $S = E(G) \setminus E(X_i)$ a selecting probability according to the weight of the arcs when we perform mutation operation on X_i . Assume that $S = E(G) \setminus E(X_i) = \{e'_i | i = 1, 2, \dots, |S|\}$. The selecting probability of the arc $e'_i \in S$ is defined as $f(e'_i) = (1/w'_i) / \sum_{e'_j \in S} (1/w'_j)$. Let $P_i = \sum_{k=1}^i f(e'_k)$, $i = 1, 2, \dots, |S|$, and $P_0 = 0$. Then the arcs in $S = E(G) \setminus E(X_i)$ is selected by spanning roulette wheel when we select the arc e_j in the above process operation. The detail operation is similar as that in the selection operation and we omitted here.

III. 5 Evaluation

The evaluation process is to calculate the fitness of chromosomes so as to evaluate the chromosomes. In the designed algorithm, the fitness f_i of the i th chromosome X_i is defined as the reciprocal of the weight $W(X_i)$ (see Definition 0.1), $i = 1, 2, \dots, pop_size$. The evaluating function is defined as

$$Eval(X_i) = f_i / \sum_{k=1}^{pop_size} f_k, i = 1, 2, \dots, pop_size.$$

III. 6 Selection Process

The selection process is to select the offsprings of the chromosomes in the genetic algorithm. Let $P_i = \sum_{k=1}^i Eval(X_k)$, $i = 1, 2, \dots, pop_size$, and $P_0 = 0$, then we employ the spanning roulette wheel to select the chromosomes: randomly generate a number $p \in (0, 1]$; if $p \in (P_{i-1}, P_i]$, then the chromosome X_i is selected. The following is the algorithm.

Selection algorithm:

Step 1. Let $k = 1$, repeat Step 2 until $k = pop_size$.

Step 2. Randomly generate a number $p \in (0, 1)$. If $p \in [P_{i-1}, P_i)$, then chromosome X_i is selected and let $k = k + 1$.

III. 7 Genetic Algorithm

Step 1. Randomly initialize pop_size chromosomes.

Step 2. Update the chromosomes by crossover process and mutation process.

Step 3. Calculate the objective values of the chromosomes.

Step 4. Calculate the fitness of each chromosome according to the objective values.

Step 5. Select the chromosomes by spanning the roulette wheel.

Step 6. Repeat Step 2 to Step 5 for a given number times.

Step 7. Report the best chromosome as the optimal solution.

IV. Conclusions

In this paper, an oriented spanning tree-based heuristic genetic algorithm is designed for solving the quadratic shortest path problem. Finally, a numerical example is given.

Abstract: This paper presents a case study on how multi-tier supply chain integration is being achieved via the use of information systems in the aerospace industry. It is based on interviews conducted with three organizations across the supply chain and an IT vendor who supplied the technology. The study finds that by using a new set of technological standards, namely Web Services, data can be taken from the systems of three disparate organizational systems and then used to help an integrated product team from three organizations manage the supply chain. In order to capture the benefits of this technology, the development of a supply chain mindset, integration of marketing and logistics activities and observing demarcation of what issues can and cannot be discussed via the multilateral relationships need to be addressed. The contribution of the paper is that emergent information systems can be used in a multi-tier context to address the problem of the Forrester effect, a phenomenon that has plagued supply chains for decades.

Keywords: SCM, E-logistics

I. Introduction

The global aerospace industry is currently enjoying a period of substantial growth, following the slump in sales that resulted from passengers' reluctance to fly after the tragic events of September the 11th. Aerospace is a sector that contributes a significant proportion of national wealth to countries such as the USA, UK and France, and it consists of four key sectors: civil aircraft, military aircraft, missiles and space. The aerospace industry consists of a supply chain that starts with prime contractors such as Boeing and Airbus, then has systems and major equipment suppliers, sub-system and major component suppliers come next, which is followed by component suppliers. This supply chain is supported by a miscellaneous range of other suppliers in areas such as information systems and manufacturing equipment. The industry can be characterized in the following terms: high levels of technological and scientific intensity; high cost and high-risk programs; long development and payback cycles; low volume, high value

products; civil-military linkages; international collaboration in design and development; central role of Government as sponsor, customer, regulatory and market gatekeeper; high barriers to entry; highly safety critical; long service life (AIGT, 2003). As with any industry, aerospace is in a continual state of change. Recent developments in the aerospace supply chain include: an increased use of supplier development activities to improve their capabilities (Reed and Walsh, 2002); an increased level of outsourcing, which has had the negative consequence of a reduction in the level of control over information for changes in supply and demand (Bales et al. 2004); an increased focus on large-scale integration of systems and platform assembly by those higher up the supply chain, and the optimization of manufacturing and supply chain operations through the adoption of lean principles (Williams et al., 2002); continual challenges in seeking appropriate, markets vs. hierarchies, supply chain relationships (Rossetti and Choi, 2005); the integral role of people and information technology management as a source of competitive advantage (Russell and Hoag, 2004).

This paper will present and analyse a case study conducted on an aerospace Original Equipment Manufacturer (OEM), which serves customers comprising of more than 500 airlines, 4,000 corporate and utility aircraft and helicopter operators, 160 armed forces and 2,000 marine based organisations. Their annual sales total approx. \$9 billion, of which 55 per cent are services revenues. The paper will start by reviewing the literature concerning supply chain management and the use of information systems as a means to improve performance in this area. It will present the rationale for the methodology that was employed and how this was operationalized. The results of the study will then be presented, including: how the technology that integrates multiple tiers in the supply chain works; the motivational antecedents that were responsible for it being developed and deployed; and the factors that were seen as being responsible for enabling the benefits attributed to the system being realised; and the benefits attributed to it.

II. Supply Chain Management

Supply chain management is a concept that is emerging in recognition that buyer-supplier relationships need to be managed beyond logistics and procurement functions

(Lambert *et al.*, 1998; Cooper *et al.*, 1997). In the literature, supply chain management has been defined as a “*connected series of activities that are concerned with planning, coordinating and controlling of materials, parts and finished goods from suppliers to customers*” (Stevens, 1989), or “*the management of upstream and downstream relationships, with suppliers and customers, to deliver superior customer value at less cost to the supply chain as a whole*” (Christopher, 1998). As supply chains often involve more than a dyadic relationship, Mentzer *et al.*, (2001) defined it as “*a set of three or more entities (organizations or individuals) who are directly involved in the upstream and downstream flows of one or more of products, finances and/or information, from a source to a customer*”.

Research in supply chain management encompasses a number of evolving factors in relation to how organizations cooperate and compete. These factors include the use of virtual teams (Bal *et al.*, 1999), sharing risks and rewards (Cooper and Ellram, 1993), integration of business processes (Stevens, 1989; Christopher, 2000), improved information sharing (Mason-Jones and Towill, 1999; Morash, 2001), and developing long-term relationships with key suppliers (Cousins, 1999; Schonsleben, 2000). Managing a single organization within a larger collaborative environment also requires a different set of competencies, such as in managing interorganizational processes (Garcia-Dastugue and Lambert, 2003) and exploiting information systems and technology to facilitate multi-tier integration (White and Daniel, 2003).

Within the management of supply chains, two paradoxes are present, which create a level of uncertainty as to what strategy supply chain managers should employ. This can be articulated in a number of ways. For example, should an organization seek to make its operations and supply chain more “lean” (Womack and Jones, 1994; Karlsson and Par, 1996) through the removal of waste (minimising inventories, reducing process inefficiencies and minimising obsolete stock) or more “agile” (Christopher, 2000) (where excess capacity is required to respond to sudden changes in factors such as demand)? Secondly, should an organisation adopt a competitive position in its relationships with suppliers (Lewis and Yildirim, 2002), and thus create a high rate of turnover of suppliers, or should it invest in longer-term collaborative relationships with suppliers (Cousins, 1999; Schonsleben, 2000)?

III. Information Systems In The Supply Chain

The use of interorganizational systems to link up different actors within a supply chain is not a new concept that originated with the advent of the Internet. These systems have been utilized by organizations for a number of years, combined with the medium of EDI (electronic data interchange), to facilitate electronic trading (Cunningham and Tynan, 1993). Whilst EDI systems brought benefits to trading partners, it's use was limited due to high costs and limited content (Frohlich, 2002) and low levels of flexibility

in it's implementation and operation (Nurmilaakso *et al.*, 2002). Nevertheless, researchers in interorganizational systems can learn much from EDI implementations, for example, in understanding the role of dominant buyers (Webster, 1995), due to the similarities between these two technologies (Soliman and Janz, 2004).

Interorganizational systems built upon the foundation of an organization's internal information systems, often referred to as ERP (Enterprise Resource Planning), are increasingly being used to manage processes that interface or integrate with customers and suppliers (Shaw, 2000). These ERP systems integrate information and information-based processes within and across functional areas, and employ reference models or process templates that claim to embody good practices within an industry (Kumar and Hillegersberg, 2000). As the importance of extending the orientation of the management of business processes, from within the organization, to between organizations (Clark and Stoddard, 1996), the evolution of information systems designed to manage supply chains occurred (Stefansson, 2002; Nedede-Amadi, 2004). These are defined as information systems that: facilitate demand and manufacturing planning and communication between trading partners, synchronize activities within the supply chain and maintain the provision of timely information (Tarn *et al.*, 2002); provide the capability to transfer more accurate and timely information that results in higher levels of visibility of demand and inventory in a supply chain (Patterson *et al.*, 2003); facilitate market mechanisms (a means to conduct a business transaction) and coordination flows (the sharing of information to coordinate the flow of products) (Garcia-Dastugue and Lambert, 2003); and are not confined to a single organizations processes, programs, data repositories but are able to interoperate with other systems that manage links in the supply chain (Yang and Papazoglou, 2000)

The important roles that information systems and technology play in the operations and management of supply chains have repeatedly been highlighted in the literature. However, much of this research is conceptual in nature (see Manthou *et al.*, 2004, Lin and Lin, 2004, Swaminathan and Tayur, 2003; Strader *et al.*, 1998 as examples), and thus a paucity of empirical papers exists. Previous research has indicated, for example, the impact of information systems and technology in increasing the performance of supply chains (Frohlich, 2002; Goutsos and Karacapilidis, 2004; Jayaram, *et al.*, 2000; Alkadi *et al.*, 2003), the alignment between supply chain strategy and business strategy (Williams *et al.*, 1997), and overall growth and profitability (Kotha and Swamidass, 2000; Byrd and Davidson, 2003). On a more operational level, the adoption of information systems and technology has been linked to an increase in product offerings and customer service levels (Kincade *et al.*, 2001), quality and timeliness of production information (Brandyberry *et al.*, 1999), lowering the total cost of supply and increasing the order fulfilment rate (Lin *et al.*, 2002). Even the perception about trading partners' technology adoption, according to previous research, could improve the

supply chain relationship between both parties (Kent and Mentzer, 2003).

A paradox also exists in the effect that information systems have on interorganizational relationships, which bears similarities to ones observed in interorganizational relationships in general. In their “move to the market” hypothesis, Malone *et al.*, (1987), suggest that increased use of interorganizational information systems will enable a greater use of markets relative to hierarchies. In contrast, in their “move to the middle” hypothesis, Clemons *et al.*, (1993) assert that due to the existence of relationship specific investments, this move to the market will not occur, rather that “*the firm will rely on fewer suppliers than before, with whom the firm will have close and long-term relationships and with whom the firm will cooperate and coordinate closely*”. In recent studies on the impact of Internet-based electronic marketplaces on buyer-supplier relationships, it was found that these entities are having an impact on the characteristics of interorganizational relationships (White and Daniel, 2004; White, *et al.*, (2004).

This review of the literature has demonstrated the increasing importance of supply chain management to contemporary organizations, and the pivotal role that information systems undertake in enabling high levels of operational performance in this area. However, both the practice of supply chain management and the use of information technologies in this domain are in a state of evolution. Therefore, there is a continual possibility of innovative practices emerging through the syntheses of developments in these two areas.

IV. Methodology

The objective of this study was to explore the potential role of emergent information systems and technologies in enabling innovative models that would increase the level of supply chain performance. The study seeks to explore a new domain for the purpose of theory generation. Such strategy would require the use of inductive, qualitative methods rather than deductive, quantitative research methods which, in contrast, is more appropriate for theory testing (Hussey and Hussey, 1997; Locke, 2001). As inductive methods are more frequently operationalized through case studies (Eisenhardt, 1989; Yin, 1989), this approach was therefore adopted. The value of the case study approach, according to Hoskisson (1999), also lies in its ability to consider theory in the context of the rich picture of the organisation studied, including its unique idiosyncrasies.

The OEM was selected because it was undertaking activities that aimed at integrating multiple tiers in its supply chain. This was something that in the experience of the authors was a very uncommon practice in how contemporary supply chains operate, and which a review of the literature substantiated. Given that problems which characterise supply chains, such as demand amplification (Forrester, 1961; Lee, *et al.* 1997), span multiple tiers in the chain, it is fair to assume that technological interventions that span

these tiers should warrant academic study. Therefore, the study adopted the following research question: to investigate the phenomenon of multi-tier integration systems (MTIS) and to examine the technical and managerial competencies needed to operate in this mode.

The supply chain under investigation involves a highly specialised manufacturing process for which there are only a very small number of suppliers globally. Moreover, the manufacturing process utilizes high quality specialist alloys, for which global demand is constrained and shortages frequently occur. The process, which is presented as Figure 1, shows how customer demand is received by the Final Build operation in the OEM. This is then communicated to the Module Build manufacturing cell, again within the OEM. From here the demand signal is passed on to a tier 1 supplier, who in this case is a producer of highly engineered metal components. They in turn pass on the signal to a tier 2 supplier of specialist materials. Inventory is positioned all along this supply chain and moves as a consequence of demand information signals.

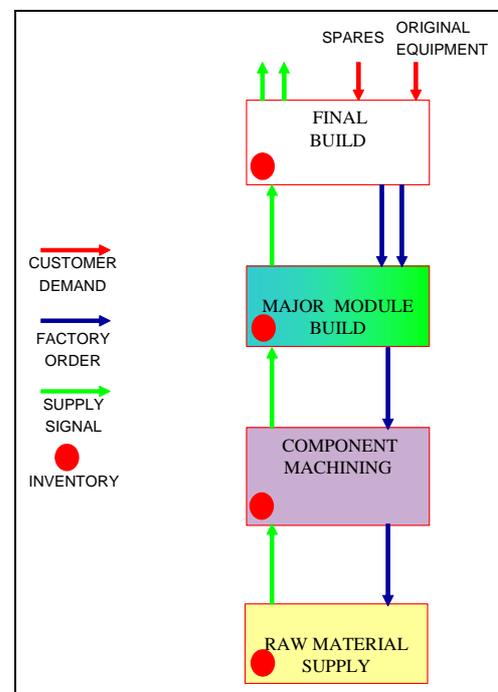

FIGURE 1 – THE OEM'S SUPPLY CHAIN

In order to investigate the use of the OEM's multi-tier integration eleven interviews were undertaken, in both the UK and in the US, with each actor in this process (see Table 1 for details). Each interview lasted between one and two hours and was tape-recorded and transcribed. The interview findings were supplemented by supporting documentation from the OEM, its suppliers and the technology vendor and from external commentators.

Organisation	OEM	Tier Supplier 1	Tier 2 Supplier	IT Vendor
Industry Sector	Aerospace	Industrial Manufacturing	Material	IT
Supply Chain Staff Interviewed	4	4	1	1
Location of Interviews	UK	US	US	UK

TABLE 1 – INTERVIEWS CONDUCTED

V. Results

V. 1 Motivational Antecedents

The motivational antecedents that were responsible for the development and deployment of the information system that integrated multiple tiers in the supply chain stemmed from a need to reduce the demand amplification that was occurring across the supply chain. This supply chain can be characterized by the following phenomena: it plays a crucial role in the building of the OEM's core product, the current build time is 120 days and has a target to be reduced to 40; demand information frequently fails to cascade down the supply chain, thus leaving suppliers working with incorrect or out of date forecast information; the consequence of this is either shortages or excesses of inventory, both of which incur financial consequences; to date there has been no means to enable visibility of demand, supply and inventory across the supply chain; due to the volatility of supply and demand signals there is a low level of reliance on the interorganizational processes that are currently in place.

The demand amplification in the supply chain was being caused, from an external perspective, by a post 9/11 growth in sales and shortages of supply for materials such as titanium. However, internal factors were also responsible. The consequence of this was a supply chain that was under performing, with the consequential impact on costs and revenue. It was described in the following terms by one supply chain manager from the OEM:

"In simplistic terms I would say that 50% of the noise [schedule variation] is generated internally from our organization and 50% by the supply chain not being able to support our delivery dates."

This demand variation appears to of been exacerbated by the adoption of "lean thinking" in the aerospace industry (Womack and Jones, 1994). Low levels of inventory, coupled with deficient processes can lead to a under performing supply chain, as described by a manager from the OEM:

"The elimination of waste and all of that type of activity is absolutely right for any organization, I agree with that. However, I believe that lean and systematic removal of waste from a process, or from any manufacturing process, can only

be achieved providing you've got stability [in demand] and you've got capable processes. The problem as I see it is that our internal manufacturing facilities and suppliers have responded with the systematic removal of inventory. The problem with removing inventory without improving your processes is that it makes you very exposed."

When looking across the supply chain, this phenomenon is exacerbated by the fact that the OEM, hitherto, has had no direct communication channel with the tier two supplier. It is this supplier who is the first to witness shortages of material, which have a consequential impact on the poor performance of the supply chain.

"The situation is that all our problems don't lie with the first tier suppliers. The first tiers often put their hands up and say it's not my fault, it's the material supplier. The problem is he [the material supplier] does not have direct communication with the OEM."

There would appear to be certain circumstances, under which multi-tier integration is appropriate, in other words, an emergent "design science" (van Aken, 2004). So what are these circumstances? Firstly, from a commercial perspective, that the number of alternative suppliers must be relatively low and the value of the transactions undertaken with them relatively high. Secondly, from an operational perspective, that the production time must be greater than the customer lead time. And finally, from a technical (and product safety) perspective, that the product must have a high impact on safety and possess a high level of technical risk.

V. 2 The Multi-Tier Information System

The MTIS works by taking data from the OEM, the tier 1 supplier and the tier 2 supplier and presenting it in a common format. The data is accessed via a website, which all three parties have access to, and regular teleconferences are held to discuss the content. This process is presented as Figure 2, which shows how the information system enables an integrated product team across the supply chain.

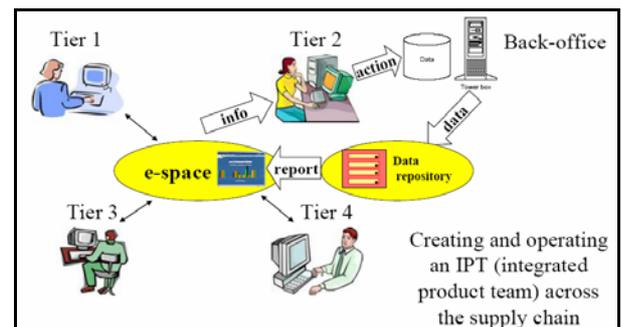

FIGURE 2 – THE INFORMATION SYSTEMS ENABLED MULTI-TIER INTEGRATED PRODUCT TEAM

The types of data which the information system manages are: inventory, its location and status (e.g. work in progress); the forecasts for future demand; and customer orders. The system uses Web Services as an underpinning technology and is based on the J2EE standard. The benefit of this type of technology was suggested to be twofold and is described

as:

“The system has got 2 layers to it. It’s got a data transport layer, which means you can transport data without having to redefine it, and the process and application layer. So the application which visualises the data has been designed with the data in mind. So these 2 things sit together, so you’ve got a transport system and an application bolted together. And that’s important because the transport system allows everybody to feed in their data without redefining the process.”

“The one thing that I didn’t want to do was to work outside of the core ERP system, and the benefit that the multi-tier system had was that it was using direct data that could be readily updated from our ERP system. That was absolutely pivotal. I didn’t want to create another ERP system within the supply chain, going all the way down and all the way back up.”

V. 3 Managerial Challenges and Implications

The use of the MTIS required a number of non-technological changes to take place in order for the potential benefits to be captured. These changes covered factors such as the emergence of a supply chain mindset, the integration of marketing and logistics functions and understanding the boundaries concerning what could be discussed and communicated via the multi-tier relationship.

V. 4 A Supply Chain Mindset

The adoption of information technology often brings with it a subsequent need for a new mindset within the organisation (Stevens, 1989; Orlikowski, 1992). The use of a MTIS was no different in this respect. What enabled this change was the ability of the information system to share data across multiple functions and organizations, and use this data to coordinate a unified response.

“What the IT does is that it enables people beyond the first tier supplier to have weekly or bi-weekly meetings given a set of data that is not open for debate. Everybody’s got the same data and will start planning around issues that might hit us if we don’t do something in 6 – 7 months time.”

This in turn gave a new perspective to operators concerning the consequences of decisions they made and constraints that the parts of the supply chain, that they hitherto had no visibility over, were under.

The value of getting the people from [the OEM] to be able to start understanding that there isn’t an infinite capacity out there.”

V. 5 Marketing / Logistics Integration

The separation of the marketing and logistics functions of an organization is increasingly being seen as a major inhibitor to a high performing supply chain. Hence the emergence of the concept and practice of demand chain management. This case illustrates this point, in that the use of the MTIS brought these two departments together to work in a much more coordinated manner:

“The purchasing people in the first tier supplier would normally not have any visibility of the interaction between us and the customer facing department. The use of multi-tier integration meant they saw the 2 year horizon that we were giving their commercial people. This enabled them to work with the commercial people and to be able to conduct a lot better planning of their procurement activity.”

Funny enough it provided clear transparency for the first tier suppliers as well, so the purchasing organisation at long last started to understand what sales people were doing, and the planning people could plan around that in the mill [tier 2]. This also enabled the sales people and the planning people within the tier one organization to work around a common set of data, and these people could be all together in the same virtual room or whatever you want to call it. This ensured everybody understood the key issues.

V. 6 Multi-Tier Relationship Boundaries

Operating multi-tier relationships, rather than just dyadic relationships, requires a realization of what the norms are that should cover these new types of relationships. These types of relationships challenge the normal dyadic structure of relationships: OEM to tier one, and then tier one to tier two. The whole point of such an exercise is that some factors are no longer solved on a bi-lateral basis, rather a multi-lateral one. The following insight from a supplier shows one aspect of the demarcation that needs to take place:

“You certainly have to be more open with the three way relationship. However, there are still things that are out of bounds. Pricing is one of them. But as far as working out issues such as quality and schedules, that makes perfect sense.”

V. 7 Realized Benefits

The major benefit of the multi-tier information system was the moving from a reactive management of the supply chain to a proactive one. The situation prior to the use of the MTIS was that *“nobody knew there was a problem till there was a problem. Then you were in a highly reactive mode”*. With the MTIS *“because we take a 12-month view, we’re always looking ahead to see where the shortfall is because we actually ask them [the supplier] to give us the view of their output for 12 months in support of our product. Now what this shows is that we can look ahead and can see if they are planning to produce less than what we need. Now we are able to say OK, well, that’s what you’ve got planned for the next 12 months and you won’t have any major cause to change that pattern unless we do something.”*

This has enabled the performance of the supply chain to improve from schedule adherence rates of around 25 – 50% before the MTIS, to 100% when it was implemented. This improved performance has been enabled by an increased level of operational responsiveness within the suppliers business. This improved responsiveness in the tier two supplier is described in the following terms:

“What they say now is look, we’re prepared, on a basis of what we’re seeing, to create raw material in bulk form at

a rate per month. We're not going to wait for your orders, we're going to plan to actually smelt and process at a set rate. So effectively they're saying that they've got confidence now because they can see through our signal without having to second guess what the tier one supplier is saying to them."

The consequence of this was that the lead times for the product that this supply chain produces has fallen from 6 or 7 months to 3 months. This is a very clear indication of an improvement in a supply chain's agility and its ability to be customer responsive. Moreover this has been achieved without any stock outs and a cost reduction has been negotiated as recognition of the reduced operational and inventory holding costs in the supply chain.

VI. Conclusions

This paper has presented a case study on a groundbreaking supply chain management information system in the aerospace sector. It has shown how multi-tier integration, between three tiers in the supply chain, can occur via the use of new technological standards, namely Web Services. This technology allows data to be taken from disparate systems across a supply chain, consolidated in a web-based information system and then the results of these data feeds presented to parties from all three tiers. This data, namely supply, demand and inventory, can then be analysed and a collective decision made regarding how the supply chain should operate. These standards allow for the manipulation of what can be regarded as supply chain processes, without interfering with the underpinning systems and the complexity that this would involve. Our study shows that the evolution to this type of planning requires a supply chain mindset to be present. This is where variables across the supply chain are considered, not just those within the operators own organization. Moreover, to fully exploit the potential of this technology, attention should be paid to the integration of the marketing and logistics functions in the tier one organisation, as communication between these two entities is pivotal to this approach. We also noted an adherence to a set of rules or principles of behaviour when operating in this environment e.g. conversations between the OEM and the tier 2 supplier must not cover issues of prices. That was considered a proprietary discussion between the tier 1 and the tier 2 organization.

Significant organisational benefits attributed to this information system were observed. These include a shift from a reactive to a proactive supply chain management approach; improved levels of schedule adherence and an improved level of operational responsiveness, which is leading to a significant reduction in the supply chains lead time.

In summary, this paper has shown that going beyond dyadic supply chain relationships is being enabled by breakthroughs in new technologies, which in turn are enabling new levels of agility to be delivered and levels of customer responsiveness achieved.

Abstract: As competition becomes more intense, it is becoming increasingly important for a firm to build an efficient supply chain for its survival and prosperity. One way to build an efficient supply chain is to integrate the supply chain activities by the member firms of different levels on the supply chain by developing cooperative relationships between firms.

Many factors are involved in developing cooperative relationships between firms, and their effects need to be studied. This paper investigates what factors are critical to build a cooperative buyer-supplier relationship in auto parts manufacturing industry.

Data was collected from two groups of firms in Korean auto parts manufacturing industry, 1st-tier parts suppliers and 2nd-tier parts suppliers. Our study reveals that there are significant differences in the way of collaboration depending on the level of the relationships.

Keywords: SCM & E-logistics; Auto industry; Multi-echelon supply chain.

I. Introduction

Nowadays supply chain management is a very popular word for industry practitioners as well as academics. As competition becomes more intense, it is becoming increasingly important for a firm to build an efficient supply chain for its survival and prosperity. One way to build an efficient supply chain is to integrate the supply chain activities by the member firms of different levels on the supply chain by developing cooperative relationships between firms, which means extending supply chain integration into further down the levels of the industry structure.

For no other industry is this true than automobile manufacturing industry of which the structure is very complex with multiple levels of firms from auto manufacturers and parts suppliers to the suppliers of suppliers, etc. Many factors are involved in developing a cooperative buyer-supplier relationship between firms in auto manufacturing industry, and their effects need to be studied. Also, researches often overlook the relationships beyond auto manufacturers and the 1st-tier part suppliers.

This paper attempts to investigate the buyer-supplier relationships in the auto parts manufacturing industry by

trying to find out what factors are critical to build a cooperative buyer-supplier relationship, and whether there are any differences in the degree of collaboration between different levels of relationships, i.e., auto manufacturers and 1st-tier parts suppliers, and 1st-tier suppliers and 2nd-tier suppliers.

For this research, we are using the data collected from Korean auto parts manufacturers. Korean auto manufacturing industry is very sizable with a 5.8% of the world total production in 2002 (Korea Auto Industries Cooperation Association, 2003), and its exports to the world market is also increasing every year. The majority of Korean auto parts manufacturers is small to medium sized enterprises (SMEs), and thus are lagging behind in implementing supply chain management in their firms due to a lack of resource in financial, human, and technology area. Also, many of them are very dependent on the buyer firms in supply chain integration issues. Our research would provide useful insights into the current situation of the industry and also future directions for working toward mutually beneficial relationships among firms.

II. Literature Review

Many previous studies investigated the relationships between buyer firms and supplier firms, and found that both groups of firms will benefit more from the cooperative relationships than the competitive relationships. Table 1 contains some of the previous research that investigated various types of the buyer-supplier relationship and its impact on the firms.

In the 1980's, Japanese auto makers made an impressive progress in the US market with high quality cars, and it was considered that the high quality could be achieved by the cooperative relationships between Japanese auto makers and their suppliers. Nishiguchi and Brookfield (1997) examined and compared US and Japanese auto industry, and their findings attributed the Japanese auto makers' success to the cooperative buyer-supplier relationships. Maloni and Benton (1997) suggest that it is essential for a firm's survival to have cooperative relationships with their suppliers. Other studies also examined various types of buyer-supplier relationship and its impact on the firms' performance and the efficiency of their supply chain.

III. Research Methodology

III.1 Hypotheses

The variables representing each factor of the model and the related previous studies are described in Table 2. Dependent variable is the degree of cooperation between firms which are auto manufacturers, 1st-tier parts suppliers, and 2nd-tier parts suppliers. Independent variables include information system related variables, firm’s commitment to the relationships, JIT (Just-in-Time) environment, and bargaining power.

Table 1. Summary of previous studies.

Researcher	Content
Nishiguchi and Brookfield (1997)	Compared US and Japanese auto industry. Japanese auto industry has more cooperative buyer-supplier relationships.
Maloni and Benton (1997)	Emphasized the importance of the buyer-supplier cooperation.
Harwick (1997)	Cooperation with the supply chain partners for improving the supply chain efficiency.
Cooper (1993)	Reasons that firms form a supply chain (inventory reduction, improving service, etc.)
Lamming (1993)	Suggest a lean supply chain model in auto industry to understand the buyer and supplier relationship.
Han (1993); Fisher et al. (1994); Imne and Morris (1993)	The importance of buyer-supplier relationship for a firm’s competitive advantage.
Shapiro (1985); Spekman (1988); Landeros and Monczka (1989); Burt (1989); Bensaou and Venkatraman (1995); Helper (1991); Helper and Sako (1995)	Investigate the various types of buyer-supplier relationship: competitive vs. cooperative open market negotiation vs. vertical integration integrated vs. structural
Smith et al. (1995);	Trust and cooperation between firms.
Landeros (1993);	Define the cooperative relationships

Figure 1 contains the research model showing the relationships between the tiers of firms in the supply chain, and hypotheses are constructed as below for each of the relationships indicated as H1 through H3.

H1: Collaboration between firms is positively related to the independent variables selected (information system, commitment, JIT environment, bargaining power).

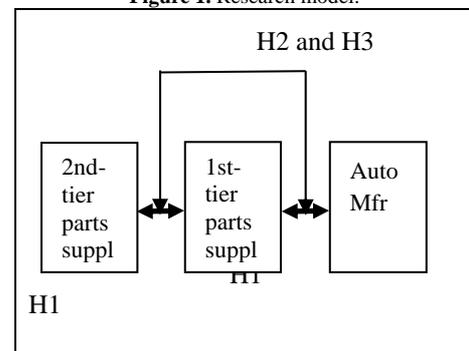

H2: The intensity of collaboration is different between the 1st-level relationship (auto manufacturer and 1st-tier parts suppliers) and the 2nd-level relationship (1st-tier and 2nd-tier parts suppliers).

H3: Important factors affecting collaboration are different between the 1st-level and the 2nd-level relationships.

Table 2. Description of the variables.

Variable	Name	Content
Independent	Information system	Informatization level Information exchange Information sharing
	Commitment	Technical cooperation Length of relationship
	JIT environment	JIT environment
	Bargaining power	Bargaining power on transaction condition
Dependent	Collaboration	Degree of cooperation

Figure 1. Research model.

III. 2 Data Collection

Data for this study was collected from auto parts manufacturers through survey in 2003-2004. The survey questionnaire consists of 35 questions. The survey was conducted by company visits and e-mails inviting managers to participate in the survey through the active server page on the web site. The respondents are the staff of the sales department in each company, and thus familiar with the relationships between their own company and their buyer company. A total of 69 companies participated in the survey, and 67 of them were used for this study after two were discarded due to incomplete responses. They were divided into two groups depending on their relationship with the

automobile manufacturers. 35 companies were the 1st-tier parts suppliers, and 32 companies were the 2nd-tier parts suppliers.

The survey questions are answered by 5-point Likert-type scale except those requiring single item answers. We used descriptive statistics, factor analysis, t-test, and regression to analyze the data. The summary of the results are presented in the tables.

IV. Analyses and Results

Tables 3 through 5 show the results of the tests to find out the relationship among the variables and to determine the acceptance of the hypotheses presented in the above.

IV. I Test of Hypothesis 1

We used simple and multiple regression analyses to find out what variables affect the inter-firm collaboration level and the results are presented in Table 3. In simple regressions, each independent variable was individually tested, and in a multiple regression analysis all the independent variables were tested with the dependent variable. Except the JIT environment, the effect of all the other variables turns out to be significant. Therefore, information sharing, commitment and bargaining power are all important for developing and improving inter-firm collaboration. However, a simple delivery of parts on time, i.e. JIT implementation alone, may not be enough to enhance the inter-firm collaboration.

Table 3. Test of Hypothesis 1 (simple regression).

Variables	b	t	p-value
Information sharing	0.491	4.541	0.000
Commitment	0.686	7.610	0.000
JIT environment	0.097	0.784	0.436
Bargaining power	0.502	4.674	0.000

IV. 2 Test of Hypothesis 2

We used t-test to determine whether there is difference in the degree of inter-firm collaboration between the 1st-level relationship (auto manufacturer and 1st-tier parts suppliers) and the 2nd-level relationship (1st-tier and 2nd-tier parts suppliers). Table 4 shows the results. The difference turned out to be significant at $\alpha = 0.05$. Thus, firms tend to have different degree of inter-firm collaboration depending on which level a firm belongs to in a multi-echelon supply chain. The suppliers in the first level seems to have a closer relationship with auto manufacturers than the relationship between the first level suppliers and the second level suppliers. A possible reason for this may be that the firms' infrastructure such as information system is more compatible in the 1st-level relationships than the 2nd-level.

Table 4. Test of Hypothesis 2 (t-test).

group	N	mean	s.d.
1st-level relationship	35	2.83	0.776
2nd-level relationship	32	2.38	0.875
t = 2.248, df = 65, p-value = 0.028			

IV. 3 Test of Hypothesis 3

We conducted simple regressions separately for the 1st-level and 2nd-level relationships and compared the results with each other. As shown in Table 5, the important variables affecting the inter-firm collaboration are not different between the two levels. For both cases, information sharing, commitment, and bargaining power turned out to be important to develop inter-firm collaboration.

Table 5. Test of Hypothesis 3 (simple regression).

Variables	1st-level	2nd-level
Information sharing	Significant (0.081)	Significant (0.002)
Information sharing	Significant (0.081)	Significant (0.002)
Commitment	Significant (0.000)	Significant (0.003)
JIT environment	Not (0.322)	Not (0.659)
Bargaining power	Significant (0.021)	Significant (0.001)

V. Conclusion

We have found several factors important for inter-firm collaboration. Specifically, important factors include information sharing, commitment, and bargaining power. JIT environment was not found to be essential for developing inter-firm collaboration. This results confirms the findings by Helper(1991) that JIT implementation was not necessarily an indication of a cooperative relationship. Secondly, the level of collaboration increased as the relationships were closer to the auto manufacturer. That is, the 1st-level relationship has a higher degree of inter-firm collaboration than the 2nd-level relationship. Lastly, there were no difference in the factors affecting inter-firm collaboration between the two levels. In both levels of relationships, the three factors of information sharing, commitment, and bargaining power had a significant impact on the inter-firm collaboration.

Summing up the results, firms need to develop a proper communication system for information sharing, and a trustworthy relationship through commitment such as a long-term contract, and allow suppliers with a certain degree of bargaining power for determining delivery, price, payment method, etc.

Abstract: Falling margins, globalization, and accelerating innovation cycles are forcing businesses to switch from traditional (linear and sequential) supply chains to adaptive supply chain that possess the flexibility needed to respond to the environment in real time. As adaptive supply chains are large and complex, they are built step-wise using structures; structures are a well-defined portion of the system, with carefully defined inputs, outputs, and functions. In addition, the structures must follow common standards, based on common architecture for seamless integration with the rest of the components. In this paper, first, we present the problem of implementing a new iterative-based distribution chain that has four distinctive modules. Second, we present a survey of commonly used structures in some of the well-known modern supply chain solutions (e.g. stages in SAP, layers in HP Real Time Supply Chain, modules in i2 Six/IBM) is presented. Third, by going through the structures, we present an optimal solution for implementation of the adaptive distribution chain.

Keywords: Supply chain, adaptive system, structures in design and development.

I. Introduction

Supply chain efficiency is one of the fundamental issues for the survival of enterprises in today's hyper-competitive business environment. In addition, in the world today, the amount of uncertainty that enterprises are facing (e.g. terrorist attacks, labor strikes, other sources of vulnerabilities such as sabotage and weather-related issues), makes supply chains much more vulnerable. Hence, enterprises implement *adaptive* supply chain to withstand unpredictable shocks, and to respond to the environment in real time without compromising on operational and financial efficiencies.

The characteristic of an adaptive supply chain is to have the highest visibility, greatest velocity, and best ability to manage variability [3][4]. Visibility is the ability of all the collaborating partners sees the vital data; velocity is the speed of information flow across the supply chain; variability is the ability to withstand unpredictable events. Achieving these three characteristics is not easy considering the complexity and diversity of the applications collaborating partners are using. Thus, most supply chain solutions develop supply chain step-wise, using well-defined structures.

easier to acquire, there are often too a large number of available features. For example, in the cases of book or movie recommendation, there can be a large number of keyword features of the products from their themes, genres, and text-based description of the products. These features may directly affect the choice of shoppers, and thus, are often used as key features of recommendation, especially for cultural and content-focused products. This problem may lead to inefficiency or ineffectiveness of recommendation. In terms of efficiency, inaccurate or irrelevant keywords may require huge system memory or lead to increased processing time; in terms of effectiveness, there can be often inaccurate or irrelevant words that may damage the recommendation quality. Consequently, it has been recognized to be very important to extract a more meaningful subset of features that can contribute better to recommendation performance [1, 5, 8].

In this study, we utilized a data set that was constructed from a virtual shopping experiment in an Internet book shopping mall in Korea to find out how feature reduction techniques that have been widely used in pattern matching or information retrieval can be applied to the recommendation problem. We used a Korean lexical analyzer to extract features and use the features to construct user and product profiles. The Term Frequency (TF), Inverse Document Frequency (IDF), TFIDF, mutual information, and Singular Value Decomposition (SVD) methods were chosen and adapted for the experiment.

The remaining part of the paper is organized as follows. In the second section, we provide a brief review of feature selection methods from other disciplines. In the third section, we explain the experiment procedure and present the results of the analysis. The fourth section concludes with discussion and further research issues.

I. 1 Problem definition

Figure-1 shows an iterative approach for developing agile distribution chain, for details see [1]. The iterative approach consists of two parts: the first part is to determine the strategic model and the second part is to determine the tactical model. The strategic model gets the initial values for the configuration of the distribution chain (e.g. number of distributors, location of distributors, etc.) from the ongoing or past collaborations of the virtual enterprise. Mixed Integer Programming (MIP) is used for determining the strategic model. In the tactical model, two issues are mainly considered: identifying routes for vehicles by genetic algorithm, and determining parameters for inventory control by probability theory.

After determining tactical model, the newly calculated

operation related parameters (e.g. the unit product delivering cost, average inventory level, etc.) are input again into the strategic model in order to re-optimize the configuration of the distribution chain. Thus, this is a complex to system to build; we need a step-wise approach to develop this supply chain using well-defined structures. The main purpose of this paper is to survey the structures in modern supply chain solutions, so that an optimal structure could be found for step-wise implementation of the adaptive distribution chain shown in figure-1. Since there are numerous business solutions available for developing adaptive supply chain, this paper surveys only the few well-known ones.

In this paper: a survey on the structures for step-wise development of modern adaptive supply chain solutions is given in section-2 (“literature review”). From this survey, an optimal structure for step-wise development of the adaptive distribution chain is given in section-3 (“Implementing Adaptive Distribution Chain”). Finally, section-4 presents some concluding remarks.

II. Literature Review

The structures that are used to develop supply chain step-wise should be a well-defined portion of the system, with carefully defined inputs, outputs, and functions [5]. In addition, the structures must follow common standards, based on common architecture for seamless integration with the rest of the components. Commonly used structures in supply chain development are:

- Stages [4],
- Layers [2], and
- Modules [3]

The following section presents some supply chain solutions and the structures used by them.

II.1 SAP: Development in Stages

The basic design methodology behind SAP’s adaptive supply chain is to map the three key process enablers (such as management of visibility, management of velocity, and

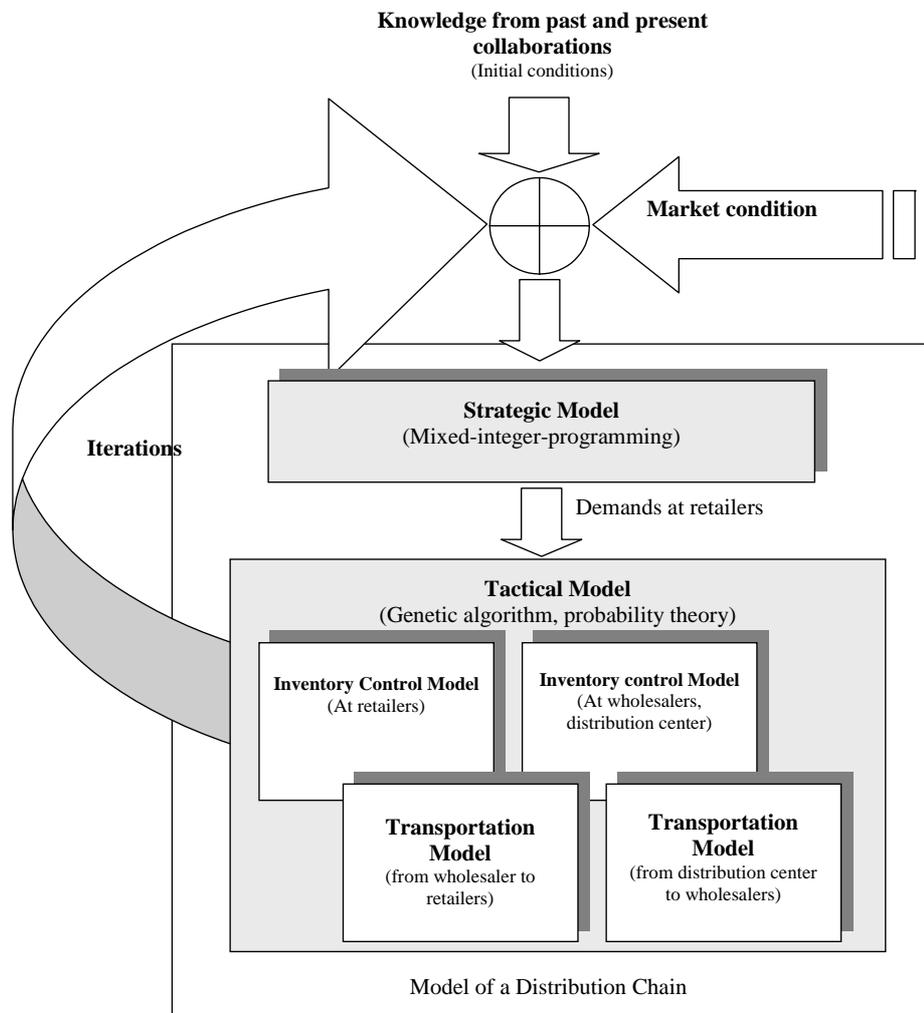

Figure-4: The iterative approach for adaptive distribution chain design

management of variability) to the three key information enablers (such as quality of information, timeliness of information, and depth of information). The mapping is strengthened in three stages such as integrated, collaborative, and adaptive [4].

The three mappings of process enablers to information enablers: Visibility of quality information is the fundamental building block for adaptive supply chain. This is because visibility to both intra- and inter-organizational information is critical for rapid response to changing market conditions. For example, information visibility of orders, plans, supplies, inventory, and shipments is key to both successfully coordinating events across the supply chain and for monitoring and taking proactive actions across the chain. Thus, the first mapping along the adaptive supply chain development is the mapping of visibility on information quality.

After achieving visibility of quality information, the next mapping is to increase the velocity of response by accessing and distributing information rapidly across the supply chain, as velocity of response is the key differentiator in business performance.

As depth of information will allow enterprises to better manage unpredictability (variability) introduced to the supply chain, mapping of these two enablers is the final aspect of developing adaptive supply chain for a dynamic business.

The three stages: To create an adaptive supply chain, SAP make sure that the enterprise advance from traditional supply chain to adaptive supply chain through three specific stages; the three stages are integrated, collaborative, and adaptive [4].

The integrated stage is the first step towards formation of adaptive supply chain where improvement of the operational visibility and efficiency is accomplished, by integrating diverse applications run by the collaborating partners. The fundamental concept behind integrated stage is that the extent of integration directly determines the degree of visibility and that visibility is the basic building block for an adaptive supply chain. In the second stage known as collaborative stage, the ability of the supply chain to exchange real time information is improved; in other words, the velocity of information is improved. The final stage is the adaptive stage, which is concerned of managing variability.

II. 2 Hewlett-Packard: The Layered Approach

Hewlett-Packard (HP) emphasizes real time application integration for developing adaptive supply chain (or in HP terminology - the real time supply chain (RTSC) [2]. The RTSC is organized around three layers:

1. The foundation layer: In this layer, the data management component creates a single, consolidated and cleansed repository of key supply chain data from all supply chain applications across the enterprise
2. The middle layer: In this layer, supply chain business

applications component integrates existing supply chain applications and provides them with a single, real time view of the entire supply chain.

3. The upper layer: In this layer, supply chain consulting and integration components provide the services and best practices from HP and its partners

In summary, HP develops adaptive supply chain in three stages: data integration, application integration, and finally service integration.

II. 3 i2: Modular Approach

i2 Six uses a modular approach for developing adaptive supply chain. The modules can be implemented independently to suit enterprise's specific needs and pressing business challenges first, enabling gradual implementation. The six modules for developing adaptive supply chain are [3]:

1. Production optimization (meeting the demand in real time),
2. Spend optimization (supplier relationship management),
3. Revenues and Profit optimization (Demand management, customer relationship management),
4. Fulfillment optimization (real time planning, build-to-order, inventory management),
5. Logistics optimization, and
6. Business optimization (Business and process definitions, supply chain analysis)

All these six modules are based on common architecture, common infrastructure, and common parameter-based tools, allowing independent implementations and addition of new functionality.

III. Implementing Adaptive Distribution Chain

Developing supply chain in stages allows an enterprise to take the time it needed; the time taken for an enterprise to implement supply chain solutions vary depending on its degree of technology mastery, the process maturity, and the characteristics of the business. The main advantage of using stages is that each stage provides a functional (it could be crude yet functional) system. The main disadvantage of the stages is that if a new stage is planned from the current stage, then it is possible that the current stage could not support evolution of the new stage from it. Then, we may have to go previous stages to make the necessary changes (meaning, rewriting code) so that current stage become robust enough to support development of a new stage from it. Hence, whenever a new stage is planned, one should anticipate drilling through several previous stages.

In developing supply chain in layers, the supply chain is broken into a number of layers (levels). The bottom layer (layer 0) is the common integrating infrastructure that connects supply chain with the communication platform; the

bottom layer is the most primitive layer offering only the basic hardware interface/communication/operating systems services. The highest layer (layer N) is the application layer interacting with the user and the rest of the applications. The main advantage of the layered approach is simplicity of construction and debugging [5]. The main disadvantage of layered approach is that a group of layers do not provide a fully functioning system; we have to have all the layers (from layer 0 to layer N) to make a functioning system offering some services to the user.

Modules give the freedom of selecting and implementing only those modules with specific functions that are needed to take care of pressing business challenges. Though modular implementation resembles layered approach, modules are more flexible than the layered system in the sense that any module can call any other module (whereas a layer can use only lower-level layers) and that modules can be implemented in any order (whereas lower-level layers must be implemented first).

None of the structures discussed above – stages, layers, or modules are adequate to develop adaptive distribution chain. The reason is that, all these structures are applicable for developing desktop applications only. However, adaptive supply or distribution chain is inherently distributed. This means, the module making strategic calculations (see figure-1) should be running on a machine at the head quarters of an enterprise, the transportation modules may be running on the computers at distributors and wholesalers, and the inventory control modules at retailers and wholesalers. This means, one expects that all the 5 modules (one strategic and four tactical) run on computers located on geographically distributed places. We need Web Services to glue the

modules together. Web services is cheap, efficient, and based on open standards; there are numerous books, articles and case studies on Web Services; see [6].

IV. Concluding Remarks

This paper surveys the structures in some of the well-known modern adaptive supply chain solutions. The structures used in those supply chain solutions were stages (e.g. SAP), layers (e.g. HP), and modules (e.g. i2). Though a supply chain solution may choose any structure (stage, layer, module, iteration, etc.) as the basic building block to ease supply chain development, it must aim to provide the basic characteristic of adaptive supply chain – namely visibility, velocity, and variability. To build an adaptive distribution chain, which is inherently distributed, the above-mentioned structures are not adequate enough. We need Web services to glue together the different modules that are running in geographically distributed places.

Abstract: Supply chain collaboration has become a critical success factor for supply chain management and effectively improves the performance of organizations in various industries. Supply chain collaboration builds on information sharing, collaborative planning and execution. Information technology is an important enabler of collaborative supply chain management. Many information systems have been developed for supply chain management from legacy systems and enterprise resource planning (ERP) into the newly developed advanced planning and scheduling system (APS) and e-commerce solutions. However, these systems do not provide sufficient support to achieve collaborative supply chain. Recently, intelligent agent technology and multi-agent system (MAS) have received a great potential in supporting transparency in information flows of business networks and modeling of the dynamic supply chain for collaborative supply chain planning and execution. This paper explores the similarities between multi-agent system and supply chain system to justify the use of multi-agent technology as an appropriate approach to support supply chain collaboration. In addition, the framework of the multi-agent-based collaborative supply chain management system will be presented.

Keywords: Supply Chain Management; Supply Chain Collaboration; Agent Technology and Multi-Agent System.

I. Introduction

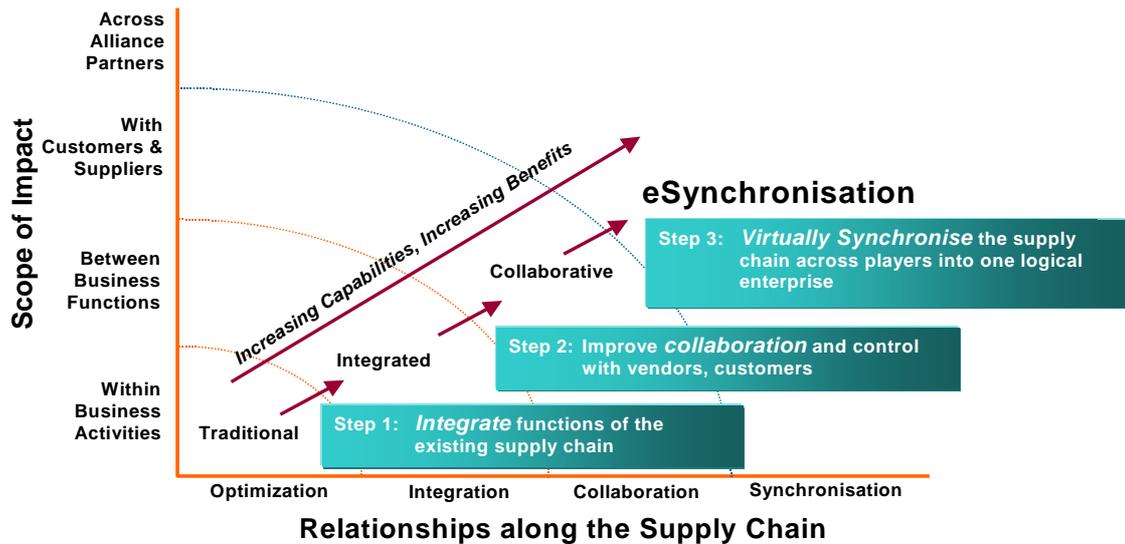

In today's competitive business environment industry is recognizing the importance of efficient and effective supply chain management. Supply Chain can be viewed as a network of facilities (that connected from the ultimate suppliers to the ultimate customers) and distribution options that performs the functions of procurement of materials, transformation of these materials into intermediate and finished products, and the distribution of these finished products to customers. These autonomous or semiautonomous business entities that perform all processes associated with the flow and transformation of goods and services from the raw material stage, through to the end user, as well as the associated information flows (Chorpa & Meindl 2004). According to Simchi-Levi (2003), the objective of supply chain management is to produce and

distribute merchandise at the right quantities, to the right locations, at the right time, in order to minimize systemwide costs while satisfying service level requirements. To realize the objective, the successful supply chain management requires effective support of advanced information technology and information system. Many information systems have been developed for the SCM from enterprise resource planning (ERP) into the newly developed advanced planning and scheduling system (APS) and e-commerce solutions. However, the capability of current information systems to support collaborative planning and control in the supply chain systemwide level is limited due to the complexity and dynamics of the supply chain in today's globalized business environment. Recently, agent-based system and technology have been applied as a new paradigm for conceptualizing, designing and implementing the software system, which offers the potential to overcome many limitations of current information systems for the SCM.

The aim of this paper to investigate the appropriateness of multi-agent based technology to support collaborative supply chain management. The remainder of this paper is organized as follows. First, issues regarding supply chain collaboration will be discussed in section two. Then, the roles and limitation of current information systems in the SCM will be discussed in section three. In section four, the characteristics of agent technology will be elucidated and its similarities between the supply chain system and multi-agent system will be analyzed. Finally, the framework of multi-agent-based collaborative supply chain management system will be presented.

II. Supply Chain Collaboration

Supply chain collaboration has become cornerstone of high performance in supply chain. According to Quinn (2001), it is believed that whether or not a company can effectively collaborate with the upstream and downstream supply chain participants has become a core business competency. Supply chain collaboration builds on two basic paradigms: sharing information, collaborative planning (Simchi-Levi 2001, Gattorna 2000, Bowersox, et al. 2002). Information sharing is the basic of collaboration in which supply chain partners share information about demand, inventory level, and promotional activities. It is recognized that only sharing information on historical or accurate sale data is not enough. Of greater importance is to share strategic information about

Source: Accenture

future activities to facilitate collaboration. Collaborative planning is the main content of supply chain collaboration. Actually, collaboration is one step along the supply chain development path for a company. According to Gattorna (2003), the adoption of collaboration tends to be evolutionary. As shown in Figure 1, it evolves from the integration of internal enterprise operation to the enterprise extension - collaborative planning with upstream suppliers & downstream customers and then extend to the supply chain system level.

As shown in the figure 1, the final stage of the evolution towards collaborative supply chain planning is the development of a network of supply chain partners who work together for mutual benefits. This network would encompass the extend supply chain and include outsourced service providers such as 3PLs and contract equipment manufacturers into an intelligent supply chain system. The competition in this brave new world has transformed from company versus company to supply chain versus supply chain. Due to the evolution of supply chain collaboration, the supply chain management is no longer focusing on inter-entity level. The philosophy of supply chain decision-making has changed to system level. Nowadays SC consists of many independent entities that are usually separated geographically due to globalization and increasing outsourcing activities. Each entity has its own operational strategies, and business decision mechanism under different constraints, i.e., they are autonomous in nature. Since SCM integrates the issues of multiple stage production and multiple stage distribution systemwide planning, the network is a complicated system.

III. Information Systems in Supply Chain Management

Collaborative supply chain such as information sharing,

collaborative planning and execution between organizations require effective support through advanced information technology. Information technology, as an important enabler of effective supply chain management, consists of tools used to collect, organize, access, share and analyze the information, and act on it to improve the performance of the supply chain. Over the last decade, various information systems have been developed to support the SCM from early less sophisticated legacy system to the ERP systems, then to the more advanced SCM systems such as the APS. However, inter-organizational coordination and collaboration increasingly require more effective information technology support and are usually not covered sufficiently by traditional information systems such as the legacy systems, ERPs and APSs (Yuan et al. 2001, Hilleberg et al. 2004). More often than not, current information systems that support the components in the supply chain process are developed by different vendors and are generally disconnected. Typically, these systems have evolved over the years based on various local and company-wide requirements and were rarely integrated (Erasala et al. 2003). Disparate IT systems and lack of integration and collaboration make it impossible for many corporations to support the required responsiveness and capability demanded by customers (Puckridge & Woolsey 2003). Although the more recently introduced E-markets and E-hubs also aim to support inter-organizational coordination, their success has been limited. They mainly provide the platform of connectivity, information exchange and support for trading between companies in a network.

Legacy system:

The problem of integrating with legacy systems was viewed as one of the major challenge and inhibitors to new IT development (Erasala et al. 2003). Legacy systems evolved as functional solutions using mainframe or minicomputers. In the past, mainframe-based legacy systems were applied to

support transactional processes within one specific function such as order entry, inventory control and accounting. These transactional processing systems were isolated and implemented with incompatible hardware and software. These system lacked integration across functional areas even within a single company (Yuan et al. 2001). Nowadays, in spite of extensive investment in state of the art application software, many firms are still dependent on legacy systems for mission-critical applications. (Erasala et al. 2003)

ERP:

The ERP system facilitates the flow of transactional data in a company relating to manufacturing, logistics, finance, sales and human resources. It mainly focuses on providing the visibility of information within the enterprise and the automation of business processes. It offers the promise of homogeneous, transactional data that can facilitate integration of functional areas within the enterprise at the operational level (Taylor 2004, Simchi-Levi et al. 2003). The ERP mainly focuses on collecting, organizing, accessing, and sharing the information within the enterprises, rather than focusing on analyzing data and information to make decision. Although some ERP vendors have begun to address this issue and add more planning modules, it remains focusing on scheduling individual production facilities and not the entire networks of facilities operating in collaboration. The ERP offers two main benefits that do not exist in non-integrated departmental systems: an enterprise-wide view of business encompasses all functions and departments; and an enterprise-wide database, in which all business transactions are recorded, processed, accessed, monitored and reported (Umble et al. 2003). Due to the fact that the information processes across functional areas within the enterprise are now integrated, it provides a much better base for inter-enterprise cooperation. However, since the major focuses of ERP are limited to intra-enterprise operation, these systems lack support for inter-enterprise collaboration in the SCM (Yuan et al. 2001).

APS:

Faster and easier access to transactional data does not automatically leads to better decision-making and competitive edge in the SCM (Shaprio, 2001). The APS system, such as production planning and scheduling, forecasting, master planning and supply chain network optimization systems, is a class of software for Decision Support System (DSS) in supply chains. It provides analytical applications to optimize the use of supply, manufacturing, distribution, and transportation resources to match the demand (Bansal 2003). It is developed and applied for evaluating and disseminating decision based on models constructed from supply chain decision databases (Shaprio 2001). APS are based on the principles of hierarchical planning and make extensive use of solution approaches known as mathematical programming to find the optimal solution for a given set of objectives. These objectives can include minimizing cost, meeting customer-

service targets, accelerating the flow of inventory, or any other combination of performance targets. It can be used to tackle strategic, tactical and day-to-day operational problems (Simch-Levi et al. 2003). Although APS system has been a powerful tool for effective supply chain planning, today it faces a main challenge from supply chain collaboration and decentralization. Due to the centralistic view of supply chain decision database and hierarchical planning underling today's APS, it might be suitable in an intra-organizational SC or a focal inter-organizational SC but not in such a complex supply chain network (Chan, F.T.S. & Chan, H.K. 2005). Developing an integrated supply chain planning information system based on current methods may requires that all systems to be re-developed into a monolithic integrated system capable of handling all foreseeable scenarios for planning and execution (Chan, F.T.S. & Chan, H.K. 2005). However, this is regarded as not feasible due to the high development and maintenance cost, not to mention the inflexibility of such a system. Furthermore, if partners are reluctant to share their data and to feed it into a central supply chain data-base while insisting on their own planning domain, modeling SC-wide flows by a single APS is no longer possible.

E-commerce:

E-commerce is promoted by the rapid growth of Internet and web technology, which has provided a great potential for networking and interaction between business and consumer (B2C) and between business partners (B2B). It encompasses the electronic buying and selling transactions between organizations, named as E-procurement (Neef 2001, Swaminathan & Tayur 2003). It can be applied to set up E-marketplaces and E-hubs for online bidding and auctions for business competition (Neef 2001, Emiliani 2000, Swaminathan & Tayur 2003). Moreover, E-commerce offers not only the solutions required for inter-company transactions but also the standards that will facilitate connection and communication among corporations (Berger 2003). However, in spite of the fact that E-commerce has improved the supply chain visibility through information sharing and the coordination between buyers and sellers through the Internet, the new technology is still needed to support for high-level knowledge sharing (not just transaction data) and facilitate more robust collaboration (not just simple buy and sell models) (Yuan, et al., 2001).

In summary it is clear that inter-organizational coordination and collaboration were not sufficiently achieved by traditional information systems. The successful supply chain collaboration requires more effective information technology supports. Recently, intelligent agent technology and multi-agent systems have shown great promise in supporting collaboration in supply chain management, particularly in supporting transparency in information flows and modeling of the dynamic supply chain for collaborative supply chain planning (Iskanius et al. 2004, Xue et al. 2005). In addition, intelligent agent technology offers the potential to overcome many limitations

of current supply chain technologies and offers new means and tools for supply chain collaboration (Gutpa et al. 2001, Frey et al. 2003).

IV. Supporting Supply Chain Collaboration by Using Agent Technology

There is no universally accepted definition of the term of agent. According to Wooldridge and Jennings (1995), an agent is a self-contained software program capable of controlling its own decision making and acting based on its perception of its environment, in order to gain one or more goals. The agent has the following main behaviour attributes: autonomous, cooperative (social), reactive, proactive, and learning (Wooldridge & Jennings, 1995). Being autonomous means that agent can act without intervention by other entities (humans or computer systems), and exercising control over one's own action/algorithms. Agents can interact with other agents (or possibly humans) via some kind of agent communication language (social). To be reactive means that agents can perceive the environment around itself and are able to respond in a timely fashion to changes in the environment (reactive). In addition, agents do not simply act in response to the environment but are parts of a more complex goal-oriented behaviour (proactive). Also, agents can change their behaviour based on their previous experience (learning).

A multi-agent system is one that consists of a number of agents that take specific roles and interact with one-another to solve problems that are beyond the capabilities or knowledge of any individual agent (Wooldridge 2002). These interactions can vary from simple information interchanges, to request for particular actions, and on to cooperation, coordination and negotiation in order to manage interdependent activities (Jennings 2000). The interaction and coordination are the core process of a multi-agent system (Lee et al, 2004). According to Jennings & Wooldridge (2002), agent technology and multi-agent system can be used to develop highly complex systems. Paranak et al. (1998, P.24) claimed, "...agent-based modelling is most appropriate for domains characterized by a high degree of localization and distribution and dominated by discrete decision..." Supply chain system is a large-scale complex system. Decentralisation, collaboration and intelligence are its essential characteristics. The greater details of the similarities of the nature of these two systems are shown as follows:

Firstly, individual agent has incomplete information, knowledge or capabilities to solve the problem and thus has a limited viewpoint. Data, information and knowledge are in distributed agents (Jennings, et al. 1998). In addition, different agents also have the different core functionalities that play the different roles in the multi-agent systems. MAS can solve problems that are beyond the capabilities or knowledge of any individual agent (Wooldridge 2002). The supply chain network has the same characteristic. A supply

chain consists of multiple autonomous participants that play the specific roles along the supply chain (Chopra & Meindl 2004). Each supply chain participant has its own resource, expertise, capabilities and capacities. It performs certain tasks and roles in making the products that conform to customer requirements (Simchi-Levi 2003). Different supply chain participants have different core competency. An individual supply chain participant cannot solve all the tasks in the supply chain.

Secondly, there is no system global control in a multi-agent system. A multi-agent system consists of different autonomous agents can play different roles and functions in the system (Jennings & Wooldridge 2002). Each agent responds on its own to monitor changing environment, proactive to take self-initiated action, and behave socially to interact and communicate with other agents. In most cases there is no single authority in the supply chain. Usually, the different functions belong to different companies in a supply chain. A single company cannot govern or control the whole supply chain performance. The supply chain participants are autonomous or semi-autonomous. They have the authority to implement different supply chain strategies and take certain action in response to the changing markets.

The third similar characteristic is collaboration and coordination. In fact coordination is the core process of the multi-agent system (Lee et al. 2004). In a multi-agent system, each agent attempts to maximize its own utility while cooperating with other agents through negotiation and cooperation to achieve their overall goal (Jennings 2000). In a supply chain, different supply chain participants may have different and conflicting objectives (Chopra & Meindl 2004, Simchi-Levi et al. 2003). To optimize performance and achieve the whole system optimization, the supply chain participants must work in a coordinated and collaborative manner (Lau et al. 2004). In the collaborative supply chain, decision-making is through multi-party negotiation and coordination in order to minimize the total cost and maximize the total supply chain profitability while meeting the customers' needs.

Finally, the structure of the multi-agent system is re-configurable. It supports handling of dynamics and is capable of making a quick response to the changing environment (Persson & Davidsson 2005). Multi-agent system is flexible. Agents in the multi-agent system can be organized according to different control and connection structure and agents can be created or discarded. In addition agents can delegate its task to other agents and coordinate other agents to form a higher-level system (Jennings 2001). The supply chain is a dynamic system and the relationship among different participants can evolve over time (Simchi-Levi et al. 2003). The supply chain participants may join or quit the supply chain. Therefore, the structure of the supply chain is flexible and is responsive to the changing environment. The structure of the supply chain can be organized differently when implementing different strategies according to different environment and business goals. Also, tasks in supply chain can be decomposed into subtasks, or

multiple tasks can be composed to form a large task.

Therefore, it can be seen that supply chain systems has many similarities with the characteristics of Multi-agent system. Thus it is reasonable to apply the multi-agent system to model the supply chain network and process, and to implement supply chain management applications. In fact, multi-agent systems involving multiple agents with distributed knowledge and information are well suited for analysing coordination problems in supply chain management (Bond & Gasser 1988).

V. Framework for Agent-Base-D Collaborative Supply Chain Management System

In this section, we will present a framework of agent-based supply chain coordination and collaboration. The supply chain coordination and collaboration is analyzed in the context of a typical multi-national corporation scenario. The proposed framework focuses on the coordination of manufacturing and distribution functions. The scenario consists of several manufacturers, distributors, suppliers and logistics service providers (see Figure 2).

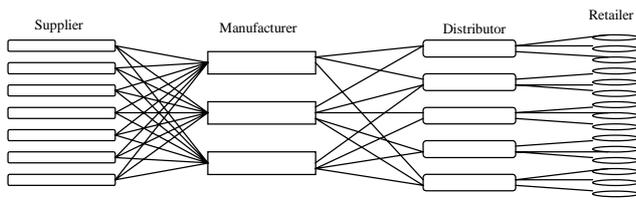

Figure 2: Supply chain network

In the framework of a multi-agent based collaborative supply chain management system, there are several agents involved: function agent, coordination agents, communication agent, and monitoring agent (Showned in figure 3). Coordination agents, communication agent and monitoring agent are designed to accomplish the manufacturing and distributing tasks in the multi-national enterprise together with existing planning and execution software (function agent). We will discuss the roles and functions of each of these agents in the proposed supply chain coordination system.

1) Function agent: Function agent is a set of existing and separate application software that are used by the distributors, manufacturers as well as by the logistics service providers. These application software are utilized in different part of planning, scheduling, and execution processes such as capacity analysis software, ERP, manufacturing execution system forecast software and so on.

2) Coordination agent: Coordination agent is designed with specified expertise, knowledge and coordination mechanism to coordinate the activities among agents in order to minimize enterprise-wide cost or maximize profitability of the whole supply chain system. Coordination agent may link to the communication agent, monitoring agent and function agent to get the necessary information.

The coordination agent is further classified into distribution coordination agent, manufacturer coordination agent and transporter coordination agent (showed in figure 4).

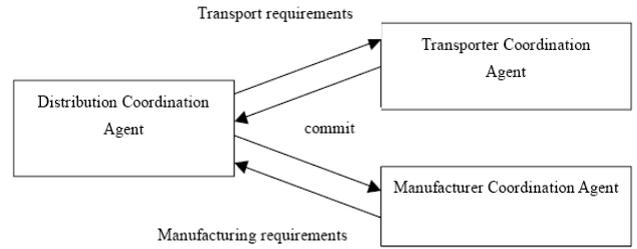

Figure 4: Agent-based supply chain coordination

a) Distribution coordination agent: Distribution coordination agent aggregates data and information from the distributors in different areas and perform distribution requirements computation. Then the distribution requirement plan can be established. It consists of four parameters, namely type, quantity, price and due date. The “type” parameter is the various kinds of products for manufacturing and transportation. The “price” parameter is the summation of all the prices of various products ordered by retailers. The “due date” parameter refers to the final date when the different distributors can receive the products and the “quantity” parameter is the desired quantity of each type of products. In addition, the distribution coordination agent can determine which “type” of products can be produced by the specific manufacturer, or by several manufacturers according to historical data and knowledge. Then, the distribution coordination agent transfers the “due date” of the “type” of the products into total “lead time” (“lead time” for manufacturers and “lead time” for transporters). Furthermore, the distribution coordination agent will coordinate with the transporters agent and the manufacturers to reach a feasible and optimized global supply chain solution. Figure 5 shows the functions of the distribution coordination agent.

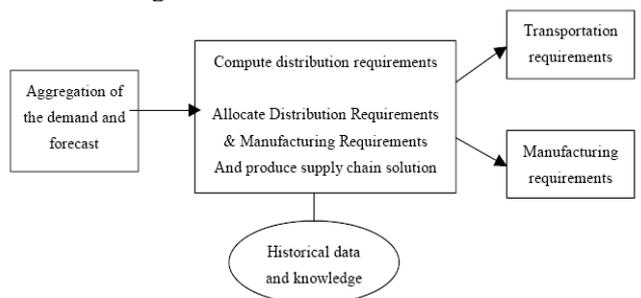

Figure 5: Distribution coordination agent

b) Transporter coordination agent: Transporters offer pickup and delivery service from different manufacturers to destination terminals or distributors. The operation decisions facing a transporter agent are: to select the right mode or modes of transportation based on costs and lead-time and to consolidate consignment for economic of scale. The transporter agent receives the transportation requirement and

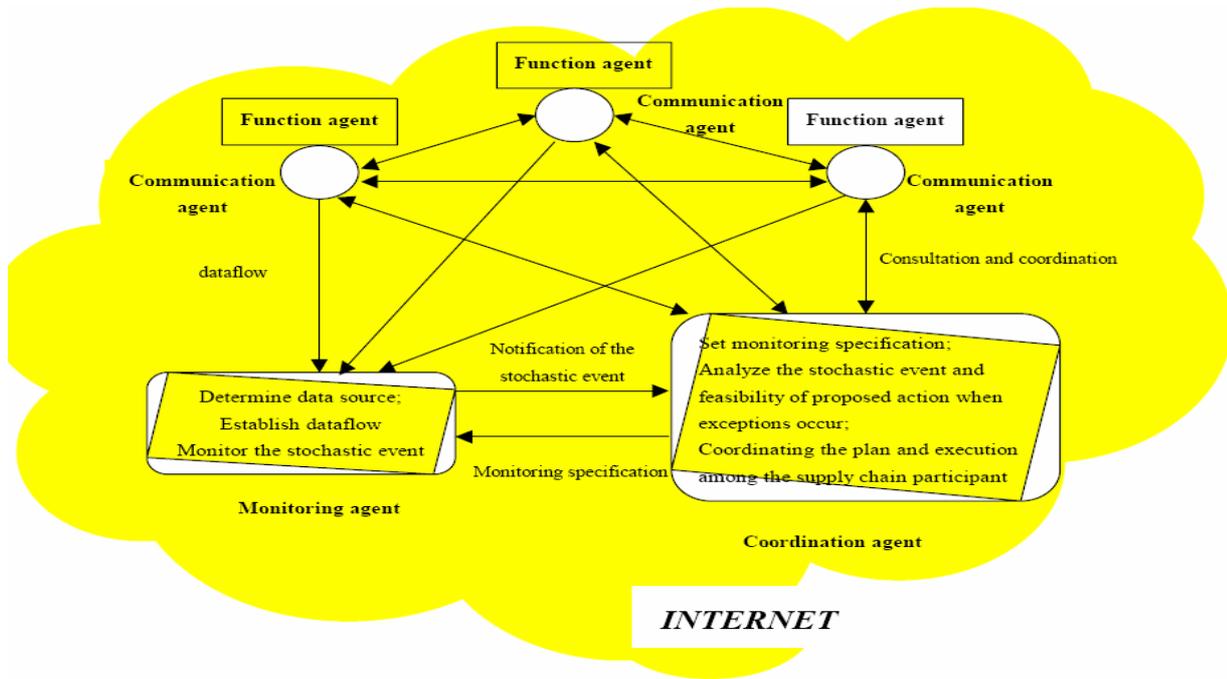

Figure 3: Framework of a multi-agent based supply chain coordination system

performs local optimization using its data on routes, schedule and consignment to conduct candidate transportation commitments.

c) **Manufacturer coordination agent:** The manufacturer agent receives manufacturing requirements from the distribution coordination agent and performs local optimization to find feasible manufacturing solutions (specified with type, quantity, lead time and price) based on capacity, inventory, suppliers' capacity and process time. It provides solutions to the distribution coordination agent for selection. The main function of the manufacturer agent is to produce the required type and quantity within the required lead-time with minimized cost. The minimizing of the total cost is subject to a set of constraints, such as quantity constraints, capacity constraints, suppliers' capacity, customer service level, lead-time, and etc.

3) **Communication agent:** Cooperation and coordination of agents in a multi-agent system requires agents to be able to understand each other and to communicate with each other effectively. Communication agent can enable the monitoring agent, function agent and coordination agent to communicate with each other. The infrastructure that supports agent cooperation in a multi-agent system includes the following key components: a common agent communication language (ACL) and protocol, a common format for content of communication, and a shared ontology.

4) **Monitoring agent:** As a monitoring agent, it receives from other agents (such as the function agent) the monitoring criteria for disturbance events concerning processing rates and notifies the coordination agents when such events occur. The function and process of the

monitoring agent is shown in Figure 3. The coordination agents decide what constitutes an exception (stochastic event). The coordination agent evaluates how much the occurrence of one stochastic event in the specific supply chain process will influence the other supply chain processes and the whole supply chain process. Then the coordination agent will identify the monitoring specification of the stochastic events in the different supply chain process. Different plan execution may have different monitoring specification. The monitoring agent determines what data is to be monitored to detect such exceptions according to the monitoring specification identified by the coordination agent and conducts actual monitoring of the data and information flow. When notified by the monitoring agent of the occurrence of the stochastic event (an exception), the coordination agent analyzes the severity of the events, coordinate with other agents to reschedule, reallocate and makes appropriate decision in consultation with the function agent. Human decision-maker may be involved during the decision-making process.

VI. Conclusions

In this paper we have discussed the similarity between supply chain and multi-agent system, and the underlying reasons why agent technology is the appropriate approach for the collaborative supply chain management. Also, a framework of multi-agent system that is capable of supporting collaborative supply chain management is presented. With this approach, a set of agents with specialized expertise has been designed. The communication

agents, which facilitate the communication among agents, can select necessary information and share the information in the Multi-agent system. In this way, it can facilitate the information sharing among the supply chain participants and improving the visibility of the supply chain network. The proposed framework wrap the current exist systems such as legacy, ERP, and APS, etc into the function agents and connect these function agents with coordination agents through certain coordination mechanism to reach the system optimization. In addition, in the proposed framework, the monitoring agents monitor the real-time supply chain performance and inform related agents and decision makers when an emergence event occurs, then the related agents and the coordination agents will work together to amend the plan and inform the decision maker or automatically execute it. The paper presented here represents only the first step of our effort toward agent-based collaborative supply chain planning and execution. Further research and experiments are needed to extend the current work to address its shortcomings and design the completed model based on proposed framework and a detailed supply chain scenario.

Abstract: Dynamic markets require that supply chain partners work together in a timely and efficient manner. This paper introduces e-Connectivity, a construct describing how technology and process standards enable cross-company collaboration amongst partners in the networked supply chain. The paper highlights the collaborative and often short-term relationships where partners coordinate their mutual capabilities to address a transitory, but important, business opportunity in order to achieve collectively beneficial outcomes.

Through a literature review and exploratory interviews, the paper proposes and defines the construct of the dynamically networked supply chain. It then introduces how information technology and related processes enable dynamic collaborative practices in the supply chain. Subsequently, e-Connectivity is discussed as a key success factor in the development and deployment of informally networked supply chains.

Further empirical validation and testing may reveal that informal coordination in networked supply chains, enabled by eBusiness, is an important capability that impacts the operational effectiveness and competitive advantage of a firm.

I. Introduction

Collaboration between firms is a powerful source of competitive advantage, calling for efficient ways to integrate relationships in the supply chain, including the development and maintenance of information, physical and financial flows. An operating system is said to be superior to that of a competitor if it responds better to market opportunities, and as such secures the long-term viability of the firm. This paper develops a conceptual model for analysing how e-Connectivity increases the operational effectiveness of a firm by providing the platform for dynamically linking the information flows of supply chain partners. The research focuses on short-term inter-firm supply chain relationships, and emphasizes how e-Connectivity can lead to improved customer service by improving the coordination between manufacturers, service providers, channel partners, and other partners that are involved in delivering products and services.

Based on a literature review and exploratory interviews,

initial findings suggest that supply chain theory does not sufficiently describe the interconnectedness and interdependencies between process and technology standards in a supply chain, and their effect on inter-firm coordination of supply chain resources.

Exploratory interviews were conducted between December 2004 and April 2005 with about 50 senior executives in person or by telephone. The interview panel consisted of senior management (C-Level, VP, Managing Directors, Directors) from a variety of industries. The Panel consisted of mainly European and Australian / New Zealand participants. The sample was chosen in this particular way as the researchers eventually want to compare Australian / New Zealand practices with practices in one other region of the world, and because they had access to relevant addresses and contact details. The panel composition is shown in Figure 1.

Figure 1: Exploratory interviews - Panel Setup

Expert Panel Industry	Country				Grand Total

Grand Total	33	15	3	3	54

In this context, there also appears to be insufficient empirical knowledge about the role that e-connectivity, i.e. technology and processes, play to enable dynamic supply chain relationships and ultimately lead to better outcomes. As such, opportunities for deploying the supply chain as a source for achieving quick response, operational effectiveness, and ultimately competitive advantage, may be lost.

We turn next to a literature review of supply chain relationships, and a discussion of dynamically networked supply chains. We introduce the role of information technology as an enabler for process change in supply chain management. We then turn to process and technology standards as the key factors driving e-Connectivity in supply chain management. This is followed by conclusions.

I. 1 Dynamically Networked Supply Chains

This research investigates market prospects that are highly dynamic and complex to execute and hence require a rapid coordination capability. Such advanced capabilities often do not exist in firms, or are inhibited because of established norms and formal approaches to managing the arrangements between the supply chain partners.

Handling complex and time-sensitive customer requirements frequently extends beyond the capabilities of a single firm [1, 2]. However, supply chain management not only needs to include the partners involved in core logistics and supply chain value adding activity, but also indirect partners such as regulators, intermediaries, financial institutions, and research and government agencies. These partners influence power, risk and knowledge structures which in turn impact on performance of supply chains. Swaminathan et al [2] define the supply chain as a network of autonomous or semi-autonomous business entities collectively responsible for procurement, manufacturing and distribution activities associated with one or more families of related products. Moeller and Halinen [3] interpret the supply chain as a network of entities where firms process information, so that they can better respond to linked partners and customers.

It is argued that expertise in coordinating activities across different firms will become an important supply chain capability in itself. This leads to the informally networked supply chain, a concept distinctly different from a more [...] simplistic, linear and unidirectional representation of flows of materials and associated information [...] [4]. This part of the research paper identifies key relationship attributes for coordinating e-business enabled supply chain capabilities in unpredictable market environments.

A paradigm shift is underway in supply chain management from a focus on explaining only dyadic relationships, i.e. transactions and relationships, towards the investigation of multidimensional relations and networked views of supply chain interaction. This is accelerated by the notion that existing categorisations of [supply chain] networks offer limited operational assistance [5, 6] for firms in understanding the full spectrum of how to leverage their capabilities in highly dynamic demand situations. It is proposed that networked supply chains represent differentiated coordination approaches depending on form and content of the inter-organisational relationships among the firms involved. It is further argued that coordination in networks supply chains in highly dynamic market situations is more responsive to dynamic relationships, time, information and other non-linear success factors in the exchange of inputs and outputs [7].

Networked supply chains are not consistently defined in the literature and vary depending on the research objective and the choice of dimensions. For our research, a classification of different supply chain network models is proposed in relation to varying network exchange relationships, as is illustrated in Figure 2.

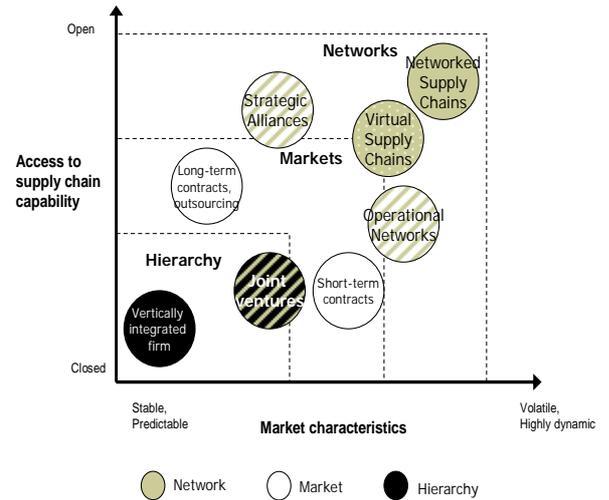

Figure 2: Landscape of supply chain networks

Formal coordination in either vertically integrated firms (internalising the coordination into the hierarchy of the own firm), through joint ventures and strategic alliances, or through long-term market contracts with 3rd party supply chain partners (using markets as the coordination mechanism) work in stable markets; while there is a risk that resources are not used efficiently in dynamic environments and stay idle most of the time. This leads to unnecessary costs and lowers operational efficiencies [8]. Examples of such rigid arrangement can be observed in the downstream mineral oil industry, which runs idle capacity for unpredictable or peak demands, or supply shortages. More flexible ways need to be introduced to cater for highly unpredictable demand.

The concept of outsourcing supply chain activities has often not produced the expected results for supply chain partners. Formalised relationships through contracts and service level agreements often increase complexities, and related efforts of coordination. Rigidity of such relationships inherent to contract specification, setup and monitoring, prevents firms to achieve competitive advantages. In particular, various ambitious new business models in the supply chain have not taken off as expected, i.e. the concept of a 4PL and e-marketplaces. Findings of a recent study on characteristics, strategies and trends for 3PL and 4PL in Australia [9] show that the benefits of inter-firm relationships have not yet materialised, although respondents confirmed the importance of such relationships for achieving better performance.

Networked supply chains display characteristics of the virtual enterprise [10],[11]. The relationship is temporary and project-like. Firms have specific capabilities, which they combine synergistically in the supply chain. The process is accompanied by an intensive use of information and communication technologies, and other network-specific coordination factors. In highly dynamic market situations, supply chain capability leverage depends on two important factors. First, generally accepted standards and methods in an industry or supply chain provide leverage for rapid

collaboration through network connectivity. Secondly, relational capability enables the rapid creation of a supply chain network for the opportunity at hand, and allows the partner to perform supply chain activities and serve the customer in highly dynamic markets.

Many firms coordinate their supply chain capabilities without formal agreements across a range of partners. As exploratory interviews reveal they anchor their activities around an understanding of dependency between business partners. Many firms have in fact indicated that they do not have any contractual relationships with their customers and suppliers for exactly the reason that their responses to market demand are highly adaptive, both in terms of response time and in terms of the breadth of solution delivered. These firms use their own and their partners' adaptable capabilities, including people, process and assets to respond to highly time-sensitive and complex customer requirements.

For example, it emerged from exploratory interviews that firms are reducing their assets and shift their attention to managing and controlling the access to information. This in particular seems to favour smaller players that can make an impact on supply chain effectiveness with relatively small shares of assets owned. Another example shows the electronics and automotive industries, where component suppliers are transforming into module suppliers, offering not only a narrow manufacturing expertise but a holistic service solution. This means that supply chain partners not only sell the product but provide services such as financing, maintenance, and replenishment [12].

Senior executives across a range of industries, i.e. chemicals, telecom equipment manufacturers, and fast moving consumer goods confirmed the informal coordination of supply chain capabilities to either enhance the efficiencies of operations, or to increase the effectiveness of serving the market with the 'best' combination of supply chain capabilities.

I. 2 IT - Enabled Supply Chains

Networked supply chains connect the players and their capabilities through robust information linkages. There are several factors that distinguish traditional supply chain relationships to the ones enabled by networks and technology. These factors include a reliance of supply chain partners on information infrastructures (Amit&Zott, 2001), the critical role of visibility and information transparency, the high reach and richness of information that can be exchanged rapidly [13] and network effects [14, 15].

The evolution of supply chain technology and the way it enables relationships is illustrated in Figure 3, using Gattorna's [16] supply chain capability/performance continuum, which categorises three different levels of supply chain integration and synchronisation. This framework forms the basis for further analysis of supply chain relationships and the coordination of capabilities in the context of short-term opportunities.

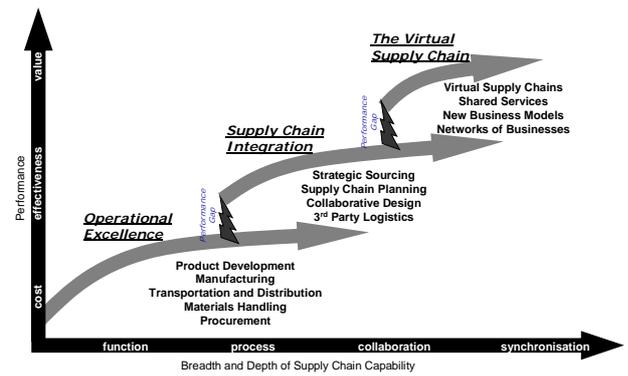

Figure 3: The supply chain capability/ performance continuum (Adapted from Gattorna, 2003)

The first curve depicts the operational and functional, and often internal, focus of coordinating supply chain capabilities with the objective to improve cost and efficiencies. Efficiencies are important, but any collaboration at this level has limited effects on overall supply chain performance. Operational efficiency by itself is rarely sufficient to create competitive advantage in highly dynamic markets. By the same token, if firms don't have their own house in order, they should not even attempt to engage in advanced supply chain activity with external partners. Efficiencies form an important prerequisite for collaborating in highly dynamic markets. For example, if IT processes and management practices are setup and maintained to industry or supply chain standards, a readiness for collaboration that adds to overall flexibility can be achieved.

The second curve shows the integration of supply chain capabilities and the impact technology makes on supply chain design. As market and customer demands evolve, supply chain managers are prompted to find innovative ways to integrate processes and technology across supply chain partners. Technology enables integrated supply chain capabilities and the process of integration creates better information, increased visibility, knowledge and learning. For example, firms may have widely applied cross-organisational business process re-engineering and implementation of ERP systems in place to achieve the benefits of integration. Some players like Walmart in the U.S. and Tesco in Europe have introduced approaches like CPFR (Collaborative Planning and Forecasting). These early attempts to leverage the integration of processes and technology resulted in significant changes to the consumer goods industry, globally. Hence, such technology availability, standards, and ease of integration become an important enabler for supply chain collaboration.

Technology and process integration across firms also leads to an increase in outsourcing, or contract logistics. These are structures where external firms perform logistics activities like warehousing, scheduling and transportation, usually based on long-term contracts and service level agreements. The integration of information flows gives the principal firm control and visibility for managing the entire

process, even though the activities and the ownership of capabilities is decentralised. Gattorna et al [9] confirm that more than half of large Australian corporations use such services, and significant and growing ratios are quoted for Europe, U.S. and other regions [17-19]. Rigid information and process integration architectures, however, have failed to provide the capability to adequately respond to highly dynamic market requirements due to inherently rigid structures [20].

The third level suggests the emergence of virtual supply chains, i.e. the virtual networking of supply chain capabilities enabled by new technologies like the Internet. The activities are integrated and synchronised in real-time using open and closed platforms with associated standards. A range of vertical and horizontal e-marketplaces are examples of formalised virtual supply chain structures. These virtual supply chains promise new value creation and efficiency opportunities, but often fail to deliver the benefits due to complexities of contracting, coordination, and monitoring of agreements. Consequently, companies have now started to seek for new dynamically networked supply chain designs that allow for ad hoc coordination of capabilities across supply chain partners. Dell and Cisco are often quoted as examples that such designs are designs are feasible and illustrate the effectiveness of such models.

In interviews senior executives confirmed that the ability to dynamically network with business partners in the supply chain will be a key driver of profitability. Indeed, asked about the how revenue and profit attributable to the ability to dynamically work in networked supply chain relationships would change in the coming three years an overwhelming majority believed that it would increase.

I. 3 E-business Enabled Supply Chains

E-business can be loosely defined as a business process that uses the Internet or other electronic medium as a channel to complete business transactions. E-business has brought new opportunities and challenges to supply chain management [21]. The Internet, a global matrix of interconnected computer networks, is emblematic of the power of information flows, and intra- and inter-firm linkages in knowledge-intensive industrial development.

Firstly, the Internet has facilitated increased information sharing within and across company borders through use of enterprise resource planning (ERP). Other supply chain technologies have developed around the linkages of distributed systems. Traditionally information and geographically distributed applications were only available to internal users, or users of supply chain partners subscribed to a closed and relatively costly intra-net or value-added network (VAN).

As decentralised supply chain technology evolved information architectures were held together by systems such as electronic data interchange (EDI), electronic funds transfer (EFT), and more recently by internet based systems using extensible mark up language (XML) [2]. There has been a proliferation of technology platforms, using lighter-weight protocols for creating electronic bonds, such as e-

marketplaces (e.g., E-Steel) or hubs (e.g., Covisint), as well as tools for inter-enterprise integration (e.g., Webmethods).

Secondly, the ability to obtain real time information and access to large computer systems is enabling firms to optimise business processes across company boundaries, and make real-time decisions on a supply-chain level. The application architectures included internet based versions of ERP systems, best-of-breed applications connected through middleware, and advanced planning and optimization solutions (APS), all transcending traditional company boundaries.

Further, there are a number of industry and IT vendor-driven efforts to standardize business processes and data exchanges between enterprises, which are expected to yield network externality benefits in easing partnering across enterprises, as well as dealing with change in existing partnerships. Interoperability frameworks have been developed for vertical markets (such as the Information and Content Exchange and RosettaNet specifications) and horizontal markets (such as Microsoft BizTalk), but have not been widely deployed [22]. In this context the Internet has created opportunities to integrate information and decision making across different business organisations and functional units, thereby creating the possibility to build and scope the extended enterprise – a virtually integrated set of applications and processes permeating traditional company boundaries [23].

Lastly, technology integration remains a challenge. A number of organisations are trying to overcome integration challenges by focusing on the development of process and technology standards [24].

Extant studies suggest that, the greater the degree of coupling or integration between the information systems of trading parties, the greater the degree of coordination and collaboration that can be achieved [25]. This suggests that firms wishing to improve the performance of their supply chain operations should invest in establishing closely coupled links between themselves and their trading partners.

In the electronic environment, customer expectations have increased as to quick and timely delivery. At the same time, the Internet has opened up opportunities for firms to share information, and efficiently coordinate their activities with other entities in the supply chain. This has created alternate avenues in traditional supply chains for doing business. For example, in supplier selection and procurement, firms have to decide whether they should join private or public exchanges, or develop highly-integrated supply partnerships. They need to determine if they should use auction and bidding for contracts and, if so, which type would be most beneficial. In distribution, decisions need to be made whether the firm will offer products through the Internet channel and, if so, how this method would differ from the traditional channel. This raises the question of how the synergies would be realized in terms of inventory, transportation, and distribution. Similarly, the availability of real-time information has raised important questions such as the degree to which the information sharing protocol should

be standard or proprietary; the amount and type of information that should be shared with other supply chain partners; and the types of collaborative processes that may be beneficial. The degree of change in issues related to the supply chain spans a huge spectrum from concepts and issues that have been marginally affected, to a whole set of new issues that have emerged as a result of e-business [26].

These outcomes support the proposition that if relationships in the supply chain become more dynamic and, more importantly, contribute significantly to companies' results, then attention must be given to the prerequisites for integration and connectivity. The following paragraph discusses this notion in the context of eBusiness.

II. E-enabled Supply Chain Coordination Through Standards

II.1 Coordination Standards

Technical and process standards are a major enabler for ad hoc and efficient supply chain collaboration. Networked supply chains connect the players and their capabilities through robust information linkages. There are several factors that distinguish traditional supply chain relationships to the ones enabled by networks and technology. These factors include a reliance of supply chain partners on information infrastructures [27], the critical role of visibility and information transparency based on reliable data, and the high reach and richness of information that can be exchanged rapidly [13].

Unlike traditional supply chains where activities and transactions are tied to specific physical assets and locations, electronically enabled infrastructures are designed to replace physical exchanges by information, thus creating virtual business models [29]. Electronic information exchange allows firms to arrange commercial transactions that bypass significant portions of traditional business transaction costs typically incurred at various stages of value chain activities, such as delivering tangible products between buyers and suppliers, managing inbound logistics, and controlling distribution channels.

The possibilities of electronic coordination also help firms speed up traditional business transactions. Thus, in the virtual supply chain, information and information processing capabilities that increase efficiency and/or convenience in networked supply chain relationships requiring coordination, become a critical source of competitive advantage. These capabilities often become tools to reduce transaction costs [30-32].

The Internet can be used to establish direct contact over a widely dispersed set of customers. Dell Computer's well-documented direct marketing experience indicates how the clever use of an interactive electronic channel allows an industrial marketer to bypass traditional distributors. In this sense, the Internet and the emerging e-commerce solutions may rapidly change the power position between current distributors and marketers, and facilitate the appearance of

virtual firms that have externalized value activities such as product development, production, and logistics, customer creation, and customer portfolio management through databases. In addition, the standard aspects of these "virtual competencies" may very well be handled through supplier partnerships with competitive service providers.

The Internet allows for standardized transacting procedures shared by many partners, and an open architecture of connection known as the World Wide Web [33]. Internet procurement has emerged with the help of "orchestrated" markets called business-to-business (B2B) exchanges. B2B exchanges create an electronic marketplace with low-cost entry and standardized transactional procedures – e.g., the display of buyer's specifications, bidding procedures, market clearing, safeguarding, and so on. Interdependencies are pooled because the bidding process is impersonal and carried out by autonomous suppliers.

II.2 Information Exchange Standards

Standardization of process and content interfaces refers to explicit or implicit agreements on common specifications for information exchange formats, data repositories, and processing tasks at the interfaces between interacting supply chain partners.

Standardization of process and content interfaces would require business partners to agree on the syntax, semantics, and pragmatic aspects of documents that are to be exchanged for the specific process being coordinated. The lack of standardization means that exchanges are idiosyncratic to each relationship. For example, a distributor in the IT industry reports spending \$17 per SKU (stock keeping unit) by having to manually update information on the 100,000 SKUs it manages yearly, due to different reporting formats used by manufacturers. On the other hand, the use of standards, such as UCCnet standards for product data in the grocery industry, is expected to cut costs by as much as \$40 billion by providing a common business language [30].

Standards play an important role in structuring relationships between companies—they help reduce the extent to which market exchanges are personalized and the scope for unethical and opportunistic behaviour. Coordination theory suggests that standardization allows for management of interdependencies, making the infrastructure more flexible and capable of supporting change. The effect of standardization on partnering flexibility is expected to be positive, given that standardization creates network effects, reduces the variety of asset and informational specifications, provides for a wider set of users, increases frequency of transactions, and reduces market uncertainty. The effect of standardization of interfaces on offering flexibility is also expected to be positive, as it helps in the establishment of a technical grammar that reduces the amount of information that needs to be exchanged between enterprises, and enables social conventions to be established to facilitate coordination in the face of change [30].

Open technology standards, particularly the ones related

to the Internet, greatly reduce marginal transaction costs of information for additional users or products, resulting in network effects. The ROSETTANET consortium, for example, is a non-profit group of more than 400 companies in the information technology and electronics domain, which aims at standardizing the trading networks between these companies by providing standards for business documents (e.g. purchase orders), as well as so-called partner interface processes (PIPs), which define process interaction between trading partners (e.g. acknowledgement of receipt etc.) [34].

Standardised application of software and hardware has improved the visibility of activities performed in supply chains across organisational boundaries. In particular, the advent and proliferation of enterprise resource planning (ERP) software supported rapid process integration within, and later across, companies. Wal-Mart's RetailLink is a buyer-based Internet exchange which connects Wal-Mart with more than 2,000 suppliers. Sales, inventory, production schedules, and demand forecasts are shared through the exchange, which is a key enabler for helping Wal-Mart achieve its supply chain excellence. Another example is Taiwan Semiconductor Manufacturing Corporation (TSMC), which is one of the world's largest contract manufacturers for integrated circuits. Through its private exchange with its customers, TSMC shares forecasts, order management information, WIP updates, and engineering specifications, allowing it to reduce customer lead times while lowering its inventory carrying costs.

Information exchange is a characteristic of networked supply chains. Through connectivity critical participation within a supply chain can be enabled. Connectivity can be defined by how many supply chain partners a business can connect with, and how comprehensively information can be exchanged. Standards are a key prerequisite for achieving connectivity.

Messaging standards integrate corporate information across the supply chain through mechanisms such as EAI middleware, based on the existing infrastructure. While a number of interoperability issues remain, a consolidation of the number of standards is very likely. Approaches such as SOAP, ebXML, ROSETTANET and WSDL have found widespread acceptance, and form a complementing framework of XML standards for inter-organizational messaging applications [34]. The operational aspects of business-to-business interactions are quite well defined, and the generation of analytical data from the operational processes provides a standardized foundation.

EDI is one such messaging standard that involves computer-to-computer exchange of information between buyers and suppliers [29]. Early (or closed) EDI systems, which gained momentum especially in the 1990s, are associated with specifically negotiated codes and a proprietary, or closed, electronic architecture to transfer information. According to Holland et al. [29], early EDI systems are "used to encourage close trading relationships with a smaller number of suppliers." As such, early EDI systems involved investments by both parties in private

computer connections and training, implying a closed architecture of connection and agreements specifying information transfer codes [35]. Many authors document two main advantages of early EDI systems: a potential reduction of transaction costs, including procurement and monitoring expenses [35], and the optimization of production through information sharing [29], shortened lead times [36], inventory reduction, and increased product quality [32]. These sources of value are strongly associated with sequential interdependencies. Additionally, private communication systems are commonly implemented by a systems initiator (e.g., a buyer), "who deploys a proprietary [system] to expand the scope of hierarchical control" to a particular firm (e.g., a supplier), "which exercises the choice between accepting or rejecting" the new system [24]. This has clearly a flavour of plan-based coordination.

At a major router manufacturer, it was observed that specific inter-enterprise IT characteristics may hinder the ability to quickly link up with new partners:

"We are in the continuous process of evaluating who can best meet our needs. If a new third-party logistics provider becomes available, how can our company get up to speed to using them? In the past, the problem was predominantly defined by physical changes, such as location, system changes, and interface changes, which can take as much as six months. The current strategy for coordination with our partners, however, relies on hardwired APIs (application interfaces). When anything changes, they falter. We need to move toward more abstract specifications that will enable us to handle changes much better."

II. 3 Process Standards

Flexibility to build ad hoc relationships represents the ease of changing supply chain partners in response to changes in the business environment. Flexibility in terms of the ability to change partners quickly corresponds to an ability to work out how the new partner's capabilities can be quickly accessed and deployed. This can be done by a redesign of partner-linked processes and systems. In EDI implementations, it has been found that adoption requires substantial investment and integration effort, resulting in high switching costs and transaction specificity, which in turn undermines flexibility. On the other hand, open EDI systems increase market coordination by reducing asset specificity and by making additional partners available. Whereas information systems improve the efficiency of coordination between buyers and suppliers, managerial innovations—such as modular product designs, "quick-connect" interfaces, and use of IT to support concurrent processes and real-time acquisition of market information—significantly improve a firm's coordination flexibility.

In order to enable transparency and visibility in the supply chain, standards have emerged through advances in and proliferation of information and communication technology. Connectivity enables transparency, i.e. the ability to access relevant supply chain information. Transparency can be achieved through standardization of the

data, information and process models.

Connectivity reduces barriers and associated transaction costs for establishing supply chain linkages. In networked supply chains, the internet and open technology standards greatly reduce transaction costs of information. For instance, travel agencies which have the ability to quickly tap into a broader range of relevant information through suites of freely available and contracted online services (i.e. Gallileo and Amadeus, country and tourist information web sites and accommodation information), can serve more customers, provide greater selection, and more complete services.

Process standards create better information, increased visibility, knowledge and learning. Process standards across firms enable network capabilities. Firms can access the capabilities of another firm to perform logistics and supply chain activities like warehousing, scheduling and transportation. While this has usually been based on long-term contracts and service level agreements (outsourcing), shorter-term, interimistic arrangements are feasible.

The integration of standardised processes and information flows gives the principal firm control and visibility for managing an end-to-end process, even though the activities and the ownership of capabilities are decentralised. Research in Australia, Europe and the US confirm this trend [17-19].

The Supply Chain Operations Reference (SCOR) Model provided by the Supply Chain Council specifies inter-organizational business processes and their information flows [21, 37]. The SCOR Model contains measures for operational control and best practices of supply chain design, and is a reference model for structure, processes, and information flow within an inter-organizational supply chain [38]. As a result, the SCOR model needs to be extended with a framework for the adjustment of internal and external business processes, in order to align an existing process infrastructure with the inter-organizational processes that are the result of a SCOR approach [39].

Supply chain wide routines enable the development of information systems as the backbone of integrated supply chains [38]. Information technology is widely perceived as the enabler for supply chain integration [40]. Firms participating as partners in a supply chain have to provide their capabilities in a way that maximizes the supply chain efficiency and effectiveness by concentrating on their core competencies.

We posit that improvement in an enterprise's information processing capabilities with reference to a supply chain relationship will allow its supply chain linkages to better support reconfiguration of offerings and partnerships.

The above discussions are summarized in Figure 4, which depicts the main factors that influence e-connectivity and the outcome of e-connectivity in producing increased flexibility and supply chain coordination.

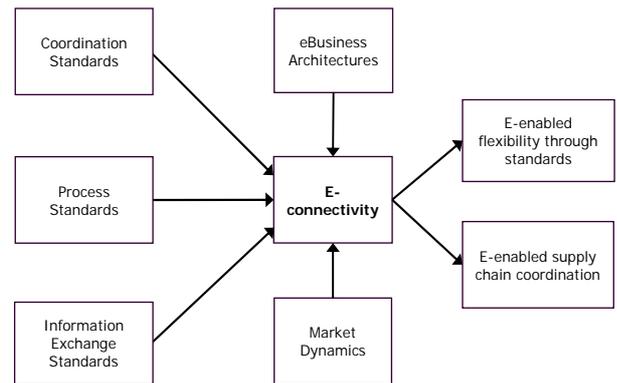

Figure 4: e-Connectivity in dynamically networked supply chains

III. Areas for further research

The paper has outlined the key concept for eConnectivity in supply chains. While this concept was validated through a literature review and expert interviews, an area for further research focuses on empirically validating the relationships between technology, process and management standards, and how they lead to improvements in connectivity and performance. This will subsequently provide additional insight for improved supply chain design.

IV. Conclusion

This paper has identified a number of drivers and enablers in an eBusiness context that supply chain partners can use to create quick and flexible linkages in their supply chains for leveraging their respective capabilities. The e-connectivity construct was introduced and examined, as it was established that information integration and resulting supply chain visibility is a key factor for quick decision-making in the supply chain.

Through a literature review and exploratory research with industry experts, the study concludes that technology is only but one key driver. Existing and further emerging technology standards enable companies to connect their operations systems easier and quicker. Standards supporting the establishment of information platforms, technology infrastructures, and process methodologies have become drivers that enable connectivity for eBusiness.

In order to achieve superior performance, our preliminary results suggest that processes and the mechanisms for coordinating capabilities need to be aligned within the capability technologies have to offer.

The findings further suggest that e-enabled supply chain infrastructures provide companies with faster and richer information, and hence allow supply chain partners to make appropriate decisions in highly dynamic market situations, allowing the entire supply chain to become both more adaptive and more proactive in capturing value opportunities.

Abstract: A collaborative design chain incorporates the different design activities performed by various design teams that may be located at different geographical locations. In a collaborative design chain, the different parts of a product can be designed by different design teams in a collaborative way. There exist different ways for distributing the different parts to the multiple design teams. If different ways are used for distributing the different part, the time for completing the design and the final functions of the product may vary. In this research, a design evaluation model for evaluating the collaborative design chain is presented. The presented new model is aimed at finding the best way for distributing the different parts to the suitable design teams such that the designed functional value of the product can be maximized. Also, the design cost composed of design operation cost and design communication cost in collaborative design is minimized. An optimized design distribution and evaluation model is presented by maximizing the total design value which is defined as the designed functional value minus the design operation cost and the design communication cost. Implementation and test results are presented.

Keywords: Collaborative commerce; SCM; Collaborative design; Design chain; Multi-plant

I. Introduction

With emerging e-business models in a global supply chain, the demand of new products from customers is growing and the time to market for a new product is shortening. As a result, the demand of new products with more new functions is increasing. In addition, the design cycle time for designing a new product needs to be reduced.

To satisfy the above demands, collaborative commerce models are introduced. In a collaborative design model, the different parts of a product can be distributed and designed by different design teams at multiple sites at various geographical locations. The main idea is that the different portion of a product can be assigned to a suitable design team which is specialized in designing the portion. In this way, the functions of the final product can be enhanced since each portion is designed by a specialized design team. Moreover, the design operations can be shared by the

multiple design teams in a concurrent way to reduce the design time. The purpose of collaborative design is to distribute the design tasks to the suitable design teams to achieve the objectives of reducing design time and increasing product functional value.

A collaborative design chain integrates different design activities performed by various design teams in order to complete the final product. The design activities mainly include design operations and design communications required for performing the design tasks. In a collaborative design chain, there may be certain added value that can be gained as a result of a collaborated design activity. Also, there may be additional cost generated because of a collaborated design activity. The value and cost created by the collaborated design activities and the multiple design teams may be more complicated than a single design team. Therefore, the gained value and the additional cost occurred in a collaborative design chain need to be analyzed and evaluated.

In this research, the total design value of a designed product can be evaluated by two main categories, the functional value that the designed product creates and the design cost that takes to produce the designed product.

The functional value of a designed product is created by the functions that the product can perform. If there is a good or a special function required by the customers, then the product can sell with a higher price. Therefore, it is a goal that the functional value can be increased.

However, a good functional value may be the result of a higher design effort. Therefore, more design operation time and more design communication may be needed in this type of a collaborative design model. Since a collaborative design chain is composed of different design teams, if a product is designed by different combinations, the product functional performance may be different. Also, because the different design teams may design the product differently, different design communication time may be required.

Therefore, for a collaborative design chain, it requires a systematic way to evaluate the total design value of the designed product. In this research, the total design value is defined by the designed functional value, the design operation cost and the design communication cost. This is represented as total design value = designed functional value – design operation cost – design communication cost. It is the purpose of the research to distribute the design tasks to the suitable design teams such that the total design value can be maximized. This can be represented as

$$\text{Max } \{D = (F - T - C)\},$$

where D = total design value,

F = designed functional value,

T = design operation cost,

C = design communication cost,

In the related research by Kvan [5], the meaning of collaborative design and computer-supported collaborated design is discussed. A recent review by Fuh and Nee [3] summaries the related works using the distributed CAD approaches using the latest IT tools to support the collaborative design activities. A comprehensive review of related work in research and development of software tools and methodologies to support distributed and collaborative design can be found in Li et al. [6]. Recent research focuses on three main topics: visualization of 3D CAD models, co-modeling of 3D CAD models, and developing distributed design environment. The related research work can be found in a web-based conceptual design prototype system presented by Qin et al. [8], a collaborative product conceptualization tool using web technology by Roy and Kodkani [10], a feature-based collaborative design by Wang et al. [13], a distributed object model for collaborative CAD environments by Barbosa et al. [1], and a process-oriented intelligent collaborative product design system, by Li et al. [7]. The related research by Tseng et al. [8] focuses on design module modeling and design task assignment in a collaborative design model.

Based on the review, previous research work focuses on developing a framework for communication of design and exchanging of data using the internet and web-based technology. Although much has been accomplished on the internet framework, it shows that little work has been done on the planning and evaluating aspect of a collaborative design process. It requires a planning and evaluating model for decision-making of a suitable way to distribute the different parts such that the cost and functional performance of the collaborative design chain can be optimized. This research presents an evaluation model for a collaborative design chain for distributing design tasks to available design teams with a maximized total design value.

II. Design Task Distribution and Design Evaluation Model

The concept of maximizing total design value can be formulate as follows. To formulate the problem under investigation, the following notations are used.

Notations:

n : design task,

k_n : part in a product,

d : design team,

p : designer,

P_{G_d} : designer in design team d ,

$T_{pn(k_n)}$: the design communication cost,

$C_{pn(k_n)}$: the design operation cost,

$F_{pn(k_n)}$: the functional value (same unit with cost) obtained,

$x_{pn(k_n)}$: decision variable,

a_{nd} : decision variable,

Objective function:

$$\begin{aligned} \max \sum_n \sum_d \sum_p \sum_{k_n} a_{nd} \times x_{pn(k_n)} \times F_{pn(k_n)} - \\ \sum_n \sum_d \sum_p \sum_{k_n} a_{nd} \times x_{pn(k_n)} \times T_{pn(k_n)} - \\ \sum_n \sum_d \sum_p \sum_{k_n} a_{nd} \times x_{pn(k_n)} \times C_{pn(k_n)} \end{aligned} \quad (1)$$

Constraints:

$$\begin{aligned} \sum_p \sum_n \sum_{k_n} x_{pn(k_n)} \times C_{pn(k_n)} &\leq 1 \\ F_{pn(k_n)} &\geq 0 \\ T_{pn(k_n)} &\geq 0 \\ C_{pn(k_n)} &\geq 0 \\ \sum_d a_{nd} \times (\sum_p x_{pn(k_n)} \mid p \in P_{G_d}) &= 1 \\ \sum_d a_{nd} &= 1 \\ \sum_n \sum_{k_n} x_{pn(k_n)} &= 1 \\ a_{nd}, x_{pn(k_n)} &\in 0, 1 \end{aligned}$$

The model is formulated with an objective of maximizing total design value which is defined as the designed functional value minus the design operation cost and minus the design communication cost.

The output information of the model is as follows:

1. The designer in a design team assigned to design a part,
2. The design completion time for designing all the parts in a module,
3. The design completion time for designing the product
4. The final product functional value.

III. Implementation And Test Results

Test software system has been developed on a personal computer to implement and test the presented model.

Several example products are tested. In this section, a mobile phone is used as an example product to show the model and the tested results in this study.

With the input information of the example product, the design distribution and evaluation model is performed. The model is solved using a linear programming solution method. The final results of design evaluation and distribution are shown in Table 1.

According to the model developed in the study, a maximized total design value can be obtained. From the example, it shows that the developed model presents a feasible evaluation method with an optimized result. It is observed that in practical cases, the presented model can be useful for most common commercial products to achieve the objectives.

IV. Conclusion

In a collaborative commerce model, a design may be distributed and performed by different design teams in a collaborative design chain. In this paper, a design evaluation model for evaluating the collaborative design chain is presented. In a collaborative design chain, different ways for distributing the parts of a product to multiple design teams may result in different design completion time and different product functional performance. In this research, the value and cost issues in a collaborative design chain are identified and defined. Based on the value and cost issues, an evaluation model is developed. The presented new model is aimed at finding the best way for distributing the different parts to the suitable design teams such that the designed functional value of the product can be maximized. An optimized design distribution can be obtained by maximizing the total design value which is defined as the designed functional value minus the design operation cost and minus the design communication cost. In future research, a more complete model can be developed with more detailed value and cost objectives for evaluating collaborative design chains.

Table 1. Test results of the example product.

Design task n	Part (k_n)	Part name	Design r (p)	Design team (d)
1	1	Upper case	P ₁	D ₁
	2	Back case	P ₄	
	3	Keyboard	P ₅	
2	4	Keyboard conductor	P ₅	D ₁
	5	Keyboard controller	P ₂	
3	6	Earphone	P ₉	D ₂

4	7	Speaker	P ₉	D ₄
	8	Microphone	P ₁₉	
	9	Power switch	P ₁₈	
5	10	Vibrator	P ₂₀	D ₂
	11	Battery	P ₁₀	
	16	SIM card frame	P ₁₁	
6	12	LCD	P ₂₁	D ₅
	13	FPC	P ₂₄	
	14	Backend IC	P ₂₅	
8	15	PCB	P ₁₄	D ₃

Abstract: In today's dynamic business environment, the capability to understand the needs and responses of stakeholders is critical as such management can devise effective plans and course of actions for long-term strategies. The advancement of the internet and its related search tools such as Google, has helped management to collect various information in order to keep abreast of time of business environment and their business communities. Yet, the management has encountered problem and uncertainty on the information quality such as content, currency, accuracy and presentation. Therefore, a new backlink search tool, namely Redips was developed. This tool has been tested by students subjects with satisfaction. However, in order to gain acceptance from the management (i.e., the end-users), the perceptions and expectations on the tool should not be overlooked. This study presents a wide range of perceptions from a group of Information Systems practitioners on the potential use of Redips.

I. Introduction

The World Wide Web presents significant opportunities for business intelligence analysis as it can provide information about a company's external environment and its stakeholders. Traditional business intelligence analysis on the Web has focused on the simple keyword searching. Recently, it has also been suggested that the incoming links, or backlinks, of a company's Web site (i.e., other Web pages which have a hyperlink pointing to the company of interest) can provide important insights about the company's "online community". Analysis of these communities can provide useful signals for a company or information about its stakeholder groups, but the manual analysis process can be very time-consuming for business analysts and consultants. In this paper, we present a tool called Redips that integrates automatically backlink meta-searching and text mining techniques to facilitate users in performing such business intelligence on the Web. We also report a focus group study involving IS practitioners to study the potential uses and user perception of the proposed tool. The rest of the paper is structured as follows. Section 2 reviews the importance of Web communities in business intelligence analysis. Section

3 presents the proposed tool and its architecture. In Section 4 we discuss our methodology and the focus group study. The preliminary results are presented in Section 5. Finally we conclude our study and suggest future research directions in Section 6.

II. Web Communities

The Internet has many well-known explicitly defined communities – groups of individuals who share a common interest, together with the Web pages most popular amongst them [10]. The Web communities consist of the following stakeholders of the firm: customers, suppliers, competitors, regulators, employees, educational institutions, court and legal institutions, financial institutions, stockholders, public-interest groups, labor unions, political parties, federal, state, local governments, etc. [11]. The stakeholders listed here can be classified into two categories: explicit and implicit Web communities.

Explicit communities are the communities that can be easily identified on the Internet. Kumar et al. [8] discussed the Porsche newsgroup as an example of explicit community of Web users interested in Porsche Boxster cars. Such communities are often found in resource collections in Web directories such as the Yahoo directory. Explicit communities are easy to be identified and analysts can simply use manual method to find a firm's explicit communities by browsing the firm's newsgroup or the category in which the firm belongs to in directories like Yahoo on the Internet.

Implicit communities are relatively more difficult to be found using a manual browsing method. According to Kumar et al. [8] implicit communities refer to the distributed, ad-hoc and random content-creation related to some common interests on the Internet. These pages often have links to each other, but the common interests of implicit communities are sometimes too narrow and detailed for the resource pages or the directories to develop explicit listings for them. As a result, it is more difficult to find the implicit communities of a firm. In identifying the explicit and implicit communities of a firm, it is reasonable to assume that the content pages created by these communities would provide hypertext links back to the firm's homepage for reference [10]. Therefore, in order to find a firm's online communities, it is necessary to find the Web pages that have

hyperlinks pointing to the firm's URL, i.e. the inbound links of the firm's Web site.

The identification of Web communities, irrespective of explicit communities or implicit communities, is important to the strategic planning process. The strategic planning process consists of five steps [3], namely, mission and objectives, environment scanning, strategy formulation, strategy implementation, evaluation and control. The extraction of Web communities is classified to the environmental scanning step in the strategic planning process. The information would be used for the analysis of the firm's industry for evaluating entry barriers, suppliers, customers, substitute products and industry rivalry.

III. Redips

Our proposed system is called Redips. The term "Redips" is the reverse spelling of the term "Spider". Traditional Web spiders (crawlers) search the Web by following outgoing links. However, in our proposed tool, we search based on the "incoming links" of a page. These incoming links can help identify the Web communities of the firm of interest.

Redips has been implemented based on the MetaSpider system developed in our previous research [6]. The main modules include the user interface, spider, Arizona noun phraser, and self-organization maps. User interface is the first point of contact between the user and the system. Spider fetched the URLs returned from those search engines. Arizona noun phraser is a natural language processing tool to do the key phrase extraction from Internet text. Self-organization maps visualize the concepts in a two-dimensional map. The technical details of the modules are discussed in another paper [5]. Here, we will present a search session with the tool from the user's perspective.

When using Redips, a user should first enter the Web site to be analyzed and the backlink search engines to be included. A sample user session with Redips is shown in Figure 1. In this example, the Web site entered is <http://www.ibm.com/>, the homepage of the IBM Web site. Optionally, the user can enter the keyword(s) to be included in the returned Web pages. The user may also specify some other search options. In this step, the user can define the intelligent analysis objectives, e.g. the firm, information source, topic, in the analysis process. After starting the search, multiple threads will be generated to start getting Web pages from the Internet. The URLs returned by the search engines will then be displayed. The user can browse these pages for exploratory, preliminary research in this step.

IV. Research Methodology

As discussed above, there are a number of new attributes embedded in Redips, which facilitate information search and add values to the management in strategic planning. Yet, the attributes of Redips perceived and developed by the system developers may be different from those of the business managers. In order to provide an effective and practical tool,

the views and comments from IS practitioners who are rich in IS knowledge and currently engage in business planning, leadership and strategic analysis are examined. The current study adopts focus group study (as an effective research method) to dig in and explore various perceptions from the IS practitioners, as such to enrich our understanding of the practicability and usefulness of Redips.

Focus group discussion is a qualitative method to trigger and solicit extensive pool of opinions that capture the respective dimensions of the domains or topics to be addressed or investigated, particularly newly emerged and illuminative concepts [7,9]. Generally speaking, focus group is a method conducive to communication through a two-hour back-and-forth discussion and interaction among a small group of individuals (usually six to ten persons). A moderator is enlisted to facilitate the discussion (e.g., to ensure topics and issues are conversed, commented upon and incorporated). In our current study, one focus group discussion was conducted. The group was composed of six practitioners (in their mid-thirties) with an average of 12 years of industry experience. They discussed on the search approaches, pros and cons of commonly used internet-based search tools. Thereafter, they engaged in a 30-minute hands-on of the Redips and explicated their opinions from various views. Large amount of broad-based ideas in participants' own words, while relatively inaccessible using other research methodologies can be obtained [4]. The coding and analysis of the data, thereby can be used to develop thematic scheme to reveal the scope, details and multiple facets of the constructs or ideas in proposed work [1, 12].

The focus group study serves as the beginning stage of research. We intend to use a mix of techniques to make sense of the qualitative data collected from the practitioners. A research plan with three stages is detailed as follows:

Stage One. In order to understand how users perceive and evaluate new systems, a reference to existing IS literature was undertaken. The pertinent literature is used as a foundation to outline the topic agenda used in the focus group sessions, while refrained from the actual discussion.

Stage Two. A series of focus group sessions is planned to be conducted. The first focus group discussion was held in August 2005 which provided a lot of useful feedbacks of Redips. More focus group sessions are planned, involving business executives from non-IS functional areas (such as sales and marketing sections in their organizations) of which the executives are expected to use the Internet-based tool frequently in their daily tasks.

Stage Three. Data collected (in handwritten notes and audio tapes) from different focus group sessions will be firstly compiled with the assistance of the computer. The results will thereby be compared and assimilated. A validated and accuracy check was conducted to compare the summary and the original transcripts. The adoption of thematic categorization [1,2,12] involves the articulation and construction of potential themes and facets of constructs that correspond with the research questions. The potential themes

were considered as a reflection of the attributes or dimensions captured under each construct. To ensure no interpretive perspectives would be lost, the transcripts (recorded in word documents) were sorted and allocated to the emerged themes using a cut and paste technique. Throughout iterative rounds of discussion and reconciliation, the discrepancies of interpretation were resolved to devise a theme summary. The theme summary includes coding systems, themes titles, descriptions, relevant examples and indicative keywords. To ascertain the effectiveness and accuracy of the system evaluation theme summary, further comments were sought from other experts (who are not involved in any stage of the current study).

V. Preliminary Results

The first focus group session was held, with large amount of ideas and opinions were sought. In essence, the practitioners are satisfied with the existing tools, in regard to its low cost (usually free of charge) and ease of use. However, the information quality in terms of amount, currency and presentation has presented limitations to their business decisions. The participants reveal that Redips can add value to their managerial tasks, as it streamlines the information search, and enables effective assessment of the Web

communities and stakeholders. A common assertion was sought that they will use Redips in addition to the existing search practice.

Some key preliminary findings are summarized as follows:

The practitioners had named Yahoo and Google as two commonly used Internet-based tools in their daily work. There are some extraordinary occasions that they may seek information from other search tools (such as www.altavista.com) given the two common tools did not provide adequate information for their purposes.

To evaluate an effective and desirable system, nine attributes are assimilated from the opinions sought in the focus group discussion (Table 1). Redips' performance shows a good match and desirable attributes with those expected by the IS practitioners. The attributes are ranked according with the number of respondents who solicit the respective aspect. Therefore, a higher the number in the bracket indicates a more common issue being conceived in the discussion session. It should be noted that one of the advantages of focus group discussion is to provide analytical generalization of what participants think and perceive, therefore, it is not meant the higher the number of a respective attribute as more important one.

Table 1. Desirable Attributes of an Internet-based Search Tool and Redips

Desirable Attributes	Details and Descriptions	Redips
Time (6)	Short and prompt search time	Quick response and fetching time
Cost (6)	Free of charge	Free of charge
Search results (6)	Links should be ranked with relevance and currency of the information	Web pages are fetched in real-time to avoid outdated indexes
Learning efforts (5)	Minimum, ease of use without attending formal training	Easy to use, logical and order search process
Technical resources (4)	No additional software be installed	Requires installation
Interface (4)	User-friendly and attractive	Practical and clean, user-friendly buttons
Language (3)	Multiple language	Limited to English
Personalization (2)	Customization of specific search requirements, prior search records	Three search engines (including Google, MSN and AltaVista) can be previewed at the same time; phrase selection to remove unrelated pages
Assistance (1)	Help, search tips and data recovery	Help menu available

Contrast to our result-oriented system design, the IS practitioners who are experienced in system development and engage in business planning share similar perception and valuation criteria that are close to those of end-users'. Most of the participants showed empathy on the business managers' pressure in time management. A system analysis manager stated that the tool should be time saving, with results displayed with highly relevant, clear, easily be

comprehended and useful content. Two other participants supported his views as they claimed the business development managers in their organizations are "extremely" hard working as they usually work for more than 54 hours per week, thus they cannot afford information search process that "wastes" their time. Therefore, they stated that the search process should be time-effective, with minimum search and loading time. They commented further

that long loading time will increase the tendency to abort the search process, thus, unfavorably affect managers' time management.

While discussing the approaches in search of information or business intelligence, the practitioners stated that their search approaches vary from task to task. One IS department assistant manager stated that if he looks for new business opportunities that he has little experience about it or the request is made on ad hoc basis, he may seek information exhaustively until the relevance of the search results diminishes. He explained "I will seek help from experienced staff within organization. Yet, sometimes good business ideas are not generated from internal people as they are indulged to the existing success. Those competitors, discussion groups provide lots of comments to our existing services, despite their words are unpleasant. Listening to our customers can let us know our inefficiency and what we need to do more." Otherwise, if he handles regular review of market positioning, he will approach a satisfactory manner. He stated "my personal experience is rich and validated in my past success. Therefore, I know when and where to get the relevant information for routine tasks, and know when to stop."

In regard to the propagation of Redips, a senior system engineer pointed out that a good design does not make the system successful and well accepted by users. He stated, "Our colleagues have a strong social network which shared lots of latest information and users' feedback on various tools." Therefore, he suggested "the success of Redips is not a mere concern of physical design and functionality; rather it is determined by the consumers who foster a good perception at the beginning. If the comment is positive, the word-of-mouth will leverage users' interest and attention to Redips." A senior software development manager put forth the opinion and stated that management should not underestimate the power of management commitment and network effect. She gave an example that a new software system was well accepted in her organization, despite the brand equity of that software system is not high. It is because the management has shown a strong support, clear vision and commitment to deploy across all departments. Middle management also plays an important role to monitor the roll out of the system. Furthermore, she recalled "most of our colleagues believe that they should get on the same board (i.e. adopt the new system) in order to become one of the majority."

VI. Conclusion

The internet-based backlink search tool, Redips provides an alternative way to assess various web communities and infer business intelligence to managers. In order to enhance its practicability and usefulness to business managers, the current study adopted focus group method to drill in various

perceptions and views from a group of IS practitioners. In essence, they find Redips and assert its value in business planning and decision making. Our present study will be continued and extended as proposed the three-stage research tasks. The nine attributes and specific findings about managerial problem solving approaches will be also incorporated as such Redips can be widely adopted.

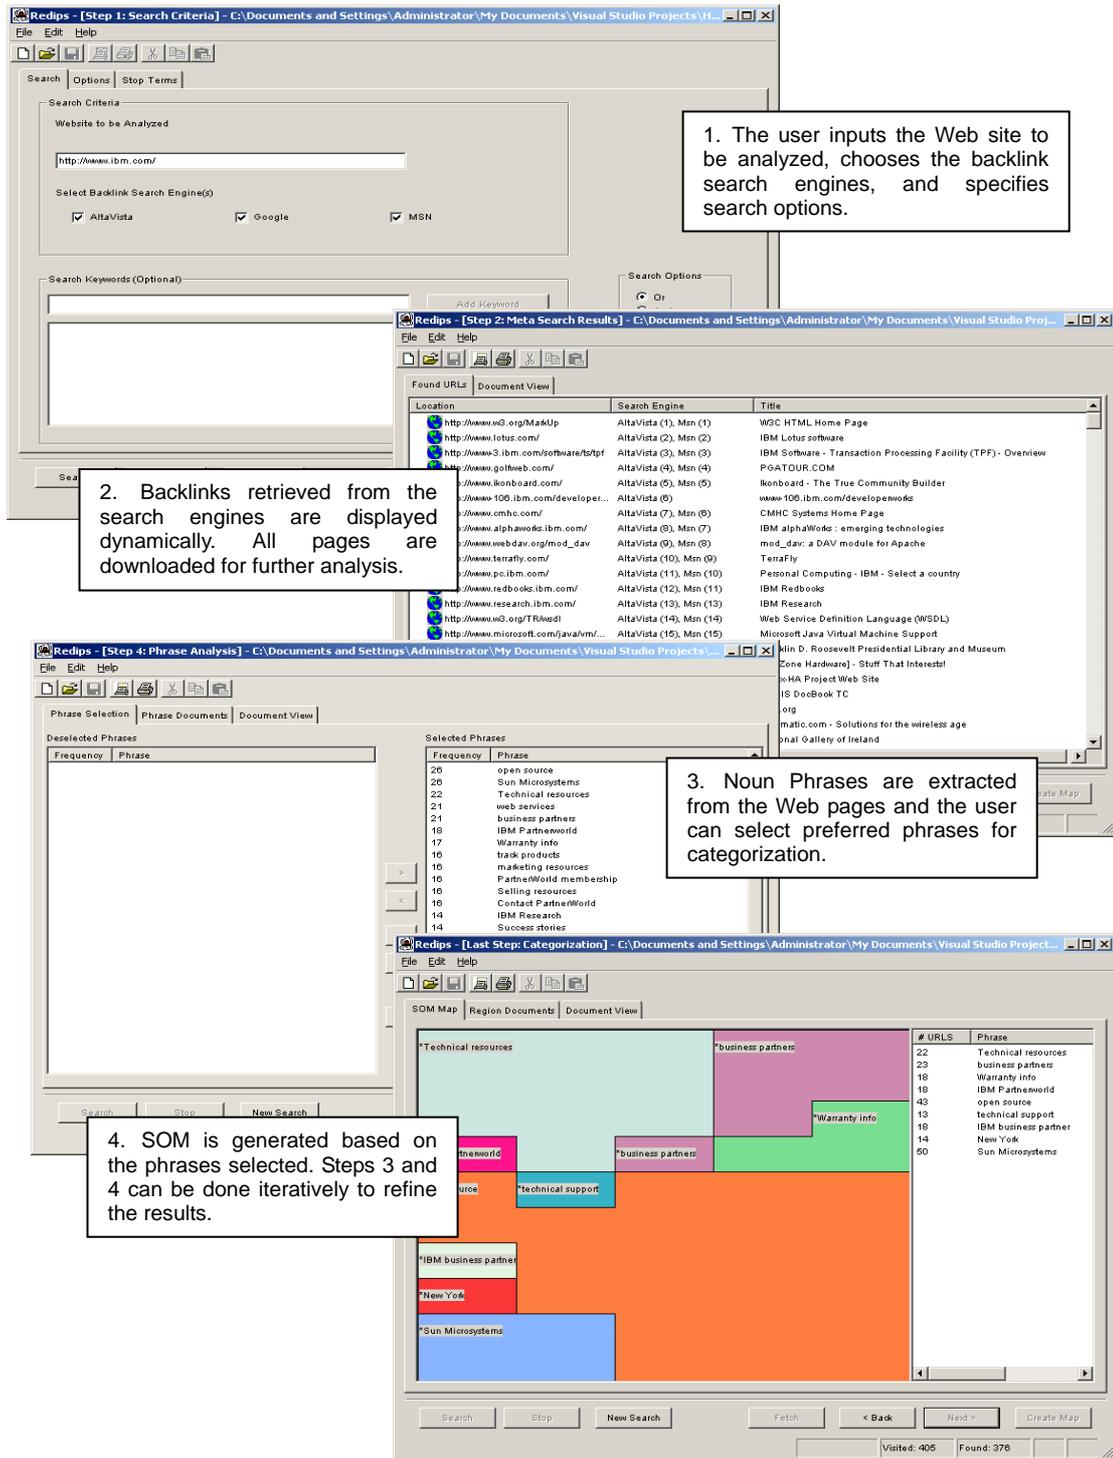

Figure 1: Example of a User Session with Redips

Using Header Session Messages to Filter-out Junk E-mails

Chih-Chien Wang, Sheng-Yi Chen
Graduate Institute of Information Management
National Taipei University

Abstract: Due to the popularity of Internet, e-mail use is the major activity when surfing Internet. However, in recent years, spam has become a major problem that is bothering the use of the e-mail. Many anti-spam filtering techniques have been implemented so far, such as RIPPER rule learning algorithm, Naïve Bayesian classifier, Support Vector Machine, Centroid Based, Decision trees or Memory-base filter. Most existed anti-spamming techniques filter junk e-mails out according to e-mail subjects and body messages. Nevertheless, subjects and e-mail contents are not the only cues for spamming judgment. In this paper, we present a new idea of filtering junk e-mail by utilizing the header session messages. In message head session, besides sender's mail address, receiver's mail address and time etc, users are not interested in other information. This paper conducted two content analyses. The first content analysis adopted 10,024 Junk e-mails collected by Spam Archive (<http://spamarchive.org>) in a two-months period. The second content analysis adopted 3,482 emails contributed by three volunteers for a one week period. According to content analysis results, this result shows that at most 92.5% of junk e-mails would be filtered out using message-ID, mail user agent, sender and receiver addresses in the header session as cues. In addition, the idea this study proposed may induce zero over block errors rate. This characteristic of zero over block errors rate is an important advantage for the anti-spamming approach this study proposed. This proposed idea of using header session messages to filter-out junk e-mails may coexist with other anti-spamming approaches. Therefore, no conflict would be found between the proposed idea and existing anti-spamming approaches.

Keywords: Web Intelligence and Web Based Information Technology, Spam, Unsolicited E-mail, Junk E-mail, E-mail Address, Filter

I. Introduction

Internet grew vigorously fast and is now a necessary of daily life for many people. According to eTForecasts's statistics, the number of Internet users in the world will surpass 1 billion in mid 2005 and the U.S. continues to lead with over 185 mill Internet users for year-end 2004[11]. According to report conducted by Center for the Digital Future at University of South California Annenberg School, the time American Internet users spend on Internet a week grew from 9.4 hours in 2000 to 12.5 hours in 2003[5]. That is to say,

surprisingly, American Internet users spend on Internet up to 1.78 hours everyday. In the year 2000 to 2003, the growth rate of time spending on Internet is 33%. Therefore, Internet has become an important role in people's life.

The survey conduct by Center for the Digital Future at University of South California Annenberg School also indicated that the Internet activity American Internet users the most do is E-mail and instant message, about 90.4% [5]. So, using E-mail is the major activity when surfing Internet. However, spam problem critically influences every Internet users' life and wastes huge resources include network bandwidth and disk storage. Obviously, existence of junk e-mails is an irritating problem when using Internet. Nine out of ten e-mails in America are spam and 76% of all e-mails globally are spam, according to Sharon Gaudin (2004) [26] [27]. The spam problem is going to get worse if we do not put effort on anti-spamming.

Jon Postel, an Internet pioneer, recognized the potential of junk e-mail problem as long ago as November 1975 and proposed Requests for Comments (RFC) 706 that draw up the problem for junk e-mail [17]. In 1982, ACM president Peter J. Denning [21] published the first article about junk e-mail on Communications of ACM. He indicated that junk e-mail will abound in E-mail mailbox. However, "Spam" word became wide-spreading in April 1994, two American lawyers named Canter and Siegel hired a programmer to write a simple script to post their advertisement to every newsgroup board on USENET in order to propagate their U.S. "green card" lottery service [19]. After this event, some people identified it as "Spam" and the word caught on. This event can be called the beginning of spam.

Many studies aimed at spamming, for example, Damiani et al. presented a peer-to-peer architecture between mail servers to collaboratively share knowledge about anti-spamming [10]. Jung and Sit focused on DNS black lists [14]. Sahami et al. applied Bayesian approach to filtering junk e-mails out [20]. Rigoutsos and Huynh presented a Chung-Kwei algorithm based on Genetic algorithm to implement a system for the analysis of junk e-mail [13]. Leiba and Borenstein found no one technique solves the spam problem fully, but different techniques excel in different ways and he present using multiple techniques in several layers in order to promote filtering effect [3]. Golbeck and Hendler presented an e-mail scoring mechanism based on a social network augmented with reputation ratings [15]. Goodman focused on the sender's IP address that cannot be faked, so it is a key for anti-spam [7].

The existed techniques could not filter out all spam emails. Spammers might find way to avoid filter out. Junk e-mails may contain faked sender's e-mail address, send in

small batch, and with subjects irrelevant with mail contents to avoid being filtered by anti-spamming mechanisms. Therefore, more efforts are needed to improve current anti-spam techniques.

In addition, some filtering techniques may result in a high rate of filtering spam out, but simultaneously cause a high rate of over-blocking normal e-mails. For example, some anti-spamming mechanisms might filter out e-mails containing the word "adult" although these solicited e-mails are for "adult continuing education" and are sent to or by a scholar majoring in this field. Moreover, a manager might want to e-mail a message to all employees, such bulk e-mails might also be filtered by anti-spam mechanisms. At these two situations, the anti-spamming mechanisms have a high over-blocking rate.

Over-blocking normal e-mails as spamming may induce loss of emails and make email service unreliable. The over-blocking problem may cause users trouble for their daily life or work. Internet users who encounter over-blocking problems may not trust e-mail anymore. People sending out an e-mail have to confirm to the receiver the delivery of email. This over-blocking problem makes email an inconvenient application.

Most existing anti-spamming techniques are memory-based approaches filtering junk e-mails out according to email subjects and body messages. However, subjects and e-mail contents are not the only cues for spamming judgment. All e-mails have a header session composed of several messages about sender's mail addresses, receiver's mail addresses, mail servers, client e-mail software, message identity number, time stamp, etc. These messages existing in header session may be used as cues for anti-spamming.

Due to the imperfection of existing anti-spamming techniques, more efforts are needed to find new anti-spamming approaches. This paper presents a new idea of filtering junk e-mail by utilizing the header session messages. Besides content and subject, e-mail has a header session containing some fields of messages. Past anti-spamming techniques usually used email subjects or contents as cues for anti-spam filtering and neglected the information in the header session.

Header session is designed for storing messages about e-mail delivery. Usually Internet users do not care messages in the header session expect sender e-mail address for replying e-mail and time stamp for sorting e-mails. Most users are not interested in other information. However, these messages which users are not interested in may be cues for anti-spam filtering.

This study uses message-ID, mail user agent, sender and receiver addresses in the header session as cues for anti-spam filtering. The e-mail addresses of sender and receiver identify sender and receiver. Spammers usually send junk e-mails with invalid sender address to avoid possible accusation and suspension of e-mail service by Internet Service Provider. In addition, most junk e-mails are sent out in bulk. Spammers usually put receivers' emails in the field of blind carbon copy and do not reveal the real receivers to avoid receivers to know that this e-mail is sent out for

enormous copies. That is, the receivers' e-mail addresses would not be found in receiver and carbon copy receiver field for most junk e-mail.

X-Mailer field of header session indicates what client software or mail user agent (MUA) was used to send the e-mail out. Normal personal communication e-mails are sent out via client software such as Outlook, Outlook Express, Lotus Note, and so on. However, junk e-mails are sent out via bulk email software. These bulk email software may not point out their software name in the X-Mailer field or randomly put unmeaningful characters in the X-Mailer field.

Message-ID field is generated either by the MUA or by the first mail transfer agent (MTA) the message passes through, uniquely identifying a piece of e-mail. Most spammers would fake the part value of Message-ID field and cause the domain name of sender address not match the domain part of message-ID. Spammers hope to avoid revealing the real domain name of the MUA or the first MTA the message passes through and thus add a fake domain name to Message-ID field.

The rest of this paper is organized as follows. In the following sections, this paper introduces reviews on anti-spamming mechanisms and efficiency of anti-spam techniques. Then, research design is presented and the results of content analysis are detailed. Finally, we discuss the possibility of using the header session messages as cues for anti-spam filtering. The results of this study indicated that these header session messages might be useful in screening out junk e-mails.

II. Anti-Spamming Approach

The rapid increase in spam traffic took a bothering problem to end users and business corporations. However, a number of methods have been proposed to filter spam out. However, these anti-spamming methods had a very limited effect so far. Various techniques for filtering spam are listed below.

II.1 Bulk E-mail Filtering

Bulk e-mail filtering is the easiest filtering technique that filters bulk e-mail out for mail server. This method is based on the assumption that junk e-mail are generally sent to a large number of recipients, so system administrator only need to set an upper limit for recipients of every e-mail at mail server. However, spammer can easily avoid this filtering technique by changing the e-mail header information constantly after sending a certain number of e-mails. In addition, this method may easily filter out important e-mail that includes a large number of recipients. The key determinant of this method's efficiency is recipients' upper limit setting. If setting is too strict, this filtering technique would easily filter out the normal e-mails. On the contrary, setting too loose would make junk e-mail not be filtered out.

II.2 Filtering by Keyword

Keyword filtering is the most frequently used anti-spamming

technique. There are two approaches for this method. The first one is an easy but inefficient approach which sets keyword and filter out all e-mails with keyword appeared in subject or content. "On Sale", "Sex" and "Get Rich" are frequent used keyword. However, this method is inefficiency, while spammer would avoid using these keywords and normal e-mails containing these keywords will be mistakenly regarded as junk e-mails.

The second way is to filter out junk e-mails basing on machine learning results. This approach is more complex and more efficient than the former one. In this approach, the keywords are determined by machine learning algorithm and frequency of all keyword is calculated to discriminate junk and normal e-mails. Many studies are based on this approach, such as RIPPER rule learning algorithm (Cohen, 1996[7]; Provost, 1999[22]), Naïve Bayesian classifier (Sahami 1998[24]; Schneider 2003[25]; Sinclair 2004[29]), Support Vector Machine (Drucker et al. 1999[9]; Kolcz and Alspector 2001[18]; Gordon and Hongyuan 2004[12]), Centroid Based (Soonthornphisaj et al. 2002[30]), Decision trees (Carreras and Marquez 2001[4]) or Memory-base filter (Androutopoulos et al. 2000[2]). This method is based on the assumption that the subject or body sector of junk e-mails may contain specific words. However, this technique does not work perfectly, and thus normal e-mails would be filtered out simply because they include too many words on the keyword list for junk e-mails.

II.3 Black List

This approach exploits a black list database to block specific address or domain name of e-mail. Such database is made available on the Internet, such as DNSBLs (<http://dsbl.org/main>) or SORBs (<http://www.us.sorbs.net>). If the database updates frequently, it can be reliable for filtering certain known spammers' address out. However, it is a defect that if mail servers improperly set normal e-mail address or domain name into black lists would filter out normal or important e-mail. Besides, spammers usually leave random assigned faked sender addresses which not in the black list. Black list approach can not function if sender addresses are faked.

II.4 White List

White list is design to avoid filtering normal e-mails out. White lists gather permitted e-mail address or domain name and often collaborate with black lists. Black lists block illegal e-mails address and White lists allow normal e-mails to pass. It is more difficult to maintain the white lists database perfectly than black list.

II.5 Sender Address Validity

In 1982, Crocker revised the Requests for Comments (RFC) 822 that is a standard for the format of ARPA Internet text messages and the format of e-mail is described in. [8] According to RFC 822, each e-mail must include the field of "From" that contains the address of the sender who wished this message to be sent. All e-mails should have at least one sender and the "From" field must be present. Although RFC

822 mandate the existence of the "From" header in e-mails, the sender address can be invalid or faked by spammer. The spammers avoid being accused of sending junk e-mail and breaking the law. Additionally, most Internet Service Providers (ISPs) or e-mail service provides would suspend the use of spammers' e-mail address or refuse to relay the e-mails they sent. According to Wang (2004)'s research, 60.3% junk e-mails provide invalid sender address [31]. Therefore, the validity of sender address left in the "From" header session may be a cue for anti-spam filtering.

II.6 Receiver Address as Cue

Also according to RFC 822 [8], the receiver addresses are list in the "TO", "CC", or "BCC" fields and like sender address, each e-mail must have at least one receiver. The "TO", "CC", or "BCC" headers are used to present the recipients of this e-mail where to sent. "TO" field contains the identity of the primary recipients of the message and "CC" standing for carbon copy, contains the identity of the secondary recipients of the message. Thus, the function of the "TO" and "CC" fields are very similar. However, "BCC" differs from "TO" and "CC". "BCC" standing for Blind Carbon Copy, contains the identity of additional recipients of the message. The contents of this field are not included in copies of the message sent to the "TO" and "CC" recipients. According to Wang's research, only 7.2% spam would put receiver address in "TO" or "CC" and spammer usually use the "BCC" for the receiver address to avoid revealing that junk e-mail are sent in bulk.[31] Hence, the presence of receiver address left in the "TO" or "CC" header session may be a cue for anti-spam filtering. However, this approach may filter out normal e-mail while people use the "BCC" for the receiver address to send normal e-mails.

II.7 Mail User Agent as Cue

In header session, RFC 822 notes the use of X- at the beginning of field names to indicate that a field is an extension. The X-Mailer field indicates what e-mail client program or MUA was used to generate the e-mail. Although this field is not required in header session, most MUA developers generally have their software add an appropriate X-Mailer field to all out-bound e-mails. According to observation made by this study, most junk e-mail do not include the X-Mailer field or include this field with random assign value. Therefore, the field of X-Mailer may be a cue for anti-spam filtering. Most frequent used MUAs, for example, Outlook Express, MS Outlook, Lotus Note or Eudora etc., marked X-Mailer field of out-bound e-mails exactly. On the contrary, an inbound e-mail that X-Mailer field value is null, meaningless random assign value may mean that this e-mail is probable junk e-mail. A normal MUA for sending bulk e-mail would not fake the X-Mailer field because feigning it as Outlook Express, MS Outlook, Lotus Notes, or some other MUA software may violate the trademark law although developing bulk e-mail software do not violate any law. As a result, the X-Mailer field can be a cue for ant-spam filtering.

II. 8 Message-ID as Cue

The unique message identifier in the header session is generated by the MUA or by the first MTA the message passes through if MUA did not yet assign one for the e-mail. This identifier is intended to be machine readable and not necessarily meaningful to humans. The format of this message ID field value is with a symbol of "@" dividing the value into two parts. The left side contains a string of characters to uniquely identify the message on the machine where it was created and is usually based on the date and time or depending on the e-mail software generating the data. The right side specifies that machine or domain name [16: pp. 32-33]. Most spammer would fake this domain value to avoid possible internet service suspend and cause the domain of sender address not match the domain part of Message-ID. Spammers hope to avoid revealing the real domain name of the MUA or the first MTA the message passes through and thus add a not existed domain name. Consequently, this condition provides a cue for deciding the possibility of an incoming e-mail is a junk-mail.

III. Efficiency of Anti-Spam Techniques

While calculating the effectiveness for anti-spam filtering techniques, two types of errors should be taken into consider. First, under-blocking occurs when e-mail is not blocked that should be filtered out. Second, over-blocking occurs when solicited normal e-mail that should not be filtered out is blocked. Shortly, it is bad anti-spamming techniques that junk e-mails are not blocked or normal e-mails are blocked. These two error rate format proposed by Resnick et al. (2004) are listed blow [23].

Under-blocking errors = unblocked junk e-mails / (blocked junk e-mails + unblocked junk e-mails)

Over-blocking errors = blocked normal e-mails / (unblocked normal e-mails + blocked normal e-mails)

Reducing both two error rates mentioning above is a good filtering technique should do. However, the importance of under-blocking errors and over-blocking errors is not same. For most e-mail users, the problem of over-blocking errors is more important than under-blocking errors. While encountering unblocked junk e-mails, users only spend additional time on deleting them. However, over-blocking normal e-mails generally can not be recovered. Thus, users would lose some important messages and it may cause troubles at communication for work or daily life. If e-mail users aware the possible risk of over-blocking, they have to ask receiver to confirm e-mail receiving. This may bring inconvenience to e-mail users and make e-mails unreliable.

The under-blocking errors and over-blocking errors are benchmark for effectiveness of anti-spam filtering techniques. However, most past researches focus on the under-blocking errors although it is important to reduce both two error rates for anti-spam filtering. For examples, Chen et al. [6] report that they can filter out 98.54% junk e-mail but

do not mention the over-blocking error rate. Woitaszek et al. [32] report as low as 96.69% under-blocking errors but not mentioning the over-blocking error. The same situations had also found in Ahmed et al.[1], Androutsopoulos et al. [2], Drucker et al. [9], Shih et al. [28] and Soonthornphisaj et al. [30]'s studies.

IV. Content Analysis for Junk and Normal E-Mails

This study conducted two content analyses. The first content analysis (study 1) adopted 10,024 Junk e-mails collected by Spam Archive (<http://spamarchive.org>) in a two-months period. Spam Archive has collected large number junk e-mails that is donated by end users and is a well known large spam repository for developing anti-spam tools. The second content analysis (study 2) adopted 3,482 emails contributed by three volunteers for a one week period. The collected 3,482 emails in study 2 were classified into three categories: normal, junk and solicited listserv and commercial ones. Normal e-mails are e-mail for personal communication. Junk e-mails are unsolicited e-mails and are usually send in bulk and for commercial purpose. However, some emails are solicited for users although they are sent in bulk. Listserv e-mail is a typical case for this category. People may join a listserv, discussion board, or family in yahoo to receive e-mails. In addition, users may subscribe retailing websites to receive updated sale messages. These kinds of listserv and commercial e-mails should be treated as solicited although most of them are sent in bulk.

This study use content analysis to examine the possibility of using header session messages as cues to discriminate normal and junk e-mails. Analyzing fields of sender, receiver addresses, messages ID, and MUA in normal and junk e-mails' header sessions are used for this purpose.

IV. 1 Sender Addresses

Sender addresses validity was check for all normal and junk e-mails this study collected. The study checked sender addresses via Domain Name Server (DNS) checking for existence of mail server and Simple Mail Transfer Protocol (SMTP) checking for existence of mail account. Each sender' email account was check if the SMPT servers refused to response to email addresses validity checks. Figure 1 and 2 indicates the sender address checking results of study 1 and 2. Of the 10,024 junk e-mails study 1 collected, 6,664 (66.48%) were with invalid sender addresses. Of the 2,248 e-mails study 2 collected, 791 (35.1%) were with invalid sender addresses. Of the 635 solicited listserv or commercial e-mails study 2 collect, only 28 (4.41%) were with invalid sender addresses. Moreover, none (0%) of normal e-mail study 2 collected was with invalid address.

The results of sender address validity checking showed that sender address may be a cue for reduce over block rate.

As figure 2 indicated, all normal e-mails were with valid sender addresses. This means that there is no side effect, no normal email will be mistakenly block out, if we filter out all e-mails with invalid sender addresses. Simply filter out e-mail without valid sender addresses may block out 66.48% junk e-mails in study 1 and 35.1% junk emails in study 2. However, 4.41% solicited listserv or commercial e-mails in study 2 will also be filter out according to this valid sender address rule. This 4.41% filtered emails might be regarded as over block e-mails if we treat solicited listserv and commercial ones as normal. Nevertheless, the over block rate will be zero if users think that it is acceptable to filter out listserv and commercial e-mails.

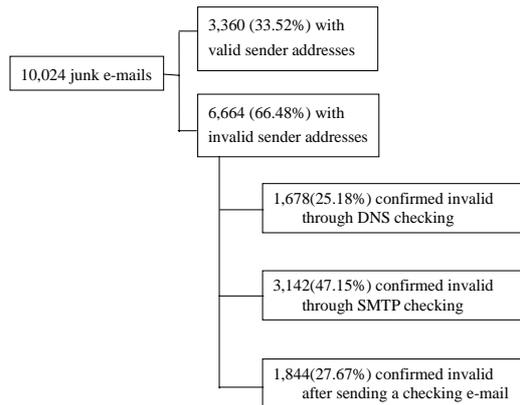

Figure 1: Sender Address Checking for Study 1 (10,024 Junk e-mails)

IV.2 Receiver Addresses

Presence of receiver address left in the “TO” or “CC” header session may be a cue for anti-spam filtering since that spammer usually use the “BCC” for the receiver address to avoid revealing that junk e-mail are sent in bulk. [31]

All receiver addresses of junk e-mails collected by spamarchive.org are omitted. So this study cannot analyze the receiver addresses of junk e-mail in study 1. The figure 3 indicated the content analysis results of receiver addresses in study 2.

It is showed that 84.64% normal e-mails containing receivers' address in “TO” and “CC” fields while 15.36% normal e-mails without receivers' address in “TO” and “CC” fields. In addition, 44.26% junk e-mails and 11.81% solicited listserv and commercial e-mails were with receivers' address in “TO” and “CC” fields while 55.74% junk e-mails and 88.19% solicited listserv and commercial e-mails without.

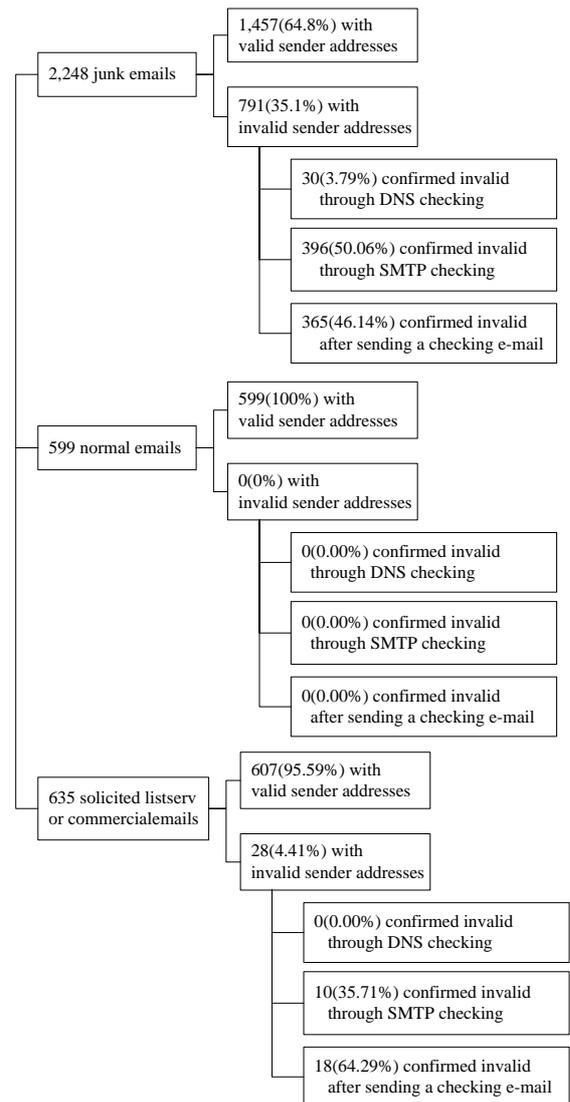

Figure 2: Sender Address Checking for Study 2 (3,482 normal, junk and solicited listserv and commercial e-mails)

Receiver address could be used as a cue for normal e-mail judgment. If an e-mail is with receivers' address in “TO” and “CC” fields, the possibility of this e-mail is normal e-mail is high. However, this should be an assist cue since that some normal e-mails purposely put receiver' e-mail addresses in the “BCC” header session.

The high block out percentage for solicited listserv and commercial e-mails are from the fact that most listserv and commercial e-mails are sent in bulk. It stands to reason to put receiver's addresses in “BCC” rather than “TO” or “CC” fields if e-mails are sent in bulk. Over block some normal e-mails (15.36%) and most solicited listserv and commercial e-mails (88.19%) are side effect of using receiver addresses to filter out e-mails. However, since that most normal emails were with receiver addresses in “TO” or “CC” fields, receiver addresses may still be assist cues for normal e-mails. In addition, receiver addresses may still be useful in anti-spamming if it is acceptable for users that over-blocking

solicited listserv and commercial e-mails.

IV.3 Mail User Agent

Mail User Agents (MUAs) are e-mail client programs used to generate the e-mail. Most normal e-mails were with X-mailer messages to present the MUA which sent the e-mails although this is not required. However, most junk e-mails do not include the X-Mailer field or include this field with random assign value.

Figure 4 and 5 indicated the content analysis results of X-mailer field. The results showed that 1.73% junk e-mails in study 1 and 4.34% junk e-mails in study 2 were sent by frequent used bulk e-mail programs. In addition, no X-mailer messages found in 58.21% junk e-mails in study 1 and 55.05% in study 2, respectively. 5.69% junk e-mail in study 1 and 9.75% in study 2 were with random assigned value for X-mailer field. 2.03% junk e-mail in study 1 and 2.75% in study were sent by infrequent used MUA.

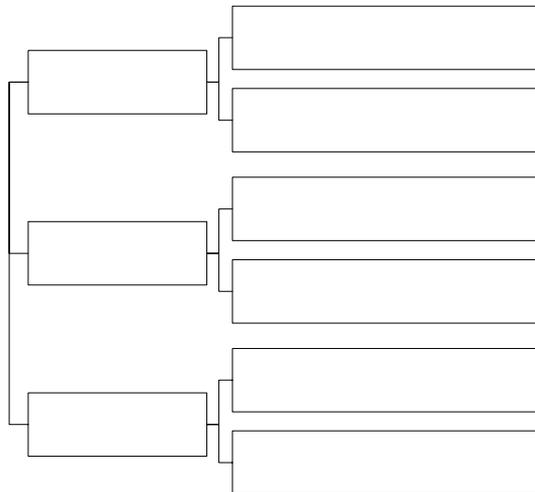

Figure 3: Receiver Addresses of Study 2

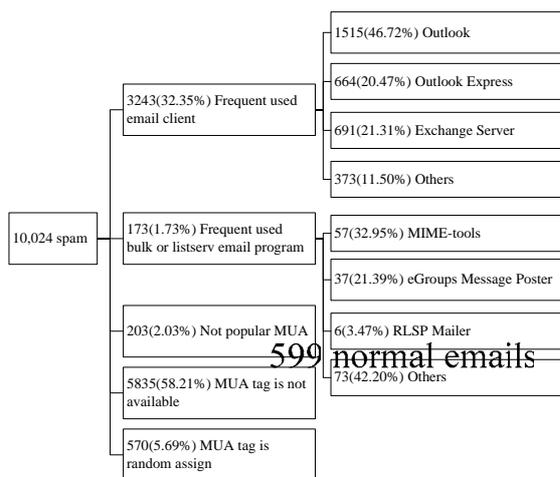

Figure 4: MUA for Study 1 (10,024 Junk e-mails)

Moreover, most normal e-mails (52.96%) in study 2

2,248 junk emails

were sent by frequent used MUA program as figure 5 indicated. Only 2.44% normal e-mails in study 2 were sent by bulk e-mails program, 0.87% by infrequent used MUA, 0.00% with random assign X-mailer value, and 43.73% were without X-mailer message.

As content analysis results point out, MUA could be used as a cue for normal e-mail judgment. The possibility of the e-mail is normal one is high if an e-mail is with frequent used MUA. On the contrary, the possibility of the e-mail is junk one is high if e-mails are sent by bulk e-mail program or the X-mailer messages are random assigned. However, this should be an assist cue since that normal e-mails send by web mail interface may have similar characteristics of X-mailer field.

IV.4 Message-ID

Message-ID is generated by the MUA or by the first MTA the message passes through if MUA did not yet assign one for the e-mail. This may be used as a judgment cue for normal e-mail. Most spammers hope to avoid revealing the real domain name of the MUA or the first MTA the message passes through and thus add a not existed domain name. So, if the sender addresses match the domain name specific in message-ID, the possibility is high of the e-mails are normal ones. However, it is not definitely junk email if the message-ID does not match sender address since that message-ID may be assign by MUA rather than MTA. If message-ID is assign by MUA such as outlook express, the computer name rather than e-mail domain name is put in right side of message-ID. Besides, according to the authors' observation, some web mail system put software or computer name rather than domain name to right side of message-ID. This also makes the not-match between message-ID and sender address.

Figure 6 and 7 indicated the analyze results of match between message-ID and sender Address. The results showed that message-IDs did not match sender address for 82.66% junk e-mails in study 1 and 39.32% junk e-mails in study 2. However, only 11.02% message-IDs of normal e-mails in study did not match sender addresses.

V. Using Header Session Message to Anti-Spam

As mention above, sender address, receiver address, MUA, and message-ID could be used as cues for anti-spamming. If sender address or receiver address is not found in "TO" or "CC" fields, the possibility is high of the e-mail is junk, as figure 3 pointed out. Besides, as figures 4 and 5 indicated, the possibility is high of an e-mail is sent in bulk if MUA is bulk e-mail program, MUA tag is not available, or is random assign. In this situation, the e-mail may be junk and should be filter out. Moreover, if message-ID does not match sender address, the possibility is high that the message-ID is

995(44.26%) contain receiver's address in "TO" and "CC" fields

1253(55.74%) without receiver's address in "TO" and "CC" fields

assigned by MUA rather than MTA or message-ID is faked to avoid possible trace. Some frequent used MUA programs, such as outlook express and some webmail programs, assign Message-IDs to all send-out e-mails base on their own rules irrelative to sender's address so that the Message-ID would not match senders' address. However, if an e-mail is not send by these kinds of MUA, the message-ID should match sender's address. If not match, the possibility is high of the e-mail is junk, as this study found in figure 6 and 7.

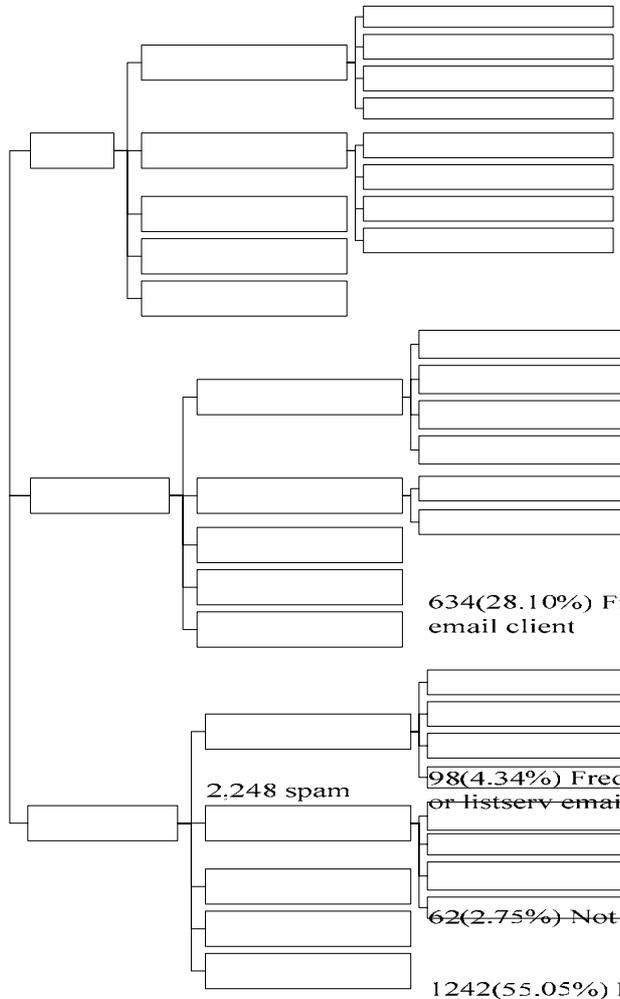

Figure 5: MUA for Study 2 (3,482 normal, junk and solicited listserv and commercial e-mails)

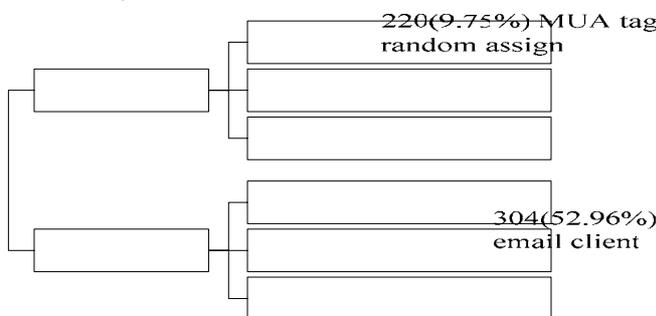

Figure 6 Match between Message ID and Sender Address for junk e-mails

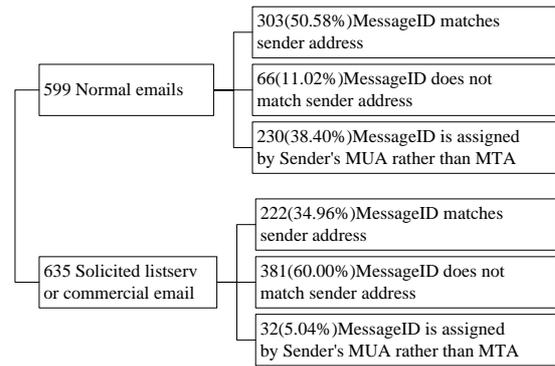

Figure 7 Match between Message ID and Sender Address for normal and solicited e-mails

Sender address, receiver address, MUA, and message-ID can not to be used alone for anti-spamming. If we simply filter out an e-mail without receiver address in "TO" and "CC" fields, we may over block some normal e-mails which is sent purposely by blind carbon copy. The similar situation will also be found in using MUA and message-ID as anti-spamming cues. Image the situation that a user hopes to send a personal notify to her or his friends in a large batch, he may adopt bulk e-mail MUA. Filter out e-mails send out by bulk e-mail MUA will also over block this kind of e-mails which should be treat as normal rather than spam. The same situation will happen for message-ID. It still could be normal e-mail when message-ID does not match sender' domain name. Some SMTP components, modules and libraries for website programming do not consider well about message-ID tag. For those users who use these kinds of MUA, message-IDs would not match senders' addresses, even what these users send out are normal emails.

This study proposed a combined anti-spamming judgment approach since single item of sender address, receiver address, MUA, and message-ID can not be used as the only cue for anti-spamming. This anti-spamming approach judge e-mails as normal or spamming according to four cues, i.e. sender address, receiver address, MUA, and message-ID. An e-mail will be judge as normal if it conform the rules of normal e-mail. Nevertheless, it will be judge as junk when conform the rules of junk. If an e-mail conform the rules of junk nor normal, the e-mail will be classified as indeterminate. Filter or not this kind e-mail should be user's personal choice.

Table 1 indicated the anti-spamming approach this study proposed. The possibility is high of an e-mail is not spam if it is with valid sender address, MUA is not frequent used bulk or automated email program, and Message-ID matches sender address or is assigned by MUA rather than sender's MTA.

However, if an e-mail is probably sent by bulk e-mail program, Message-ID does not match sender address, is carbon copy to receivers, and is with invalid sender addresses, the possibility of the e-mail is junk.

Qualifications for spam rules mentioned in table 1 are too strict. An e-mail could still be spam if it does not reach

574 normal emails	14(2.44%) Frequent used bulk or listserv email program	10(71.47%) MIME-tools

all four rules mention in table 1. This study proposed an idea that an e-mail will be regarded as spamming if with invalid sender address or if it matches two of remain three rules, rules 2, 3 and 4, of table 1. This study advocated that rule 1, invalid sender address, is enough to filter out an e-mail although some listserv e-mails will be mistakenly filter out. It is unreasonable to send an e-mail with valid sender address even if it is sent automatically.

Table 2 and 3 indicated the anti-spamming results of study 1 and 2. The junk e-mail filter out rate for study 1 is 79.11% if we filter out the e-mails which are judged as spam. However, this rate will raise 13.39% to 92.50% if filtering out e-mails which are judged as indeterminate and keep only e-mails which are judged as normal. For study 2, the junk e-mail filter out rate is 75.66% if we filter out the e-mails which are judged as spam. This filter out rate will raise 2.97% to 78.63% if filtering out e-mails which are judged as indeterminate. However, the anti-spamming approach this study proposed filtered out 88.50% solicited listserv and commercial e-mails. This rate would increase 2.76% to 91.26% if filter out e-mails which are judged as indeterminate. Most solicited listserv and commercial e-mails look like junk e-mails. The proposed anti-spamming approach would filter most of them, 88.50%, as table 3 indicated.

Table 4 summary anti-spam efficiency of the approach this study proposed. If a user who hope to filter out junk e-mails as many as possible, he can choice to keep only e-mails which are judged as normal and filter out both spam and indeterminate. This may be named as stick filter. However, some normal e-mails are judged as indeterminate as table 3 indicated. Users have to accept the risk of mistakenly filtering normal e-mails out. On the contrary, users may choice a safe strategy and filter out only e-mails which are judged as spam. In this situation, all normal and indeterminate e-mails are kept. This may be named as slack filter since that only confirmed spam are block.

The over block errors rate reflect the phenomenon that normal e-mail that should not be filtered out is blocked. It is not available for study 1 since that study 1 containing spam e-mails only. The block errors rate is zero if slack filter is adopted for study 2. This means that there is no side effect if slack filter is adopted. No normal e-mails would be filtered out mistakenly. However, the under block errors rate of slack filter is high when comparing with stick filter. The under block errors rate would reduce from 20.89% to 7.50% in study 1 and 24.34% to 21.37% in study 2, if stick rather than slack filter is adopted. This means that 92.50% junk e-mails in study 1 and 78.63% in study 2 would be blocked. Meanwhile, over block errors rate would increase from zero to 10.28%. It is users' own choice that adopting slack or stick filter.

VI. Discussion

Spam is one of the most important problems which going to get worse. Many studies aimed at spamming. However, the

existed techniques could not filter out all spam emails. More efforts are need to improve current anti-spam techniques.

Most existed anti-spamming techniques filter junk e-mails out according to e-mail subjects and body messages. However, subjects and e-mail contents are not the only cues for spamming judgment. This paper presents a new idea of filtering junk e-mail by utilizing the header session messages.

According to content analysis results, this study found that message-ID, mail user agent, sender and receiver addresses in the header session as cues for anti-spam filtering. At most 92.5% of junk e-mails would be filtered out using message-ID, mail user agent, sender and receiver addresses in the header session as cues.

Besides, some filtering technique may cause a high rate on over blocking normal e-mails. Over-blocking normal e-mails may induce lose of normal emails and make email service un-reliable. However, the idea this study proposed may induce zero over block errors rate if slack filter is adopt. This characteristic of zero over block errors rate is an important advantage for the anti-spamming approach this study proposed.

Some may argue that the filter out efficiency is not too high of anti-spamming approach this study proposed. Some studies may have filter out rate of as high as 98.54% [30] or 96.69% [31]. However, the anti-spamming approach this study proposed is a supplementary rather than a replacement for other filter out techniques. This proposed idea of using header session messages to filter-out junk e-mails may coexist with other anti-spamming approaches. No conflict would be found between the proposed idea and existing anti-spamming approaches.

An Adaptive Interface for Customer Transaction Assistant in Electronic Commerce

Chien-Chang Hsu, Zhen-Han Kuo
Department of Computer Science and Information Engineering,
Fu-Jen Catholic University
510 Chung Cheng Rd., Hsinchuang, Taipei, TAIWAN 242

Abstract: Personalized service and adaptive interface play important factors in electronic commerce. This work proposes an adaptive interface to for helping the customer transaction in electronic commerce. The adaptive interface collects the consumer behaviors by monitoring the customer operations, excluding unnecessary operations, and recognizing the behavior patterns. The interface uses the Bayesian belief network and the RBF neural networks to achieve the above tasks. The interface then evaluates knowledge and skill proficiency according to the customer behavior patterns. Finally, the interface generates the adaptive interface to the consumers for helping the transaction process.

Keywords: Web intelligence and web-based information technology, Adaptive interface, Proficiency evaluation

I. Introduction

Electronic commerce (EC) is the business activity that occurs over the electronic network. The customers purchase goods or services through the business platform of the EC systems. Personalized service and adaptive interface become the important factors to attract their customers. They should provide a friendly environment for the customer to buy goods according to the past consuming behaviors. Customer transaction behavior analysis becomes the important function in the system. Many systems have been proposed for applying the past user transaction history to different applications [3] [7] [8] [9] [10] [11] [13]. These systems are insufficiently specific regarding the analysis of the customer behavior. The system also did not provide the interaction activities analysis for effective customer behavior analysis. Some interface usability tools or systems were designed to overcome the above shortcomings [1] [2] [5] [6] [12]. Many problems still need to be solved. First, most systems use a resident monitoring program in the application system to collect user information from the interaction information between the end user and application system. The monitoring of user behaviors usually uses the cookies and the log files to record the user operations [5] [12]. Cookies were used to keep the user information in the client side. The drawbacks of cookies contain the limited amount of the information in the client side and the dangerous of information loss in the business session. Moreover, the

drawbacks of log files include the collection of passive user request information and the complexity of interaction events. Second, most systems acquire the static and specific business information from the content of the web pages. They do not analyze the interaction operations of the user in the applications. Third, most systems assume the user is an experimented operator and may not commit wrong operations. The collected data are presumed correct and valid information. Finally, most systems lack the customer proficiency evaluation to provide an adaptive interface in the application domain.

This work proposes an adaptive interface for customer transaction assistant in electronic commerce. The system uses the customer transaction behaviors to provide an adaptive interface and transaction guidance. The interface analyzes the transaction behavior and excludes unnecessary operations by Bayesian network. The interface then uses the RBF neural networks to discriminate the behavior patterns based on customer operations. Finally, the interface evaluates the knowledge and skill proficiency of the consumer to provide the intelligent assistant. The interface provides three assistant functions for the customers based on the fuzzy degree of the knowledge and skill proficiency. The interface also provides guidance for the customer to complete the transaction.

II. System Architecture

The system architecture contains two modules, namely, interface manager and behavior analyzer (Fig. 1). The interface manager collects the interactions performed by the customer in the client-side and server-side. It captures the customer interactions from the browser and EC server and filters the customer operations from the customer interactions and recognizes the behavior patterns. It uses the Bayesian belief networks to exclude redundant and irrelevant operations. It then uses the RBF neural network for discriminating the customer behavior from the interaction message

The behavior analyzer uses the behavior patterns to evaluate the knowledge and skill proficiency degree of customer. The former uses the personal ontology and the latter uses the usefulness, precision, dependency, and efficiency measurements to evaluate the consumers. Finally, the interface provides three assistant functions for the customers based on the above evaluation to guide the customer for completing the transaction.

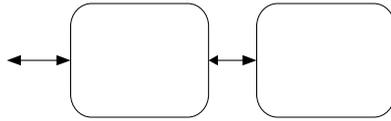

Fig. 1 System architecture

III. Interface Manager

The interface manager is responsible for collecting the transaction behavior and recognizing behavior patterns. First, the interface manager collects Customer operations performed by the customer in the client-side and server-side. First, the interface manager captures the customer interactions from the browser and EC server. Fig. 2 shows the interaction pattern of the system. The interface manager then filters the customer operations from the customer interactions and recognizes the behavior patterns. It uses the Bayesian belief networks to exclude redundant and irrelevant operations. Redundant operations are those which the customer use the same operation for the same subtask. The irrelevant operations are those that are not effective in performing the subtask. The directed acyclic graph is used to represent the relationship among customer operations (Fig. 3). The circular node represents the operation of the customer and the link represents the relationship between operations. Both of two operations $\langle O_1, O_2 \rangle$ and $\langle O_3, O_4 \rangle$ can use to do the same subtask ST_1 . If the customer operates sequence is O_1, O_3, O_2 and O_5 . The operation O_5 is the irrelevant operation and O_3 is the redundant operation for the subtask ST_1 . The probability of the subtask ST_1 , $P(ST_1) = P(O_1) * P(O_2)$. Redundant and unnecessary operations can be removed by computing the joint probability of the operations according to the causal relations of the Bayesian belief network.

The behavior pattern recognition uses the RBF neural model as the behavior pattern classifier for discriminating the customer behavior from the interaction message. The RBF neural model contains three layers, namely, the input, hidden, and output layers (Fig. 4). Notably, the input layer uses 35 nodes to represent the interaction information. The input of the interaction information includes the interaction events, focus object, request method, and query items. The node number of the interaction information in the input layer is 9, 10, 6, and 10 correspondingly. Each interaction event uses three digits to represent the operation. Table 1 lists the code of the interaction event. The character of the focus object, request method, and query items are encoded following the sequence of the alphabetically. Each character then is normalized into a real number ranging between 0 and 1. For example, the request method of "Get" was coded into (7/26, 5/26, 20/26, 0, 0, 0). The interface manager forwards the behavior patterns for use by the behavior analyzer in customer behavior analysis [4].

IV. Behavior analyzer

The behavior analyzer uses the behavior patterns to analyze

the activities and evaluate the proficiency level of the customer. First, it evaluates the knowledge and skill proficiency degree of customer. The knowledge proficiency degree (KP) evaluates the structure similarity between personal ontology and domain ontology. The KP is evaluated by using internal path length of the personal ontology and domain ontology.

$$KP = \frac{IPL_{Personal}}{IPL_{Domain}} \quad (1)$$

where $IPL_{Personal}$ and IPL_{Domain} are the internal path length of personal ontology and domain ontology. The KP is partitioned into three proficiency level, namely, novice, knowledgeable surfer, and expert (Fig. 5). Notably, the personal domain ontology stores the terminology and the relations between them of the application domain which was visited or used by the customer. It is constructed by using the merchandise name contained in the transaction operation [4]. The skill proficiency degree classifies customer's experience into one of the following three levels, namely, novice, skilled surfer, and expert. Figure 6 shows the fuzzy partition of the skill proficiency. Furthermore, the skill proficiency degree (SP) is computed by evaluating the skill measure.

$$SP = F(U, P, D, E) = U * W_u + P * W_p + D * W_d + E * W_e \quad (2)$$

where U, P, D, E refer to the measure of usefulness, precision, dependency, and efficient. $W_u, W_p, W_d,$ and W_e are respective weights. The usefulness, U , evaluates the correctness and validity of the customer operations.

$$U = 1 - \frac{\sum_{i=1}^n e_i}{n} \quad (3)$$

where e_i represents the ratios of error or nullify operations, $e_i \in [0, 1]$ and n is the operation number.

Precision, P , computes the average number of operations for completing the tasks.

$$P = \frac{\sum_{i=1}^n t_i}{n} \quad (4)$$

where t_i represents the number of operations to achieve the i th task and n is the task number.

Dependency, D , represents the behavior correlation.

$$D = \frac{\sum_{i=1}^n B_i \Rightarrow B_{i+1}}{n} \quad (5)$$

where B_i and B_{i+1} represent the i^{th} and $(i+1)^{\text{th}}$ behaviors, \Rightarrow represents the sequence relationships, and n is the behavior number.

Efficiency, E , measures the average time of the customer for completing the tasks.

$$E = \frac{\sum_{i=1}^n w_i}{n} \quad (6)$$

where w_i represents the time for completing the i^{th} task and n is the task number.

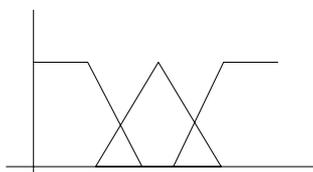

Fig. 5 Fuzzy partition of knowledge proficiency

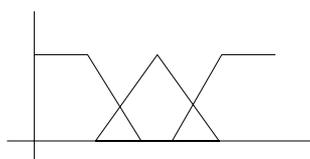

Fig. 6 Fuzzy partition of the skill proficiency

The system uses the values of KP and SP to help the customer for completing the transactions and customizing the interface. The intelligent interface provides three assistant functions for the customers, that is, transaction help, interaction style selection, and control panel expansion. Table 2 lists the assistant functions according to the knowledge and skill proficiency degree of customers. Basically, the transaction help provides three assistant types, namely, personal recommendations, collaborative ranking, and unconstrained transaction, for the customer. The transaction recommendations suggest the most possible merchandises for the customer according to the product hierarchy in the personal domain ontology. The collaborative ranking uses collaborative filtering to rank the possible business transactions for the customers. The unconstrained transaction didn't provide any helps for experienced consumers. The interaction style selection provides three interaction patterns, that is, simple, weak, and strong, for the customers. The simple interaction provides transaction guidance to help the customer in completing the transaction tasks. The weak interaction uses distinct and click-and-selection interface elements, such as menu, radio, and combo buttons, to interact with customers conveniently. Moreover, the strong interaction provides advanced interaction patterns, such as, form fill in and checklists, to interact with experienced customers. Finally, the control panel expansion provides static, semi-adaptable, and fully adaptable interface for customers to insert new control panels in the interface. The static interface provides fixed control panel for the customer who can not modify the web page layout. The semi-adaptable interface provides the panel for the customer to add new personalized icons regarding as the shortcut for doing the transaction. The fully adaptable interface provides the entire control panels for the customer to rearrange the block layout of web page.² Notably, the layout of web pages contains six blocks, that is, EC task bar, personalized icons, transaction behaviors, assistant function, recommendation, and guidance in the sequence of top-left and right bottom (Fig. 7).

V. Conclusions

Behavior patterns

This paper presents an intelligent interface for customer transaction assistant in electronic commerce. The system contains two modules, i.e, interface manager and transaction manager. The interface manager extracts the customer

Hidden layer

operations by analyzing the transaction behavior. The exclusion of unnecessary operations uses the Bayesian network to reduce the computation of irrelevant operations. The behavior pattern recognition uses the RBF neural networks to discriminate the behavior patterns based on customer operations. Finally, the behavior analyzer uses the knowledge and skill proficiency evaluation to provide the intelligent assistant. It provides three assistant functions for the customers according the fuzzy degree of the KP and SP. It also provides guidance for the customer to complete the transaction.

Question analysis and answering system for the internet usages by using Ontology and Concept Weighting

Narroup Ragnam, Anongnart Srivihok
Department of Computer Science, Faculty of Science, Kasetsart University, Thailand
email: {g4764229, anongnart.s@ku.ac.th}

Abstract: This study proposed a system for an automatic question analysis and answering that applies information extraction techniques for extracting the relevant information from questions of the Internet connections. The study uses both ontology, and concept weighting to extract, and classify questions. The information extractions are divided in two steps as follows. First, ontology is used to create a decision tree according to the concepts of questions. Second, concept weighting is applied; the weight of each concept is given by its frequency in the past documents. The results from this study reveal that it is possible to develop an automatic question answering system. The proposed system had been tested with sample questions from the Internet service provider: True Corporation Call Center. Precision of the system is about 0.77 which is good. This study offers useful information regarding the areas of information extraction for Call Center or Web Based Support Systems.

Keywords: Question analysis; Ontology; concept weighting; Call Center.

I. Introduction

The number of internet usages is increasing tremendously every year. Problems of users with the Internet connections are also increasing. Thus, the Internet Service Provider also needs to help users solve these problems. It is claimed that 80% of internet connection problems are simple and can be solved by users without the assistance of call center. These problems include telephone cord is not plugged tightly, or misspelling password for authentications. In July 2005, the number of phone calls related to internet usage problems in True Corporation which is one of the largest internet service in Thailand are about 71,628 calls. This is huge and these calls consume a lot of service time.

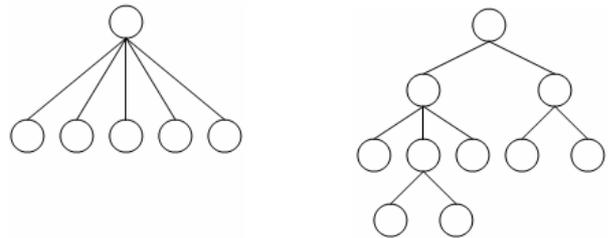

The objective of this study is to offer the proposed question answering systems by using ontology and concept weighting. This study include four main sections. Section 2 is the related theories and studies in the past. Section 3 is research methodology. Last, section 4 is conclusion of the study.

II. Literature Review

II.1 Text Classification

The text are classified by using a classifier which might be

a decision tree. The structure of decision tree can be divided in two categories: hierarchical and flat structure (Figure 1). It was reported that using hierarchical structure for text classification provides higher performance than flat structure [3].

(a) Flat Structure

(b) Hierarchical

Figure 1. Structure of decision trees.

Ontology is a formal, explicit specification of a shared conceptualization [2]. Also, Ontology has been applied in various studies. Miller (1993) introduced WordNet which is an on-line lexical database. This study used ontology for conceptualizing words by lexical order such as verbs or nouns. Wordnet uses semantic in categorising the questions. Yeh and coworker (2003) applied semantic inference on ontology for data mining of medical FAQ. In Thailand, Mounpai and Koatrakul (2003) applied ontology in the classification of One Tambol One Product (OTOP) database which includes large variety of Thai handicrafts and food products.

II.2 Concept weighting

In 2004, Jinarat and Soonthornphisaj [2] used probability method-Naïve Bayes and feature weighting in text classification. The feature weights are changed according to their frequency in the documents. This study reveals that the classifier has better performance after adjusting concept weights. Further, Reinforcement theory is applied in feature weighting of an intelligent agent for tourism. Features are awarded and increased their weights if the user selects the provided trips. On the other hand, they will be penalised by decreasing feature weights if they are not selected. By this way, the weights of trip features are adjusting according to the user selections [7].

II.3 Searching

After the classifier weights are adjusted, then the answers matching for each concepts have been linked. By this way, the customers who want to find the clues for trouble shooting can use the system.

III. Research Methodology

This study presents methods for question analysis and answering system of call center. The system can help customers in trouble shooting of errors in the Internet connections without the assistant of call center. The reseach design includes four steps (1) question extracting by Latent Semantic Analysis (LSA), (2) Ontology, and (3) Concept weighting. Ontology is applied for classification of concepts in knowledge base and store in hierarchical structure.

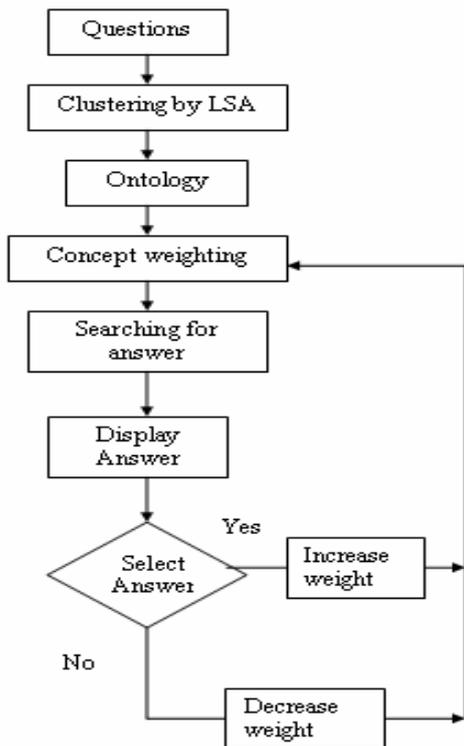

Figure 2: Flow of question analysis and answering system

III. 1 Question Extracting

Thai documents are written continuously without stop words or spaces between words. First the questions need to be separated into single words by using Swath program developed by Paisarn (1997). Then Latent Semantic Analysis is applied for solving problems of words which have many meanings namely polynymous and the case of many words which have the same meaning synonym. Then similar words are grouped in one concept. Figure 3 depicts the word synonym.

Word synonymy	Intension
Connect, เชื่อมต่อ, ต่อเน็ต, connected	การเชื่อมต่อ / Connect
คิด...ดับ, หลุด, เน็ตตัด, disconnected	เน็ตหลุด / Frequently disconnected
Hisp, high speed internet, ไสปีด, hi speed internet	Hi-speed internet
เออเรอ, Error, Errors	Message Error
...ช้า, เร็ว...k, speed...MB, slow	ความเร็ว / Speed

Figure 3: Word synonym and grouping

III. 2 Document Classification by Ontology

Ontology is applied to build the hierrachical structure classifier. In this study, problems in the Internet connections are classified and built in decision tree which have hierrachical structure (Figure 4). This ontology is developed by the assistant of experts and engineers in the Internet and networking. The problems in internet connections are divided in two main categories: (1) internet can not be connected and (2) internet can be connected but there are some problems. Then each category is divided in subcategories. Each node of the decision tree contains clues or answers which help customers to solve their problems in the Internet connections. Figure 4 reveals the structure of decision tree used in this study.

III. 3 Concept Weighting

The frequency of occurrences of each problem is differrent, thus each concept in the decision tree has different weight. As well, concept weight is depended on the frequency of it occurrence in the Internet connection. From 71,628 calls at call center, about 81% (57,803 calls) complain about unable to connect the Internet. Whereas, the one which can perform the Internet connection still has problems.

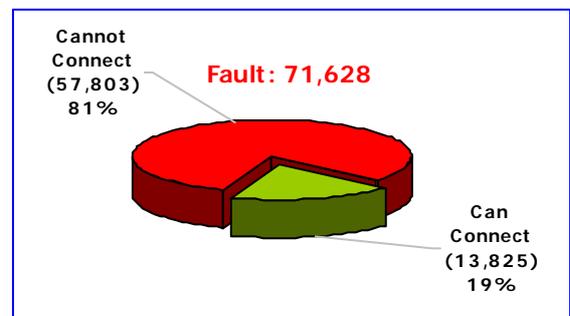

Figure 5: Probabilities of errors in the Internet usages reported at Call Center

Next step is adjusting the concept weights. In this step, each concept will be assigned with a weight according to its occurrence from historical data (Figure 6). For example, the highest frequency of concept which causes internet disconnect is due to no installation of splitter in the computer system which is 42%. The second higher is broken connection line or noise which 21%. Next is connection time out is 19%. Last is virus computer or spyware is 18%.

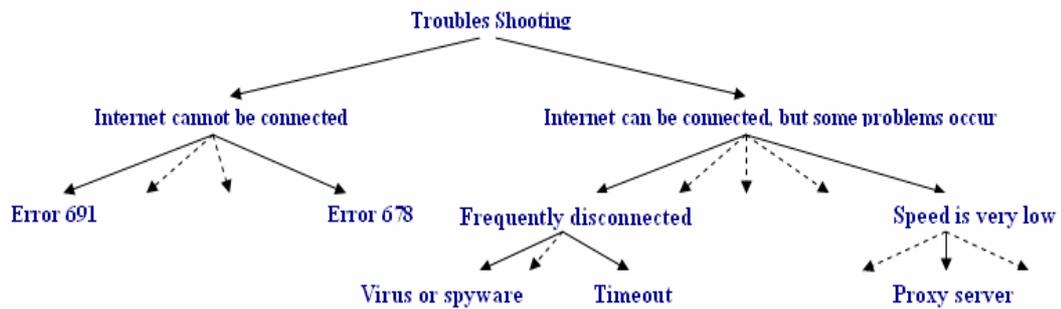

Figure 4: Hierarchical Structure of trouble shooting of the Internet connections

Probability	Cause
0.42	Splitter installation
0.21	broken connection line or noise
0.19	connection time out
0.18	virus computer or spyware

Figure 6: Probability of the cause of the Internet Disconnection

Customer who has problems with internet connection requests for assistants. The system provides answers to customer, then customer responds whether the answers work or not. Customer responses are used in weight adjusting.

Weight Adjustment:

$$W_{ti} = W_{ti} + Q_i$$

W_{ti} = weight of each concept

Whereas Q_i is defined as:

0.1 if user agree that the provided information works

-0.1/n-1 if user does not agree that the provided information works ; n is total number of features

$$\text{Precision} = \frac{\text{Number of correct retrieved answers}}{\text{Total number of retrieved answers}}$$

Example of Weight adjusting for user agrees that splitter installation advice works:

$$W1 = 0.42 + 0.1 = 0.52$$

$$W2 = 0.21 - 0.033 = 0.177$$

$$W3 = 0.19 - 0.033 = 0.157$$

$$W4 = 0.18 - 0.033 = 0.147$$

Figure 7 reveals the advice for splitter installation according to customer requests. Also the system asks for the feedback after customer has solved the problem with the provided information.

Splitter should be installed to prevent disturbing signal during hi-speed Internet access, by following the below instructions.

1. Connect True telephone line to Line socket of the Splitter.
2. Connect telephone line from Phone socket of the splitter to the telephone set.
3. Connect the line from Modem socket of the splitter to the ADSL modem.

[Click here to see how to install splitter](#)

After following the above steps, can the problem of frequent disconnections be solved?

Yes, it can.

No, it cannot.

Figure 7. Suggestion by system for trouble shooting.Conclusion

IV. Results

The system is evaluated in two steps (1) performance of question extraction (Pf) and (2) performance of retrieving the answer by using precision. The two steps are conducted by using the following formular.

Performance in question extraction (Pf) :

$$Pf = \frac{\text{Number of the correct extracted questions}}{\text{Total number of extracted questions}}$$

Sample data in this study is obtained from Call Center at True Corporation. Data was cleaned and selected for the one that related to the Internet connection problems. Then, experts in computer network answered questions from call center. These questions-answers are stored in the knowledgebase. Then, 2,800 samples are tested with this system on the performance of question extraction and precision in retrieving correct answer. Results show that question extraction performance is very good, the correctness is about 91%. Further, the precision of retrieving correct answer is about 77% ,which is good.

% correct question extraction	% correct searching
91 %	77 %

Figure 8: Comparisons of the performance of word extraction and searching

The precision of the system is not high as performance of question extraction. Since, in the process of question answering, there are some questions that should not be answered in public so the clues are not provided. Further, some provided answers in solving the Internet connection are too complex and can not be operated by novice customers.

V Conclusion

This study proposed question analysis and answering system for call center. Ontology and concept weighting are applied in this system. The system has been evaluated in two categories: performance of question extraction and precision. Then, it was tested with 2800 samples. The performance of question extraction is very good, the correctness is 91%, while system precision in searching for correct answer is 77% which is good. Future research should be done on the development of intelligent systems/agent for call center, this system can be an automatic system that help customers and company to work more efficiently and effectively.

Abstract: One of the major problems for seamlessly electronic business is how to find a suitable web services. Only the syntax and semantic comparison do not precisely find the suitable web services for they are procedures embedded with a complicated thought. In this paper, we propose an effective approach based on the ontology to solve this problem. With the help of ontology-based metrics, we can measure a web service matching degree to a given request and determine the rank in which the advertisement matches the request. Simulations are also performed, and the results show that our method can have a good precision and recall rate.

Keywords: Web Services, Ontology-based metrics.

I. Introduction

The web services stack of standards is designed to support the reuse and the interoperability of software components on the web [1]. The promise of web services is to enable a distributed environment in which any number of application components can interoperate seamlessly among organizations in a platform-neutral and language-neutral fashion [2]. In the Service-Oriented Architecture (SOA), service providers develop the web services and publish the services to the UDDI (Universal, Description, Discovery and Integration) registry. When service requesters need some services, they search for the web services in the UDDI registry. If the requester finds a suitable web service, he can send SOAP (Simple Object Access Protocol) messages to invoke the web services.

Since there are many web services issued by different corporations, a critical step to find the suitable services is how to discover and find suitable web services against the request. The current services discovery approach in the UDDI registry is based on categories and keywords, as relies on the shared common understanding of services providers and requesters. Generally, the selection of keywords and the classification of categories for a same object are different for different individuals. The found web services based on the above criterion will not always precisely match the request [1]. For example, if we want to find a DogSelling service, it is clear that a PetSelling service does not match the request since the keywords, DogSelling and PetSelling, do not

match with each other in syntax. In fact, Dog and Pet have a strong relationship in semantics. But the WSDL (Web Service Description Language) used to describes the characteristics of the web service inherently can not embed the semantics of keywords in its structure.

To embed the semantic of a web service, the Web Ontology Language (OWL) is proposed as a description language of web services [9]. With the emergence of OWL, the web services can be described not only syntactically but semantically. OWL-S is another more powerful descriptive language for the web service, which can represent an OWL-based Web service ontology. The OWL-S can supply Web service providers with a core set of markup language constructs for describing the properties and capabilities of those Web services in an unambiguous and computer-interpretable form [10]. Though the web description is more expressive, the matching between the request and the web provider is not discussed until now. In this paper, we use OWL-S to complement WSDL for web services descriptions and propose an approach to make matchmaking between the requirements and the advertisements of the web services.

A web service can be formally defined as three main elements: {S, C, E}, where S, C and E denote the content descriptions, the capabilities, and the properties of end points respectively [11]. The content descriptions refer to what the web service is commented about such as the text description of the service; the capabilities refer to what the functionalities that the service provides such as what requirement is needed for performing the service and how the service performs; the properties of end points are related to the information and constraints of the end point such as cost, payment ways, response time, etc. The main elements of web services can be described by the service description language such as WSDL or OWL-S. If these main elements of the requested services are similar to those of the advertised services, we can allege that they are matched.

Former researchers consider what requirement is needed for performing the service and how the service performs as the service capabilities [3, 6]. However, the capabilities of web services become more complex and can not be just defined according to all inputs and outputs of the web services. In this paper, a complete web services discovery approach, which compares the degree of similarity between requirements and advertisements according to the whole main elements of web services, is proposed. The proposed approach is a three-metric matching approach, including text matching, construction matching, and parameter matching.

Each metric is used for examining one kind of main elements of web services between requirements and advertisements and then calculates their matching scores. In addition to the complete consideration of matching criterion, the proposed approach is based on the semantic matching.

II. Previous Work

II.1 Component Comparison and OWL-S

Since a web service accepts inputs and sends off output after processing, the task to discover web services in a UDDI registry is similar to the task of software component retrieval in a component library. For the automatic software component search and retrieval, the existing approach can be divided into four different methods [7], namely, simple keyword and string search, faceted classification and retrieval, behavioral matching and signature matching. The method of the simple keyword and string search to find the components is based on the frequency of the keywords occurring in the components. The drawback of the method is the lack of precision since the keywords cannot fully delineate the whole ability of the software component. The method of faceted classification and retrieval is to classify components based on taxonomies such as functions the software performs, types of the system, and so on. The method can have more insights about the software. However, it is difficult for software component developers to appropriately classify components based on taxonomies since that some components may overlap several categories. The third method, i.e. behavioral matching, executes each component with random inputs and generates outputs. The comparison between expected outputs and the actual outputs can help to select the matched component. But it can not perform well when the software components have complex behaviors. Precisely, assume that components have many functions. These functions may affect each other, and the behavioral matching will have low precision. The last method, i.e. signature matching, is the comparison of the function types and argument types between the components and the query specified by the user, as is the practical approach. In the area of web services discovery for web services discovery, many researchers also claim that services discovery should base on the match between a declarative description of the service being sought and a description of the service being offered [1, 3, 4, 5, 6]. Note that in this paper, the declarative description of the service being sought is called "requirement" and the one of the service being offered is called "advertisement".

Ontology defines the common words in a specified domain and the relationships between the words to represent the knowledge of the specified domain. The OWL Web Ontology Language is the W3C recommended language used to define ontology. The purpose of OWL is to describe the knowledge in specified domains and the relationships between words in each domain can be interpreted by a machine without human support. OWL has more facilities for expressing semantics than XML (eXtensible Markup

Language) and RDF (Resource Description Framework), and thus OWL goes beyond these languages in its ability to represent machine interpretable content on the Web. There are three sublanguages provided by OWL to define ontologies with three different degrees of expressive abilities. The three sublanguages are OWL Lite, OWL DL and OWL Full. OWL Full is the powerful expressive one and OWL Lite is the simplified expressive one. For each of these sublanguages, the preceding one is the descendant of the rear one. What can be expressed validly in the descendant can also be expressed validly in the elder generation.

OWL-S (Web Ontology Language for Services) is developed by the OWL Services Coalition for describing the ontology of web services. OWL-S defines the overall structure of the ontology and is divided into three parts: Service Profile, Service Process Model and Service Grounding. The part of Service Profile defines the fundamental information about this service such as service name, service text descriptions, service category, provider contact information, etc; the part of Service Process Model contains the information about how the service is constructed; the last part of Service Grounding is to define the details of how to access the service included the communication protocols, the message formats, etc. In this paper, we utilize the Service Profile since it provides the information about content descriptions, capabilities, and end points information and the Service Process Model which provides the information about service construction to make matchmaking.

II.2 Web Services Discovery and Semantic Matching

Paolucci [3] proposed a semantic matching approach that is based on the service capabilities and defined four matching degrees, namely, exact, plug in, subsume and fail, respectively. For explaining how the approach works, we use Rout and Aout to represent an output of the request and an output of the advertisement. They use four matching degrees, namely, exact, plug in, subsume, and fail, which are in descending order. Precisely, exact is the best matching degree and fail represents not matched.

Wang [1] also proposed the flexible interface matching for web service discovery. The description language used in the proposed approach is WSDL. The approach needs the service requester to provide the ideal service description and then find the matched services in the repository. They first use the vector space model to compare the information within the <documentation> tag described in natural language between the requirement and the advertisement. After the first stage, there are lists of ranked candidate web services returned. Then they use the structure matching to refine the quality of the candidate service set. The criteria used by this approach are the content descriptions, capabilities and service construction. However there is no semantic concept in this approach because of the used description language, WSDL.

Paolucci [3] proposed the semantic web services matching based on services capabilities. Many researchers

have cited the proposed concept for making a semantic web services matchmaking. The criterion used by this approach is the service capability. The proposed approach is good at the matching of the service capabilities but is weak for using only one criterion for matching.

Sirin [6] proposed two filters for selecting semantic web services including the input/output matching and the parameter matching. The proposed approach uses the criteria of capabilities and properties of end points to make a semantic web services matching. However the lack of the criteria including content descriptions and the service construction will reduce the precision and recall of the matching. The following table shows the comparison of these approaches.

Table 1. The comparison of the related research

	Service description language	Criteria	Matching approach
Wang [1] 2003	WSDL	Content descriptions; Capabilities; Construction	Vector-space model; Structure matching
Paolucci [3] 2002	DAML-S	Capabilities	Semantic matching approach
Sirin [6] 2003	OWL-S	Capabilities; End point information	Semantic matching approach; Parameter matching

III. Ontology-based Comparison Approach

This paper proposes a three-metric matching approach for finding suitable web services for requesters according to the criteria of content descriptions, service capabilities, service construction and properties of end points. The three metrics includes text matching, construction matching, and parameter-matching. The first metrics can filter the most irrelevant advertisements in the registry and give the qualified services the ranking. The remaining two metrics, i.e. the construction matching and the parameter matching, are used to refining the initial ranking of the qualified advertisements. Finally, lists of ranked web services are returned to the requester.

Before the matchmaking, the requesters are assumed to figure out what web services they need in an OWL-S format. In other words, the requester should provide an OWL-S file describing the ideal service. Then the proposed approach compares the description with the advertisements in the registry and returns the required web services. The proposed metrics work sequentially when the comparison of the degree of similarities between the requirement and each advertisement are executed. Each metric can produce one matching score. Therefore there are three matching scores produced for each advertisement. Then the relevant web

services are returned according to the degree of the similarities. The following is the metrics used in the proposed approach.

III. 1 Text Matching

Many methods for text matching have been proposed in the field of IR. The simple and realistic method is the vector space model [12]. In the Service Profile of OWL-S, there is an optional tag, <profile:textDescription>, in which the service providers can have some comments in natural language for their services and the requesters can describe what their ideal requirements are. According to the vector space model, the part commented in natural language can be treated as a multi-dimensional vector. Each term in the part can represent one dimension in the vector. The weight of each dimension in the vector is directly proportional to the frequency that the term occurs in the document and inversely proportional to the number of documents which contain the term. The weight can be computed according to the following formulas:

$$W_{ij} = tf_{ij}idf_i,$$

$$idf_i = \log_2(N/df_i),$$

Where W_{ij} represents the weight of the dimension i in the vector. tf_{ij} represents the number of occurrences of the term i in document j . idf_i represents the result of the total number of documents divided by the number of documents which contain the term i . N represents the total number of the documents. df_i represents the number of documents which contain the term i .

For restraining the impact of idf_i , \log_2 is used to dampen the effect relative to idf_i [13]. Thus we have two vectors respectively for the requirement and the advertisement, and we can derive the similarity coefficient of the two vectors from the production of them. For each advertisement, our approach will return a similarity coefficient derived from the comparison. The derived similarity coefficient is the matching score of the text matching.

III. 2 Construction Matching

The construction matching is the consideration of which processes the inputs and outputs belong to. In the construction matching, we utilize the information provided by Service Process Model of OWL-S. The comparison of the construction is a multi-step process: it involves the comparison of the processes between the requirement and the advertisement, which is based on the comparison of the compositions of the inputs and outputs within the processes. In the input/output matching, we compare all the inputs and outputs between the requirement and the advertisement. In

the construction matching, we compare all of the inputs and outputs within one process in the requirement to all of the inputs and outputs within one process in the advertisement. Therefore we can get the matching score of each pair-wise process between the requirement and the advertisement. The pair-wise processes can form many kinds of combinations like the combinations in the input/output matching. Then we find the combination with the highest score among all the combinations. Finally we can define the highest score of the construction matching between the requirement and the advertisement as the construction matching score.

III.3 Parameter Matching

The parameter matching utilizes the information provided by Service Profile of OWL-S to examine the matching score of the properties of end points between the requirement and the advertisement. The parameter matching can be considered as adding the constraints into the matching processes for finding the suitable web services. The parameter in the parameter matching can be divided into two parts. The first part is the OWL-S predefined parameters such as `contactInformation` and `ServiceCategory`. The comparison of parameters in this part needs to find the corresponding parameter name between the requirement and the advertisement and then compare the value of each attribute of the parameter. If the value of each attribute of the parameter in the requirement is the same with the value of each corresponding attribute of the corresponding parameter in the advertisement, we define that the two parameters between the requirement and the advertisement are matched. We define the matching scores according to the numbers of the matched parameters. Each matched parameter desires 10. The second part is the self-defined parameters such as the service quality rating. The comparison of parameters in the part needs to first compare the parameter names between the requirement and the advertisement. If the parameter names are the same, we can compare the value of the parameters. Because the value of the parameter is an URI referring to the class in the ontology, we use the semantic matching approach to compare the value of the parameter. As the above mention, the matching degree of the Exact level is defined as score 10; the Plug-in level is defined as score 6; the Subsume level is defined as score 4; the Fail level is defined as score 0. Finally we accumulate each matching scores and the total score represent for the matching degree of the parameter matching.

III.4 Ranking System

The three metrics introduced above can produce three scores for representing the matching degree between the requirement and the advertisement. First we can utilize the two scores derived from text matching and input/output matching to filter the most irrelevant advertisements. We use the formulation to representing how it works.

$$\text{Relevant Score} = W_1 * S_1 + W_2 * S_2, \text{ where } W_1 \text{ and } W_2$$

are used for normalizing S_1 and S_2 to avoid either of them influence the relevant score too much. S_1 and S_2 denote the scores derived from text matching and input/output matching respectively.

We can set a threshold for the relevant score. If the relevant score between the requirement and the advertisement is higher than the threshold, the advertisement is considered as qualified for the candidates. After we have the candidates, we need to rank them according to their matching degree. We use the following formulation to represent how to do it.

$$\text{Matching Score} = \text{Relevant Score} + W_3 * S_3 + W_4 * S_4,$$

where W_3 and W_4 are used for normalizing S_3 and S_4 to avoid that either of them influence the matching score too much. S_3 and S_4 denote the scores derived from construction matching and parameter matching respectively. We can rank the qualified advertisements according to the matching scores in descending. Therefore we can return the suitable ranked services to the service requester.

IV. Evaluation Method

The proposed three metrics can be implemented to develop the matching system. We use Java language to implement the system. The OWL-S API developed by MINDSWAP (Maryland Information and Network Dynamics Lab Semantic Web Agents Project) helps us to parse the OWL-S document [14]. The RACER system [15] is an OWL reasoner system. It helps us to identify the relation of the input/output between the requirement and the advertisement and we can proceed the semantic matching and define the matching score of the input/output matching and the construction matching. At present the general web service description language is WSDL. However, our approach uses the OWL-S for the web service description language. We need to translate WSDL to OWL-S first and then we can use our system to make a matchmaking. The WSDL2OWL-S developed by the Softagents Lab of Carnegie Mellon University can help us to translate the WSDL document to OWL-S document. The whole system architecture is shown in figure 1.

To evaluate the proposed approach, we have to collect lots of WSDL documents of web services as the advertisements. The XMethods [16] is a web site which provides lots of web services for users to give a trial. We can collect the WSDL documents from the web site to form the advertised collection. Then we classify the collection into several categories. We take one advertisement from one of the categories as the requirement. After executing the comparison of the proposed approach, the matching system will return lists of suitable web services. If the returned service is same category with the requirement, we define that it is relevant. Otherwise, the returned service is not

relevant. Based on the definition of the relevance, we can compute the precision and recall for our proposed approach. The way to compute the precision and recall is defined as follows:

$$\text{Precision} = \# \text{ of Relevant retrieve} / \# \text{ of Retrieve};$$

$$\text{Recall} = \# \text{ of Relevant retrieve} / \# \text{ of Relevant.}$$

The two metrics are chosen for the experiments. In the search for the web service, we limit up 5 UDDI server to be accessed. All the retrieval web services are ranked, and only the top 30 web services are returned by our web service search engine through the proposed criterion. The simulation results for the requests of “translation_from_mile_to_kilometer” and “translation_from_French_to_English” are summarized in Figures 2 and 3, respectively. From these two tables, we can find some interesting characteristics. First, we found the retrieval for the request “translation_from_mile_to_kilometer” has higher precision than that for the request the request “translation_from_French_to_English”. Since the former request has less descriptive vocabularies than that of the second one. Perhaps the metric of the text matching will let more possible web services to enter the second and third metric comparison. And the second and third metric can have a better rank ability for the simple request. However, the recall rate for the former request is smaller than that of the latter one. It is guessed that the former has less characteristic than the latter. The judge of similarity in the former is more difficult than the latter.

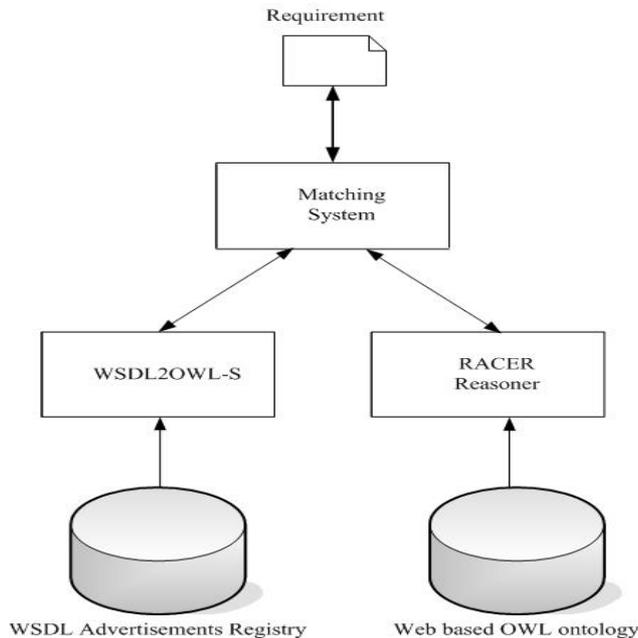

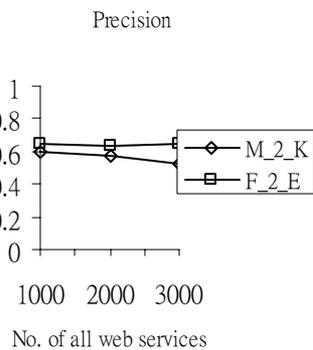

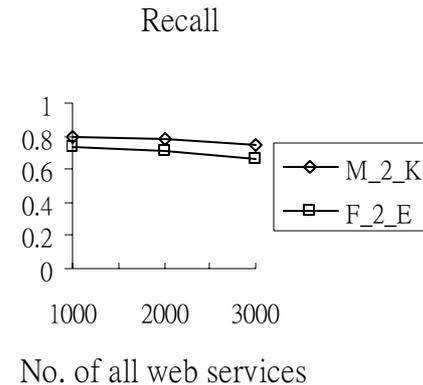

Figure 1. The system architecture

Figures 3 and 4. The recall and precision rates of web service searching for the M_2_K (Mile_to_Kilometer) and F_2_E (French_to_English).

V. Conclusion

As the application of Web services grow exponentially, it has become a crucial problem to provide effective search tools to increase the speed and precision of searching for the suitable ones. The credit assignment for the ranked search can be significantly improved by adequate metrics. In this paper, we propose a method to assign the order of web services for a request. The extensive simulation is performed and shown that our method can effectively estimate the proper suitability of web services.
